cAggregate

Combines a number of messages together into a single message.

**cAggregate Standard properties**

These properties are used to configure cAggregate running in the Standard Job framework.

The Standard cAggregate component belongs to the Routing family.

**Basic settings**

| **Language** | Select the language of the expression you want to use to filter your messages, from None, Bean, CONSTANT, ESBCorrelationID, EL, GROOVY, HEADER, JAVASCRIPT, JoSQL, JsonPath, JXPATH, MVEL, OGNL, PHP, PROPERTY, PYTHON, SIMPLE, SpEL, SQL, XPath, and XQUERY. Select CorrelationID to use the existing correlation ID of the message as the correlation key if the correlation ID is available in the closest cSOAP connected to this component. For more information about the cSOAP component, see cSOAP on page 78. |
| **Correlation expression/Expression** | Type in the expression that evaluates the correlation key to be used for the aggregation. This field disappears when CorrelationID is selected in the Language list. In this case, the existing correlation ID from the closest cSOAP connected to this component will be used. For more information about the cSOAP component, see cSOAP on page 78. |
| **Correlation expression/Add Namespaces** | This option appears when XPath is selected in the Language list. Select this check box to add namespaces for the Xpath expression. Click [+] to add as many namespaces as required to the table and define the prefix and URI in the corresponding columns. |
| **Strategy** | Specify a Java bean to use as the aggregation strategy. |
| **Completion conditions/Number of messages** | Select this check box to specify the number of messages to aggregate per batch before the aggregation is complete. **Note:** By default, this check box is selected and the number of messages is set to 3. If you clear this check box, and at least one of the other four completion conditions is met, all the messages retrieved will be aggregated in one batch. |
| **Completion conditions/Inactivity timeout (in milliseconds)** | Select this check box to specify the time (in milliseconds) that an aggregated exchange should be inactive before it is complete. This option can be set as either a fixed value or using an Expression which allows you to evaluate a timeout dynamically. |
### Completion conditions/Scheduled interval (in milliseconds)

Select this check box to specify a repeating period (in milliseconds) by which the aggregator will complete all current aggregated exchanges.

**Note:**
You cannot use this option together with Scheduled interval. Only one of them can be used at a time.

### Completion conditions/Predicate matched

Select this check box to specify a predicate to indicate when an aggregated exchange is complete.

### Completion conditions/Batch consumer

Select this check box to aggregate all files consumed from a file endpoint in a given poll.

### Advanced settings

#### Check completion before aggregating

Select this check box to check for completion when a new incoming exchange has been received. This option influences the behavior of the Predicate matched option as the exchange being passed in changes accordingly. When this option is disabled, the exchange passed in the predicate is the aggregated exchange which means any information you may store on the aggregated exchange from the aggregation strategy is available for the predicate. When this option is enabled, the exchange passed in the predicate is the incoming exchange, which means you can access data from the incoming exchange.

#### Close correlation group

Select this check box to indicate that if a correlation key has already been completed, then any new exchanges with the same correlation key will be denied. When using this option, enter a number in the **Maximum bound** field to keep that last number of closed correlation keys.

#### Ignore invalid correlation key

Select this check box to ignore the invalid correlation key which could not be evaluated to a value. By default Camel will throw an Exception on encountering an invalid correlation key.

#### Group arriving exchange

Select this check box to group all aggregated exchanges into a single combined holder class that holds all the aggregated exchanges. As a result only one exchange is being sent out from the aggregator. This option can be used to combine many incoming exchanges into a single output exchange.

#### Use persistence

Select this check box to plug in your own implementation of the repository which keeps track of the current in-flight aggregated exchanges. By default, Camel uses a memory based implementation.

#### Repository

This field appears when the **Use persistence** check box is selected. The repository is **AggregationRepository**, **Repository**
cAggregate

HawtDBAggregationRepository, or RecoverableAggregationRepository.

AggregationRepository: The default repository used by Camel which is a memory based implementation. Enter the name of the repository in the field.

HawtDBAggregationRepository: HawtDBAggregationRepository is an AggregationRepository which persists the aggregated messages on the fly. This ensures that you will not lose messages. With this repository selected, the following options appear:

Use persistent file: Select this check box to store the aggregated exchanges in a file. Enter the name of the file for the persistent storage in the Persistent file field. If the file does not exist on startup, it will be created.

Recovery/Use recovery: Select this check box to recover failed aggregated exchanges and have them resubmitted automatically. In the Recovery interval field, enter the interval (in milliseconds) to scan for failed exchanges to recover and resubmit. By default this interval is 5000 milliseconds. In the Dead letter channel field, enter an endpoint URI for a Dead Letter Channel where exhausted recovered exchanges will be moved. In the Maximum redeliveries field, enter the maximum number of redelivery attempts for a given recovered exchange.

RecoverableAggregationRepository: RecoverableAggregationRepository is a JDBC based AggregationRepository which persists the aggregated messages on the fly. This ensures that you will not lose messages. Enter the name of the repository in the field.

With this repository selected, the following options appear:

Recovery/Use recovery: Select this check box to recover failed aggregated exchanges and have them resubmitted automatically. In the Recovery interval field, enter the interval (in milliseconds) to scan for failed exchanges to recover and resubmit. By default this interval is 5000 milliseconds. In the Dead letter channel field, enter an endpoint URI for a Dead Letter Channel where exhausted recovered exchanges will be moved. In the Maximum redeliveries field, enter the maximum number of redelivery attempts for a given recovered exchange.

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>cAggregate is used as a middle or end component in a Route.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connections</td>
<td>Aggregate: select this link to route messages to the next endpoint according to the selected aggregation strategy. Route: select this link to route all the messages from the sender to the next endpoint.</td>
</tr>
</tbody>
</table>

Aggregating three messages into one

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.
In this scenario, the **cAggregate** component combines three messages from the local file system into one and prints the messages in the console. A Java bean will be used as the aggregation strategy.

**Creating a Java bean as the aggregation strategy**

**About this task**

To aggregate the messages, we will use a Java bean that will help us build an aggregation strategy.

**Procedure**

1. From the repository tree view, expand the **Code** node and right click the **Beans** node. In the contextual menu, select **Create Bean**.

2. The **New Bean** wizard opens. In the **Name** field, type in a name for the bean, for example, **AggregateBody**. Click **Finish** to close the wizard.
3. Type in the codes as shown in the figure below. In this use case, we just want to aggregate all messages into a single message.

```java
package beans;

import org.apache.camel.Exchange;
import org.apache.camel.processor.aggregate.AggregationStrategy;

public class AggregateBody implements AggregationStrategy {

    public Exchange aggregate(Exchange oldEx, Exchange newEx) {
        if (oldEx == null) {
            return newEx;
        }
        String oldBody = oldEx.getIn().getBody(String.class);
        String newBody = newEx.getIn().getBody(String.class);
        newEx.getIn().setBody(oldBody + newBody);
        return newEx;
    }
}
```

4. Press Ctrl+S to save your bean.

Dropping and linking the components

About this task

Procedure

1. From the Palette, expand the Connectivity folder, and drop a cFile component onto the design workspace.
2. Expand the Routing folder, and drop a cAggregate component onto the design workspace.
3. Expand the Custom folder, and drop two cProcessor components onto the design workspace.
4. Right-click the cFile component, select Row > Route from the contextual menu and click the first cProcessor component.
5. Repeat this operation to connect the first cProcessor component to the cAggregate component.
6. Right-click the cAggregate component, select Row > Aggregate from the contextual menu and click the second cProcessor component.
7. Label all the components to better identify their functionality, as shown above.

Configuring the components

Procedure

1. Double-click the cFile component, which is labelled File_source, to display its Basic settings view in the Component tab.
2. In the **Path** field, browse to or enter the input file path, and leave the other parameters as they are.

   In this scenario, there are four text files in the specified directory: *a.txt*, *b.txt*, *c.txt* and *d.txt*, the contents of which are *This is a!*, *This is b!*, *This is c!*, and *This is d!* respectively.

3. Double-click the **cAggregate** component, which is labelled **Aggregator**, to display its **Basic settings** view in the **Component** tab.

4. In the **Language** field, select **Constant** or **Simple** as the expression language.

   In the **Expression** field, enter the expression "*getBody(String.class)*" to retrieve the body of the message.

   In the **Strategy** field, enter the name of the Java bean **AggregateBody** you just created.

   Select the **Number of messages** check box and type in 2 in the field.

5. Double-click the **cProcessor** component labelled **Monitor_before** to display its **Basic settings** view in the **Component** tab.
6. In the **Code** box, customize the code as follows so that the **Run** console displays the message contents before an aggregation takes place:

```java
System.out.println("Before aggregation: "+
exchange.getIn().getBody(String.class));
```

7. In the same way, configure the **cProcessor** component labelled **Monitor_after** so that the **Run** console displays the message contents after an aggregation takes place:

```java
System.out.println("After aggregation: "+
exchange.getIn().getBody(String.class));
```

8. Press **Ctrl+S** to save your route.

**Viewing code and executing the Route**

**Procedure**

1. Click the **Code** tab at the bottom of the design workspace to have a look at the generated code.
As shown in the code, a message from the File_source endpoint is routed via cProcessor_1 and then aggregated according to the condition .aggregate.

2. Click the **Run** view to display it and click the **Run** button to launch the execution of your route. You can also press **F6** to execute it.

RESULT: The four messages are aggregated in two batches, two messages combined into one each batch.
[statistics] connecting to socket on port 3714
[statistics] connected
Before aggregation: This is a!
Before aggregation: This is b!
After aggregation: This is a! This is b!
Before aggregation: This is c!
Before aggregation: This is d!
After aggregation: This is c! This is d!
**cAMQP**

Exchanges messages between a Route and a JMS provider using the AMQP broker.

**cAMQP Standard properties**

These properties are used to configure cAMQP running in the Standard Job framework.

The Standard cAMQP component belongs to the Connectivity family.

### Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>URI/Type</td>
<td>Select the messaging type, either queue or topic.</td>
</tr>
<tr>
<td>URI/Destination</td>
<td>Type in a name for the message queue or topic in the message broker.</td>
</tr>
<tr>
<td>ConnectionFactory</td>
<td>Click [...] and select an MQ connection factory to be used for handling messages.</td>
</tr>
</tbody>
</table>

### Advanced settings

**Parameters**

Set the optional parameters in the corresponding table. Click [...] as many times as required to add parameters to the table. Then click the corresponding Value field and enter a value. See the site [http://camel.apache.org/amqp.html](http://camel.apache.org/amqp.html) for available options.

Be sure to set the clientId parameter to a unique value if you need to deploy multiple Routes using this component to Runtime. Otherwise the Routes will throw exception in Runtime.

### Usage

**Usage rule**

*cAMQP* can be a start, middle or end component in a Route. It has to be used with the *cMQConnectionFactory* component, which creates a connection to a MQ server. For more information about *cMQConnectionFactory*, see *cMQConnectionFactory* on page 230.

**Limitation**

n/a

### Sending messages to and receiving messages from an AMQP broker

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

This scenario will show you how to use the *cAMQP* component to send messages to and consume messages from a JMS Queue or Topic. To do this, two Routes are built, a message producer Route, and
Building the producer Route

Dropping and linking the components

About this task

Procedure

1. From the Palette, drag and drop a **cMQConnectionFactory**, a **cTimer**, a **cSetBody**, a **cAMQP**, and a **cLog** component onto the design workspace.
2. Label the components for better identification of their roles and link them with the **Row > Route** connection as shown above.

Configuring the components

Procedure

1. Double-click the **cMQConnectionFactory** component to display its **Basic settings** view in the **Component** tab.
   
   ![Basic settings view](image)

2. From the **MQ Server** list, select **AMQP 1.0** to handle messages. Keep the default settings of the other options.
3. Double-click the **cTimer** component to open its **Basic settings** view in the **Component** tab.
4. In the **Repeat** field, enter 5 to generate the message exchange five times. Keep the default settings of the other options.

5. Double-click the **cSetBody** component to open its **Basic settings** view in the **Component** tab.

6. Select **SIMPLE** from the **Language** drop-down list and type in "Hello world" in the **Expression** field as the message body.

7. Double-click the **cAMQP** component to open its **Basic settings** view in the **Component** tab.

8. From the **Type** list, select **queue** or **topic** to send the messages to a JMS queue or topic. In this use case, **queue** is used.

   In the **Destination** field, type in a name for the queue, for example "myqueue".

   In the **ConnectionFactory** field, click [...] and select the MQ connection factory that you have just configured to handle messages.

9. Keep the default settings of the **cLog** component to log the message exchanges.
10. Press Ctrl+S to save your Route.

Viewing the code and executing the Route

Procedure

1. Click the Code tab at the bottom of the design workspace to check the generated code.

   ```java
   public void configure() throws java.lang.Exception {
       from(uriMap.get("cTimer_1"))
           .routeId("Starter_cTimer_1")
           .setBody()
               .simple("Hello World!").id("cSetBody_1")
           .to(uriMap.get("cAMQP_1")).id("cAMQP_1")
           .to(uriMap.get("cLog_1"))
               .id("cLog_1");
   }
   
   As shown above, the message flow from cTimer_1 is given a payload by cSetBody_1 and then sent to cAMQP_1 and cLog_1.

2. Press F6 to execute the Route. The logs of the message exchange are printed in the console.

3. In the ActiveMQ Web Console, you can see that the message queue myqueue has been created.
Building the consumer Route

Adding components to arrange the flow

About this task

Procedure

1. From the Palette, drag and drop a `cMQConnectionFactory`, a `cAMQP`, and a `cLog` component onto the design workspace.

2. Label the components for better identification of their roles and link them with the Row > Route connection as shown above.
Configuring how the message is processed

Procedure

1. Double-click the `cMQConnectionFactory` component to display its Basic settings view in the Component tab.

2. From the MQ Server list, select AMQP 1.0 to handle messages. Keep the default settings of the other options.

3. Double-click the `cAMQP` component to display its Basic settings view in the Component tab.

4. Specify the same URI Type and Destination in the consumer `cAMQP` component as in the producer.

   In the ConnectionFactory field, click [...] and select the MQ connection factory that you have just configured to handle messages.

5. Keep the default settings of the `cLog` component to log the message exchanges.

6. Press Ctrl+S to save your Route.
**Executing the Route**

**Procedure**

1. Click the **Code** tab at the bottom of the design workspace to check the generated code.

   ```java
   public void configure() throws java.lang.Exception {
       from(uriMap.get("cAMQP_1")).routeId("Consumer_cAMQP_1")
           .to(uriMap.get("cLog_1"))
           .id("cLog_1");
   }
   ``

   As shown above, the message flow is routed from `cAMQP_1` to `cLog_1`.

2. Press **F6** to execute the Route. The logs of the message exchange are printed in the console.

   ![Execution output]

   ```
   [statistics] connecting to socket on port 3992
   [statistics] connected
   [INFO ]: cAMQP_consumer.cLog_1 - Exchange[ExchangePattern:
   InOnly, BodyType: String, Body: Hello World!]
   [INFO ]: cAMQP_consumer.cLog_1 - Exchange[ExchangePattern:
   InOnly, BodyType: String, Body: Hello World!]
   [INFO ]: cAMQP_consumer.cLog_1 - Exchange[ExchangePattern:
   InOnly, BodyType: String, Body: Hello World!]
   [INFO ]: cAMQP_consumer.cLog_1 - Exchange[ExchangePattern:
   InOnly, BodyType: String, Body: Hello World!]
   [INFO ]: cAMQP_consumer.cLog_1 - Exchange[ExchangePattern:
   InOnly, BodyType: String, Body: Hello World!]
   [INFO ]: cAMQP_consumer.cLog_1 - Exchange[ExchangePattern:
   InOnly, BodyType: String, Body: Hello World!]
   ```

3. In the ActiveMQ Web Console, you can see that the messages in `myqueue` have been consumed.
<table>

cAWSConnection

Establishes a connection to Amazon Web Services for data storage and retrieval.

**cAWSConnection Standard properties**

These properties are used to configure cAWSConnection running in the Standard Job framework. The Standard cAWSConnection component belongs to the AWS and Connectivity families.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Access Key</strong></td>
<td>The Access Key ID that uniquely identifies an AWS Account. For how to get your Access Key and Access Secret, see Access keys (access key ID and secret access key).</td>
</tr>
<tr>
<td><strong>Secret Key</strong></td>
<td>The Secret Access Key, constituting the security credentials in combination with the access Key. To enter the secret key, click [...] next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Inherit credentials from AWS role</strong></td>
<td>Select this check box to obtain AWS security credentials from Amazon EC2 instance metadata. To use this option, the Amazon EC2 instance must be started and your Route must be running on Amazon EC2. For more information, see Using an IAM Role to Grant Permissions to Applications Running on Amazon EC2 Instances, Instance Metadata and User Data, and IAM Roles for Amazon EC2.</td>
</tr>
<tr>
<td><strong>Region</strong></td>
<td>Specify the AWS region by selecting a region name from the list or entering a region between double quotation marks (e.g. &quot;us-east-1&quot;) in the list. For more information about AWS Regions, see AWS Regions and Endpoints.</td>
</tr>
</tbody>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Config Client</strong></td>
<td>Select this check box to set the optional parameters for your AWS client in the corresponding table. Click [+ ] as many times as required and add the available parameters from the list to the table. Then click the corresponding Value field and enter a value. See the site Class ClientConfiguration for more information.</td>
</tr>
</tbody>
</table>

**Usage**

| Usage rule | cAWSConnection cannot be added directly in a Route. |

**Related scenario:**

For related scenarios, see:

- Sending messages to and receiving messages from Amazon’s S3 service on page 28
- Sending Email using the cAWSSES component on page 36
- Sending messages to Amazon’s SNS topic on page 42
- Sending messages to and receiving messages from Amazon’s SQS queue on page 49
**cAWSS3**

Stores and retrieves objects from/to Amazon’s Simple Storage Service (S3)

**cAWSS3 Standard properties**

These properties are used to configure cAWSS3 running in the Standard Job framework.

The Standard cAWSS3 component belongs to the AWS and Connectivity families.

**Basic settings**

<table>
<thead>
<tr>
<th><strong>Connection</strong></th>
<th>Select an AWSS3 connection component from the list to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Bucket Name</strong></td>
<td>Specify the name of the bucket, namely the top level folder, on Amazon’s S3 service.</td>
</tr>
</tbody>
</table>

The following options are available only when the cAWSS3 is used as a Producer:

<table>
<thead>
<tr>
<th><strong>Storage Class</strong></th>
<th>Select from <strong>Standard</strong>, <strong>Standard - Infrequent Access</strong> and <strong>Reduced Redundancy</strong>. For more information about storage classes, see the site <a href="http://docs.aws.amazon.com/AmazonS3/latest/dev/storage-class-intro.html">http://docs.aws.amazon.com/AmazonS3/latest/dev/storage-class-intro.html</a>.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Delete After Write</strong></td>
<td>Select this check box to delete the local file object after it is uploaded to the S3 service.</td>
</tr>
<tr>
<td><strong>Multi Part Upload</strong></td>
<td>Select this check box to upload the file with multi part format, and specify part size in the corresponding field. The default size is 25M.</td>
</tr>
<tr>
<td><strong>Server Side Encryption</strong></td>
<td>Select this option to encrypt the object on the server side using the AWS-managed keys.</td>
</tr>
</tbody>
</table>

**Message Headers**

Set the message headers in the corresponding table. Click [+] as many times as required to add message headers to the table. Then click the corresponding Value field and enter a value. See the site [http://camel.apache.org/aws-s3.html](http://camel.apache.org/aws-s3.html) for available headers. Be sure to set the CamelAwsS3Key header which will be used as the name of the S3 file.

**Use User Defined Headers**

Select this check box to set user defined headers in the corresponding table. Click [+] as many times as required to add message headers to the table. Then click the corresponding Value field and enter a value. Note that user defined headers must start with `x-amz-meta-`.

The following options are available only when the cAWSS3 is used as a Consumer:

<p>| <strong>File Name</strong> | Specify the name of the file to be consumed. |</p>
<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Max Messages Per Poll</td>
<td>The maximum number of objects that can be retrieved in one poll.</td>
</tr>
<tr>
<td>Prefix</td>
<td>Specify the prefix of files so that only files with that prefix will be consumed.</td>
</tr>
<tr>
<td>Delete After Read</td>
<td>Select this check box to delete the object from the S3 service after it has been retrieved.</td>
</tr>
<tr>
<td>Include Body</td>
<td>Select this check box to include the exchange body in the content of the file. Otherwise only the headers will be set with the S3 object metadata and the body will be null.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| Advanced | Set the optional parameters in the corresponding table. Click [+] as many times as required to add parameters to the table. Then click the corresponding Value field and enter a value. See the site [http://camel.apache.org/aws-s3.html](http://camel.apache.org/aws-s3.html) for available options. |

**Usage**

<table>
<thead>
<tr>

## Sending messages to and receiving messages from Amazon’s S3 service

This scenario applies only to [Talend Open Studio for ESB](http://camel.apache.org), [Talend Data Services Platform](http://camel.apache.org), and [Talend Data Fabric](http://camel.apache.org).

This scenario will show you how to use the **cAWSS3** component to send messages to and consume messages from Amazon’s S3 service. To do this, two Routes are built, a message producer Route, and a consumer Route. Messages are sent to the Amazon’s S3 service in the producer Route and then consumed in the consumer Route.
Building the producer Route

Dropping and linking the components

About this task

Procedure

1. From the Palette, drag and drop a cAWSConnection, a cFile, and a cAWSS3 component onto the design workspace.

2. Label the components for better identification of their roles and link them with the Row > Route connection as shown above.

Configuring the components

Procedure

1. Double-click the cAWSConnection component to display its Basic settings view in the Component tab.

2. In the Access Key and Secret Key fields, enter the authentication credentials of your AWS account. For how to get your Access Key and Access Secret, see Access keys (access key ID and secret access key).

3. Double-click the cFile component to open its Basic settings view in the Component tab.
4. In the **Path** field, browse to or enter the input file path.
   In the **fileName** field, enter the name of file to be uploaded to the S3 service.
   In this scenario, a TXT file with the name `talend` that contains a simple string `Hello World!` is used.

5. Double-click the **cAWSS3** component to open its **Basic settings** view in the **Component** tab.

6. In the **Connection** list, select the **cAWSConnection** component that you have just configured to connect to Amazon's S3 service.
   In the **Bucket Name** field, enter the name of the bucket to upload the file, "talend-s3-demo" in this use case.
Under the **Message Headers** table, click [+] to add two rows in the table. Set the header **CamelAwsS3Key** with the value `talend.txt` as the name of the S3 object, and the header **CamelAwsS3ContentLength** with the value 5 to define the length of the object.

7. Press **Ctrl+S** to save your Route.

### Viewing the code and executing the Route

#### Procedure

1. Click the **Code** tab at the bottom of the design workspace to check the generated code.

```java
from 
"file://F:/data" + "?noop=true" + "&autoCreate=true" + "&flatten=false" + "&fileName=talend.txt" + "&charset=UTF-8" + "&bufferSize=128"
.routeId("s3producer_cFile_1")
.setHeader("CamelAwsS3Key", constant("talend.txt"))
.setHeader("CamelAwsS3ContentLength", constant(5))
.to("aws-s3:talend-s3-demo" + ";amazonS3Client=#conn_cAWSConnection_1")
.id("s3producer_cAWSS3_1");
```

As shown above, the message is routed from `s3producer_cFile_1` to `s3producer_cAWSS3_1`.

2. Press **F6** to execute the Route. The logs of the message exchange are printed in the console.

3. In the Amazon's S3 Web Console, you can see that the object `talend.txt` has been created.
Building the consumer Route

Arranging the flow of the message

About this task

Procedure

1. From the **Palette**, drag and drop a **cAWSConnection**, a **cAWSS3** and a **cProcessor** component onto the design workspace.

2. Label the components for better identification of their roles and link them with the **Row > Route** connection as shown above.

Configuring how the message is processed

Procedure

1. Configure the **cAWSConnection** using the same properties as in the producer Route.
2. Double-click the `cAWSS3` component to display its **Basic settings** view in the **Component** tab.

![cAWSS3 component](Image)

3. In the **Connection** list, select the `cAWSConnection` component to connect to Amazon’s S3 service. In the **Bucket Name** field, enter the name of the bucket that contains the file to be consumed, "talend-s3-demo" in this use case. In the **File Name** field, enter the name of the file, "talend.txt". Clear the **Delete After Read** check box to keep the S3 object file after it is consumed.

4. Double-click the `cProcessor` component to display its **Basic settings** view in the **Component** tab.

![cProcessor component](Image)

5. In the **Code** box, enter the following code to print the file name and its content in the execution console:

```java
BufferedReader br = new BufferedReader(new InputStreamReader((InputStream) exchange.getIn().getBody()));
System.out.println("FileName: " + exchange.getIn().getHeader("CamelAwsS3Key") + "Content: " + br.readLine());
```

6. Press **Ctrl+S** to save your Route.

**Executing the Route**

**Procedure**

1. Click the **Code** tab at the bottom of the design workspace to check the generated code.
As shown above, the message flow is routed from s3consumer_cAWSS3_1 and processed by s3consumer_cProcessor_1.

2. Press F6 to execute the Route. The logs of the message exchange are printed in the console.

The content of the file is Hello as the length of the object is defined to 5 when uploading the file to the S3 service.
cAWSSES

Sends emails with Amazon's Simple Email Service (SES).

**cAWSSES Standard properties**

These properties are used to configure cAWSSES running in the Standard Job framework.

The Standard cAWSSES component belongs to the AWS and Connectivity families.

**Basic settings**

<table>
<thead>
<tr>
<th>Connection</th>
<th>Select an AWS connection component from the list to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Subject</td>
<td>Specify the email subject. It can be overridden by the CamelAwsSesSubject header.</td>
</tr>
<tr>
<td>From</td>
<td>Specify the sender's email address. It can be overridden by the CamelAwsSesFrom header.</td>
</tr>
<tr>
<td>To</td>
<td>Specify one or more destination email addresses. It can be overridden by the CamelAwsSesTo header.</td>
</tr>
<tr>
<td>Return Path</td>
<td>Specify the email address to which bounce notifications are to be forwarded. It can be overridden by the CamelAwsSesReturnPath header.</td>
</tr>
<tr>
<td>Reply to Addresses</td>
<td>Specify the reply-to email address(es) for the message. It can be overridden by the CamelAwsSesReplyToAddresses header.</td>
</tr>
</tbody>
</table>

**Message Headers**

Set the message headers in the corresponding table. Click [+] as many times as required to add message headers to the table. Then click the corresponding Value field and enter a value. See the site http://camel.apache.org/aws-ses.html for available headers.

**Advanced settings**

| Advanced       | Set the optional parameters in the corresponding table. Click [+] as many times as required to add parameters to the table. Then click the corresponding Value field and enter a value. See the site http://camel.apache.org/aws-ses.html for available options. |

**Usage**

| Usage rule       | cAWSSES can be a start, middle or end component in a Route. It has to be used with the cAWSConnection component, which creates a connection to Amazon Web Services. For more information about cAWSConnection, see cAWSConnection on page 26. |
Sending Email using the cAWSSES component

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

This scenario will show you how to use the cAWSSES component to send emails with Amazon’s SES service.

Dropping and linking the components

About this task

Procedure
1. From the Palette, drag and drop a cAWSConnection, a cTimer, a cSetBody, a cAWSSES, and a cProcessor component onto the design workspace.
2. Label the components for better identification of their roles and link them with the Row > Route connection as shown above.

Configuring the components

Procedure
1. Double-click the cAWSConnection component to display its Basic settings view in the Component tab.
2. In the Access Key and Secret Key fields, enter the authentication credentials.
3. Double-click the cTimer component to open its Basic settings view in the Component tab.
4. In the **Repeat** field, enter 1 to generate the message exchange one time. Keep the default settings of the other options.

5. Double-click the **cSetBody** component to open its **Basic settings** view in the **Component** tab.

6. Select **CONSTANT** from the **Language** drop-down list and type in "Hello world" in the **Expression** field as the message body.

7. Double-click the **cAWSSES** component to open its **Basic settings** view in the **Component** tab.
8. In the **Connection** list, select the **cAWSConnection** component that you have just configured to connect to Amazon SES service.

   In the **Subject** field, enter the email subject, for example, "Hello" in this use case.

   In the **From** and **To** fields, enter the sender’s email address and the destination email address respectively.

   In the **Return Path** field, enter the email address to which bounce notifications are to be forwarded.

   In the **Reply To** field, enter the email address to receive replies.

9. Double-click the **cProcessor** component to display its **Basic settings** view in the **Component** tab.
10. In the Code box, enter the following code to print the CamelAwsSesMessageId in the execution console:

```java
System.out.println("CamelAwsSesMessageId: " + exchange.getIn().getHeader("CamelAwsSesMessageId"));
```

11. Press Ctrl+S to save your Route.

**Viewing the code and executing the Route**

**Procedure**

1. Click the Code tab at the bottom of the design workspace to check the generated code.

```java
from("timer:cTimer_1" + "?repeatCount=1 &delay=1000")
    .routeId("sesproducer_cSetBody_1")
    .constant("Hello World!")
    .id("sesproducer_cSetBody_1")
    .to("aws-ses:noreply@talend.com" + "?amazonSESClient#conn_cAWSConnection_1" + "&subject=Hello" + "&to=mwang@talend.com" + "&returnPath=jihang@talend.com" + "&replyToAddresses=jzhang@talend.com")
    .id("sesproducer_cAWSSES_1")
    .process(new org.apache.camel.Processor() {  
        public void process(org.apache.camel.Exchange exchange) 
            throws Exception {
                /*
                 * Provide own codes to consume or translate the message exchanges.
                 * @param org.apache.camel.Exchange exchange
                 */
                System.out.println("CamelAwsSesMessageId: 
                + exchange.getIn().getHeader("CamelAwsSesMessageId");
    });
    .id("sesproducer_cProcessor_1");
```
As shown above, the message flow from sesproducer_cTimer_1 is given a payload by sesproducer_cSetBody_1. Then it is sent to sesproducer_cAWSSES_1 and processed by sesproducer_cProcessor_1.

2. Press F6 to execute the Route. The logs of the message exchange are printed in the console.

```
Starting job sesproducer at 17:01 10/10/2016:

[statistics] connecting to socket on port 3437
[statistics] connected
CamelAwsSesMessageId: 01000187add3cbfc-4d8129a9-01f1-4e28-93c4-726a24c00ea6-000000
```

3. An email is sent to the destination address.

```
Mon 10/10/2016 5:02 PM
noreply@talend.com
Hello

Hello World!
```

4. When replying the email, the destination is the email address specified in the To field of the cAWSSES component.

Subject: Hello

Hello World!
cAWSSNS

Sends messages to an Amazon’s Simple Notification topic.

**cAWSSNS Standard properties**

These properties are used to configure cAWSSNS running in the Standard Job framework. The Standard cAWSSNS component belongs to the AWS and Connectivity families.

**Basic settings**

<table>
<thead>
<tr>
<th>Connection</th>
<th>Select an AWS connection component from the list to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Topic</td>
<td>Specify the name of the topic on Amazon's Simple Notification Service (SNS) to send message to.</td>
</tr>
<tr>
<td>Subject</td>
<td>Specify a subject for the message. It can be overridden by the message header CamelAwsSnsSubject.</td>
</tr>
</tbody>
</table>

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th><strong>cAWSSNS</strong> can only be an end component in a Route. It has to be used with the <strong>cAWSConnection</strong> component, which creates a connection to Amazon Web services. For more information about <strong>cAWSConnection</strong>, see <strong>cAWSConnection</strong> on page 26.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limitation</td>

</tr>
</tbody>
</table>

**Sending messages to Amazon’s SNS topic**

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

This scenario will show you how to use the **cAWSSNS** component to send message to the Amazon’s SNS topic.

You must have a valid Amazon Web Services developer account, and be signed up to use Amazon’s SNS. For more information, see Amazon SNS.
Dropping and linking the components

About this task

Procedure
1. From the Palette, drag and drop a `cAWSConnection`, a `cTimer`, a `cSetBody`, and a `cAWSSNS` component onto the design workspace.
2. Label the components for better identification of their roles and link them with the Row > Route connection as shown above.

Configuring the components

Procedure
1. Double-click the `cAWSConnection` component to display its Basic settings view in the Component tab.

![cAWSConnection_1](image)

2. In the Access Key and Secret Key fields, enter the authentication credentials of your AWS account. For how to get your Access Key and Access Secret, see Access keys (access key ID and secret access key).
3. Double-click the `cTimer` component to open its Basic settings view in the Component tab.
4. In the **Repeat** field, enter 1 to generate the message exchange one time. Keep the default settings of the other options.

5. Double-click the **cSetBody** component to open its **Basic settings** view in the **Component** tab.

![Set_message_body(cSetBody_1)](image)

6. Select **CONSTANT** from the **Language** drop-down list and type in "Hello world" in the **Expression** field as the message body.

7. Double-click the **cAWSSNS** component to open its **Basic settings** view in the **Component** tab.

8. In the **Connection** list, select the **cAWSConnection** component that you have just configured to connect to Amazon's SNS service.

   In the **Topic** field, enter the name of the topic to send message to, "talend-com-tesb-sns" in this use case.

   In the **Subject** field, give a subject for the message, for example "Talend".

9. Press **Ctrl+S** to save your Route.

**Viewing the code and executing the Route**

**Procedure**

1. Click the **Code** tab at the bottom of the design workspace to check the generated code.

   ```java
   from("timer:cTimer_1" + ";repeatCount=1 + ";delay=1000")
   .routeId("sns_cTimer_1")
   .setBody()  
   .constant("Hello World!")  
   .id("sns_cSetBody_1")  
   .to("aws-sns:talend-com-tesb-sns"  
   + ";amazonSNSClient=conn_cAWSConnection_1"  
   + ";subject=Talend").id("sns_cAWSSNS_1");
   ```

   As shown above, the message flow from **sns_cTimer_1** is given a payload by **sns_cSetBody_1** and then sent to **sns_cAWSSNS_1**.

2. Press **F6** to execute the Route. The logs of the message exchange are printed in the console.
3. An email address has already subscribed to the SNS topic as shown below. For more information about how to subscribe to a topic, see the site http://docs.aws.amazon.com/sns/latest/dg/SubscribeTopic.html.

An notification of the message is sent to the Email address:
Hello World!

--
If you wish to stop receiving notifications from this topic, please click or visit the link below to unsubscribe:

Please do not reply directly to this email. If you have any questions or comments regarding this email, please contact us at https://aws.amazon.com/support
cAWSSQS

Sends and receives messages to/from Amazon’s Simple Queue Service (SQS). The AWS SQS FIFO Feature for Queues are supported.

**cAWSSQS Standard properties**

These properties are used to configure cAWSSQS running in the Standard Job framework.

The Standard cAWSSQS component belongs to the AWS and Connectivity families.

**Basic settings**

<table>
<thead>
<tr>
<th><strong>Connection</strong></th>
<th>Select an AWS connection component from the list to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Queue Name</strong></td>
<td>Enter the name of the queue to send message to or receive message from. When the cAWSSQS is used as a producer, the queue will be created if it does not exist. Queue names must be 1-80 characters in length and be composed of alphanumeric characters, hyphens (-), and underscores (_).</td>
</tr>
</tbody>
</table>

The following options are available only when the cAWSSQS is used as a Producer:

<table>
<thead>
<tr>
<th><strong>Delay (in seconds)</strong></th>
<th>Specify the amount of time to delay the first delivery of all messages added to this queue.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Wait Time (0 to 20 seconds)</strong></td>
<td>Specify the maximum amount of time in seconds (0 to 20) that a long polling receive call will wait for a message to become available before returning an empty response.</td>
</tr>
</tbody>
</table>

The following options are available only when the cAWSSQS is used as a Consumer:

<table>
<thead>
<tr>
<th><strong>Delete Message / After Read (processed by route)</strong></th>
<th>Select this check box to delete the message from the queue after it is read and processed by the Route.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Delete Message / If Filtered (matched by filter)</strong></td>
<td>Select this check box to delete the messages from the queue that are filtered in the Route, even if the exchange fails to get through a filter.</td>
</tr>
<tr>
<td><strong>Allow Multiple Threads</strong></td>
<td>Select this check box to allow multiple threads to poll the SQS queue to increase throughput. When this option is enabled, you need to specify the maximum number of concurrent consumers and objects that can be retrieved in one poll in the <strong>Concurrency Number</strong> and <strong>Max Messages Per Poll</strong> fields respectively.</td>
</tr>
<tr>
<td><strong>Extend Message Visibility</strong></td>
<td>Select this check box to enable a scheduled background task to keep extending the message visibility on SQS. This is needed if it takes a long time to process the message. When this option is enabled, you need to set the duration in seconds that the received messages are hidden from subsequent retrieve requests in the <strong>Visibility Timeout</strong> field. For more information, see the site http://</td>
</tr>
</tbody>
</table>
Select this check box to retrieve the standard Amazon SQS attributes along with each message. For more information about the Amazon SQS attributes, see ReceiveMessage > Request Parameters.

Select this check box to retrieve the ApproximateFirstReceiveTimestamp attribute only along with each message. For more information about the Amazon SQS attributes, see ReceiveMessage > Request Parameters.

Select this check box to retrieve the ApproximateReceiveCount attribute only along with each message. For more information about the Amazon SQS attributes, see ReceiveMessage > Request Parameters.

Select this check box to retrieve the SenderId attribute only along with each message. For more information about the Amazon SQS attributes, see ReceiveMessage > Request Parameters.

Select this check box to retrieve the SentTimestamp attribute only along with each message. For more information about the Amazon SQS attributes, see ReceiveMessage > Request Parameters.

Specify the queue owner’s AWS account ID when you need to connect the queue with different account owner.

Set the optional queue attributes in the corresponding table. Click [+] as many times as required to add attributes to the table. Then click the corresponding Value field and enter a value. The following attributes are available:

- **Default Visibility Timeout (in seconds):** The default visibility timeout for the queue in seconds.
- **Max Message Size (in bytes):** The maximum message size in bytes that an SQS message can contain for the queue.
- **Message Retention Period (in seconds):** The period in seconds that a message will be retained by SQS for the queue.
- **Receive Message Wait Time (in seconds):** The duration in seconds that the ReceiveMessage action call will wait until a message is in the queue to include in the response.
- **Message GroupId Strategy (for FIFO queue):** To send messages to FIFO queue of Amazon SQS, you have to specify the value of this attribute from the following to set the Message Group ID:
  - useConstant: The Message Group ID is the fixed string CamelSingleMessageGroup.
  - useExchangeId: The Message Group ID is the camel exchangeId, for example, ID=xldai-PC-1545104566148-0-1.
• usePropertyValue: The Message Group ID is specified from the Camel property CamelAwsMessageGroupId.

• Message DeduplicationId Strategy(for FIFO queue): This attribute is optional for sending messages to FIFO queue of Amazon SQS. Specify the value of this attribute from the following for how messages are deduplicated:
  • useExchangeId: the messages are deduplicated by exchangeId.
  • useContentBasedDeduplication: the messages are deduplicated by message content.

<table>
<thead>
<tr>
<th>Request Message Attribute</th>
<th>This option is only available when cAWSSQS is used as a Consumer. Select this check box and add the attribute to be retrieved along with each message.</th>
</tr>
</thead>
</table>

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>cAWSSQS can be a start, middle or end component in a Route. It has to be used with the cAWSConnection component, which creates a connection to Amazon SNS service. For more information about cAWSConnection, see cAWSConnection on page 26.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Limitation</th>
<th>n/a</th>
</tr>
</thead>
</table>

### Sending messages to and receiving messages from Amazon’s SQS queue

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

This scenario will show you how to use the cAWSSQS component to send messages to and consume messages from an SQS queue. To do this, two Routes are built, a message producer Route, and a consumer Route. Messages are sent to the SQS queue in the producer Route and then consumed in the consumer Route.

You must have a valid Amazon Web Services developer account, and be signed up to use Amazon SQS. For more information, see Amazon SQS.
Building the producer Route

Dropping and linking the components

About this task

1. From the Palette, drag and drop a cAWSConnection, two cTimer, two cSetBody, two cAWSSQS components onto the design workspace.

2. Label the components for better identification of their roles and link them with the Row > Route connection as shown above.

Configuring the components

Procedure

1. Double-click the cAWSConnection component to display its Basic settings view in the Component tab.

2. In the Access Key and Secret Key fields, enter the authentication credentials of your AWS account. For how to get your Access Key and Access Secret, see Access keys (access key ID and secret access key).

3. Double-click the cTimer labelled repeat=2 to open its Basic settings view in the Component tab.
4. In the **Repeat** field, enter 2 to generate the message exchange twice. Keep the default settings of the other options.

5. Configure the **cTimer** labelled `repeat=3` in the same way to generate the message exchange three times.

6. Double-click the **cSetBody** component labelled `body=hello` to open its **Basic settings** view in the **Component** tab.

7. Select **CONSTANT** from the **Language** list and type in `hello` in the **Expression** field as the message body.

8. Configure the **cSetBody** labelled `body=world` in the same way to set the message body as `world`. 
9. Double-click the cAWSSQS labelled Producer_1 to open its Basic settings view in the Component tab.

10. In the Connection list, select the cAWSConnection component that you have just configured to connect to Amazon's SQS service.
    In the Queue Name field, type in the name of the SQS queue to send the messages.

11. Configure the cAWSSQS labelled Producer_2 with the same properties to send the messages to the same queue.

12. Press Ctrl+S to save your Route.

Viewing the code and executing the Route

Procedure

1. Click the Code tab at the bottom of the design workspace to check the generated code.

```java
from("timer:cTimer_1" + "+"repeatCount=" + 2 + "+"delay=" + 1000)
    .routeId("sqspproducer_cTimer_1")
    .setBody()
    .constant("hello")
    .id("sqspproducer_cSetBody_1")
    .to("aws-sqs:talend-com-tesb-camel-sqs" + "?amazonSQSClient=#cAWSSQS_cAWSSQSConnection_1")
    .id("sqspproducer_cAWSSQS_1");
from("timer:cTimer_2" + "+"repeatCount=" + 3 + "+"delay=" + 1000)
    .routeId("sqspproducer_cTimer_2")
    .setBody()
    .constant("world")
    .id("sqspproducer_cSetBody_2")
    .to("aws-sqs:talend-com-tesb-camel-sqs" + "?amazonSQSClient=#cAWSSQS_cAWSSQSConnection_1")
    .id("sqspproducer_cAWSSQS_2");
```
As shown above, in the first sub-route, the message flow from sqsproducer_cTimer_1 is given a payload by sqsproducer_cSetBody_1 and then sent to sqsproducer_cAWSSQS_1. The second sub-route is in the same way.

2. Press F6 to execute the Route. The logs of the message exchange are printed in the console. The warn message shows that header fireTime is not put into the message attribute.

3. In the SQS Web Console, you can see that there are now 5 messages in the queue talend-com-tesb-camel-sqs.
Building the consumer Route

Arranging the flow of the message

About this task

Procedure

1. From the Palette, drag and drop a `cAWSConnection`, a `cAWSSQS`, a `cMessageFilter` and a `cLog` component onto the design workspace.
2. Link the `cAWSSQS` to `cMessageFilter` with the Row > Route connection and `cMessageFilter` to `cLog` with the Row > Filter connection.
3. Label the components for better identification of their roles.

Configuring how the message is processed

Procedure

1. Configure the `cAWSConnection` using the same properties as in the producer Route.
2. Double-click the `cAWSSQS` component to display its Basic settings view in the Component tab.

3. In the Connection list, select the `cAWSConnection` component to connect to Amazon’s SQS service.
   
   In the Queue Name field, enter the name of the queue to consume the message from.
   
   Select the Delete Message / After Read check box and clear the If Filtered check box to delete the messages that are read and keep those that are not consumed.

4. Double-click the `cMessageFilter` component to display its Basic settings view in the Component tab.
5. Select **Simple** from the **Language** list and enter `"${body} == 'hello'"` in the **Expression** field to sort out messages with *hello* as the message body.

6. Keep the default settings of the **cLog** component to log the message exchanges.

7. Press **Ctrl+S** to save your Route.

**Executing the Route**

**Procedure**

1. Click the **Code** tab at the bottom of the design workspace to check the generated code.

   ```java
   from(
       "aws-sqs:talend-com-tcsb-camel-sqs"
       + "/?amazonSQSClient=#CAWSSQS_CAWSConnection_1"
       + "/?deleteIfFiltered=false + "/?attributeNames=All"
   )
   .routeId("sqscconsumer_cAWSSQS_1").filter()
   .simple("${body} == 'hello'")
   .id("sqscconsumer_cMessageFilter_1")
   .id("sqscconsumer_cLog_1" + "/?level=WARN")
   .id("sqscconsumer_cLog_1");
   ``

   As shown above, the message flow from `sqscconsumer_cAWSSQS_3`, is filtered by `sqscconsumer_cMessageFilter_1`, and then routed to `sqscconsumer_cLog_1`.

2. Press **F6** to execute the Route. The messages with the body *hello* are consumed and are printed in the console.
In the SQS Web Console, you can see that there are now 3 three messages left in the queue `talend-com-ttesb-camel-sqs`. The two messages with the body `hello` have been consumed and deleted as configured in the `cAWSSQS` component.
cBean

Invokes a Java bean that is stored in the Code node of the Repository or registered by a cBeanRegister.

cBean Standard properties

These properties are used to configure cBean running in the Standard Job framework.
The Standard cBean component belongs to the Custom family.

Basic settings

<table>
<thead>
<tr>
<th>Reference</th>
<th>Select this option to reference a Java bean registered by a cBeanRegister.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>In the Id field that appears, enter the Id of the Java bean.</td>
</tr>
<tr>
<td>New Instance</td>
<td>Select this option to invoke a Java bean that is stored in the Code node of the Repository.</td>
</tr>
<tr>
<td></td>
<td>In the Bean class field that appears, enter the name of the bean class.</td>
</tr>
<tr>
<td></td>
<td>For more information about creating and using Java Beans, see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Specify the method</td>
<td>Select this check box to enter the name of a method to be included in the bean.</td>
</tr>
</tbody>
</table>

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>cBean can be a start, middle or end component in a Route.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limitation</td>
<td>n/a</td>
</tr>
</tbody>
</table>

Related Scenario

For a related scenario, see:

- cConvertBodyTo: Converting the body of an XML file into an org.w3c.dom.Document.class on page 72.
cBeanRegister

Registers a Java bean in the registry to be used in message exchanges.

**cBeanRegister Standard properties**

These properties are used to configure cBeanRegister running in the Standard Job framework.

The Standard cBeanRegister component belongs to the Custom family.

### Basic settings

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Id</strong></td>
<td>Enter any string which is used to look up the bean in the registry.</td>
</tr>
<tr>
<td><strong>Simple</strong></td>
<td>Select this option to call a bean class that is stored in the Code node of the Repository.</td>
</tr>
<tr>
<td><strong>Customized</strong></td>
<td>Select this option to define the Java bean by entering the code in the Code box.</td>
</tr>
<tr>
<td><strong>Class Name</strong></td>
<td>This field appears when the Simple option is selected. Enter the name of the bean class that is stored in the Code node of the Repository. For more information about creating and using Java Beans, see Talend Studio User Guide.</td>
</tr>
<tr>
<td><strong>Specify Arguments</strong></td>
<td>This check box appears when the Simple option is selected. Select this check box to set the optional arguments in the corresponding table. Click [+] as many times as required to add arguments to the table.</td>
</tr>
<tr>
<td><strong>Imports</strong></td>
<td>This box appears when the Customized option is selected. Enter the Java code that helps to import, if necessary, external libraries used in the Code box.</td>
</tr>
<tr>
<td><strong>Code</strong></td>
<td>This box appears when the Customized option is selected. Enter the code of the bean in the box.</td>
</tr>
</tbody>
</table>

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>cBeanRegister cannot be added directly in a Route.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limitation</td>
<td>n/a</td>
</tr>
</tbody>
</table>

### Related Scenario

For a related scenario, see:

- **cConvertBodyTo**: Converting the body of an XML file into an org.w3c.dom.Document.class on page 72.
cConfig

Sets the CamelContext using Java code.

**cConfig Standard properties**

These properties are used to configure cConfig running in the Standard Job framework.

The Standard cConfig component belongs to the Custom family.

**Basic settings**

</tr>
</thead>
<tbody>
<tr>
<td>Code</td>
<td>Write a piece of code to manipulate the CamelContext.</td>
</tr>
<tr>
<td>Dependencies</td>
<td>Click [+] to add the library or libraries that are required by the CamelContext or Typeconverter Registry to the Studio. Click [...] in the Lib Path field to show the Select Module dialog box. Select the inner module from the list or browse to the external module of your choice and click OK to close the dialog box. The version of the external module is extracted, If not, a default Snapshot version 0.0.1-SNAPSHOT is given to the library. You can change it as needed. If you are connected to a remote project with Talend Studio, when saving the Route, the external libraries will be uploaded to the Talend Artifact Repository configured in the Talend Administration Center. The libraries with the -SNAPSHOT suffix in the version number will be published to the Snapshot repository. Otherwise it will be published to the Release repository. If you change the version of the library and save the Route, a new version of the library will be uploaded to the Talend Artifact Repository. For more information about how to install Talend Artifact Repository, see Talend Installation Guide. For how to set the Artifact repository connection preferences, see Talend Administration Center User Guide. For how to connect to a remote project, see Talend Studio User Guide.</td>

**Advanced settings**

| Use MDC Logging | Select this check box to enable the use of MDC logging. To be able to use this option, you need to open the Log4j view in the Project Settings dialog box by clicking File > Edit Project Properties on the toolbar of the Studio main window. Select the Activate log4j in components check box to activate the log4j feature. Then change the ConversionPattern in the log4j template to add your custom MDC property like %X{mdcPropertyName}. To show the MDC information in the log, use the cLog component and a cProcessor before and after the cLog. In the cProcessor before the cLog, enter the code org.apache.log4j.MDC.put("Key", "Value"); |

59
to add the custom property. In the `cProcessor` after the `cLog`, enter the code `org.apache.log4j.MDC.remove("Key");` to remove the MDC property.

For information on how to activate log4j in components and how to customize log4j configuration, see `Talend Studio User Guide`.

For more information about MDC logging, see the website `http://camel.apache.org/mdc-logging.html`.

For more information about the `cLog` component, see `cLog` on page 192.

---

**Check**

Click this button to check the version of the libraries that are added to the Route in the Talend Artifact Repository. The libraries are listed in the table below, with the versions shown in the **Update To** column. If the version of the local library is the same as in the Talend Artifact Repository, a `√` is shown in the **Status** column. If the version of the local library is older than in the Talend Artifact Repository, a `×` is shown in the **Status** column, and the check box in the **Sync** column is selected by default.

**Sync**

Select the check box in the **Sync** column of the table for the libraries that you want to update and click the **Sync** button to download and install the newer version from the Talend Artifact Repository into the Studio.

---

**Usage**

**Usage rule** | `cConfig` cannot be added directly in a Route.
---|---
**Limitation** | n/a

---

**Implementing a dataset from the Registry**

This scenario applies only to `Talend Open Studio for ESB`, `Talend Data Services Platform` and `Talend Data Fabric`.

In this scenario, an instance of dataset is added in the Registry and implemented by a `cMessagingEndpoint` component.

---

![Diagram of dataset implementation](Create_dataset.png)

![Diagram of dataset implementation](Read_dataset.png)
Dropping and linking the components

Procedure

1. From the Palette, expand the Custom folder, and drop a cConfig component onto the design workspace.
2. Expand the Connectivity folder, and drop a cMessagingEndpoint component onto the design workspace.
3. Expand the Custom folder, and drop a cProcessor component onto the design workspace.
4. Right-click the input cMessagingEndpoint component, select Row > Route from the contextual menu and click the cProcessor component.
5. Label the components to better identify their functionality.

Configuring the components

Procedure

1. Double-click the cConfig component, which is labelled Create_dataset, to display its Basic settings view in the Component tab and set its parameters.

2. Write a piece of code in the Code field to register the dataset instance foo into the registry, as shown below.

```java
SimpleDataSet dataset = new SimpleDataSet(1);
String messageBody = "testbody";
dataset.setDefaultBody(messageBody);
registry.put("foo", dataset);
```

3. Double-click the input cMessagingEndpoint component, which is labelled Read_dataset, to display its Basic settings view in the Component tab.
4. In the URI field, enter \textit{dataset:foo} between the quotation marks.
5. Double-click the \texttt{cProcessor} component, which is labelled \textit{Monitor}, to display its Basic settings view in the Component tab.

6. In the Code box, customize the code as follows so that the Run console displays the message contents:

   ```java
   System.out.println("Message content: " + exchange.getIn().toString());
   ```

7. Press Ctrl+S to save your route.

**Viewing code and executing the Route**

**Procedure**

1. Click the Code tab at the bottom of the design workspace to have a look at the generated code.
As shown in the code, a message route is built from the endpoint identified by `Read_dataset` and `cProcessor_1` gets the message content and displays it on the console.

2. Click the **Run** view to display it and click the **Run** button to launch the execution of your route. You can also press **F6** to execute it.

RESULT: The message content is printed in the console.
cContentEnricher

Uses a consumer or producer to obtain additional data, respectively intended for event messaging and request/reply messaging.

**cContentEnricher Standard properties**

These properties are used to configure cContentEnricher running in the Standard Job framework. The Standard cContentEnricher component belongs to the Transformation family.

**Basic settings**

<table>
<thead>
<tr>
<th>Resource URI</th>
<th>This refers to the destination to which a message will be delivered if using a producer is selected; it refers to the source from which a message will be obtained if using a consumer is selected.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Using a producer</td>
<td>Select this check box to use a producer to provide additional data, that is to say sending a message to the defined URI.</td>
</tr>
<tr>
<td>Using a consumer</td>
<td>Select this check box to use a consumer to obtain additional data, that is to say requesting a message from the defined URI.</td>
</tr>
<tr>
<td>Use Aggregation Strategy</td>
<td>Select this check box to define the aggregation strategy for assembling the basic message and the additional data.</td>
</tr>
</tbody>
</table>
| Specify timeout | This area appears when Using a consumer is selected. The timeout options are as follows:  
  **Wait until a message arrive**: the component keeps waiting for a message.  
  **Immediately polls the message**: the component immediately polls from the defined URI.  
  **Waiting at most until the timeout triggers**: select this check box to type in a timeout value in Millis. The component waits for the message only within the defined time period. |

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>cContentEnricher allows you to use a consumer or producer to obtain additional data, respectively intended for event message messaging and request/reply messaging.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limitation</td>
<td>n/a</td>
</tr>
</tbody>
</table>

**Receiving messages from a list of URLs**

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.
In this scenario, we will use the Camel component HTTP4 and the cContentEnricher component to retrieve messages from a list of URLs. To do this, we need to build two sub-routes, one to read a file with a list of URLs and send the messages to the local file system, the other to retrieve the messages on these URLs.

In this use case, we will take a list of URLs on the local Tomcat server as the example. So we need to start Apache Tomcat before executing the Route.

A TXT file URLlist is used to provide the list of URLs, as shown below.

```plaintext
docs/introduction.html
docs/setup.html
```

**Dropping and linking the components**

**Procedure**

1. From the Palette, drag and drop a cSplitter, a cJavaDSLProcessor, a cContentEnricher, two cFile, two cMessagingEndpoint, and three cSetHeader components onto the design workspace.
2. Label the components properly for better identification of their roles and link them using the Row > Route connection as shown above.

**Configuring the components**

Press Ctrl+S to save your Route.

**Configuring the first sub-route**

**Procedure**

1. Double-click the URLlist component to display its Basic settings view in the Component tab.
2. In the **Path** field, browse to the file path where the URL list file is saved. In the **FileName** field, enter the filename *URLList.txt*.

3. Double-click the **cSplitter** component to display its **Basic settings** view in the **Component** tab.

4. Select **None** in the **Language** list. In the **Expression** field, enter the code `body(String.class).tokenize("\r\n")` to split the message in each row into sub-messages.

   **Note:**
   
   Note that this piece of code is for Windows only. For Unix, change it to `body(String.class).tokenize("\n")`, and for Mac, `body(String.class).tokenize("\r")`.

5. Double-click the **cJavaDSLProcessor** component to display its **Basic settings** view in the **Component** tab.
6. In the **Code** area, enter the code `.log("splitterOutput: ${body}" )` to get the split message body.

7. Double-click the **cContentEnricher** component display its **Basic settings** view in the **Component** tab.

8. Select using a **producer** to use a producer to provide additional data and send the message to a defined URI.

   In the **Resource URI** field, enter "direct:fetchURL" where the message will be delivered.

9. Double-click the **setFileName** component to display its **Basic settings** view in the **Component** tab.

10. Click `[+]` to add a row to the **Headers** table.

    In the **Name** field, enter `org.apache.camel.Exchange.FILE_NAME` to define the file name for each incoming message.

    Select **Simple** in the **Language** list.

    In the **Value** field, enter "${header.CamelHttpPath}" to get the URI's path of the incoming message.
11. Double-click the retrievedFiles component to display its Basic settings view in the Component tab.

![retrievedFiles component](image1)

12. In the **Path** field, browse to the destination file path where you want the messages to be saved.

**Configuring the second sub-route**

**Procedure**

1. Double-click the fetchURL component to display its Basic settings view in the Component tab.

![fetchURL component](image2)

2. In the **URI** field, enter "direct:fetchURL" that is defined in the cContentEnricher component.

3. Double-click the setURI component to display its Basic settings view in the Component tab.

![setURI component](image3)

4. Click [+] to add a row to the Headers table.

   In the **Name** field, enter `org.apache.camel.Exchange.HTTP_URI` to define the HTTP URI of each message.
   
   Select **Simple** in the **Language** list.
In the **Value** field, enter "http://localhost:8080" of the local Tomcat server.

5. Double-click the **setPATH** component to display its **Basic settings** view in the **Component** tab.

![setPATH Component](image)

6. Click [+] to add a row to the **Headers** table.

   In the **Name** field, enter `org.apache.camel.Exchange.HTTP_PATH` to define the HTTP path of each message.

   Select **Simple** in the **Language** list.

   In the **Value** field, enter "${body}" that is split from the original message.

7. Double-click the **http4Endpoint** component to display its **Basic settings** view in the **Component** tab.

![http4Endpoint Component](image)

8. In the **URI** field, enter "http4:localhost:8080" to consuming HTTP resources on the local Tomcat server.

9. Click the **Advanced settings** view. Click [+] at the bottom of the **Dependencies** list to add a row and select **http4** from the drop-down list. For more information about HTTP4, see the site [http://camel.apache.org/http4.html](http://camel.apache.org/http4.html).
Viewing code and executing the Route

Procedure
1. Click the **Code** tab at the bottom of the design workspace to have a look at the generated code.

```java
public void configure() throws java.lang.Exception {
    from(uriMap.get("URLList_cFile_1"))
        .routeId("URLList_cFile_1")
        .split(body(String.class).tokenize("\r\n")).id("cSplitter_1")
        .log("splitterOutput: ${body}").id("cJavaDSLProcessor_1")
        .enrich("direct:fetchURL")
        .id("cContentEnricher_1")
        .setHeader("org.apache.camel.Exchange.FILE_NAME")
        .simple("${header.CamelHttpPath}").id("cSetHeader_1")
        .to(uriMap.get("retrievedFiles_cFile_2"), id("cFile_2");
    from(uriMap.get("fetchURL_cMessagingEndpoint_1"))
        .routeId("fetchURL_cMessagingEndpoint_1")
        .setHeader("org.apache.camel.Exchange.HTTP_URI")
        .simple("http://localhost:8080").id("cSetHeader_2")
        .setHeader("org.apache.camel.Exchange.HTTP_PATH")
        .simple("${body}").id("cSetHeader_3")
        .to(uriMap.get("http4Endpoint_cMessagingEndpoint_2"))
        .id("cMessagingEndpoint_2");
}
```

As shown above, a message route is built from the **URLList** to the **retrievedFiles** via the .split, .log, .enrich, and .setHeader. The other message route is built from **fetchURL** to **http4Endpoint** via two .setHeader.

2. Press **F6** to execute the Route.

RESULT: The split message is printed on the **Run** console.
The messages from the list of URLs are saved in defined directory of the local file system.
cConvertBodyTo

Converts the message body to the given class type.

**cConvertBodyTo Standard properties**

These properties are used to configure cConvertBodyTo running in the Standard Job framework.

The Standard cConvertBodyTo component belongs to the Transformation family.

**Basic settings**

<table>
<thead>
<tr>
<th>Target Class Name</th>
<th>Enter the name of the class type that you want to convert the message body to.</th>
</tr>
</thead>
</table>

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>cConvertBodyTo is used as a middle component in a Route.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limitation</td>
<td>n/a</td>
</tr>
</tbody>
</table>

**Converting the body of an XML file into an org.w3c.dom.Document.class**

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

In this scenario, a cConvertBodyTo component is used to convert the body of an XML file into an org.w3c.dom.Document.class. Then a cBean component imports the org.w3c.dom.Document class, checks its content and prints out the root element name and the content of each category element.

The XML file is as follows:

```xml
<bookstore>
  <bookshelf>
    <category>Cooking</category>
    <quantity>100</quantity>
  </bookshelf>
  <bookshelf>
    <category>Languages</category>
    <quantity>200</quantity>
  </bookshelf>
  <bookshelf>
    <category>Arts</category>
    <quantity>300</quantity>
  </bookshelf>
  <bookshelf>
    <category>Science</category>
    <quantity>400</quantity>
  </bookshelf>
</bookstore>
```
Creating a Bean

Procedure

1. From the repository tree view, expand the Code node and right click the Beans node. In the contextual menu, select Create Bean.

2. The New Bean wizard opens. In the Name field, type in a name for the bean, for example, PrintConvertToBean. Click Finish to close the wizard.
3. Enter the following code in the design workspace.

```java
package beans;
import org.w3c.dom.Document;
import org.w3c.dom.Element;
import org.w3c.dom.NodeList;
public class PrintConvertToBean {
    /**
     * print input message
     * @param message
     */
    public static void helloExample(Document message) {
        if (message == null) {
            System.out.println("There's no message here!");
            return;
        }
        Element rootElement = message.getDocumentElement();
        if (rootElement == null) {
            System.out.println("There's no root element here!");
            return;
        }
        System.out.println("The root element name is:");
        rootElement.getNodeName();
        System.out.println("The book categories are:");
        NodeList types = rootElement.getElementsByTagName("category");
        for(int i = 0;i<types.getLength();i++){
            Element child = (Element) types.item(i);
            System.out.println(child.getFirstChild().getNodeValue());
        }
    }
}
```

4. Press `Ctrl+S` to save your bean.

Results

For more information about creating and using Java Beans, see *Talend Studio User Guide*.

Dropping and linking the components

Procedure

1. Drag and drop a `cFile`, a `cConvertBodyTo`, a `cBean` and a `cBeanRegister` from the Palette onto the workspace.

2. Link the `cFile`, `cConvertBodyTo` and `cBean` using the *Row > Route* connection as shown above.

3. Label the components to better identify their functionality.
Configuring the components

Procedure

1. Double-click the cFile component to open its Basic settings view in the Component tab.

   ![Read_message(cFile_1)](image)

   - In the Path field, enter or browse to the path to the source XML file.
   - If the source file folder contains more than one file, enter the name of the XML file of interest in the FileName field, and leave the other parameters as they are.

2. Double-click the cConvertBodyTo component to open its Basic settings view in the Component tab.

   ![Convert_message_body(cConvertBodyTo_1)](image)

   - In the Target Class Name field, enter your target class name, org.w3c.dom.Document.class in this scenario.

3. Double-click the cBeanRegister component to open its Basic settings view in the Component tab.

   ![Register.bean(cBeanRegister_1)](image)

   - In the Id field, enter "bean".
Select the **Simple** option and in the **Class Name** field, enter the name of the bean to be invoked, `beans.PrintConvertToBean` in this scenario.

7. Double-click the **cBean** component to open its **Basic settings** view in the **Component** tab.

8. Select **Reference** and in the **Id** field, enter "bean" to call the bean that is registered by the **cBeanRegister**.

9. Press **Ctrl+S** to save your Route.

**Viewing code and executing the Route**

**Procedure**

1. Click the **Code** tab at the bottom of the design workspace to check the generated code.

   ```java
   public void initRoute() throws Exception {
       routeBuilder = new org.apache.camel.builder.RouteBuilder() {
           public void configure() throws Exception {
               from(uriMap.get("Read_message_cFile_1"))
                   .routeId("Read_message_cFile_1")
                   .convertBodyTo(org.w3c.dom.Document.class)
                   .id("cConvertBodyTo_1").beanRef("bean")
                   .id("cBean_1");
           }
       }
       getCamelContexts().get(0).addRoutes(routeBuilder);
   }
   ```

   As shown above, the message from the endpoint **Read_message_cFile_1** has its body converted to `org.w3c.dom.Document.class` by **cConvertBodyTo_1**, and then processed by bean invoked by **cBean_1**.

2. Press **F6** to execute the Route.

RESULT: The root element name and the contents of the **category** elements are displayed.
[statistics] connecting to socket on port 3759
[statistics] connected
The root element is: bookstore
The book categories are:
Cooking
Languages
Arts
Science
cSOAP

Provides integration with Apache CXF for connecting to JAX-WS services.

**cSOAP Standard properties**

These properties are used to configure cSOAP running in the Standard Job framework.

The Standard cSOAP component belongs to the Connectivity family.

**Basic settings**

| Address | The service endpoint URL where the Web service is provided. In case cSOAP is used to consume a Web service and the endpoint lookup shall use the Service Locator (the Use Service Locator check box is selected), the URL needs to be "locator://anyAddress/".

| Type | Select which type you want to use to provide Web service. Either wsdlURL or serviceClass.

wsdlURL: Select this type to provide the Web service from a WSDL file. Choose Repository or File to provide the Web service from a Route Resource or the file system.

serviceClass: Select this type to provide the Web service from an SEI (Service Endpoint Interface) Java class.

| WSDL File | This field appears when the wsdlURL service type is selected. If the WSDL file is from the file system, browse to or enter the path to the WSDL file. If the WSDL file is from a Route Resource, click [...] and select the one you want from the Resources tree view. The Version list appears allowing you to choose from all the versions of the Route Resource.

| Service configuration | This option appears when wsdlURL is selected in the Type list. It allows you to configure the service endpoint information conveniently. Click [...] to open the service configuration wizard.

The WSDL field in the wizard is filled in with the WSDL file defined in the WSDL File field automatically. You can also set the WSDL file directly in the service configuration wizard in one of the following ways:

- Click Browse... to browse to or enter the path to the WSDL file in the file system.
- Click Services to select a service under the Services.
- Click Resources to select a service under the Resources node.

After setting the WSDL file, click 🔄 to show the port(s) and operation(s) available in the Port Name and Operation boxes respectively. Select the one you want to use and click Finish. The Operation box only shows when the cSOAP component is used to consume a Web service.
<table>
<thead>
<tr>
<th><strong>Service Class</strong></th>
<th>This field appears when the serviceClass service type is selected. Enter the name of the service class to be used to provide the Web service.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Dataformat</strong></td>
<td>The exchange data style. POJO, PAYLOAD, RAW, or CXF_MESSAGE.POJO (Plain Old Java Objects) are the Java parameters to the method being invoked on the target server. PAYLOAD is the message payload, the contents of the soap:body. RAW is the raw message that is received from the transport layer without SAM (Service Activity Monitor) support. CXF_MESSAGE is the raw message that is received from the transport layer with SAM support.</td>
</tr>
<tr>
<td><strong>Use GZip Compress</strong></td>
<td>Select this check box to compress the incoming messages into GZip format before sending.</td>
</tr>
<tr>
<td><strong>Service Name</strong></td>
<td>The service name this service is implementing. It maps to the wsdl:service@name in the format of ns:SERVICE_NAME where ns is a namespace prefix valid at this scope. This field gets filled in automatically upon completion of the Service configuration.</td>
</tr>
<tr>
<td><strong>Port Name</strong></td>
<td>The endpoint name this service is implementing. It maps to the wsdl:port@name, in the format of ns:PORT_NAME where ns is a namespace prefix valid at this scope. This field gets filled in automatically upon completion of the Service configuration.</td>
</tr>
<tr>
<td><strong>Allow Streaming</strong></td>
<td>This option appears when PAYLOAD is selected in the Dataformat list. Select this check box to keep the payload as a javax.xml.transform.Source object that would allow streaming over buffering. If this option is disabled, the cSOAP component will parse the incoming messages into DOM elements.</td>
</tr>
<tr>
<td><strong>Operation Name</strong></td>
<td>The operation name this service is implementing. It maps to the wsdl:operation@name, in the format of ns:OPERATION_NAME where ns is a namespace prefix valid at this scope. This option appears when the cSOAP component is used consume a Web service. This field gets filled in automatically upon completion of the Service configuration.</td>
</tr>
<tr>
<td><strong>Use Service Registry</strong></td>
<td>This option is only available if you subscribed to Talend Enterprise ESB solutions. Select this check box to enable the service registry. It provides dynamic endpoint lookup and allows services to be redirected based upon information retrieved from the registry. It works in Runtime only. When the cSOAP component is used to provide a Web service, the service deployed in Runtime will work with the service registry. When the cSOAP component is used to consume a Web service:</td>
</tr>
</tbody>
</table>
In the **Correlation Value** field, specify a correlation ID or leave this field empty. For more information, see the **Use Business Correlation** option.

In the **Username** and the **Password** fields, enter the authentication credentials. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

If SAML token is registered in the service registry, you need to specify the client’s role in the **Role** field. You can also select the **Propagate Credentials** check box to make the call on behalf of an already authenticated user by propagating the existing credentials. You can enter the username and the password to authenticate with STS to propagate credentials using username and password, or provide the alias, username and the password to propagate using certificate. For more information, see the **Use Authentication** option.

For more information about how to set up and use the Service Registry, see the *Talend Administration Center User Guide* and *Talend ESB Infrastructure Services Configuration Guide*.

---

**Use Service Locator**

Provides service consumers with a mechanism to discover service endpoints at runtime without specifying the physical location of the endpoint. Additionally, it allows service providers to automatically register and unregister their service endpoints at the Service Locator.

**Note:**

For service consumers, the URL additionally needs to be set to "locator://anyAddress/" in the **CXF Configuration / Address** field.

The **Custom Properties** table appears when the **Use Service Locator** check box is selected. Click **»** to add as many properties as needed to the table. Enter the name and the value of each property in the **Property Name** field and the **Property Value** field respectively to identify the service. For more information, see *Talend ESB Infrastructure Services Configuration Guide* for how to install and configure the Service Locator.

**Use Service Activity Monitor**

Captures events and stores this information to facilitate in-depth analysis of service activity and track-and-trace of messages throughout a business transaction. This can be used to analyze service response times, identify traffic patterns, perform root cause analysis and more.

This feature is not supported when **MESSAGE** is used as the processing mode. When **MESSAGE** is selected in the **Dataformat** field, the **Use Service Activity Monitor** check box is disabled.

This option is also disabled when the **Use Service Registry** check box is selected if you subscribed to Talend Enterprise ESB solutions.

**Use Authentication**

Select this check box to enable the authentication option. Select from **Username Token**, **SAML Token (ESB runtime only)**, **HTTP Basic**, and **HTTP Digest**.
When the cSOAP component is used to produce a Web service, authentication with the **Username Token**, **SAML token**, and **HTTP Basic** work in runtime only. **HTTP Digest** is not supported. When **SAML Token (ESB runtime only)** is selected, cSOAP will get the SAML Token from the request header for further use in the message routing.

When the cSOAP component is used to consume a Web service, authentication with the **Username Token**, **HTTP Basic**, and **HTTP Digest** work in both the studio and runtime. Authentication with the **SAML token** works in runtime only. Enter a username and a password in the corresponding fields as required. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

When **SAML Token (ESB runtime only)** is selected, you can either provide the user credentials to send the request or make the call on behalf of an already authenticated user by propagating the existing credentials. Select from:

- **Propagate using U/P**: Enter the user name and the password used to authenticate via STS.
- **Propagate using Certificate**: Enter the alias and the password used to authenticate via STS.

This check box disappears when the **Use Service Registry** check box is selected.

---

### Use Authorization

This option is only available if you subscribed to Talend Enterprise ESB solutions. It appears when **SAML Token (ESB runtime only)** is selected in the **Use Authentication** list.

When the cSOAP component is used to provide a Web service, select this check box to enable authorization.

When the cSOAP component is used to consume a Web service, select this check box to invoke authorized call and specify the client’s role in the **Role** field.

For more information about the management of user roles and rights, see the [Talend Administration Center User Guide](#) and [Talend ESB Infrastructure Services Configuration Guide](#).

---

### Use Business Correlation

Select this check box to enable the correlation option so that chained service calls will be grouped under the same correlation ID.

When cSOAP is used to provide a Web service:

- cSOAP will extract the correlation ID from the request message.
- If the request message does not contain a correlation ID, the provider will create a correlation ID automatically in the SOAP header.

When cSOAP is used to consume a Web service:

You can specify a correlation ID in the **Correlation Value** field using a string or a simple expression. If you leave this field empty, this value will be generated automatically at runtime. The correlation ID will be created in the custom SOAP header of the request message and passed on to the service it calls.
Advanced settings

Arguments

Set the optional arguments in the corresponding table. Click [+] as many times as required to add arguments to the table. Then click the corresponding Value field and enter a value. See the site http://camel.apache.org/cxf.html for available URI options.

Usage

Usage rule
cSOAP can be a start, middle or end component in a Route.

Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

Multiple cSOAP components with the same label in a Route is not supported.

When cSOAP is used to consume a Web service, if you use the CXF_MESSAGE data format, the request body type need to be javax.xml.transform.Source.class, or the request body will be empty.

For simple proxy use cases, for example, from cSOAP to cProcessor to cSOAP, if you use the RAW data format, the request body will be reset. If it is printed by cProcessor, the output request body will be empty.

When cSOAP is used to consume a Web service and the data format is POJO, PAYLOAD, or CXF_MESSAGE, if fault response is returned the message routing will stop. In this case, it is recommended to use the cErrorHandler component to catch the fault message. For more information about cErrorHandler, see cErrorHandler on page 122.

Providing a Web service using cSOAP from a WSDL file

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

In this scenario, a Web service is produced by a cSOAP component using a WSDL file.
Dropping and linking the components

About this task

This use case requires one cSOAP component and one cProcessor component.

Procedure

1. From the Palette, expand the Connectivity/Services folder, and drop a cSOAP component onto the design workspace.
2. Expand the Custom folder, and drop a cProcessor component onto the design workspace.
3. Right-click the cSOAP component, select Row > Route from the contextual menu and click the cProcessor component.
4. Label the cSOAP component for better identification of its functionality.

Configuring the components

About this task

In this scenario, the cProcessor component is used only to enable the cSOAP component to function as a service producer. Therefore, it does not need any configuration.

Procedure

1. Double-click the cSOAP component to display its Basic settings view in the Component tab.
2. In the Address field, type in the service endpoint URL for the Web service to be provided, http://192.168.0.212:8000/service.endpoint in this example.
3. From the Type list, select wsdlURL to enable producing the Web service from a WSDL file.
4. In the Wsdl File field, browse to or type in the path to the WSDL file to be used.
5. Click [...] next to Service Configuration to open the service configuration wizard. The WSDL field has been filled in with the selected WSDL file. Click to show the available port in the Port
Name box. Select the airportSoap port and click Finish to close the wizard. The Service Name and Port Name fields in the Basic settings view are filled in automatically.

6. From the Dataformat list, select PAYLOAD mode for the wsdlURL data format.
7. Press Ctrl+S to save your route.

Viewing code and executing the Route

Procedure
1. Click the Code tab at the bottom of the design workspace to have a look at the generated code.

```java
org.apache.camel.component.cxf.CxfEndpoint endpoint_cSOAP_1 = getCxfEndpoint("cx://" + "http://192.168.0.212:8000/service" + "?dataFormat=PAYLOAD" + "&allowStreaming=false"
+ "&wsdlURL="
+ "D:/talend_files/input/airport_soap_route.wsdl"
+ "&serviceName="
+ "{http://airportsoap.sopera.de}airport"
+ "&endpointName="
+ "{http://airportsoap.sopera.de}airportSoap", true,
false, false, {String[]} null);
```

As shown in the code, the cSOAP component produces the Web service from an input file airport_soap_route.wsdl using the endpoint URL http://192.168.0.212:8000/service.endpoint.

2. Click the Run view to display it and click the Run button to launch the execution of your Route. You can also press F6 to execute it.

RESULT: The service is successfully started. You can access it from a Web browser using the service endpoint URL followed by ?wsdl.
Providing a Web service using cSOAP from a Java class

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

In this scenario, a Web service is provided from a Java class file using a cSOAP component.

Creating a Java class

Procedure

1. From the repository tree view, expand the Code node and right click the Beans node. In the contextual menu, select Create Bean.

2. The New Bean wizard opens. In the Name field, type in a name for the bean, for example, CXFdemobeans. Click Finish to close the wizard.
3. Change the class type to `interface`, change the return type to `string` and remove the message body.

```java
package beans;

public interface CXFdemobean {
    public String helloExample(String message) ;
}
```

4. Press `Ctrl+S` to save your bean.

**Dropping and linking the components**

**About this task**

This use case requires one `cSOAP` component and one `cProcessor` component.

**Procedure**

1. From the `Palette`, expand the `Connectivity/Services` folder, select the `cSOAP` component and drop it onto the design workspace.
2. Expand the `Custom` folder, select the `cProcessor` component and drop it onto the design workspace.
3. Right-click the cSOAP component, select **Row > Route** in the contextual menu and click the cProcessor component.

4. Label the components for better identification of their functionality.

**Configuring the components**

**About this task**

In this scenario, the cProcessor component is used only to enable the cSOAP component to function as a service producer. Therefore, it does not need any configuration.

**Procedure**

1. Double-click the cSOAP component to display its **Basic settings** view in the Component tab.

![Component configuration](image)

2. In the **Address** field, type in the service endpoint URL for the Web service to be provided, `http://192.168.0.212:8001/service.endpoint` in this example.

3. From the **Type** field, select **serviceClass** to start the Web service from a Java class.

4. In the **Service Class** field, specify the predefined bean class, `CXFdemobean` in this example.

5. From the **Dataformat** list, select **POJO** as the serviceClass service data format.

6. Press **Ctrl+S** to save your Route.

**Viewing code and executing the Route**

**Procedure**

1. Click the **Code** tab at the bottom of the design workspace to have a look at the generated code.

```java
org.apache.camel.component.cxf.CxfEndpoint endpoint_cSOAP_1 = getCxfEndpoint("http://192.168.0.212:8001/service.endpoint"
    + "?dataFormat=POJO" + "&loggingFeatureEnabled=true"
    + "&serviceClass=" + "beans.CXFdemobean", true, false,
    false, (String[]) null);
```
As shown in the code, the cSOAP component produces the Web service from a predefined bean beans.CXFdemobean using the endpoint URL http://192.168.0.212:8001/service.endpoint.

2. Click the Run view to display it and click the Run button to launch the execution of your Route. You can also press F6 to execute it.

RESULT: The service is successfully started. You can access it from a Web browser using the service endpoint URL followed by ?wsdl.

Providing a Web service from a Route Resource

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

In this scenario, a Web service is provided from a Route Resource using a cSOAP component.

Creating a Route Resource

Procedure

1. From the Repository tree view, right-click the Resources node and select Create Resource from the context menu.

2. The New Route Resource wizard opens. In the Name field, type in a name for the Resource, for example, DemoServiceWsdl. Click Finish to close the wizard.
3. Browse to an existing WSDL file from the local file system and click Finish.
4. Press Ctrl+S to save your Route Resource.

**Dropping and linking the components**

**About this task**

This use case requires a cSOAP and a cProcessor component.

**Procedure**

1. From the Palette, expand the Connectivity/Services folder, and drop a cSOAP component onto the design workspace.
2. Expand the Custom folder, and drop a cProcessor component onto the design workspace.
3. Right-click the cSOAP component, select Row > Route from the contextual menu and click the cProcessor component.
4. Label the cSOAP component for better identification of its functionality.
Configuring the components

About this task

In this scenario, the cProcessor component is used only to enable the cSOAP component to function as a service producer. Therefore, it does not need any configuration.

Procedure

1. Double-click the cSOAP component to display its Basic settings view in the Component tab.

2. In the Address field, type in the service endpoint URL for the Web service to be provided, http://localhost:8000/service.endpoint in this example.

3. From the Type list, select wsdlURL and use the Repository property type to start the Web service from the Route Resource that we have created.

4. In the WSDL File field, click the [...] button and select DemoServiceWsdl from the Resources tree view. Click OK to close the wizard.

5. Click [...] next to Service Configuration to open the service configuration wizard. The WSDL field has been filled in with the selected WSDL file. Click to show the available port in the Port Name box. Select the DemoServicePort port and click Finish to close the wizard. The Service Name and Port Name fields in the Basic settings view are filled in automatically.
6. Press Ctrl+S to save your Route.

**Viewing code and executing the Route**

**Procedure**

1. Click the **Code** tab at the bottom of the design workspace to have a look at the generated code.

   ```java
   org.apache.cxf.endpoint.endpoint_cSOAP_1 = getCxfEndpoint(
       "cxfs://
       + "http://localhost:8000/service.endpoint"
       + "?dataFormat=PAYLOAD"
       + "&allowStreaming=false"
       + "&wsdlURL="
       + getClass().getResource("/DemoServiceWsd1_0.1"
       .toString() + "&serviceName="
       + "{http://www.talend.org/service/}DemoService"
       + "&endpointName="
       + "{http://www.talend.org/service/}DemoServicePort",
       true, false, false, (String[]) null);
   
   As shown in the code, the cSOAP component produces the Web service from an predefined Route Resource DemoServiceWsd1_0.1 using the endpoint URL http://localhost:8000/service.endpoint.
   
   2. Click the **Run** view to display it and click the **Run** button to launch the execution of your Route. You can also press F6 to execute it.

   **RESULT:** The service is successfully started. You can access it from a Web browser using the service endpoint URL followed by ?wsdl.
<?xml version="1.0" encoding="UTF-8"?>
<wsdl:definitions name="DemoService" xmlns:xsd="http://www.w3.org/2001/XMLSchema"
xmlns:soap="http://schemas.xmlsoap.org/wsdl/soap/"
targetNamespace="http://www.talend.org/service/">
  <wsdl:types>
    <wsdl:message name="DemoServiceOperationResponse">
      <wsdl:part name="parameters" element="tns:DemoServiceOperationRequest"/>
    </wsdl:message>
    <wsdl:message name="DemoServiceOperationRequest">
      <wsdl:portType name="DemoServicePortType">
        <wsdl:operation name="DemoServiceOperation"/>
      </wsdl:portType>
      <wsdl:binding name="DemoServiceBinding" type="tns:DemoServicePortType">
        <soap:binding transport="http://schemas.xmlsoap.org/soap/http" style="document"/>
        <wsdl:operation name="DemoServiceOperation"/>
      </wsdl:binding>
    </wsdl:binding>
    <wsdl:service name="DemoService">
      <wsdl:port name="DemoServicePort" binding="tns:DemoServiceBinding"/>
    </wsdl:service>
  </wsdl:types>
</wsdl:definitions>
cREST

Provides integration with Apache CXF for connecting to JAX-RS services.

**cREST Standard properties**

These properties are used to configure cREST running in the Standard Job framework.

The Standard cREST component belongs to the Connectivity family.

### Basic settings

<table>
<thead>
<tr>
<th>API definition</th>
<th>Click [...] to browse to the OAS/Swagger 2.0 file to initialize your component endpoint, API mappings and documentation from your API definition.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Endpoint</strong></td>
<td>The service endpoint URL where the REST service is provided. You can either specify an explicit port number, for example, &quot;<a href="http://localhost:8088/services/customers">http://localhost:8088/services/customers</a>&quot;, or use the default port of Talend and specify the relative path only, for example, &quot;*/services/customers&quot;.</td>
</tr>
<tr>
<td></td>
<td>The default port is different depending on the build type or where you run the service:</td>
</tr>
<tr>
<td></td>
<td>• To run the service inside Talend Studio: 8090</td>
</tr>
<tr>
<td></td>
<td>• To run the service in a Talend Runtime Container: for HTTP 8040 is used for all services, and if HTTPS is enable on Talend Runtime the service is also exposed on 9001.</td>
</tr>
<tr>
<td></td>
<td>• To run the service as a Microservice: 8065</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Select which type you want to use to provide the REST service. Either Manual or resourceClass.</td>
</tr>
<tr>
<td></td>
<td><strong>Manual</strong>: Determine the REST API mapping manually in the table if cREST is used as a service provider, or set HTTP Method and other parameters if the component is used as a service consumer.</td>
</tr>
<tr>
<td></td>
<td><strong>resourceClass</strong>: Select this type to provide the resource class which you want to export as the REST service.</td>
</tr>
<tr>
<td><strong>REST API Mapping</strong></td>
<td>This table appears when the Manual service type is selected and cREST is used as a service provider.</td>
</tr>
<tr>
<td></td>
<td>Click [+ ] under the table to add as many rows as needed to specify the HTTP request:</td>
</tr>
<tr>
<td></td>
<td><strong>Output Flow</strong>: Specify the name of an output flow.</td>
</tr>
<tr>
<td></td>
<td><strong>HTTP Verb</strong>: Select a HTTP method from GET, POST, PUT, DELETE, OPTIONS and HEAD in the list.</td>
</tr>
<tr>
<td></td>
<td><strong>URI pattern</strong>: Fill this field with the REST URI that describes the resource.</td>
</tr>
<tr>
<td></td>
<td><strong>Consumes</strong>: Select the format type of the consume content that the component will use from XML or JSON, XML, JSON, Form, Multipart, and Any when HTTP Verb is POST or PUT.</td>
</tr>
</tbody>
</table>
**Produces**: Select the format type of the produce content that the component will use from **XML or JSON**, **XML**, **JSON**, **HTML**, or **Any** when HTTP Verb is **GET**, **POST**, **PUT** or **DELETE**.

**Bean class**: Set the bean class when the HTTP Verb is **POST** or **PUT** and the consume content format is **XML or JSON**, **XML**, or **JSON**.

### Resource Class
This field appears when the `resourceClass` service type is selected. Enter the name of the resource class which you want to export as the REST service.

### Operation
This field appears when the `resourceClass` service type is selected and **cREST** is used as the service consumer. Enter the name of the operation.

### Relative Path
This field appears when the `Manual` service type is selected and **cREST** is used as the service consumer. Enter the relative path of the REST server to be invoked.

### HTTP Method
This option appears when the `Manual` service type is selected and `cREST` is used as the service consumer. Select a HTTP method from **GET**, **POST**, **PUT**, and **DELETE** in the list.

**Warning:**
When using the **POST** method to create an object, by default, the created object ID will not be get back from the header. By default, the **cREST** filters any header except system headers. To get the created object ID, you need to set `javax.ws.rs.core.Response` as the response class.

### Content Type
This option appears when the `Manual` service type is selected and **cREST** is used as the service consumer. Select **XML**, **JSON**, or **FORM** according to the media type of the content to be uploaded to the server end. This list appears only when you select the **POST** or **PUT** in the **HTTP Method** list.

### Accept Type
This field appears when the `Manual` service type is selected and **cREST** is used as the service consumer. Select the media type the client end is prepared to accept for the response from the server end. Available options are **XML**, **JSON**, and **ANY**. When **ANY** is selected, the response message can be of any type and will be transformed into a string. This list does not appear when you select the **DELETE** method.

### Response Class
This field appears when the `Manual` service type is selected and the **cREST** is used as the service consumer. Enter the name of the response class.

### Use Service Locator
Select this check box to enable the Service Locator. Specify the service namespace and the service name in the corresponding fields.

### Enable the Service Activity Monitoring
Select this check box to enable the Service Activity Monitor. Note that this option works in Runtime only. When running the Route in the Studio, it is recommended to clear this.
Use Authentication

Select this check box to enable the authentication option. Select the authentication type from:

- **HTTP Basic**: The simplest technique for enforcing access controls to web resources using standard fields in the HTTP header.
- **SAML Token (ESB runtime only)**: An XML-based, open-standard data format for exchanging authentication and authorization data between an identity provider and a service provider.
- **Open ID Connect**: An extension for OAuth2 which allows Clients to verify the identity of the End-User based on the authentication performed by an Authorization Server, as well as to obtain basic profile information about the End-User in an interoperable and REST-like manner.

When the cREST component is used as consumer, enter a username and a password in the corresponding fields as required. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

Use Authorization

This option is only available if you subscribed to Talend Enterprise ESB solutions. It appears when SAML Token (ESB runtime only) is selected in the Use Authentication list.

When the cREST component is used as the service provider, select this check box to enable authorization.

When the cREST component is used as the service consumer, select this check box to invoke authorized call and specify the client’s role in the Role field.

Use Business Correlation

Select this check box to create a correlation ID in this component.

You can specify a correlation ID in the Correlation Value field.

Advanced settings

Log messages

Select this check box to log the message exchanges in the Route.

Expose Swagger specification

This option appears when cREST is used as a service provider, and is available only when the Manual service type is selected. Select this check box to expose the Swagger specification and include the Swagger UI into the REST service, which provides an online API Documentation in human-readable form and some basic test features.

If the Route is running in the Studio, the Swagger specification will be available at http://127.0.0.1:8090/ENDPOINT/swagger.json and http://127.0.0.1:8090/ENDPOINT/swagger.yaml. The Swagger UI is not available.

If the Route is running in Talend Runtime, the Swagger specification will be available at http://127.0.0.1:8040/services/ENDPOINT/swagger.json and

If the Route is running as a ESB Microservice, the Swagger specification will be available at http://127.0.0.1:8065/services/ENDPOINT/swagger.json and http://127.0.0.1:8065/services/ENDPOINT/swagger.yaml. The Swagger UI will be available at http://127.0.0.1:8065/services/ENDPOINT/api-docs?url=/services/ENDPOINT/swagger.json.

For more information about how to build a Route to a ESB Microservice and how to run the Microservice, see Talend Studio User Guide.

### Include Documentation into Swagger Spec

This option appears when cREST is used as a service provider and the Expose Swagger specification check box is selected. Select this option to add content in the Comment field of the Documentation tab of this component into the Swagger specification and the Swagger UI page.

For more information about the Documentation tab, see Talend Studio User Guide.

### Arguments

Set the optional arguments in the corresponding table. Click [+] as many times as required to add arguments to the table. Then click the corresponding Value field and enter a value. See the site http://camel.apache.org/cxfrs.html for available URI options.

### Usage

**Usage rule**

cREST can be a start component in a Route as the service provider, or middle or end component as the service consumer.

**Limitation**

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

## Providing and consuming a REST service using cREST

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

This scenario demonstrates how to use the cREST component to provide and consume a REST service. To do so, two Routes are built, a service provider Route and a consumer Route. The service provider Route will be accessible for requests and respond with some predefined customer information. The consumer Route will send a request to the REST service.
Building the service provider Route

This Route provides a REST Web service using the cREST component. In this Route, a cBeanRegister component is used to set the customer information in a Java bean. The bean is then called by a cSetBody as the response of the service.

Dropping and linking the components

About this task

Procedure

1. From the Palette, drag and drop a cREST, a cSetBody, a cLog and a cBeanRegister component onto the design workspace.
2. Link the cREST, cSetBody and cLog using the Row > Route connection.
3. Label the components for better identification of their roles.

Configuring the components

Procedure

1. Double-click the cBeanRegister component to display its Basic settings view in the Component tab.
2. The **cBeanRegister** component registers a Java bean, in which the customer information is set with the **firstName**, **lastName**, **city**, and **id** values.

In the **Id** field, enter "customers" to name the bean.

Select the **Customized** option and enter the following code in the **Code** box to create two customers and set the **firstName**, **lastName**, **city**, and **id** values for each of them:

```java
beans.Customers customers = new beans.Customers();

beans.Customer customer = new beans.Customer();
customer.setFirstName(TalendDataGenerator.getFirstName());
customer.setLastName(TalendDataGenerator.getLastName());
customer.setCity(TalendDataGenerator.getUsCity());
customers.addCustomer(customer);

customer = new beans.Customer();
customer.setFirstName(TalendDataGenerator.getFirstName());
customer.setLastName(TalendDataGenerator.getLastName());
customer.setCity(TalendDataGenerator.getUsCity());
customers.addCustomer(customer);

beanInstance = customers;
```

3. Double-click the **cREST** component to display its **Basic settings** view in the **Component** tab.
4. The cREST component is used to provide the REST service.

In the Endpoint field, type in the endpoint URL where the Web service will be provided, "http://localhost:8040/services/customers" in this example.

From the Type list, select Manual to determine the REST API mapping manually.

In the REST API mapping table, click [+] to add a row in the table. In the Output Flow field, enter getAllCustomers as the name of it. Select GET in the HTTP Verb list. Keep the default settings in the other columns.

5. Double-click the cSetBody component to display its Basic settings view in the Component tab.

6. Select SIMPLE from the Dataformat list. In the Expression field, enter "ref:customers" to refer to the bean defined in the cBeanRegister component as the message body of the service response.

7. Keep the default settings of the cLog component to log the message exchanges.

8. Press Ctrl+S to save your route.
Viewing code and executing the Route

Procedure

1. Click the Code tab at the bottom of the design workspace to have a look at the generated code.

```java
from("cxf://bean://cREST_1" + "?loggingFeatureEnabled=false")
    .process(new org.apache.camel.Processor() {
        public void process(org.apache.camel.Exchange exchange)
            throws Exception {
                org.apache.camel.Message inMessage = exchange.getIn();
                inMessage
                    .setHeader("http_query",
                        org.apache.cxf.jaxrs.utils.JAXRSUtils.getStructuredParams(
                            String inMessage
                                .getHeader(org.apache.camel.Exchange.HTTP_QUERY),
                            "#", false, false));
                }}, routeId("provider_cREST_1"), id("provider_cREST_1"),
                .simple("ref:customers"), id("provider_cSetBody_1"),
                .to("log:cRest_log_1" + "?level=WARN")
                .id("provider_cLog_1");
```

As shown in the code, the Route is built from cREST_1, set message body in cSetBody_1 and then to cLog_1.

2. Click the Run view to display it and click the Run button to launch the execution of your Route. You can also press F6 to execute it.

RESULT: The service is successfully started. You can access it from a Web browser using the service endpoint URL. The customer information is shown in the browser.
Building the service consumer Route

This Route will consume the REST service that is built in the provider Route.

Arranging the flow of the message

About this task

![Diagram of the flow](image)

Procedure

1. From the Palette, drag and drop a cTimer, a cREST, and a cLog component onto the design workspace.
2. Link the cTimer, cREST and cLog using the Row > Route connection.
3. Label the components for better identification of their roles.

Configuring how the message is processed

Procedure

1. Double-click the cTimer component to display its Basic settings view in the Component tab.

![cTimer Basic settings](image)

2. In the Repeat field, enter 1 to generate the message exchange one time. Keep the default settings of the other options.
3. Double-click the cREST component to display its Basic settings view in the Component tab.
4. This cREST component will consume the REST service built in the provider Route. In the Endpoint field, type in the URL of the service, "http://localhost:8040/services/customers" in this example. Select Manual from the Type list. In the Relative Path field, enter constant(""). Select GET in the HTTP Method list. Keep the default settings of the other options.

5. Keep the default settings of the cLog component to log the message exchanges.

6. Press Ctrl+S to save your route.

Executing the Route

Procedure
1. Click the Code tab at the bottom of the design workspace to have a look at the generated code.
As shown in the code, the Route is built from `cTimer_1`. The `HTTP_PATH`, `HTTP_METHOD`, and `ACCEPT_CONTENT_TYPE` are set in `cREST_1`. The message is then routed to `cLog_1`.

2. Click the Run view to display it and click the Run button to launch the execution of your Route. You can also press F6 to execute it.

RESULT: The customers information is displayed in the console.
cDataset

Creates a new dataset or reference an existing dataset to send or receive messages.

**cDataset Standard properties**

These properties are used to configure cDataset running in the Standard Job framework.

The Standard cDataset component belongs to the Testing family.

**Basic settings**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Id</td>
<td>The ID of the Dataset bean.</td>
</tr>
<tr>
<td>Produce Delay</td>
<td>Specify a delay in milliseconds to cause producers to pause.</td>
</tr>
<tr>
<td>Consume Delay</td>
<td>Specify a delay in milliseconds to cause consumers to pause.</td>
</tr>
<tr>
<td>Preload Size</td>
<td>Specify how many messages should be sent before the Route completes its initialization.</td>
</tr>
<tr>
<td>Initial Delay</td>
<td>Specify the time in milliseconds to wait before starting sending messages.</td>
</tr>
<tr>
<td>Minimum Rate</td>
<td>Specify the least number of messages that the dataset should contain before starting sending messages.</td>
</tr>
<tr>

<tr>
<th>Usage rule</th>
<th>cDataset can be a start, middle, or end component of a Route.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limitation</td>
<td>n/a</td>
</tr>
</tbody>
</table>

**Using cDataset to create messages**

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

In this scenario, a cDataset component is used to create a DataSet instance as a source of messages.
Dropping and linking the components

Procedure

1. From the Testing folder, drag and drop a cDataset component onto the design workspace.
2. From the Core folder, drag and drop a cSetBody component onto the design workspace.
3. From the Miscellaneous folder, drag and drop two cLog components onto the design workspace.
4. Connect the components using Row > Route connections.
5. Label the components to better identify their roles in the Route, as shown above.

Configuring the components

Procedure

1. Double-click the cDataset component to open its Basic settings view in the Component tab.

2. In the Id field, enter "myDataset" as the dataset bean ID.
3. In the Arguments table, click [+] to add a row and enter 1000 in the Value field to create 1000 messages. Keep the default settings of the other options.
   - In the Bean Class field, the default implementation that is shipped by Camel org.apache.camel.component.dataset.SimpleDataSet is set. In this use case, a new dataset bean is registered.
4. Double-click the cSetBody component to open its Basic settings view in the Component tab.
5. Select **Constant** in the **Language** list and enter "Hello!" in the **Expression** field as the message body.

6. Keep the default settings of the **cLog** components to monitor the message exchanges.

7. Press **Ctrl+S** to save your Route.

**Viewing the code and executing the Route**

**Procedure**

1. Click the **Code** tab at the bottom of the design workspace to have a look at the generated code.

   ```java
   from("dataset:myDataset").routeId("cDataset_cDataset_1")
   .to("log:test.cLog_1" + "?level=WARN")
   .id("cDataset_cLog_1").setBody().constant("Hello!")
   .id("cDataset_cSetBody_1").to("log:test.cLog_2" + "?level=WARN")
   .id("cDataset_cLog_2");
   ```

   As shown in the code, the Route is built from the **cDataset_cDataset_1** endpoint, routed to the **cDataset_cLog_1**, set the message body as "Hello!" by the **cDataset_cSetBody_1**, and then routed to the **cDataset_cLog_2**.

2. Press **F6** to execute the Route.

   A DataSet of 1000 messages is created and logged in the execution console. The default message body is `<hello>world!</hello>`. It is changed to **Hello!**.
cDelayer

Delays the delivery of messages.

**cDelayer Standard properties**

These properties are used to configure cDelayer running in the Standard Job framework. The Standard cDelayer component belongs to the Orchestration family.

**Basic settings**

| Time to wait (in ms) | Fill this field with an integer (in milliseconds) to define the time to wait before sending the message to the subsequent endpoint. |

**Usage**

| Usage rule | This component is usually used in the middle of a Route. |
| Limitation | n/a |

**Using cDelayer to delay message routing**

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

In this scenario, a **cDelayer** component is used to delay the routing of each message to the target endpoint by 20 seconds.

**Dropping and linking the components**

**About this task**

This use case requires one **cDelayer** component, two **cFile** components, and two **cProcessor** components.

**Procedure**

1. From the Connectivity folder of the Palette, drop two **cFile** components onto the design workspace, one to read files from a local folder and the other to write the files to another local folder.
2. From the Custom folder of the Palette, drop two **cProcessor** components onto the design workspace, one next to the reading component to monitor messages read from the source file...
folder, and the other next to the writing component to monitor messages written to the target file folder.

3. From the **Orchestration** folder of the **Palette**, drop one cDelayer component onto the design workspace, between the message reading monitor component and the message writing component.

4. Connect the components using **Row > Route** connections.

5. Label the components to better identify their roles in the Route, as shown above.

### Configuring the components

**Procedure**

1. Double-click the first **cFile** component, which is labelled **Read**, to open its **Basic settings** view in the **Component** tab.

   ![Read(cFile_1)](image)

   1. In the **Path** field, enter or browse to the path to the source files, and leave the other parameters as they are.

   2. Repeat these steps to define the target folder in property settings of the second **cFile** component, which is labelled **Write**.

2. Double-click the first **cProcessor** component, which is labelled **Read_monitor**, to open its **Basics settings** view in the **Component** tab.

   ![Read_monitor(cProcessor_1)](image)

5. In the **Code** area, customize the code to display the time each message is read from the source:

   ```java
   Date date=new Date();
   SimpleDateFormat formatter = new SimpleDateFormat("HH:mm:ss");
   String s = formatter.format(date);
   System.out.println("Message "+exchange.getIn().getHeader("CamelFileName")+" read at "+(s));
   ```
6. Repeat these steps to configure the second **cProcessor** component, which is labelled **Write_monitor**, to display the time each message is written to the target:

```java
Date date = new Date();
SimpleDateFormat formatter = new SimpleDateFormat("HH:mm:ss");
String s = formatter.format(date);
System.out.println("Message " + exchange.getIn().getHeader("CamelFileName") + " written at "+(s));
```

7. Double-click the **cDelayer** component, which is labelled **Delay_timer**, to open its **Basic settings** view in the **Component** tab.

8. In the **Time to wait (in ms)** field, enter the number of milliseconds by which you want to delay message delivery. Note that the value must be a positive integer.

   In this use case, we want each message to be delivered after a 20-second delay.

9. Press **Ctrl+S** to save your Route.

### Viewing the code and executing the Route

**Procedure**

1. Click the **Code** tab at the bottom of the design workspace to have a look at the generated code.

   ```java
   public void initRoute() throws Exception {
       routeBuilder = new org.apache.camel.builder.RouteBuilder() {
           public void configure() throws Exception {
               from(uriMap.get("Read")).routeId("Read").process(
                   new org.apache.camel.Processor() {
                       public void process(
                           org.apache.camel.Exchange exchange)
                           throws Exception {
                           Date date = new Date();
                           SimpleDateFormat formatter = new SimpleDateFormat("HH:mm:ss");
                           String s = formatter.format(date);
                           System.out.println("\nMessage "
                               + exchange.getIn().getHeader("CamelFileName")
                               + " read at "+(s));
                   }
               )
           }.id("cProcessor_1").delay(20000).id("cDelayer_1").to(uriMap.get("Write")).id("cFile_2").process();
   }
   ```

   As shown in the code, a 20-second delay is implemented according to `.delay(20000)` in the message routing from the Read endpoint to the Write endpoint.
2. Press **F6** to execute the Route.

RESULT: Each message read from the source folder is routed to the target folder after a 20-second delay.
cDirect

Produces and consumes messages synchronously in different threads within a single CamelContext.

**cDirect Standard properties**

These properties are used to configure cDirect running in the Standard Job framework.

The Standard cDirect component belongs to the Core family.

**Basic settings**

<table>
<thead>
<tr>
<th>Name</th>
<th>This option appears when cDirect is used as a start component in a Route. Type in any string that uniquely identifies the endpoint.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use Exist cDirect</td>
<td>This option appears when cDirect is used as a middle or end component in a Route. Click [...] and select the corresponding consumer in the dialog box.</td>
</tr>
</tbody>
</table>

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>cDirect is used as a start, middle, or end component in a Route.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limitation</td>
<td>n/a</td>
</tr>
</tbody>
</table>

**Related scenario:**

For a related scenario, see Using cSEDA, cVM and cDirect to produce and consume messages separately on page 272.
cDirectVM

Produces and consumes messages synchronously in different threads within a single CamelContext and across CamelContexts in the same JVM. You can use this mechanism to communicate across Web applications.

cDirectVM Standard properties

These properties are used to configure cDirectVM running in the Standard Job framework.

The Standard cDirectVM component belongs to the Core family.

**Basic settings**

<table>
<thead>
<tr>
<th>When using as a start component in a Route:</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Endpoint Name</strong></td>
<td>Type in any string that uniquely identifies the endpoint.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>When using as a middle or end component in a Route:</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Select From Existing(s)</strong></td>
<td>Click this radio button to select an existing consumer. Click [...] beside the Consumer field to show the existing consumer(s) and select the one to consume the message.</td>
</tr>
<tr>
<td><strong>Input Endpoint Name</strong></td>
<td>Click this radio button to enter the name of the consumer in the Endpoint Name field.</td>
</tr>
<tr>
<td><strong>Block if Consumer is not active</strong></td>
<td>Select this check box to let the producer block if the consumer is not active in the Timeout period.</td>
</tr>
<tr>
<td><strong>Timeout</strong></td>
<td>This option appears when the block is enabled. Specify the time in milliseconds before the producer stops waiting for the consumer to become active.</td>
</tr>
</tbody>
</table>

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>cDirectVM is used as a start, middle, or end component in a Route.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Limitation</strong></td>
<td>n/a</td>
</tr>
</tbody>
</table>

**Direct and synchronous messaging within the same JVM**

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

In this scenario, a message exchange is triggered in one sub-route and synchronously consumed in another sub-Route using the Direct-VM mechanism. At the consumer end, the message content is processed and displayed on the console.
Dropping and linking the components

Procedure

1. From the Palette, drag and drop the following components onto the design workspace: a cTimer, a cSetHeader, a cSetBody, two cDirectVM, and a cProcessor.

2. Link the cTimer, the cSetHeader, the cSetBody and the first cDirectVM components using Row > Route connections to form a sub-route.

3. Link the other cDirectVM component to the cProcessor component using a Row > Route connection to form another sub-route.

4. Label the components to better identify their roles in the Route.

Configuring the components

Configuring the first sub-route

Procedure

1. Double-click the cTimer component (labelled Starter in this example) to display its Basic settings view on the Component tab.

2. In the Repeat field, enter 1 so that the message exchange is triggered only once. Leave the other settings as they are.

3. Double-click the cSetHeader component (labelled Set_message_headers in this example) to display its Basic settings view on the Component tab.
4. Click the [+] button to add two headers in the **Headers** table, and then give each header a name and a value.

   In this example, we name the headers **Name** and **Company** respectively, and enter **Bill** and **Talend** as their values.

5. Double-click the **cSetBody** component (labelled **Set_message_body** in this example) to display its **Basic settings** view on the **Component** tab.

6. Select **SIMPLE** from the **Language** list as we will trigger a simple text message exchange in this example.

7. In the **Expression** field, enter **Hi there** in double quotation marks as the content of the message body.

8. Double-click the first **cDirectVM** component (labelled **D-VM_producer** in this example) to display its **Basic settings** view on the **Component** tab.

9. Select an existing consumer endpoint, or specify the name of the consumer endpoint.

   In this example, we will name the consumer endpoint **dvm**, so select the **Input Endpoint Name** option, and enter the name of the consumer endpoint **dvm** in the **Endpoint Name** field.
Configuring the second sub-route

Procedure

1. Double-click the second cDirectVM component (labelled D-VM_consumer in this example) to display its Basic settings view on the Component tab.

2. In the Endpoint Name field, enter dvm in double quotation marks to name the endpoint.

3. Double-click the cProcessor (labelled Show_message in this example) component to display its Basic settings view.

4. In the Code area, enter the following code to display the content of the message headers and the message body:

```java
import java.util.List;

/*
 * Provide own codes to consume or translate the message exchanges
 * @param cmsg.apache.camel.Exchange exchange
 */
exchange.getOut().setHeader("header1", exchange.getIn().getHeader("Name"));
exchange.getOut().setHeader("header2", exchange.getIn().getHeader("Company"));
exchange.getOut().setBody(exchange.getIn().getBody(String.class));
System.out.println();
System.out.println("Message for "+exchange.getOut().getHeader("header1")
  +" of "+exchange.getOut().getHeader("header2")+":");
System.out.println(exchange.getOut().getBody(String.class));
```

Executing the Route

Click the Run view and click the Run button to launch your Route. You can also press F6 to execute it.
RESULT: The message generated in the first sub-route is consumed synchronously in the consumer endpoint and displayed on the console after processing. The message exchange is triggered once as configured.
cDynamicRouter

Routes a message or messages to different endpoints on specified conditions.

**cDynamicRouter Standard properties**

These properties are used to configure cDynamicRouter running in the Standard Job framework.

The Standard cDynamicRouter component belongs to the Routing family.

**Basic settings**

<table>
<thead>
<tr>
<th>Bean class</th>
<th>Enter the name of the bean class to be used for the dynamic router.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specify the method</td>
<td>Select this check box to specify the method to be used which is defined in the bean class.</td>
</tr>
<tr>
<td>Ignore Invalid Endpoints</td>
<td>Select this check box to ignore unresolved endpoint URIs. Clear the check box to throw an exception when endpoint URIs are not valid.</td>
</tr>
</tbody>
</table>

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>cDynamicRouter is used as a middle or end component in a Route.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limitation</td>
<td>n/a</td>
</tr>
</tbody>
</table>

**Routing files conditionally to different file paths**

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

In this scenario, three file messages containing people information are routed to different endpoints according to the city names they contain.

The following is an extract of the example XML files used in this use case:

*Message 1.xml:*

```xml
<person>
  <firstName>Ellen</firstName>
  <lastName>Ripley</lastName>
  <city>Washington</city>
</person>
```

*Message 2.xml:*

```xml
<person>
  <firstName>Peter</firstName>
  <lastName>Green</lastName>
  <city>London</city>
</person>
```
A predefined Java bean, `setDynaURI`, is called in this use case to return endpoint URIs according to the city name contained in each message, so that the message containing the city name `Washington` will be routed to endpoint `Washington` and so forth.

For more information about creating and using Java Beans, see *Talend Studio User Guide*.
Procedure

1. From the Palette, expand the Connectivity folder, and drop one cFile and three cMessagingEndpoint components onto the design workspace.
2. Expand the Routing folder, and drop a cDynamicRouter component onto the design workspace.
3. Expand the Custom folder, and drop three cProcessor components onto the design workspace.
4. Label the components for better identification of their respective functionality.
5. Right-click the cFile component, select Row > Route from the contextual menu and click the cDynamicRouter component.
6. Repeat this operation to connect the cMessagingEndpoint components to the cProcessor components.

Configuring the components and connections

Procedure

1. Double-click the input cFile component to display its Basic settings view in the Component tab and set its properties.
   In this use case, simply specify the input file path and leave the other parameters as they are.

2. Double-click the cDynamicRouter component to display its Basic settings view in the Component tab.
3. In the Bean class field, type in the name of the predefined Java bean. Leave the Specify the method check box unselected as there is only one method in the Java bean and leave the Ignore Invalid Endpoints check box unselected if you want the component to throw an exception when endpoint URIs are not valid.
4. Double-click the first **cMessagingEndpoint** component, which is labelled *Washington*, to display its **Basic settings** view in the **Component** tab, and type in the URI in the **URI** field for the destination of your message.

Here, we want to use this component to retrieve the message routed to the URI *direct:Washington*, as shown below.

5. Repeat this step to set the endpoint URIs for the other two **cMessagingEndpoint** components: *direct:London* and *direct:Beijing* respectively.

6. Double-click the first **cProcessor** component, which is labelled *Monitor_Washington*, to display its **Basic settings** view in the **Component** tab.

7. In the **Code** box, customize the code to display the file name of the message routed to the endpoint *Washington* on the console.

   ```java
   System.out.println("Message on endpoint Washington: " +
   exchange.getIn().getHeader("CamelFileName"));
   ```

8. Repeat these steps to configure the other two **cProcessor** components to display the file names of the messages routed to the endpoints *London* and *Beijing* respectively.

9. Press Ctrl+S to save your Route.
Viewing code and executing the Route

Procedure

1. Click the **Code** tab at the bottom of the design workspace to have a look at the generated code.

```java
public void initRoute() throws Exception {
    routeBuilder = new org.apache.camel.builder.RouteBuilder()
        .public void configure() throws Exception {
            from(uriMap.get("Message_source")).routeId("Message_source").dynamicRouter(
                bean(bean.setDynaURI.class).id("cDynamicRouter_1"));
            from(uriMap.get("Washington")).routeId("Washington");
        }
}
```

As shown in the code, the incoming message from the endpoint `Message_source` is routed by `.dynamicRouter` to endpoints the URIs of which are dynamically set according to `bean.setDynaURI.class`.

2. Click the **Run** view to display it and click the **Run** button to launch the execution of your Route. You can also press **F6** to execute it.

RESULT: The source messages are routed to different endpoints based on the city names contained in the messages.

![Execution result](image)

INFO Total 4 routes, of which 4 is started.
[main ] DefaultCamelContext
INFO Apache Camel 2.0.2 (CamelContext: cDynamicRouter_s1-ctx) started in 0.747 seconds

Message on endpoint London: Message_2.xml
Message on endpoint Beijing: Message_3.xml
cErrorHandler

Processes errors in the message routing.

**cErrorHandler Standard properties**

These properties are used to configure cErrorHandler running in the Standard Job framework.

The Standard cErrorHandler component belongs to the Exception Handling family.

**Basic settings**

<table>
<thead>
<tr>
<th>Default Handler</th>
<th>This error handler does not support a dead letter queue and will return exceptions back to the caller.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Set Maximum Redeliveries</strong>: select this check box to set the number of redeliveries in the Maximum Redeliveries (int) field.</td>
<td></td>
</tr>
<tr>
<td><strong>Set Redelivery Delay</strong>: select this check box to set the initial redelivery delay (in milliseconds) in the Redelivery Delay (long) field.</td>
<td></td>
</tr>
<tr>
<td><strong>Set Retry Attempted Log Level</strong>: select this check box to select the log level in the Level list for log messages when retries are attempted.</td>
<td></td>
</tr>
<tr>
<td><strong>Asynchronous Delayed Redelivery</strong>: select this check box to allow asynchronous delayed redelivery.</td>
<td></td>
</tr>
<tr>
<td><strong>More Configurations by Code</strong>: select this check box to enter codes in the Code box for further configuration.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Dead Letter</th>
<th>This handler supports attempting to redeliver the message exchange a number of times before sending it to a dead letter endpoint.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Dead Letter Uri</strong>: select this check box to define the endpoint of the dead letter queue. Other parameters share the same meaning as those of the default handler.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Logging Handler</th>
<th>This handler logs the exceptions.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Set Logger Name</strong>: select this check box to give a name to the logger in the Name field.</td>
<td></td>
</tr>
<tr>
<td><strong>Set Log Level</strong>: select this check box to decide the log level from the Level list.</td>
<td></td>
</tr>
</tbody>
</table>

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>cErrorHandler is used separately or as a middle or end component in a Route. If this component is used separately, it will handle errors in all sub-routes. If this component</th>
</tr>
</thead>
</table>
is used in the middle or end of a sub-route, it will only handle exceptions that happen in the components of this sub-route, either before or after the cErrorHandler.

| Limitation | n/a |

Logging the exception thrown during a client/server talk

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

In this scenario, a Jetty server is started before a client browser requests access to it. Then an exception is thrown at the server side and logged by cErrorHandler.

Dropping and linking the components

Procedure

1. Drop the following components from the Palette onto the workspace: cMessagingEndpoint, cErrorHandler and cProcessor, labelled as Jetty_Server, Error_Handler and Throw_Exception respectively.

2. Link cMessagingEndpoint and cProcessor using a Row > Route connection.

Configuring the components

Procedure

1. Double-click cErrorHandler to open its Basic settings view in the Component tab.

2. Select Logging Handler to log the exceptions that are thrown.

3. Double-click cMessagingEndpoint to open its Basic settings view in the Component tab.
4. In the Uri field, enter jetty:http://localhost:8889/service to specify the Jetty server.

5. Click Advanced settings for further setup.

6. In the Dependencies table, click the [+] button to add a line and select jetty from the Camel component list.

7. Double-click cProcessor to open its Basic settings view in the Component tab.

8. In the Code box, enter throw new Exception("server side error") to throw an exception.

9. Press Ctrl+S to save your Route.

**Viewing code and executing the Route**

**Procedure**

1. Click the Code tab at the bottom of the design workspace to check the generated code.
As shown above, the route starts from the endpoint Jetty_Server and throws the exception of server side error via cProcessor_1.

2. Press **F6** to execute the Route.

The Jetty server has started.

3. Launch an Internet browser and enter `http://localhost:8889/service` (the Jetty server URI configured above) in the address bar to access the server.

As shown above, the request failed due to the server error.

4. Go to the Studio and check the results in the **Run** tab.
As shown above, **cErrorHandler** has logged the exception at the level of **ERROR**.
cExchangePattern

Sets the message exchange mode in a Route.

**cExchangePattern Standard properties**

These properties are used to configure cExchangePattern running in the Standard Job framework.

The Standard cExchangePattern component belongs to the Core family.

**Basic settings**

| Exchange Patterns | Select the message exchange mode from InOnly or InOptionalOut, InOut, OutIn, OutOptionalIn, RobustInOnly, RobustOutOnly. |

**Usage**

| Usage rule | As a middle component in a Route, cExchangePattern allows you to set the message exchange mode. |
| Limitation | |

**Enabling the InOut exchange pattern to get replies**

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

In this scenario, a **cExchangePattern** component is used to enable the request/reply exchange pattern in the Route, so that the client can get a reply from the server.

To send requests to the server side, a soapUI is needed and its configuration will be briefed in the following contents.

To build the Route, do the following.

**Dropping and linking the components**

**Procedure**

1. From the Palette, drag and drop a **cSOAP**, a **cExchangePattern** and a **cProcessor** onto the workspace, and label them **WebService_producer**, **Set_exchange_mode** and **Build_reply_message** respectively to better identify their roles in the Route.
2. Link **cSOAP** to **cExchangePattern** using a **Row > Route** connection.
3. Link cExchangePattern to cProcessor using a Row > Route connection.

Configuring the components

Procedure

1. Double-click cSOAP to open its Basic settings view in the Component tab.

2. In the Address field, leave the default setting unchanged.
3. In the Type list, select wsdlURL.
4. In the WSDL File field, enter the URL of the wsdl file. You can also click the three-dot button to browse for it.
5. Click [...] next to Service Configuration to open the service configuration wizard. The WSDL field has been filled in with the selected WSDL file. Click 📂 to show the available port in the Port Name box. Select the airportSoap port and click Finish to close the wizard. The Service Name and Port Name fields in the Basic settings view are filled in automatically.
6. In the Dataformat list, select PAYLOAD.

7. Double-click cExchangePattern to open its Basic settings view in the Component tab.

8. In the Exchange Patterns list, select InOut to enable the request/reply message exchange mode.

9. Double-click cProcessor to open its Basic settings view in the Component tab.
10. In the Code box, enter the code below.

```java
StringBuilder sb = new StringBuilder();
sb.append("<tns:getAirportInformationByISOCountryCodeResult>This is a response</tns:getAirportInformationByISOCountryCodeResult>");
exchange.getOut().setBody(sb.toString());
```

As shown above, a string is built here and is used as a reply message of the route. It is in line with the message definition of the above wsdl file.

11. Press Ctrl+S to save your Route.

Viewing code and executing the Route

Procedure

1. Click the Code tab at the bottom of the design workspace to check the generated code.

```java
public void initRoute() throws Exception {
    // CXW endpoint for WebService_producer
    org.apache.camel.Endpoint endpoint = endpoint(URI
        .get("WebService_producer"));
    from("WebService_producer").netExchangePattern(
        org.apache.camel.ExchangePattern.InOut).id(
        "cExchangePattern_1").process(
            new org.apache.camel.Processor() {
                public void process(
                    org.apache.camel.Exchange exchange)
                    throws Exception {
                    StringBuilder sb = new StringBuilder();
                    sb.append("<tns:getAirportInformationByISOCountryCodeResult>This is a response</tns:getAirportInformationByISOCountryCodeResult>");
                    exchange.getOut().setBody(sb.toString());
                }
            }).id("cProcessor_1");
```

As shown above, the route has its message exchange pattern set as InOut using the method .setExchangePattern(org.apache.camel.ExchangePattern.InOut). In the meantime, a string is created using StringBuilder sb = new StringBuilder() at cProcessor_1 and is used as the reply message via the method exchange.getOut().setBody(sb.toString()).

2. Press F6 to execute the Route.

The server Route gets started.

Creating and sending a request to the server Route and getting a reply

Procedure

1. In the soapUI, create a Test project and edit a request, as illustrated below:
Note that the wsdl file must be same as that configured for cSOAP, so that the request can be in line with the definition of the web service.

2. Send the request to the server Route and you can get the reply, as illustrated below:
cFile

Provides access to file systems, allowing files to be processed by any other components or messages from other components to be saved to the disk.

**cFile Standard properties**

These properties are used to configure cFile running in the Standard Job framework.

The Standard cFile component belongs to the Connectivity family.

**Basic settings**

<table>
<thead>
<tr>
<th>Path</th>
<th>Path to the file or files to be accessed or saved.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parameters/Noop</td>
<td>Select this check box to keep the file or files in the original folder after being read.</td>
</tr>
<tr>
<td>Parameters/Flatten</td>
<td>Select this check box to flatten the file name path to strip any leading paths. This allows you to consume recursively into sub-directories, but when you, for example, write the files to another directory, they will be written in a single directory.</td>
</tr>
<tr>
<td>Parameters/AutoCreate</td>
<td>Select this check box to create the directory specified in the Path field automatically if it does not exist.</td>
</tr>
<tr>
<td>Parameters/BufferSize(kb)</td>
<td>Write buffer sized in bytes.</td>
</tr>
<tr>
<td>Encoding</td>
<td>Specify the encoding of the file, ISO-8859-15, UTF-8, or CUSTOM.</td>
</tr>
<tr>
<td>FileName</td>
<td>The name of the file to be processed. Use this option if you want to consume only a single file in the specified directory.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| Advanced | Set the optional arguments in the corresponding table. Click [+] as many times as required to add arguments to the table. Then click the corresponding Value field and enter a value. See the site http://camel.apache.org/file2.html for available URI options. |

**Usage**

| Usage rule | cFile can be a start, middle or end component in a Route. |
| Limitation | n/a |
Reading files from one directory and writing them to another

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

In this scenario, an input **cFile** component is configured to visit a local file directory and send the files in the directory to an output **cFile** component which writes the files in another directory.

Dropping and linking the components

**Procedure**

1. From the **Palette**, expand the **Connectivity/File** folder and select the **cFile** component. Drop one as the input component and another as the output component onto the design workspace.
2. Right-click the input **cFile** component, select **Row > Route** in the contextual menu and click the output **cFile** component.
3. Label the components to better identify their respective functionality.

Configuring the components

**Procedure**

1. Double-click the input **cFile** component to display its **Basic settings** view in the **Component** tab.
   
   ![Message_source(cFile_1)](image)

   2. In the **Path** field, browse to or enter the input file path, and leave the other parameters as they are.
   3. Double-click the output **cFile** component to display its **Basic settings** view in the **Component** tab.
4. In the Path field, browse to or enter the output file path, as shown above. Leave the other parameters as they are.

5. Press Ctrl+S to save your route.

**Viewing code and executing the Route**

**Procedure**

1. Click the Code tab at the bottom of the design workspace to have a look at the generated code.

```java
public void initRoute() throws Exception {
    routeBuilder = new org.apache.camel.builder.RouteBuilder() {
        public void configure() throws Exception {
            from(uriMap.get("Message_source")).routeId("Message_source").to{
                uriMap.get("Message_destination")
            }.id("cFile_2");
        }
    }
    getCamelContext().get(0).addRoutes(routeBuilder);
}
```

As shown in the code, a message route is built from one endpoint to another.

2. Click the Run view to display it and click the Run button to launch the execution of your Route. You can also press F6 to execute it.

RESULT: The input files are written to specified output directory.
cFlatPack

Processes fixed width or delimited files or messages using the FlatPack library

**cFlatPack Standard properties**

These properties are used to configure cFlatPack running in the Standard Job framework.

The Standard cFlatPack component belongs to the Transformation family.

**Basic settings**

<table>
<thead>
<tr>
<th>When using as a start component in a route:</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>PZMAP FileType</strong></td>
<td>The PZMAP file is the Flatpack configuration file that is used to configure the structure of the input file. For more information about the PZMAP file configuration, see the website <a href="http://flatpack.sourceforge.net/documentation/index.html">http://flatpack.sourceforge.net/documentation/index.html</a>. Select the PZMAP file type from Filename and Repository Resource. <strong>Filename</strong>: The PZMAP file is stored in the local file system. <strong>Repository Resource</strong>: The PZMAP file is stored in the Resources node of the Repository.</td>
</tr>
<tr>
<td><strong>PZMAP Filename</strong></td>
<td>This option appears when Filename is selected in the PZMAP FileType list. Enter or browse to the path to the PZMAP file.</td>
</tr>
<tr>
<td><strong>PZMAP Repository Resource</strong></td>
<td>This option appears when Repository Resource is selected in the PZMAP FileType list. Click [...] and select the PZMAP file under the Resources node in the dialog box.</td>
</tr>
<tr>
<td><strong>Fixed Positional file</strong></td>
<td>Select this option if the file is a fixed format file.</td>
</tr>
<tr>
<td><strong>Delimited file</strong></td>
<td>Select this option if the file is delimited. <strong>Text Qualifier</strong>: Specify the text qualifier for delimited files. The default value is &quot;.&quot;. <strong>Text Delimiter</strong>: Specify the character delimiter for delimited files. The default value is &quot;,&quot;.</td>
</tr>
<tr>
<td><strong>Split Rows</strong></td>
<td>Select this check box to process each row one by one.</td>
</tr>
<tr>
<td><strong>Ignore First Record</strong></td>
<td>Select this check box to ignore the first line for delimited files (for the column headers). This option is only available if the Delimited file option is selected.</td>
</tr>
<tr>
<td><strong>Allow Short Lines</strong></td>
<td>Select this check box to allow lines shorter than expected by the PZMAP file.</td>
</tr>
<tr>
<td><strong>Ignore Extra Columns</strong></td>
<td>Select this check box to allow lines longer than expected by the PZMAP file and ignore the extra characters.</td>
</tr>
</tbody>
</table>

| When using as a middle or end component in a Route: |  |
Use Exist cFlatPack

| Use Exist cFlatPack | Click [...] and select the cFlatPack component to be used as the file parser in the dialog box. |

Usage

| Usage rule | cFlatPack can be a start, middle, or end component in a Route. |
| Limitation | n/a |

Parsing delimited file using the cFlatPack component

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

In this scenario, a cFile component reads a delimited file from the local file system, which contains the customers information including id, first name, surname, and order id, as shown below:

1,"Harry",Carter,21
2,Padre,Boulevard,22
3,Andrew,Polk,23
4,Herbert,Reagan,"24"
5,Chester,Eisenhower,25

The file is parsed by the cFlatPack component, using a predefined PZMAP XML file:

```xml
<?xml version="1.0"?>
<!DOCTYPE PZMAP SYSTEM "flatpack.dtd" >

<PZMAP>
  <COLUMN name="id" length="5" />
  <COLUMN name="name" length="20" />
  <COLUMN name="surname" length="20" />
  <COLUMN name="orderid" length="5" />
</PZMAP>
```

The customer information is then printed in the execution console by a cBean component.

For more information about the PZMAP file configuration, see the website http://flatpack.sourceforge.net/documentation/index.html.

Creating a Bean

About this task

In this section, a Java bean is created to print the id, first name, and surname from the customer information with the corresponding column names into the execution console.

Procedure

1. From the repository tree view, expand the Code node and right click the Beans node. In the contextual menu, select Create Bean.

The New Bean wizard opens. In the Name field, type in a name for the bean, for example, ReadOrder. Click Finish to close the wizard. The bean is opened automatically in the design workspace.
2. Enter the following code in the design workspace.

```java
package beans;
import org.apache.camel.Exchange;

public class ReadOrder {

    public static void getCustomer(Exchange exch) {
        if(exch.getIn().getBody() !=null) {
            java.util.Map data = exch.getIn().getBody(java.util.Map.class);
            if(data != null) {
                String id = (String)(data.get("id"));
                System.out.println("id :"+id);
                String name = (String)(data.get("name"));
                System.out.println("name :"+name);
                String surname = (String)(data.get("surname"));
                System.out.println("surname :"+surname);
                exch.getIn().setBody("<customer><id>" + id + "</id><name>" + name + "</name><surname>" + surname + "</surname></customer>", String.class);
            }
        }
    }
}
```

3. Press Ctrl+S to save your bean.

**Results**

For more information about creating and using Java Beans, see *Talend Studio User Guide*. 
Dropping and linking the components

About this task

![Diagram showing the components and connections]

**Procedure**

1. From the **Palette**, drag and drop a **cFile**, two **cFlatPack**, a **cBean**, and a **cLog** component onto the design workspace.
2. Link the components using the **Row > Route** connection as shown above.
3. Label the components to better identify their roles in the Route.

Configuring the components and connections

**Procedure**

1. Double-click **Delimited_file** in the design workspace to display its **Basic settings** view in the **Component** tab.

![Delimited_file settings](image)

2. In the **Path** field, browse to or enter the file path where the flatpack file is located. In the **FileName** field, enter the name of the file to be processed.
3. Double-click **Flat_file_parser** to display its **Basic settings** view in the **Component** tab.
4. Click [...] and in the Select a Node: wizard, select FlatPack_config to configure the structure of the input file.

5. Double-click FlatPack_config to display its Basic settings view in the Component tab.

6. In the PZMAP FileType list, select Filename to use the PZMAP XML file from the local file system to configure the structure of the input file. Then in the PZMAP Filename field, browse to path where the PZMAP XML file is located.
   Select the Allow Short Lines check box to allow lines shorter than expected by the PZMAP file.
   Keep the default settings of the other options.

7. Double-click ReadOrder to display its Basic settings view in the Component tab.
8. Select the New Instance option to invoke a Java bean that is stored in the Code node of the Repository.
   In the Bean class field, enter the name of the bean class, `beans.ReadOrder.class` which is just created.

9. Keep the default settings of the cLog component to log the message exchanges.

10. Press Ctrl+S to save your Route.

**Viewing code and executing the Route**

**Procedure**

1. Click the Code tab at the bottom of the design workspace to have a look at the generated code.

   ```java
   public void configure() throws java.lang.Exception {
       from(uriMap.get("cFile_1")).routeId("Delimited_file_cFile_1")
           .to(uriMap.get("cFlatPack_2")).id("cFlatPack_1");
       from(uriMap.get("cFlatPack_2")).routeId("FlatPack_config_cFlatPack_2")
           .bean(beans.ReadOrder.class)
           .id("cBean_1")
           .log(org.apache.camel.LoggingLevel.INFO, "cLog_1", "${in.body}")
           .id("cLog_1");
   }
   ```

   As shown in the code, one route is built from "Delimited_file_cFile_1", to "cFlatPack_1". The other is built from cFlatPack_2, processed by "cBean_1" and "cLog_1" sequentially.

2. Click the Run view to display it and click the Run button to launch the execution of your Route. You can also press F6 to execute it.
RESULT: The delimited file is parsed. The id, first name, and surname of the customer information with the corresponding column names is shown in the execution console.
cFtp

Provides access to remote file systems over the FTP, FTPS and SFTP protocols.

**cFtp Standard properties**

These properties are used to configure cFtp running in the Standard Job framework.

The Standard cFtp component belongs to the Connectivity family.

**Basic settings**

<table>
<thead>
<tr>
<th>Parameters/Type</th>
<th>Select the file transfer protocol, ftp or sftp, ftsp.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parameters/server</td>
<td>Type in the remote server address to be accessed.</td>
</tr>
<tr>
<td>Parameters/port</td>
<td>Type in the port number to be accessed.</td>
</tr>
<tr>
<td>Parameters/username</td>
<td>Type in the user authentication information.</td>
</tr>
<tr>
<td>Parameters/password</td>
<td>Type in the user authentication information. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Parameters/directory</td>
<td>Enter the directory you want to access on the remote server. If not specified, the root directory will be accessed.</td>
</tr>
</tbody>
</table>

**Advanced settings**

Advanced

Set the optional arguments in the corresponding table. Click [+] as many times as required to add arguments to the table. Then click the corresponding Value field and enter a value. See the site http://camel.apache.org/ftp.html for available URI options.

**Usage**

Usage rule

cFtp can be a start, middle or end component in a Route.

**Related scenarios**

No scenario is available for the Standard version of this component yet.
cHttp

Provides HTTP-based endpoints for consuming and producing HTTP resources.

**cHttp Standard properties**

These properties are used to configure cHttp running in the Standard Job framework.

The Standard cHttp component belongs to the Connectivity family.

**Basic settings**

<table>
<thead>
<tr>
<th><strong>Uri</strong></th>
<th>The URI of the Http resource to call.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Client</strong></td>
<td>Select this option to use cHttp as a client to call external servers.</td>
</tr>

<tr>
<td><strong>Server Configuration / Use Transfer-Encoding</strong></td>
<td>This option is enabled by default. If this check box is cleared, Jetty servlet will disable the HTTP streaming and set the content-length header on the response.</td>
</tr>
<tr>
<td><strong>Server Configuration / Enable JMX</strong></td>
<td>Select this option to enable Jetty JMX support for this endpoint. For more information about this option, see the site <a href="http://camel.apache.org/jetty.html#Jetty-JettyJMXsupport">http://camel.apache.org/jetty.html#Jetty-JettyJMXsupport</a>.</td>
</tr>
<tr>
<td><strong>Server Configuration / Match on URI Prefix</strong></td>
<td>Select this check box to use the CamelServlet to find a target consumer by matching the URI prefix if no exact match is found. For more information about this option, see the site <a href="http://camel.apache.org/how-do-i-let-jetty-match-wildcards.html">http://camel.apache.org/how-do-i-let-jetty-match-wildcards.html</a>.</td>
</tr>
<tr>
<td><strong>Server Configuration / Use Jetty Continuation</strong></td>
<td>Select this check box to use Jetty continuations for the Jetty Server. For more information about this option, see the site <a href="http://wiki.eclipse.org/Jetty/Feature/Continuations">http://wiki.eclipse.org/Jetty/Feature/Continuations</a>.</td>
</tr>
<tr>
<td><strong>Server Configuration / Enable HTTP TRACE</strong></td>
<td>Select this option to enable the HTTP TRACE method.</td>
</tr>
</tbody>
</table>
### Advanced settings

| Headers | Click the [+] button to add lines as needed and define the key and value for headers. |

### Usage

| Usage rule | cHttp provides Http based endpoints for consuming external Http resources, that is to say as a client to call external servers using Http. |
| Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |

### Retrieving the content of a remote file

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

In this scenario, cHttp is used to request the body of a weather condition definition file that is available at http://wsf.cdyne.com/WeatherWS/Weather.asmx.

### Dropping and linking the components

**Procedure**

1. Drop the following components from the Palette onto the workspace: cMessagingEndpoint, cSetBody, cHttp and cProcessor, labelled as STARTER, HTTP_REQUEST_BODY, GET_WEATHER_DESCRIPTION and PRINT_RESPONSE respectively.

2. Link the components using a Row > Route connection.

![Diagram](image)

### Configuring the components

**Procedure**

1. Double-click cMessagingEndpoint to open its Basic settings view in the Component tab.
2. In the **URI** field, enter `timer:go?repeatCount=1` to define a timer for starting message exchanges. In this example, only one message exchange will be carried out due to the setting of `repeatCount=1`.

3. Double-click `cSetBody` to open its **Basic settings** view in the **Component** tab.

4. In the **Language** field, select **Constant**.

5. In the **Expression** field, enter the following as the body of the request message:

```xml
<soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
```

6. Double-click `cHttp` to open its **Basic settings** view in the **Component** tab.

7. In the **Uri** field, enter the location of the file to fetch, `http://wsf.cdyne.com/WeatherWS/Weather.asmx` in this example.

8. Click the **Client** radio button to use this `cHttp` component as a client.

9. Select **POST** in the **Method** list and then the **Use Message Body** radio button. Select `text/xml` in the **Content-Type** list.

10. Click **Advanced settings** for further setup.
11. Click the [+] button to add a line in the Headers table. Type in SOAPAction and http://ws.cdyne.com/WeatherWS/GetWeatherInformation for the Key and Value fields.

12. Double-click cProcessor to open its Basic settings view in the Component tab.

13. In the Code area, enter the following to print the response from the remote website, the body of the desired file:

```java
System.out.println("-------------------RESPONSE-------------------");
System.out.println(exchange.getIn().getBody(String.class));
System.out.println("-------------------END-------------------");
```

14. Press Ctrl+S to save your Route.

**Viewing code and executing the Route**

**Procedure**

1. Click the Code tab at the bottom of the design workspace to check the generated code.
As shown above, the message exchange starts from the endpoint STARTER, gets its body set to
<soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
<soapenv:Body><weat:GetWeatherDefinitionInformation/></soapenv:Body></soapenv:Envelope>
at cSetBody_1, and then is sent out to the specified website by cHttp_1. Finally, the response is printed out via cProcessor_1.

2. Press F6 to execute the Route.

As shown above, the retrieved file defines up to 37 weather conditions with detailed description.

As shown above, the retrieved file defines up to 37 weather conditions with detailed description.
Using cHttp to produce a Web service

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

In this scenario, cHttp is used to as a server to start a Web service. A cProcessor component is used to request the service.

Dropping and linking the components

Procedure
1. Drag and drop a cHttp and a cProcessor from the Palette onto the design workspace.

2. Link the components using a Row > Route connection.
3. Label the components for better identification of their roles.

Configuring the components

Procedure
1. Double-click cHttp to open its Basic settings view in the Component tab.

2. In the URI field, enter "http://localhost:8088/user" where the service will be accessible for requests.
3. Click the Server radio button to use this cHttp component as a server. Keep the default settings of the other options.
4. Double-click cProcessor to open its Basic settings view in the Component tab.
5. In the **Code** area, enter the following code to get the header `id` of the exchange message:

```java
System.out.println(exchange.getIn().getHeader("id"));
```

6. Press **Ctrl+S** to save your Route.

**Viewing code and executing the Route**

**Procedure**

1. Click the **Code** tab at the bottom of the design workspace to check the generated code.

```java
public void configure() throws java.lang.Exception {
    from(urlMap.get("server_cHttp_1"))
        .routeId("server_cHttp_1").process(new org.apache.camel.Processor() {
            public void process(org.apache.camel.Exchange exchange) 
                throws Exception {
                    System.out.println(exchange.getIn().getHeader("id"));
                }
        }).id("cProcessor_1");
}
```

As shown above, the route is built from the endpoint `server_cHttp_1` and the message header `id` is printed out by `cProcessor_1`.

2. Press **F6** to execute the Route.

3. Start a Web browser. In the address bar, type in `http://localhost:8088/user?id=1` and click **Enter**. A blank page opens up.
4. Switch back to the studio. The id 1 is printed in the console.
cIdempotentConsumer

Identifies messages that have already been sent to the receiver and eliminates them. Messages are still sent by the sender but are ignored by the receiver at the delivery stage.

cIdempotentConsumer deduplicates messages and thereby prevents the receiving message endpoint from receiving duplicate messages.

**cIdempotentConsumer Standard properties**

These properties are used to configure cIdempotentConsumer running in the Standard Job framework.
The Standard cIdempotentConsumer component belongs to the Routing family.

**Basic settings**

| Repository Type | Message identifiers need to be stored in a repository. For new incoming messages, identifiers are checked against the ones stored in the repository to identify and drop duplicates. There are two ways to store them:
| Memory: messages identifiers are stored temporarily. |
| Warning: *The in-memory storage mode can easily run out of memory and does not work in a clustered environment.* |
| File: messages identifiers are stored in a file. Specify the path to this file in the File store field. |

| File store | Specify the path and name of the file storing messages identifiers. |

| Cache Size | Type in the size of the cache, namely the number of message identifiers to store. |

| Use language | Select this check box if you want to specify the language used in the Predicate field to specify the identifier of the messages. In the Language list, select from None, Bean, Constant, CorrelationID, EL, Groovy, Header, JavaScript, JoSQL, JSONPath, JXPath, MVEL, OGNL, PHP, Property, Python, Ruby, Simple, SpEL, SQL, XPath, and XQuery. For more information about how to use the languages to create an expression, see the site [http://camel.apache.org/languages.html](http://camel.apache.org/languages.html). |

| Predicate | Type in the expression to use to specify the identifier of the messages. |

| Add Namespaces | This option appears when XPath is selected in the Language list. Select this check box to add namespaces for the XPath expression. Click [+] to add as many namespaces as required to the table and define the prefix and URI in the corresponding columns. |
Eager

Select this check box to detect duplicate messages even when messages are currently in progress; clear it to detect duplicates only when messages have successfully been processed.

By default, this check box is selected.

SkipDuplicate

Select this check box to drop duplicates; clear it to ignore duplicates so that all messages will be continued.

By default, this check box is selected.

Usage

Usage rule

clidempotentConsumer is used as a middle component in a Route.

Connections

idemp: The idemp link retrieves messages deduplicated by the clidempotentConsumer component.

Route: As an optional link, the Route link retrieves all messages from the message sender.

Limitation

n/a

Deduplicating messages while routing them

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

In this scenario, duplicated messages are filtered and only the unique one is routed to the destination.

Three XML files that have the same content, as shown below, are used in this use case.

```
<people>
  <person id="8">
    <firstName>Ellen</firstName>
    <lastName>Ripley</lastName>
    <city>Washington</city>
  </person>
</people>
```

Dropping and linking the components

About this task

This use case requires one cFile component, one clidempotentConsumer component, and two cProcessor components.
Procedure

1. From the Palette, expand the Connectivity folder, select the cFile component, and drop it onto the design workspace as the message source component.
2. Expand the Routing folder, select the cIdempotentConsumer component and drop it onto the design workspace as the message deduplicator.
3. Expand the Custom folder, drop two cProcessor components onto the design workspace, one as the consumer for deduplicated messages and another for all messages.
4. Right-click the cFile component, select Row > Route from the contextual menu and click the cIdempotentConsumer component.
5. Right-click the cIdempotentConsumer component, select Row > idemp from the contextual menu and click the cProcessor component on the top.
6. Connect the cIdempotentConsumer component to the other cProcessor component using a Row > Route connection. This optional connection will retrieve all the messages coming from the source.
7. Label the components to better identify their roles in the Route.

Configuring the components and connections

Procedure

1. Double-click the cFile component, which is labelled Source, to display its Basic settings view in the Component tab.

   ![Source View](image)

   - **Path:** Specify the file path to the message source.
   - **Encoding:** Select the encoding type of your source files, and leave all the other parameters as they are.
3. Double-click the `cIdempotentConsumer` component, which is labelled `Deduplicator`, to display its **Basic settings** view in the **Component** tab.

4. From the **Repository Type** list, select between **Memory** and **File** to specify where the message identifiers will be stored before the deduplication process. For this scenario, select **File**.

   In the **File store** field, specify the location of the file storing message identifiers.

   In the **Expression** field, enter an expression to filter the messages. In this scenario, enter the following expression to filter the messages according to the `person` node of the XML files: `xpath("/people/person")`, and leave all the other parameters as they are. Alternatively, you can select the **Use language** check box, select **XPath** from the **Language** list, and enter `/people/person" in the **Predicate** field.

5. Double-click the `cProcessor` component labelled **Unique** to display its **Basic settings** view in the **Component** tab.

6. In the **Code** area, customize the code to display the file name of the message that passes the deduplication:

   ```java
   System.out.println("Message consumed on Unique: "+
                     exchange.getIn().getHeader("CamelFileName"));
   ```

7. Repeat these steps to configure the other `cProcessor` component, which is labelled **All**, to display the file names of all the messages coming from the source:

   ```java
   System.out.println("Message consumed on All: "+
                     exchange.getIn().getHeader("CamelFileName"));
   ```

8. Press **Ctrl+S** to save your Route.
Viewing code and executing the Route

Procedure

1. Click the **Code** tab at the bottom of the design workspace to view the generated code.

   ```java
   public void initRoute() throws Exception {
      routeBuilder = new org.apache.camel.builder.RouteBuilder() {
         public void configure() throws Exception {
            from(uriMap.get("Source"))
               .routeId("Source")
               .idempotentConsumer(
                  xpath("/people/person"),
                  org.apache.camel.processor.idempotent.fileIdempotentRepository
                     .fileIdempotentRepository(
                         new java.io.File(
                            "D:\talend_files/cab/camel_temp.txt"),
                         200)).eager(true)
               .skipDuplicate(true)
               .id("cIdempotentConsumer_1").process{
                  new org.apache.camel.Processor()
               }
      }
   }
   ```

   In this partially shown piece of code, messages from the **Source** are filtered according to the expression `xpath("/people/person")` and deduplicated by `cIdempotentConsumer_1`.

2. Click the **Run** view to display it and click the **Run** button to launch the execution of your Route. You can also press **F6** to execute it.

   RESULT: When several files have the same content, only the first one is routed to the receiving endpoint.
clIntercept

Intercepts each message sub-route and redirects it in another sub-route without modifying the original one. When this detour is complete, message routing to the originally intended target endpoints continues. This can be useful at testing time to simulate error handling.

clIntercept Standard properties

These properties are used to configure clIntercept running in the Standard Job framework.

The Standard clIntercept component belongs to the Exception Handling family.

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>clIntercept is a start component of a sub-route.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connections</td>
<td>Row / Route: Select the Route link to intercept all the messages of all the sub-routes listened to by the clIntercept.</td>
</tr>
<tr>
<td>Trigger / When</td>
<td>Select the When link to filter the messages to intercept and click the Component view. In the Type list, select the type of language you will use to declare your condition. In the Condition field, type in the condition that will be used to filter the messages. All the messages that do not match this condition are dropped by default or can be retrieved with the Otherwise link to a different channel.</td>
</tr>
<tr>
<td>Limitation</td>
<td>To keep the original sub-routes untouched, clIntercept only be used in a separate sub-route.</td>
</tr>
</tbody>
</table>

Intercepting several routes and redirect them in a single new route

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

In this scenario, messages on two sub-routes are intercepted and routed along a new sub-route, which is then terminated before the original sub-routes continue.
Dropping and linking the components

About this task
This scenario requires five `cFile` components, one `cIntercept` component, one `cProcessor` component, and one `cStop` component.

Procedure
1. From the Connectivity folder of the Palette, drop four `cFile` components onto the design workspace.
2. Connect the two pairs of `cFile` components using Row > Route connections. Messages on these two sub-routes will be intercepted.
3. From the Exception Handling folder, drop a `cIntercept` component onto the design workspace.
4. From the Custom folder, drop a `cProcessor` component onto the design workspace.
5. From the Connectivity folder, drop a fifth `cFile` component onto the design workspace.
6. From the Miscellaneous folder, drop a `cStop` component onto the design workspace.
7. Connect these four components one to the next using Row > Route connections. Along this sub-route, intercepted messages will be directed to a new endpoint before the entire Route is terminated.
8. Label the components to better identify their roles in the Route.

Configuring the components and connections

About this task
In this scenario, the `cIntercept` component intercepts all the messages on all the sub-routes as soon as the messages are sent and does not have properties to set. The `cStop` component stops the sub-route on which it is dropped before it completes and does not have properties to set. Therefore, you only need to configure the messaging endpoints and monitor components.

Procedure
1. Double-click the `cFile` component labeled `Sender_1` to display its Basic settings view in the Component tab.
2. In the **Path** field, specify the file path to the first source you are going to send messages from, and leave the other parameters as they are.

3. Double-click the **cFile** component labeled **Receiver_1** to display its **Basic settings** view in the **Component** tab.

4. In the **Path** field, specify the file path to the first destination you are going to send messages to, and leave the other parameters as they are.

5. In the same way, set the **cFile** components labeled **Sender_2** and **Receiver_2** across the second sub-route.

6. Double-click the **cProcessor** component, which is labeled **Monitor**, to display its **Basic settings** view in the **Component** tab, and customize the code in the **Code** area to display the file names of the messages intercepted on the console:

   ```java
   System.out.println("Message intercepted: "+
     exchange.getIn().getHeader("CamelFileName"));
   ```

7. Double-click the **cFile** component labeled **Receiver_3** to display its **Basic settings** view in the **Component** tab.
8. In the Path field, specify the file path to the destination for the intercepted messages, and leave the other parameters as they are.

9. Press Ctrl+S to save your Route.

**Viewing code and executing the Route**

**Procedure**

1. Click the Code tab at the bottom of the design workspace to have a look at the generated code.

```java
public void initRoute() throws Exception {
    routeBuilder = new org.apache.camel.builder.RouteBuilder() {
        public void configure() throws Exception {
            intercept()
                .routeId("Interceptor")
                .process(new org.apache.camel.Processor() {
                    public void process(
                        org.apache.camel.Exchange exchange)
                        throws Exception {
                            System.out
                                .println("Message intercepted: 
                                    + exchange
                                    .getIn()
                                    .getHeader("CamelFileName");
                
                uriMap.get("Receiver_3")
                    .id("cFile_5")
                        .stop()
                            .id("cStop_1");
                from(uriMap.get("Sender_1 ")).routeId("Sender_1 ").to(
                    uriMap.get("Receiver_1 ")).id("cFile_2");
                from(uriMap.get("Sender_2 ")).routeId("Sender_2 ").to(
                    uriMap.get("Receiver_2 ")).id("cFile_4");
            }
        }
    });
    getCamelContexts().get(0).addRoutes(routeBuilder);
```

As shown in this piece of code, Interceptor intercepts all messages on route, the intercepted messages are directed to the endpoint Receiver_3, and cStop_1 terminates message routing.
before the messages are routed from the endpoint Sender_1 to the endpoint Receiver_1 and from the endpoint Sender_2 to the endpoint Receiver_2.

2. Click the Run view and click the Run button to launch the execution of your Route. You can also press F6 to execute it.

RESULT: Files are sent from the endpoints, caught by the cIntercept component, monitored by the cProcessor component and sent to a new endpoint, and then the original sub-routes are terminated before they can continue.
cJavaDSLProcessor

Implements producers and consumers of message exchanges or implements a message translator using the Java Domain Specific Language (DSL).

cJavaDSLProcessor can quickly whirls up some code using Java DSL. If the code in the inner class gets a bit more complicated it is of course advised to refactor it into a separate class.

**cJavaDSLProcessor Standard properties**

These properties are used to configure cJavaDSLProcessor running in the Standard Job framework. The Standard cJavaDSLProcessor component belongs to the Core family.

**Basic settings**

<table>
<thead>
<tr>
<th>Code</th>
<th>Type in the code you want to implement using Java DSL.</th>
</tr>
</thead>
</table>

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>cJavaDSLProcessor is used as a middle or end component in a Route.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limitation</td>
<td>n/a</td>
</tr>
</tbody>
</table>

**Related scenario:**

For a related scenario, see Wiretapping a message in a Route on page 322.
cJMS

Exchanges messages between a Route and a JMS provider.

**cJMS Standard properties**

These properties are used to configure cJMS running in the Standard Job framework.

The Standard cJMS component belongs to the Connectivity family.

**Basic settings**

<table>
<thead>
<tr>
<th>URI/Type</th>
<th>Select the messaging type, either <strong>queue</strong> or <strong>topic</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>URI/Destination</td>
<td>Type in a name for the JMS queue or topic.</td>
</tr>
<tr>
<td>ConnectionFactory</td>
<td>Click the three-dot button and select a JMS connection factory to be used for handling messages or enter the name of the corresponding <strong>cMQConnectionFactory</strong> component directly in the field.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| URI Options | Set the optional arguments in the corresponding table. Click `[*]` as many times as required to add arguments to the table. Then click the corresponding value field and enter a value. See the site [http://camel.apache.org/jms.html](http://camel.apache.org/jms.html) for available URI options. |

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>cJMS can be a start, middle or end component in a Route. It has to be used with the <strong>cMQConnectionFactory</strong> component, which creates a connection to a MQ server. For more information about <strong>cMQConnectionFactory</strong>, see <a href="#">cMQConnectionFactory on page 230</a>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limitation</td>
<td><strong>n/a</strong></td>
</tr>
</tbody>
</table>

**Sending and receiving a message from a JMS queue**

In this scenario, a cJMS component sends messages from the local file system to a message queue in one sub-route, and the messages are then consumed by another cJMS component in the other sub-route.
Dropping and linking the components

Procedure

1. From the **Palette**, expand the **Connectivity/Messaging** folder, and drop a **cMQConnectionFactory** component onto the design workspace to specify the JMS connection factory for handling messages.
2. From the **Connectivity** folder, drop one **cFile** and two **cJMS** components onto the design workspace.
3. From the **Custom** folder, drop a **cProcessor** component onto the design workspace.
4. Connect the **cFile** component to a **cJMS** component using a **Row > Route** connection as the message producer sub-route.
5. Connect the other **cJMS** component to the **cProcessor** component using a **Row > Route** connection as the message consumer sub-route.
6. Label the components properly for better identification of their functionalities.

Configuring the components

Procedure

1. Double-click the **cMQConnectionFactory** component to display its **Basic settings** view in the **Component** tab.

2. From the **MQ Server** list, select an MQ server. In this use case, we use the default ActiveMQ server to handle the messages.
   In the **Broker URI** field, type in the URI of the message broker. Here we simply use the default URI "vm://localhost?broker.persistent=false".
3. In the message producer sub-route, double-click the **cFile** component to display its **Basic settings** view.
4. Define the properties of the cFile component.
   In this use case, simply specify the path to the folder that holds the source file to be sent as electronic message, and leave the other parameters as they are.

5. Double-click the cJMS component labeled Message_producer to display its Basic settings view.

6. From the Type list, select queue to send the messages to a JMS queue.
   In the Destination field, type in a name for the JMS queue, "queue.hello" in this use case.
   Double-click the [...] button next to ConnectionFactory. Select the MQ connection factory that you have just configured in the dialog box and click OK.

7. Switch to the message consumer sub-route, and double click the cJMS component labeled Message_consumer to display its Basic settings view.
8. Configure the message consumer using exactly the same parameters as in the message producer.
9. Double-click the **cProcessor** component to display its **Basic settings** view.

10. In the **Code** area, customize the code as shown below to display the file names of the consumed messages on the **Run** console.

    ```java
    System.out.println("Message consumed: "+
    exchange.getIn().getHeader("CamelFileName");
    )
    ```

11. Press **Ctrl+S** to save your Routes.

### Viewing code and executing the Route

**Procedure**

1. Click the **Code** tab at the bottom of the design workspace to have a look at the generated code.

    ```java
    public void configure() throws java.lang.Exception {
        from(uriMap.get("cFile_1")).routeId("File_source_cFile_1")
            .to(uriMap.get("cJMS_1")).id("cJMS_1");
        from(uriMap.get("cJMS_2")).routeId("Message_consumer_cJMS_2")
            .process(new org.apache.camel.Exchange exchange) {
                public void process(org.apache.camel.Exchange exchange) throws Exception {
                    System.out.println("Message consumed: "+
                        exchange.getIn().getHeader("CamelFileName");
                }
            };
    }
    ```
In the partially shown code, a message route is built from the File_source_cFile_1 to the cJMS_1 which then sends the message to a message queue via a broker identified by vm://localhost?broker.persistent=false. The message from the Message_consumer_cJMS_2 is processed by cProcessor_1.

2. Click the Run button in the Run view to launch the execution of your Route. You can also press F6 to execute it.

RESULT: The message is received by the consumer, as shown on the Run console.

Setting up a JMS local transaction

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

In this scenario, a local transaction with three steps is performed to send, test and consume a JMS message:

1. The first Route is used to send a "hello world!" message to feed the queue.hello JMS queue.
2. The second Route is used to test the received JMS message. This message is redelivered six times to the queue.hello queue and is then moved to the Dead Letter JMS queue. The Route is programmed to throw an exception every time an exchange is processed by the Route.
3. The last Route is used to consume the "hello world!" message from the Dead Letter JMS queue.

In this use case, we use the local ActiveMQ server to handle messages between different Routes. The ActiveMQ server need to be started before executing the Routes. For more information on installing and launching ActiveMQ server, see the Apache Web site http://activemq.apache.org/index.html.
Sending a message to the `queue.hello JMS` queue

![Diagram of components](image)

**Dropping and linking the components**

**Procedure**

1. From the **Palette**, drop the five following components onto the design workspace: one `cMQConnectionFactory`, one `cConfig`, one `cMessagingEndpoint`, one `cJMS` and one `cProcessor` component.
2. Connect the `cMessagingEndpoint` component to the `cJMS` using a `Row > Route` connection.
3. Connect the `cJMS` component to the `cProcessor` component using a `Row > Route` connection.

**Configuring the components**

**Procedure**

1. Double-click the `cMQConnectionFactory` component labelled `AMQ_Send_ConnectionFactory` to display its **Basic settings** view in the **Component** tab.

![AMQ_Send_ConnectionFactory](image)

2. From the **MQ Server** list, select an MQ server. In this use case, we use the default ActiveMQ server to handle the messages.
3. In the **Broker URI** field, type in Active MQ's default URI of the localhost server: `"tcp://localhost:61616"`.
4. Double-click the `cConfig` component, which is labelled `DatasetConfig`, to display its **Basic settings** view in the **Component** tab and set its parameters.
5. Write a piece of code in the **Code** field to register the dataset instance *hello* into the registry, as shown below.

```
org.apache.camel.component.dataset.SimpleDataSet dataset = new org.apache.camel.component.dataset.SimpleDataSet(1);
dataset.setDefaultBody("Test Data: hello world!");
org.apache.camel.impl.SimpleRegistry registry = new org.apache.camel.impl.SimpleRegistry();
registry.put("hello",dataset);
camelContext.setRegistry(registry);
```

6. Double-click the **cMessagingEndpoint** component, which is labelled *SimpleDatasetGen*, to display its **Basic settings** view in the **Component** tab. and set its parameters.

7. In the **URI** field, enter *dataset:hello* between the quotation marks.

8. Double-click the **cJMS** component labeled *AMQ_Send* to display its **Basic settings** view.
9. From the **Type** list, select **queue** to send the message to a JMS queue. In the **Destination** field, type in a name for the JMS queue, “queue.hello” in this use case. Double-click the [...] button next to **ConnectionFactory**. Select the MQ connection factory that you have just configured in the dialog box and click **OK**.

![Select a Node: AMQ_Send_ConnectionFactory](image)

10. Double-click the **cProcessor** component labelled **PrintSendMsg** to display its **Basic settings** view in the **Component** tab, and customize the code in the **Code** area to display the sent message intercepted on the console.

    ```java
    System.out.println("AMQ Send: "+
    exchange.getIn().getBody(String.class));
    ```

**Executing the Route**

**Procedure**

Click the **Run** button in the **Run** view to launch the execution of your Route. You can also press **F6** to execute it.

**RESULT:** One "hello world!" message is sent to the JMS Queue, as shown in the **Run** console.

![Execution](image)
Testing the received message

Linking the components

Procedure
1. From the Palette, drop the four following components onto the design workspace: one cJMS, two cProcessor components and one cMQConnectionFactory.
2. Connect the cJMS component to the first cProcessor using a Row > Route connection.
3. Connect the first cProcessor component to the second cProcessor component using a Row > Route connection.

Defining the settings of the components

Procedure
1. Double-click the cMQConnectionFactory component labelled AMQ_Rev_ConnectionFactory to display its Basic settings view in the Component tab.

   ![AMQ_Rev_ConnectionFactory](image)

   1. From the MQ Server list, select an MQ server. In this use case, we use the default ActiveMQ server to handle the messages.
   2. Select the Use transaction check box.
   3. In the Broker URI field, type in ActiveMQ’s default URI of the localhost server: “tcp://localhost:61616”.
   4. Double-click the cJMS component labeled AMQ_Rev to display its Basic settings view.

   ![AMQ_Rev](image)
5. From the **Type** list, select **queue** to send the messages to a JMS queue.
   In the **Destination** field, type in a name for the JMS queue, “queue.hello” in this use case.
   Double-click the [...] button next to **ConnectionFactory**. Select the MQ connection factory that you have just configured in the dialog box and click **OK**.

![Select a Node:](image)

6. Double-click the first **cProcessor** component labelled **PrintRevMsg** to display its **Basic settings** view in the **Component** tab, and customize the code in the **Code** area to display the received message intercepted on the console.

   ```java
   System.out.println("AMQ Receive: " + exchange.getIn().getBody(String.class));
   ```

7. Double-click the second **cProcessor** component labelled **ThrowEx** to display its **Basic settings** view in the **Component** tab, and customize the code in the **Code** area to throw the **Force fail** exception every time an exchange is processed by the route.

   ```java
   throw new Exception("Force fail")
   ```

**Running the Route**

**Procedure**

Click the **Run** button in the **Run** view to launch the execution of your Route. You can also press **F6** to execute it.

**RESULT:** The “hello world!” message is tested and a rollback transaction is performed. Once the message redelivery attempts exceeds six times, the pending message is sent to the **Dead Letter JMS Queue**.

**Consuming the message from the DeadLetter JMS queue**
Arranging the flow of the message

Procedure

1. From the Palette, drop the three following components onto the design workspace: one cMQConnectionFactory, one cJMS and one cProcessor component.
2. Connect the cJMS component to the cProcessor component using a Row > Route connection.

Configuring how the message is processed

Procedure

1. Double-click the cMQConnectionFactory component to display its Basic settings view in the Component tab.

2. From the MQ Server list, select an MQ server. In this use case, we use the default ActiveMQ server to handle the messages.
3. In the Broker URI field, type in ActiveMQ’s default URI of the localhost server: "tcp://localhost:61616".
4. Double-click the cJMS component labeled DeadLetterQueueJMS to display its Basic settings view.

5. From the Type list, select queue to send the messages to a JMS queue.
   In the Destination field, type in a name for the JMS queue, “ActiveMQ.DLQ” in this use case (the default Dead Letter Queue in ActiveMQ).
   Double-click the [...] button next to ConnectionFactory. Select the MQ connection factory that you have just configured in the dialog box and click OK.
6. Double-click the **cProcessor** component labelled **PrintMsg** to display its **Basic settings** view in the **Component** tab, and customize the code in the **Code** area to display the received message intercepted on the console.

```java
System.out.println("AMQ Receive: "+ exchange.getIn().getBody(String.class));
```

**Launching the execution of the Route**

**Procedure**

Click the **Run** button in the **Run** view to launch the execution of your Route. You can also press **F6** to execute it.

RESULT: The "hello world!" message that was in the **Dead Letter** queue is consumed, as shown in the **Run** console.

**Sending and receiving a scheduled delivery of messages from a JMS Queue using Camel Quartz**

This scenario applies only to **Talend Open Studio for ESB**, **Talend Data Services Platform** and **Talend Data Fabric**.

This scenario will show you how to use the **Camel Quartz** component to provide a scheduled delivery of messages from a JMS Queue.
To do this, we will build two Routes, a message producer Route and a consumer Route. We will implement the Quartz component in the producer Route to send scheduled messages to a JMS Queue. The messages are then consumed by the consumer Route.

In this use case, we will use Apache ActiveMQ as the message broker. We need to launch the ActiveMQ server before executing the Route. For more information about installing and launching ActiveMQ server, see the site http://activemq.apache.org/index.html.

Building the producer Route

Dropping and linking the components

About this task

![Diagram of components](image)

Procedure

1. From the Palette, drag and drop a `cMQConnectionFactory`, a `cJMS`, a `cSetBody`, and two `cMessagingEndpoint` components onto the design workspace.
2. Label the components for better identification of their roles and link them with the `Row > Route` connection as shown above.

Configuring the components

Procedure

1. Double-click the `cMQConnectionFactory` component to display its Basic settings view in the Component tab.

   ![MQConnectionFactory settings](image)

   2. From the MQ Server list, select `ActiveMQ` to handle messages.

   In the Broker URI field, type in the URI of the local Active MQ server, "tcp://localhost:61616".

In the broker URI field, type in the URI of the local Active MQ server, "tcp://localhost:61616".
Select the **Use PooledConnectionFactory** check box and keep the default settings.

3. Double-click the **quartzConsumer** component to open its **Basic settings** view in the **Component** tab.

4. In the **URI** field, enter the code "quartz://HelloWorld?trigger.repeatInterval=2000&trigger.repeatCount=-1" to define a timer for starting message exchanges. In this use case, we want the message to be delivered endlessly between an interval of two seconds. For more information about Quartz, see the site [http://camel.apache.org/quartz.html](http://camel.apache.org/quartz.html).

5. Click the **Advanced settings** view. Click at the bottom of the **Dependencies** list to add a row and select **quartz** from the drop-down list. For more information about the Quartz component, see the site [http://camel.apache.org/quartz.html](http://camel.apache.org/quartz.html).

6. Double-click the **cSetBody** component to open its **Basic settings** view in the **Component** tab.

7. Select **Simple** from the **Language** list box and type in "Hello world" in the **Expression** field.

8. Double-click the **logMessage** component to open its **Basic settings** view in the **Component** tab.
9. In the URI field, enter "log:quartzMessage" where the message exchanges are logged.

10. Double-click the jmsProducer component to display its Basic settings view in the Component tab.

11. From the Type list, select queue to send the messages to a JMS queue.

   In the Destination field, type in a name for the JMS queue, "quartzTest" in this use case.

   In the ConnectionFactory field, click [...] and select the MQ connection factory that you have just configured.

12. Press Ctrl+S to save your Route.

**Viewing the code and executing the Route**

**Procedure**

1. Click the Code tab at the bottom of the design workspace to check the generated code.

   ```java
   public void initRoute() throws Exception {
       routeBuilder = new org.apache.camel.builder.RouteBuilder() {
           public void configure() throws Exception {
               from(uriMap.get("quartzConsumer"))
                   .routeId("quartzConsumer")
                   .setBody().simple("Hello world")
                   .id("cSetBody_1")
                   .to(
                       uriMap.get("logMessage")
                           .id("logMessage")
                           .id("cMessagingEndpoint_2")
                           .id("cMessagingEndpoint_2")
                           .id("cJMS_1");
           }
       }
   }
   
   getCamelContexts().get(0).addRoutes(routeBuilder);
   
   As shown above, the message flow from quartzConsumer is given a payload by cSetBody_1 and then sent to logMessage and jmsProducer.

2. Press F6 to execute the Route.

   RESULT: The logs of the message exchange are printed in the console.
Building the consumer Route

Arranging the flow of the message

About this task

Procedure

1. From the Palette, drag and drop a cMQConnectionFactory, a cJMS, and a cMessagingEndpoint component onto the design workspace.

2. Label the components for better identification of their roles and link them with the Row > Route connection as shown above.

Configuring how the message is processed

Procedure

1. Double-click the cMQConnectionFactory component to display its Basic settings view in the Component tab.
2. Configure the `cMQConnectionFactory` component the same as in the producer Route.
3. Double-click the `jmsConsumer` component to display its Basic settings view in the Component tab.
4. Configure the `jmsConsumer` component the same as the `jmsProducer` component in the producer Route to consume the messages in the defined queue "quartzTest".
5. Double-click the `logMessage` component to open its Basic settings view in the Component tab.

6. In the URI field, enter "log:quartzMessage" where the message exchanges are logged.
7. Press Ctrl+S to save your Route.

**Executing the Route**

**Procedure**

1. Click the Code tab at the bottom of the design workspace to check the generated code.

   ```java
   public void initRoute() throws Exception {
       routeBuilder = new org.apache.camel.builder.RouteBuilder() {
           public void configure() throws Exception {
               from(uriMap.get("jmsConsumer")).routeId("jmsConsumer")
                   .to(uriMap.get("logMessage")).id("cMessagingEndpoint_1");
           }
       }
   }
   ```

   As shown above, the message flow is routed from `jmsConsumer` to `logMessage`.

2. Press F6 to execute the Route.

   RESULT: The logs of the message exchange are printed in the console.
cKafka

Communicates with Apache Kafka message broker.

**cKafka Standard properties**

These properties are used to configure cKafka running in the Standard Job framework.

The Standard cKafka component belongs to the Connectivity family.

**Basic settings**

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Broker List</td>
<td>Specify the list of Kafka message brokers in the form hostname1:port1,hostname2:port2,hostname3:port3.</td>
</tr>
<tr>
<td>Client Id</td>
<td>Specify an Id string of the client to pass to the server when making requests.</td>
</tr>
<tr>
<td>Topic</td>
<td>Type in a name for the message topic in the message broker.</td>
</tr>
<tr>
<td>GroupId</td>
<td>Enter the Id of the Kafka Connect cluster group.</td>
</tr>
<tr>
<td>Partitioner</td>
<td>Enter the partitioner that determines how data is distributed across the Kafka cluster.</td>
</tr>
<tr>
<td>Serializer Class</td>
<td>Enter the class name of the serializer to be used.</td>
</tr>
<tr>
<td>Key Serializer Class</td>
<td>Enter the class name of the key serializer to be used.</td>
</tr>
<tr>
<td>Send Buffer (bytes)</td>
<td>The size of the TCP send buffer to use when sending data.</td>
</tr>
<tr>
<td>Request Required Acks</td>
<td>Specify whether the producer waits for an acknowledgement from the broker that the message was received by entering:</td>
</tr>
<tr>
<td>Request Timeout (ms)</td>
<td>Specify the maximum amount of time in milliseconds that the client will wait for the response of a request. If the response is not received before the timeout elapses, the client will resend the request if necessary or fail the request if retries are exhausted.</td>
</tr>
<tr>
<td>Compression Codec</td>
<td>Select compression type from NONE, GZIP, SNAPPY, and LZ4.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>Buffer Memory Size</strong></td>
<td>Specify the total bytes of memory the producer can use to buffer records waiting to be sent to the server. If records are sent faster than they can be delivered to the server, the producer will block for Max Block (ms) after which it will throw an exception.</td>
</tr>
<tr>
<td><strong>Retries</strong></td>
<td>Specify a value greater than 0 for the client to resend any record that failed to be sent with a potentially transient error.</td>
</tr>
<tr>
<td><strong>Retry Backoff (ms)</strong></td>
<td>Specify the amount of time to wait before attempting to retry a failed request to a given topic partition. This avoids repeatedly sending requests in a tight loop under some failure scenarios.</td>
</tr>
<tr>
<td><strong>Batch Size</strong></td>
<td>The producer will attempt to batch records together into fewer requests whenever multiple records are being sent to the same partition. This helps performance on both the client and the server. Specify the default batch size in bytes in this field.</td>
</tr>
<tr>
<td><strong>Connection Idle Max (ms)</strong></td>
<td>Specify the time in milliseconds after which idle connections will be closed.</td>
</tr>
<tr>
<td><strong>Linger (ms)</strong></td>
<td>Specify how long, in milliseconds, the producer must wait to group together any records that arrive into a single batched request, in order to reduce the number of requests. Note that, if the producer has received the amount of records specified by the Bath Size, it will send out the records immediately, regardless of what is specified in this setting.</td>
</tr>
<tr>
<td><strong>Max Block (ms)</strong></td>
<td>Specify the maximum amount of time in milliseconds that the producer will wait either because the buffer is full or metadata unavailable.</td>
</tr>
<tr>
<td><strong>Max Request Size</strong></td>
<td>Specify the maximum size of a request in bytes. This setting will limit the number of record batches the producer will send in a single request to avoid sending huge requests.</td>
</tr>
<tr>
<td><strong>Receive Buffer (bytes)</strong></td>
<td>Specify the size of the TCP receive buffer to use when reading data. If the value is -1, the OS default will be used.</td>
</tr>
<tr>
<td><strong>Max in Flight Request</strong></td>
<td>Specify the maximum number of unacknowledged requests that the client will send on a single connection before blocking. Note that if this setting is set to be greater than 1 and there are failed sends, there is a risk of message re-ordering due to retries if retries are enabled.</td>
</tr>
<tr>
<td><strong>Metadata Max Age (ms)</strong></td>
<td>Specify the period of time in milliseconds after which a refresh of metadata occurs even if there are no partition leadership changes to proactively discover any new brokers or partitions.</td>
</tr>
<tr>
<td><strong>Reconnect Backoff (ms)</strong></td>
<td>Specify the amount of time in milliseconds to wait before attempting to reconnect to a given host. This avoids repeatedly connecting to a host in a tight loop.</td>
</tr>
</tbody>
</table>

The following options are available only when the **cKafka** is used as a Consumer:
<table>
<thead>
<tr>
<th><strong>Send Buffer (bytes)</strong></th>
<th>Specify the size of the TCP send buffer to use when sending data. If the value is –1, the OS default will be used.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Retry Backoff (ms)</strong></td>
<td>Specify the amount of time to wait before attempting to retry a failed request to a given topic partition. This avoids repeatedly sending requests in a tight loop under some failure scenarios.</td>
</tr>
<tr>
<td><strong>Connection Idle Max (ms)</strong></td>
<td>Specify the time in milliseconds after which idle connections will be closed.</td>
</tr>
<tr>
<td><strong>Receive Buffer (bytes)</strong></td>
<td>Specify the size of the TCP receive buffer to use when reading data. If the value is –1, the OS default will be used.</td>
</tr>
<tr>
<td><strong>Metadata Max Age (ms)</strong></td>
<td>Specify the period of time in milliseconds after which a refresh of metadata occurs even if there are no partition leadership changes to proactively discover any new brokers or partitions.</td>
</tr>
<tr>
<td><strong>Reconnect Backoff (ms)</strong></td>
<td>Specify the amount of time in milliseconds to wait before attempting to reconnect to a given host. This avoids repeatedly connecting to a host in a tight loop.</td>
</tr>
<tr>
<td><strong>Barrier Await Timeout (ms)</strong></td>
<td>Specify the amount of time in milliseconds that the batching consumer task waits if the message exchange exceeds the batch size. The default is 10000.</td>
</tr>
<tr>
<td><strong>Auto Commit Enable</strong></td>
<td>Select this check box to periodically commit the offset of messages in the background. Specify the frequency in milliseconds in the <strong>Auto Commit Interval (ms)</strong> that the consumer offsets are committed to Kafka.</td>
</tr>
<tr>
<td><strong>Fetch Min (bytes)</strong></td>
<td>Specify the minimum amount of data in bytes that the server should return for a fetch request. If insufficient data is available, the request will wait for that much data to accumulate before answering the request. The default setting of 1 byte means that fetch requests are answered as soon as a single byte of data is available or the fetch request times out waiting for data to arrive. Setting this to something greater than 1 will cause the server to wait for larger amounts of data to accumulate which can improve server throughput a bit at the cost of some additional latency.</td>
</tr>
<tr>
<td><strong>Fetch Wait Max (ms)</strong></td>
<td>Specify the maximum amount of time the server will block before answering the fetch request if there isn’t sufficient data to immediately satisfy the requirement given by <strong>Fetch Min (bytes)</strong>.</td>
</tr>
</tbody>
</table>
| **Auto Offset Reset** | Choose what to do when there is no initial offset in Kafka or if the current offset does not exist any more on the server from the following:  
  - **EARLIEST**: automatically reset the offset to the earliest offset;  
  - **LATEST**: automatically reset the offset to the latest offset;  
  - **NONE**: throw exception to the consumer if no previous offset is found for the consumer’s group. |
### Heartbeat Interval (ms)
Specify the expected time in milliseconds between heartbeats to the consumer coordinator when using Kafka's group management facility. Heartbeats are used to ensure that the consumer's session stays active and to facilitate rebalancing when new consumers join or leave the group. This value must be set lower than **Session Timeout (ms)**, but typically should be set no higher than \(1/3\) of that value. It can be adjusted even lower to control the expected time for normal rebalances.

### Maximum Partition Fetch (bytes)
Specify the maximum amount of data per-partition in bytes that the server will return. If the first message in the first non-empty partition of the fetch is larger than this limit, the message will still be returned to ensure that the consumer can make progress.

### Session Timeout (ms)
Specify the timeout in milliseconds used to detect consumer failures when using Kafka's group management facility. The consumer sends periodic heartbeats to indicate its liveness to the broker. If no heartbeats are received by the broker before the expiration of this session timeout, the broker will remove this consumer from the group and initiate a rebalance.

### Partition Assignor
Specify the class name of the partition assignment strategy that the client will use to distribute partition ownership amongst consumer instances when group management is used.

### Request Timeout (ms)
Specify the maximum amount of time in milliseconds that the client will wait for the response of a request. If the response is not received before the timeout elapses the client will resend the request if necessary or fail the request if retries are exhausted.

### Advanced settings

<table>
<thead>
<tr>
<th>Kafka Properties</th>

</tbody>
</table>

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>cKafka is used as a start, middle or end component in a Route.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limitation</td>
<td>n/a</td>
</tr>
</tbody>
</table>

**Related scenarios**

No scenario is available for the Standard version of this component yet.
**cLoadBalancer**

Distributes the messages it received to multiple endpoints according to the load balancing policy.

**cLoadBalancer Standard properties**

These properties are used to configure cLoadBalancer running in the Standard Job framework.

The Standard cLoadBalancer component belongs to the Routing family.

### Basic settings

<table>
<thead>
<tr>
<th>Strategy</th>
<th>Select between Random, Round Robin, Sticky, Topic, Failover, and Custom. Each method is described below.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Random</td>
<td>The receiving endpoint is chosen randomly at each exchange.</td>
</tr>
<tr>
<td>Round Robin</td>
<td>Messages are distributed according to the round robin method which distributes the load evenly.</td>
</tr>
<tr>
<td>Sticky</td>
<td>Language: Select the language of the expression to use in the Expression field to distribute the messages from None, Bean, Constant, CorrelationID, EL, Groovy, Header, JavaScript, JoSQL, JsonPath, JXPath, MVEL, OGNL, PHP, Property, Python, Ruby, Simple, SpEL, SQL, XPath, and XQuery. For more information about how to use the languages to create an expression, see the site <a href="http://camel.apache.org/languages.html">http://camel.apache.org/languages.html</a>.</td>
</tr>
<tr>
<td></td>
<td><strong>Expression</strong>: Type in the expression that will be used to calculate a correlation key that will determine the endpoint to choose.</td>
</tr>
<tr>
<td>Topic</td>
<td>Select this option to send all the messages to all the endpoints.</td>
</tr>
<tr>
<td>Failover</td>
<td><strong>Basic mode</strong>: By default, the failover load balancing always sends the messages to the first endpoint. If the first endpoint fails, the messages are sent to subsequent endpoints.</td>
</tr>
<tr>
<td></td>
<td><strong>Specify exceptions</strong>: Specify the exceptions to which the failover should react to in the Exception table.</td>
</tr>
</tbody>
</table>
|                   | **Use with Round robin**: Select this option to use failover with advanced options. From the Maximum failover attempt list, select the number of attempt to be proceed before giving up the transfer:  
|                   | • Attempt forever: always attempts to transfer the messages and always try to failover.  
|                   | • Never failover: gives up immediately the transfer of messages and never try to failover.                |
cLoadBalancer

- **Number of attempts**: attempts \( n \) number of time to transfer messages, specify that number in the **Number of attempts** field.

- **Inherit error handler**: Select *true* if you want Camel error handler to be used. If you select *false*, the load balancer will immediately failover when an exception is thrown.

- **Use Round robin**: Select *true* if you want to combine failover with round robin. Failover load balancing with round robin mode distributes the load evenly between the services, and it provides automatic failover.

| Custom | Load balancer: Type in the name of your custom load balancer. |

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>cLoadBalancer is used as a middle component in a Route.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connections</td>
<td>Load Balance: Select this link to route messages to the next endpoint according to the selected load-balancing strategy.</td>
</tr>
<tr>
<td>Route</td>
<td>Select this link to route all the messages from the sender to the next endpoint.</td>
</tr>
<tr>
<td>Limitation</td>
<td>n/a</td>
</tr>
</tbody>
</table>

**Distributing messages to receiver endpoints based on round robin**

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

In this scenario, a cLoadBalancer component is used to distribute four messages evenly to two receiving endpoints in accordance with the round robin load balancing method.

**Dropping and linking the components**

This scenario requires one cFile component as the message sender, one cLoadBalancer component to distribute the messages to two different receivers in a load balancing manner, two cJavaDSLProcessor components to define the URIs of the receivers, two cMessagingEndpoint components to retrieve the messages routed to the two receivers, and two cProcessor components to display the effect of round robin load balancing.
**Procedure**

1. From the **Connectivity** folder of the **Palette**, drop one **cFile** component and two **cMessagingEndpoint** components onto the workspace, and label them according to their roles in the Route: **Sender**, **Receiver_A**, and **Receiver_B** respectively.

2. From the **Routing** folder, drop a **cLoadBalancer** component onto the design workspace, and label it **Load_balancer**.

3. From the **Core** folder, drop two **cJavaDSLProcessor** components onto the design workspace, and label them according to their roles in the Route: **To_Receiver_A** and **To_Receiver_B** respectively.

4. From the **Custom** folder, drop two **cProcessor** components onto the design workspace, and label them according to their roles in the Route: **Monitor_A**, and **Monitor_B** respectively.

5. Link the **cFile** component to the **cLoadBalancer** component using a **Row > Route** connection.

6. Link **cLoadBalancer** to each of the two **cJavaDSLProcessor** components using a **Row > Load Balance** connection.

7. Link each of the two **cMessagingEndpoint** components to the corresponding **cProcessor** component using a **Row > Route** connection.

**Configuring the components and connections**

**Procedure**

1. Double-click the **cFile** component to open its **Basic Settings** view in the **Component** tab.
2. In the Path field, specify the file path to message source.

3. From the Encoding list, select the encoding type of your message files. Leave the other parameters as they are.

4. Double-click the cLoadBalancer component to open its Basic Settings view in the Component tab, and select the load balancing method you want to use from the Strategy list. In this scenario, we use the default Round robin method.

5. Double-click the cJavaDSLProcessor component labeled To_Receiver_A to open its Basic Settings view in the Component tab, and enter URI of the first receiver between the double quotation marks in the Code area, direct:a in this example. Repeat this step to define the URI of the other receiver, direct:b, in the cJavaDSLProcessor component labeled To_Receiver_B.

6. Double-click the cMessagingEndpoint component labeled Receiver_A to open its Basic Settings view in the Component tab, and enter URI of the first receiver between the double quotation marks in the URI field, direct:a in this example.
Repeat this step to define the URI of the other receiver, direct:b, in the cMessagingEndpoint component labeled Receiver_B.

7. Double-click the cProcessor component labeled Monitor_A to open its Basic Settings view in the Component tab, and customize the code in the Code area to display the file names of the messages routed to Receiver_A on the console:

```java
System.out.println("Message on Receiver_A: "+
exchange.getIn().getHeader("CamelFileName"));
```

Repeat this step to customize the code in the cProcessor component labeled Monitor_B to display the file names of the messages routed to Receiver_B on the console.

8. Press Ctrl+S to save your Route.

**Viewing the code and executing the Route**

Procedure

1. Click the Code tab at the bottom of the design workspace to check the generated code:

```java
public void initRoute() throws Exception {
    routeBuilder = new org.apache.camel.builder.RouteBuilder() {
        public void configure() throws Exception {
            from(uriMap.get("Sender")).routeId("Sender")
            .loadBalance().roundRobin().id("cLoadBalancer_1")
            .to("direct:a").id("cJavaDSLProcessor_1")
            .to("direct:b").id("cJavaDSLProcessor_2");
        }
    }
}
```

As shown above, while messages are routed from the source endpoint .to the destination endpoints, routing load balancing is implemented according to the .roundRobin() method by cLoadBalancer_1.

2. Press F6 to run your Route.

RESULT: Of the four messages from the sender, two are routed to Receiver_A and two are routed to Receiver_B in a round robin manner.
started in 0.723 seconds
[statistics] connecting to socket on port 3905
[statistics] connected
Message on Receiver_A: Message_1.xml
Message on Receiver_B: Message_2.xml
Message on Receiver_A: Message_3.xml
Message on Receiver_B: Message_4.xml
cLog

Logs message exchanges in a Route.

**cLog Standard properties**

These properties are used to configure cLog running in the Standard Job framework.

The Standard cLog component belongs to the Miscellaneous family.

**Basic settings**

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

<td>Limitation</td>
<td>n/a</td>
</tr>
</tbody>
</table>

**Related scenario:**

For a related scenario, see Routing messages according to a criterion on page 205.
cLoop

Processes messages repetitively and possibly in different ways.

**cLoop Standard properties**

These properties are used to configure cLoop running in the Standard Job framework.

The Standard cLoop component belongs to the Orchestration family.

**Basic settings**

| Loop Type          | Select a type of loop to be carried out: **Expression**, **Header**, or **Value**.
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Expression</strong>: Use an expression to determine the loop count. <strong>Header</strong>: Use a header to determine the loop count. <strong>Value</strong>: Use an argument to set the loop count.</td>
</tr>
<tr>
<td></td>
<td>When using <strong>Expression</strong>: In the <strong>Language</strong> field, select the language of the expression you want to use to determine the loop count between <strong>Constant</strong>, <strong>EL</strong>, <strong>Groovy</strong>, <strong>Header</strong>, <strong>Javascript</strong>, <strong>JoSQL</strong>, <strong>JXPath</strong>, <strong>MVEL</strong>, <strong>None</strong>, <strong>OGNL</strong>, <strong>PHP</strong>, <strong>Property</strong>, <strong>Python</strong>, <strong>Ruby</strong>, <strong>Simple</strong>, <strong>SpEL</strong>, <strong>SQL</strong>, <strong>XPath</strong>, <strong>XQuery</strong>. Type in the expression in the <strong>Expression</strong> field. For more information about how to use the languages to create an expression, see the site <a href="http://camel.apache.org/languages.html">http://camel.apache.org/languages.html</a>. The <strong>Add Namespaces</strong> option appears when <strong>XPath</strong> is selected in the <strong>Language</strong> list. Select this check box to add namespaces for the Xpath expression. Click <code>[+]</code> to add as many namespaces as required to the table and define the prefix and URI in the corresponding columns.</td>
</tr>
<tr>
<td></td>
<td>When using <strong>Header</strong>: Enter the name of the header that you want to use to determine the loop count in <strong>header</strong> field.</td>
</tr>
<tr>
<td></td>
<td>When using <strong>Value</strong>: Enter an integer you want to set as the loop count in the <strong>value</strong> field.</td>
</tr>
<tr>
<td>Copy</td>
<td>Select this check box to use the copy mode. It is cleared by default. <strong>If this option is disabled, the same exchange will be used for each iteration. So the result from the previous iteration will be visible for the next.</strong> <strong>If this option is enabled, each iteration restarts with a fresh copy of the input exchange.</strong></td>
</tr>
</tbody>
</table>

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>cLoop can be a middle component in a Route.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limitation</td>
<td>n/a</td>
</tr>
</tbody>
</table>
Related scenarios

No scenario is available for the Standard version of this component yet.
cMail

Sends or receives mails in a Route.

cMail provides access to Email via Spring’s Mail support and the underlying Java Mail system.

**cMail Standard properties**

These properties are used to configure cMail running in the Standard Job framework.
The Standard cMail component belongs to the Connectivity family.

**Basic settings**

<table>
<thead>
<tr>
<th>Protocols</th>
<th>List of protocols for sending or receiving mails.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>Host name of the mail server.</td>

<thead>
<tr>
<th>Usage rule</th>
<th>When used as a start component, cMail is intended to receive mails. Otherwise, it is intended to send mails.</th>
</tr>
</thead>
</table>

| Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. |

Using cMail to send and receive mails

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

This scenario includes two routes. The first one sends a mail while the second receives it.

Now we build a route to send a mail.

As shown above, the mail has been sent out successfully.

Now we build a route to receive the mail.

Mail sending

**Procedure**

1. Drop the components from the Palette onto the workspace: **cFile**, **cMail** and **cProcessor**, respectively labelled as **Mail_to_send**, **Send_Mail** and **Mail_Sent**.

2. Link the components using a **Row > Route** connection.

3. Double-click **cFile** to open its **Basic settings** view in the **Component** tab.

4. Click the [...] button next to the **Path** field to select the folder that has the file to send.

5. In the **FileName** field, enter the name of the file to send, **test mail.txt** in this use case. Keep the default setup of other items.

   The content of this file is **test mail body**.

6. Double-click **cMail** to open its **Basic settings** view in the **Component** tab.
7. In the **Protocols** list, select `smtps`.
   In the **Host** field, type in the host name of the smtp server, `smtp.gmail.com` in this use case.
   In the **UserName** and **Password** fields, enter the login authentication credentials, which are in the form of context variables in this example. For more information about context variable setup, see *Talend Studio User Guide*.
   Keep the default setting of the **ContentType** field, `text/plain`.
   In the **To** field, enter the receiver of the mail, which is also in the form of context variable in this example.

8. Double-click **cProcessor** to open its **Basic settings** view in the **Component** tab.

9. In the **Code** box, enter the code below to give a prompt after the mail is sent.

   ```java
   System.out.println("Mail sent");
   ```

10. Save the route and press **F6** to run.

    ```
    [statistics] connecting to socket on port 3612
    [statistics] connected
    Mail sent
    ```

### Mail receiving

**Procedure**

1. Drop the components from the **Palette** onto the workspace: **cMail** and **cProcessor**, respectively labelled as **Receive_Mail** and **Mail_Body**.

2. Link the components using a **Row > Route** connection.

3. Double-click **cMail** to open its **Basic settings** view in the **Component** tab.
In the Protocols list, select `imaps`.

In the Host field, type in the host name of the imap server, `imap.gmail.com` in this use case.

In the Port field, type in the port number, `993` in this use case.

In the UserName and Password fields, enter the login authentication credentials, which are in the form of context variables in this example. For more information about context variable setup, see Talend Studio User Guide.

Keep the default setting of the ContentType field, `text/plain`.

Double-click cProcessor to open its Basic settings view in the Component tab.

In the Code box, enter the code below to print the mail body.

```java
System.out.println(exchange.getIn().getBody(String.class));
```

Save the route and press F6 to run.

```
[statistics] connecting to socket on port 3915
[statistics] connected
test mail body
```

As shown above, the mail has been received and its content is `test mail body`. 
cMessageFilter

Filters the content of messages according to the specified criterion and routes the filtered messages to the specified output channel. All messages that do not match the criteria will be dropped.

**cMessageFilter Standard properties**

These properties are used to configure cMessageFilter running in the Standard Job framework.

The Standard cMessageFilter component belongs to the Routing family.

**Basic settings**

| Language | Select the language of the expression you use to filter your messages from **None**, **Bean**, **Constant**, **CorrelationID**, **EL**, **Groovy**, **Header**, **JavaScript**, **JoSQL**, **JSON**, **Property**, **Python**, **Simple**, **SpEL**, **SQL**, **XPath**, and **XQuery**.

For more information about how to use the languages to create an expression, see the site [http://camel.apache.org/languages.html](http://camel.apache.org/languages.html).

| Expression | Type in the expression to use to filter the messages.

| Add Namespaces | This option appears when **XPath** is selected in the **Language** list.

Select this check box to add namespaces for the Xpath expression. Click [+] to add as many namespaces as required to the table and define the prefix and URI in the corresponding columns.

**Usage**

| Usage rule | cMessageFilter is used as a middle component in a Route.

| Connections | **Filter**: Select this link to route the filtered messages to the next endpoint.

| Route: Select this link to route all the messages from the sender to the next endpoint.

| Limitation | n/a

**Filtering messages according to a criterion**

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

In this use case, we filter XML messages that are sent from the sending endpoint according to a defined criterion: only the XML files in which the value of the **city** node is **Paris** are sent to a folder named **Paris_only**.
Of the four XML files used in this scenario, *Message_1.xml* and *Message_4.xml* contain the city name of Paris. The following is an example:

```xml
<person>
    <firstName>Pierre</firstName>
    <lastName>Dupont</lastName>
    <city>Paris</city>
</person>
```

### Dropping and linking the components

#### About this task

This scenario requires one `cMessageFilter` component to filter the messages from the sender, one `cFile` component as the message sender, one `cFile` component to receiver the messages containing Paris, one `cFile` component to receiver all the messages from the sender, and two `cProcessor` components to monitor the messages routed to the two receivers.

#### Procedure

1. From the **Connectivity** folder of the **Palette**, drop three `cFile` components onto the design workspace, and label them *Sender*, *Paris_only*, and *Unfiltered* respectively to better identify their roles.
2. From the **Routing** folder, drop a `cMessageFilter` component onto the design workspace, and label it *Filter*.
3. From the **Custom** folder, drop two `cProcessor` components onto the design workspace, and label them *Monitor_Paris* and *Monitor_Unfiltered* respectively.
4. Right-click the `cFile` component labeled *Sender*, select **Row > Route** from the contextual menu and click the `cMessageFilter` component.
5. Right-click the `cMessageFilter` component, select **Row > Filter** from the contextual menu and click the `cFile` component labeled *Paris_only*. This endpoint will retrieve the messages that meet the defined criterion.
6. Right-click the `cMessageFilter` component, select **Row > Route** from the contextual menu and click the `cFile` component labeled *Unfiltered*. This endpoint will collect all the messages, including those meeting the filter criterion. This connection is optional.
7. Right-click the `cFile` component labeled *Paris_only*, select **Row > Route** from the contextual menu and click the `cProcessor` component labeled *Monitor_Paris*. Repeat this step to connect the `cFile` component labeled *Unfiltered* to the `cProcessor` component labeled *Monitor_Unfiltered*. 

Configuring the components and connections

Procedure

1. Double-click the cFile component labeled Sender to open its Basic settings view in the Component tab.

2. In the Path field, specify the file path to message source.

3. From the Encoding list, select the encoding type of your message files. Leave the other parameters as they are.

4. Double-click the cMessageFilter component to open its Basic settings view in the Component tab.

5. Select the language of the expression you want to use to filter your messages, and enter an expression to define a criterion according to which you want to filter your messages.

   In this scenario, we want to sort out the XML files containing a city node with the value of Paris, so we select XPath from the Language list, and fill the in the Expression field with this expression: 

   

4. Double-click the cFile component labeled Paris_only to open its Basic settings view in the Component view, and specify the path for the messages meeting the filter criterion in the Path field.
Repeat this step to define the path for all the messages from the sender in the **cFile** component labeled *Unfiltered*.

7. Double-click the **cProcessor** component labeled *Monitor_Paris* to open its **Basic settings** view in the **Component** view, and customize the code in the **Code** area to display the file names of the messages that meet the filter criterion on the console:

```java
System.out.println("Message sent to folder Paris_only: \" + exchange.getIn().getHeader("CamelFileName\") + ");
```

Repeat this step to customize the code in the **cProcessor** component labeled *Monitor_Unfiltered* to display the file names of all the messages from the sender.

8. Press **Ctrl+S** to save your Route.

### Viewing the code and executing the Route

**Procedure**

1. To have a look at the generated code, click the **Code** tab at the bottom of the design workspace.
As shown in this piece of code, messages from the sender are filtered by `cMessageFilter_1` according to `xpath("/person[city='Paris']")` and the messages matching the filter are sent to the endpoint `Paris_only`, while all messages are sent to the endpoint `Unfiltered`.

2. Click the Run view to display it and click the Run button to launch the execution of your Route. You can also press F6 to execute it.

RESULT: The messages are filtered according to the defined criterion and the messages containing "Paris" are redirected to the `Paris_only` folder, all the messages, including those containing "Paris", are sent to the `Unfiltered` folder.
cMessageRouter

Creates different channels for each filtered message type according to specified conditions so that messages can later on be treated more accurately in each new channel.

cMessageRouter Standard properties

These properties are used to configure cMessageRouter running in the Standard Job framework. The Standard cMessageRouter component belongs to the Routing family.

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>cMessageRouter is used as a middle component in a Route. It can only have one input channel but multiple output channels. Messages can be outputted through either a When, Otherwise or Route types of connection.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connections</td>
<td>Row / Route: Select this link to pass on all the messages to the next component.</td>
</tr>
<tr>
<td>Trigger / When: Select the When link and click the Component view. In the Type list, select the type of language you will use to declare your condition from none, bean, constant, correlation, el, groovy, header, javascript, sql, jsonpath, xpath, mvel, ognl, php, property, python, ruby, simple, spel, sql, xpath, and xquery. Append endChoice(): If the When link is followed by a cMessageFilter or cLoadBalancer and so on, there will be a compile error. This is because once there is such a component there, the flow type will change from choice() to loadbalance(), which can not be followed by a When or Otherwise link. Select this check box to change the flow type back from loadbalance() to choice(). In the Condition field, type in the condition that will be used to filter the messages. All the messages that do not match this condition are retrieved with the Otherwise link to a different channel or dropped if an Otherwise link does not present.</td>
<td></td>
</tr>
<tr>
<td>Trigger / Otherwise: This link automatically retrieves the messages that do not match the When conditions.</td>
<td></td>
</tr>
<tr>
<td>Limitation</td>
<td>It is recommended not to put any message handling after the When or the Otherwise link. Always use a Mock/Direct</td>
</tr>
</tbody>
</table>
Routing messages according to a criterion

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

In this use case, we route XML messages that are sent from the sending endpoint according to a defined criterion: those XML files in which the value of the city node is Paris are sent to a folder named Paris_only, and other messages are sent to a folder named Other_cities.

Of the four XML files used in this scenario, Message_1.xml and Message_4.xml contain the city name of Paris. The following is an example:

```xml
<person>
  <firstName>Pierre</firstName>
  <lastName>Dupont</lastName>
  <city>Paris</city>
</person>
```

Dropping and linking the components

Procedure

1. From the Connectivity folder of the Palette, drop three cFile and four cMessagingEndpoint components onto the design workspace, and label them Sender, Receiver_Paris, and Receiver_Others, directParis, directOthers, directParisRoute, and directOthersRoute respectively to better identify their roles.
2. From the Routing folder, drop a cMessageRouter component onto the design workspace, and label it Message_router.
3. From the Miscellaneous folder, drop two cLog components onto the design workspace, and label them Monitor_Paris and Monitor_Others respectively.
4. Right-click the cFile component labeled Sender, select Row > Route from the contextual menu and click the cMessageRouter component.
5. Right-click the `cMessageRouter` component, select `Trigger > When` from the contextual menu and click the `cMessagingEndpoint` component labeled `directParis`. This endpoint will retrieve the messages that meet the defined criterion.

6. Right-click the `cMessageRouter` component, select `Trigger > Otherwise` from the contextual menu and click the `cMessagingEndpoint` component labeled `directOthers`. This endpoint will collect all the messages that do not meet the filter criterion.

7. Right-click the `cMessagingEndpoint` component labeled `directParis`, select `Row > Route` from the contextual menu and click the `cFile` component labeled `Receiver_Paris`. Repeat this operation to link the component labeled `Receiver_Paris` to `Monitor_Paris`, `directOthersRoute` to `Receiver_Others`, and `Receiver_Others` to `Monitor_Others` respectively using the `Row > Route` connection.

Configuring the components and connections

**About this task**

The `cMessageRouter` component does not have any property as it filters and routes the messages from one endpoint to others based on the conditions set in its `When` connection(s).

**Procedure**

1. Double-click the `cFile` component labeled `Sender` to open its `Basic settings` view in the `Component` tab.

   ![Sender(cFile_1)](image)

   - In the `Path` field, specify the file path to message source.
   - From the `Encoding` list, select the encoding type of your message files. Leave the other parameters as they are.

2. In the `Type` list, select `xpath` because the format of the messages used is XML.

   ![when1](image)

3. In the design workspace, click the `When` connection you created and click the `Component` view to define a filter against which messages will be routed.

4. In the `Type` list, select `xpath` because the format of the messages used is XML.
In the **Condition** field, type in "/person[city='Paris']" to retrieve only those messages in which the value of the **city** node is **Paris**.

5. Double-click the **cMessagingEndpoint** component labeled **directParis** to open its **Basic settings** view in the **Component** tab.

6. In the **URI** field, enter the endpoint URI, for example, "direct:Paris" to receive the filtered message.

7. Repeat these steps to set the endpoint URI of the **cMessagingEndpoint** components labeled **directOthers** as "direct:Others". Set the endpoint URIs of the **cMessagingEndpoint** components labeled **directParisRoute** and **directOthersRoute** as "direct:Paris" and "direct:Others" respectively.

8. Double-click the **cFile** component labeled **Receiver_Paris** to open its **Basic settings** view in the **Component** tab, and specify the path for the messages meeting the filter criterion in the **Path** field.

Repeat this step to define the path for all the other messages from the sender in the **cFile** component labeled **Receiver_Others**.

9. Double-click the **cLog** component labeled **Monitor_Paris** to open its **Basic settings** view in the **Component** tab.
10. Select INFO in the Level list. Select the Specify output log message option and enter the following code in the Message field to display the filename of the message sent to the specified directory.

```
Message sent to folder Paris_only: ${header.CamelFileNameOnly}
```

Repeat this step to customize the message in the cLog component labeled Monitor_Others to display the filename of the message sent to the specified directory.

11. Press Ctrl+S to save your Route.

**Viewing code and executing the Route**

**Procedure**

1. Click the Code tab at the bottom of the design workspace to have a look at the generated code.

```java
public void initRoute() throws Exception {
    routeBuilder = new org.apache.camel.builder.RouteBuilder() {
        public void configure() throws Exception {
            from(uriMap.get("Sender")).routeId("Sender").choice()
                .id("cMessageRouter_1").when().xpath("/person[city='Paris']").to(uriMap.get("directParis")).id("cMessagingEndpoint_1").otherwise().to(uriMap.get("directOthers")).id("cMessagingEndpoint_2");
            from(uriMap.get("directParisRoute"))
                .routeId("directParisRoute")
                .to(uriMap.get("Receiver_Paris"))
                .id("cFile_1")
                .log(org.apache.camel.Logging Level.INFO,
                    "Monitor_Paris",
                    "Message sent to folder Paris_only: ${header.CamelFileNameOnly}")
                .id("cLog_1");
            from(uriMap.get("directOthersRoute"))
                .routeId("directOthersRoute")
                .to(uriMap.get("Receiver_Others"))
                .id("cFile_2")
                .log(org.apache.camel.Logging Level.INFO,
                    "Monitor_Others",
                    "Message sent to folder Other_cities: ${header.CamelFileNameOnly}")
                .id("cLog_2");
```

As shown in the code, the messages are routed according to conditions initialized with the .choice() piece of code. The filter you defined is initialized with the .when() piece of code, and the non filtered messages are routed through the .otherwise() piece of code.

2. Click the Run button in the Run view or press F6 to execute your Route.

RESULT: The files containing "Paris" are sent to a folder named Paris_only, and the other messages are sent in a folder called Other_cities.
[statistics] connecting to socket on port 3887
[statistics] connected
[t/messagerouter] Monitor_Paris
INFO Message sent to folder Paris_only: Message_1.xml
[t/messagerouter] Monitor_Others
INFO Message sent to folder Other_cities: Message_2.xml
[t/messagerouter] Monitor_Others
INFO Message sent to folder Other_cities: Message_3.xml
[t/messagerouter] Monitor_Paris
INFO Message sent to folder Paris_only: Message_4.xml
cMessagingEndpoint

Allows two applications to communicate by either sending or receiving messages.

Commonly used Camel components

The following table lists the most commonly used Camel components that can be called by cMessagingEndpoint. Click the links in the table to go to the Apache Camel’s Website for the latest information of the these components. Make sure to use the information applicable for the Camel Version included in Talend ESB. See also Talend ESB Mediation Developer Guide for details of the Camel components.

</table>
| **CXF (camel-cxf)**
  cxf:beanId:address | Works for SOAP WebServices using Apache CXF. |
| **Disruptor (camel-disruptor)**
  disruptor:name | To provide asynchronous SEDA behavior using LMAX Disruptor. |
| **EHCache (camel-cache)**
  cache:cacheName | To perform caching operations using EHCache as the Cache Implementation. This component is deprecated. |
| **Elasticsearch (camel-elasticsearch)**
  elasticsearch:clusterName | For interfacing with ElasticSearch server. |
| **EISQL (camel-elsql)**
  elsql:elsqlName:resourceUri | The EISQL component is an extension to the existing SQL Component that uses ElSql to define the SQL queries. |
| **etcd (camel-etcd)**
  etcd:namespace/path | To work with Etcd, a distributed reliable key-value store. |
| **Exec (camel-exec)**
  exec:executable | To execute OS system commands. |
| **Facebook (camel-facebook)**
  facebook:methodName | To provide access to all of the Facebook APIs accessible using Facebook4J. |
| **Flatpack (camel-flatpack)**
  flatpack:type:resourceUri | The flatpack component supports fixed width and delimited file parsing via the FlatPack library. |
| **FOP (camel-fop)**
  fop:outputType | To render a message into different output formats using Apache FOP. |
| **Freemarker (camel-freemarker)**
  freemarker:resourceUri | Transforms the message using a FreeMarker template. |
| **FTP (camel-ftp)**
  ftp:host:port/directoryName | For uploading or downloading files from FTP servers. |
| **Geocoder (camel-geocoder)**
  geocoder:address:latlng | For looking up geocodes (latitude and longitude) for a given address or reverse lookup. |
| **Git (camel-git)**
  git:localPath | For working with git repositories. |
| **Guava EventBus (camel-guava-eventbus)**
  guava-eventbus:eventBusRef | Provides integration bridge between Camel and Google Guava EventBus. |
| **Grape (camel-grape)**
  grape:defaultCoordinates | To fetch, load and manage additional jars when CamelContext is running. |
| **HBase (camel-hbase)**
  hbase:tableName | For reading/writing from/to an HBase store (Hadoop database). |
<table>
<thead>
<tr>
<th>Component / ArtifactId / URI</th>
<th>Description</th>
</tr>
</thead>
</table>
| **HDFS (camel-hdfs)**      | hdfs:hostName:port/path
For reading/writing from/to an HDFS file system using Hadoop 1.x. This component is deprecated. |
| **HDFS2 (camel-hdfs2)**    | hdfs2:hostName:port/path
For reading/writing from/to an HDFS file system using Hadoop 2.x. |
| **HTTP4 (camel-http4)**    | http4:httpUri
For calling out to external HTTP servers using Apache HTTP Client 4.x. |
| **Ignite Cache (camel-ignite)** | ignite-cache:cacheName
The Ignite Cache endpoint is one of camel-ignite endpoints which allows you to interact with an Ignite Cache. |
| **Infinispan (camel-infinispan)** | infinispan:cacheName
For reading/writing from/to Infinispan distributed key/value store and data grid. |
| **IronMQ (camel-ironmq)**  | ironmq:queueName
The ironmq provides integration with IronMQ an elastic and durable hosted message queue as a service. |
| **JBPM (camel-jbpm)**      | jbpm:connectionURL
Provides integration with jBPM (Business Process Management). |
| **JCache (camel-jcache)**  | jcache:cacheName
To perform caching operations using JSR107/JCache as cache implementation. |
| **JCR (camel-jcrl)**       | jcr:host/base
To add/read nodes to/from a JCR compliant content repository. |
| **JDBC (camel-jdbc)**      | jdbc:dataSourceName
To access databases through JDBC where SQL queries are sent in the message body. |
| **Jetty 9 (camel-jetty9)** | jetty:httpUri
Provides HTTP-based endpoints for consuming and producing HTTP requests. |
| **JGroups (camel-jgroups)**| jgroups:clusterName
Provides exchange of messages between Camel and JGroups clusters. |
| **JMS (camel-jms)**        | jms:destinationType:destinationName
Allows messages to be sent to, or consumed from a JMS Queue or Topic. |
| **JMX (camel-jmx)**        | jmx:serverURL
To receive JMX notifications. |
| **JOLT (camel-jolt)**      | jolt:resourceUri
To process JSON messages using an JOLT specification (such as JSON-JSON transformation). |
| **JPA (camel-jpa)**        | jpa:entityType
To store and retrieve Java objects from databases using JPA. |
| **Jsch (camel-jsch)**      | scp:host:port/directoryName
To copy files using the secure copy protocol (SCP). |

</table>
Configuring connection to the WebSphere MQ native server using the WMQ component

When using the cMessagingEndpoint to address an endpoint in a WebSphere MQ native server by calling WMQ, the connection to the MQ QueueManager can be configured in the URI field or in a properties file. The following properties can be configured:

- **queueManagerName**: The name of the MQ QueueManager. If not specified, the component falls back to default.
- **queueManagerHostname**: The hostname of the MQ QueueManager.
- **queueManagerPort**: The port of the MQ QueueManager.
- **queueManagerChannel**: The channel of the MQ QueueManager.
- **queueManagerUserID**: The user ID (optional, only required for authentication).
- **queueManagerPassword**: The user password (optional, only required for authentication).
- **queueManagerCCSID**: The CCSID (optional, only required for authentication).

If the `queueManagerHostname`, `queueManagerPort`, and `queueManagerChannel` is not specified in the URI, the component loads a `mq.properties` file from the classloader. An example of a `mq.properties` shown as follows:

```properties
default.hostname=localhost
default.port=7777
default.channel=QM_TEST.SVRCONN
```

The `mq.properties` can contain multiple MQ Queue Managers definition. The format is:

```properties
name.hostname
name.port
name.channel
```

where the `name` is the QueueManager name. For example, the `mq.properties` file can contain:

```properties
default.hostname=localhost
default.port=7777
default.channel=DEFAULT.SVRCONN
test.hostname=localhost
test.port=7778
test.channel=QM_TEST.SVRCONN
```

The `mq.properties` also supports the `userID`, `password`, and `CCSID` properties. For example:

```properties
default.hostname=localhost
default.port=7777
default.channel=DEFAULT.SVRCONN
default.userID=mqm
default.password=mqm
default.CCSID=1208
```

To call the `mq.properties`, use a cConfig component and add it to the Dependencies table.

To run the Route with this component in the studio, you need to download the `com.ibm.mq.jar`, `com.ibm.mq.commonservices.jar`, `com.ibm.mq.headers.jar`, `com.ibm.mq.jmqi.jar` and `connector.jar` from the IBM web site and add them to the Dependencies list of the cConfig too. For more information about the cConfig component, see cConfig on page 59.

If the Route with this component is deployed in Runtime, the `mq.properties` file will be called from `<TalendRuntimePath>/container/etc` folder. Furthermore, you need to download `com.ibm.mq.osgi.java_7.5.0.5.jar` from the IBM web site and add it to the `<TalendRuntimePath>/container/deploy` folder. Alternatively, copy the `com.ibm.mq.jar`, `com.ibm.mq.commonservices.jar`
r, com.ibm.mq.headers.jar, com.ibm.mq.jmqi.jar and connector.jar to the \<TalendRuntimePath>/container/lib/ext folder and change \<TalendRuntimePath>/container/etc/custom.properties by adding the MQ packages to org.osgi.framework.system.packages.extra:

```
org.osgi.framework.system.packages.extra = \
  com.ibm.mq; \
  com.ibm.mq.constants; \
  com.ibm.mq.exits; \
  com.ibm.mq.headers; \
  com.ibm.mq.headers.pcf; \
  com.ibm.mq.jmqi; \
  com.ibm.mq.pcf; \
  ...
```

For more information about the WMQ component, see the site https://github.com/camel-extra/camel-extra/tree/master/components/camel-wmq.

You can also use the cMQConnectionFactory component to create a connection to the WebSphere MQ native server, and use the cWMQ to communicate with the MQ QueueManager. For more information, see cMQConnectionFactory on page 230 and cWMQ on page 326.

**cMessagingEndpoint Standard properties**

These properties are used to configure cMessagingEndpoint running in the Standard Job framework. The Standard cMessagingEndpoint component belongs to the Core family.

**Basic settings**

<table>
<thead>
<tr>
<th>URI</th>
<th>URI of the messages to send or receive. It can be of different format:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>- File: &quot;file:/&quot;,</td>
</tr>
<tr>
<td></td>
<td>- Database: &quot;jdbc:/&quot;,</td>
</tr>
<tr>
<td></td>
<td>- Protocols: &quot;ftp:/&quot;, &quot;http:/&quot;</td>
</tr>
<tr>
<td></td>
<td>- etc.</td>
</tr>
<tr>
<td></td>
<td>You can add parameters to the URI using the generic URI syntax, for example:</td>
</tr>
<tr>
<td></td>
<td>&quot;file:/directoryName?option=value&amp;option=value&quot;</td>
</tr>
</tbody>
</table>
|     | For more information on the different components that can be used in cMessagingEndpoint, see Apache Camel's Website: http://camel.apache.org/components.html.

**Advanced settings**

<table>
<thead>
<tr>
<th>Dependencies</th>
<th>By default, the camel core supports the following components: bean, browse, class, dataset, direct, file, language, log, mock, properties, ref, seda, timer, vm. To use other components, you have to provide the dependencies corresponding to those components in the cMessagingEndpoint component. To do so: Click the plus button to add new lines in the Camel component list. In the line added, select the component you want to use in cMessagingEndpoint. For more</th>
</tr>
</thead>
</table>
information about the commonly used Camel components, see Commonly used Camel components on page 210.

<table>
<thead>
<tr>
<th>Use a custom component</th>
<th>If you want to use a custom component, select this check box and click the three-dot button to upload a jar file with your own component.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Note: All the transitive dependencies of this custom component should be included in the jar file.</td>
</tr>
</tbody>
</table>

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component can be used as sending and/or receiving message endpoint according to its position in the Route.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limitation</td>
<td>n/a</td>
</tr>
</tbody>
</table>

### Moving files from one message endpoint to another

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

This scenario uses two cMessagingEndpoint components to read and move files from one endpoint to another.

#### Dropping and linking the components

**Procedure**

1. From the Core folder of the Palette, drag and drop two cMessagingEndpoint components onto the design workspace, one as the message sender and the other as the message receiver, and label them Sender and Receiver respectively to better identify their roles in the Route.
2. Right-click the component labeled Sender, select Row > Route in the menu and drag to the Receiver to link them together with a route link.

#### Configuring the components and connections

**Procedure**

1. Double-click the component labeled Sender to open its Basic settings view in the Component tab.
2. In the URI field, type in the URI of the messages you want to route.
   - As we are handling files, type in "file:///" and the path to the folder containing the files.
3. Double-click the component labeled Receiver to open its Basic settings view in the Component tab.

4. In the URI field, type in the URI of the folder where you want to route your message. As we are handling files, type in `file:///` and the path to the folder to which the files will be sent.

5. Press Ctrl+S to save your Route.

**Viewing code and executing the Route**

**Procedure**

1. To have a look at the generated code, click the Code tab at the bottom of the design workspace.

   ```java
   public void initRoute() throws Exception {
       routeBuilder = new org.apache.camel.builder.RouteBuilder() {
           public void configure() throws Exception {
               from(uriMap.get("Sender")).routeId("Sender").to(
                   uriMap.get("Receiver")).id("cMessagingEndpoint_2");
           }
       };
       getCamelContexts().get(0).addRoutes(routeBuilder);
   }
   ```

   The code shows the from and to corresponding to the two endpoints: from for the sending one and to for the receiving one.

2. In the Run view, click the Run button to launch the execution of your Route. You can also press F6 to execute it.

   RESULT: The files are moved from their original folder to the target one. Furthermore, a new .camel folder is created in the source folder containing the consumed files. This is Camel’s default behavior. Thus, the files will not be processed endlessly but they are backed up in case of problems.
Sending files to another message endpoint

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

This scenario accesses FTP service and transfers files from one endpoint to another.

Dropping and linking components

Procedure

1. From the Core folder of the Palette, drag and drop two cMessagingEndpoint components onto the design workspace, one as the message sender and the other as the message receiver, and label them Sender and Receiver respectively to better identify their roles in the Route.

2. Right-click the component labeled Sender, select Row > Route in the menu and drag to the Receiver to link them together with a route link.

Configuring the components and connections

Procedure

1. Double-click the component labeled Sender to display its Basic settings view in the Component tab.

2. In the URI field, type in the URI of the message you want to route. Here, we are using an FTP component: ftp://indus@degas/remy/camel with URI specific parameters authenticating the FTP connection: ?username=indus&password=indus.

3. For the FTP component to work in Camel, click the Advanced settings tab of cMessagingEndpoint, click the [+] button to add a Camel component in the Dependencies table, and select ftp from the Camel component list to activate the FTP component.
4. Double-click the component labeled Receiver to open its Basic settings view in the Component tab.

5. In the URI field, type in the URI of the folder to which you want your message to be routed. As we are handling files, type in "file:///" and the path to the folder to which the files will be sent.

6. Press Ctrl+S to save your Route.

**Viewing code and executing the Route**

**Procedure**

1. To have a look at the generated code, click the Code tab at the bottom of the design workspace.

```java
protected void initUriMap() {
    uriMap = new java.util.HashMap<String, String>();
    uriMap.put("Sender", "ftp://indus@degas/remy/camel?username=indus&password=indus");
    uriMap.put("Receiver", "file:///l/talend_files/eso/output");
}
```
In this part of code, we can see a route represented by `from` and `.to`, corresponding to the sending and receiving endpoints.

2. In the Run view, click the Run button to launch the execution of your Route. You can also press F6 to execute it.

RESULT: The message is sent (copied) to the receiving endpoint.

### Using an XQuery endpoint to filter messages

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

In this scenario, we will use a `cMessagingEndpoint` component to call a Route Resource as an XQuery parser to extract messages from the local file system.

The following sample XML file is used in this scenario:

```
<people>
  <person id="8">
    <firstName>Ellen</firstName>
    <lastName>Ripley</lastName>
    <city>Washington</city>
  </person>
  <person id="9">
    <firstName>Peter</firstName>
    <lastName>Green</lastName>
    <city>London</city>
  </person>
</people>
```

### Creating a Route Resource

**Procedure**

1. From the repository tree view, right-click the Resources node and select Create Resource from the context menu.

2. The New Route Resource wizard opens. In the Name field, type in a name for the Resource, for example, SampleXquery. Click Finish to close the wizard.
3. Enter the following code in the editor to extract the *firstName* and *lastName* of all the *person* elements.

```
declare namespace ns0="http://com.sap/b";
<people>
  { for $p in /people//person
    return
      <person>
        <firstName>{$p/firstName/text()}</firstName>
        <lastName>{$p/lastName/text()}</lastName>
      </person>
  }
</people>
```

4. Press Ctrl+S to save your Route Resource.

**Dropping and linking the components**

**About this task**
Procedure

1. From the Connectivity folder of the Palette, drag and drop a cFile and a cMessagingEndpoint component onto the design workspace.
2. From the Custom folder, drag and drop a cProcessor component onto the design workspace.
3. Link the components with the Row > Route connection as shown above.
4. Label the components for better identification of their functionality.

Configuring the components and connections

Procedure

1. Double-click the cFile component to open its Basic settings view in the Component tab.

   ![Message_source(cFile_1)](image)

   - In the Path field, specify the path where the source file people.xml is located.
   - Right-click the Route from the repository tree view and select Manage Route Resources from the context menu.

   ![Manage Route Resources](image)

   The Manage Route Resources wizard is opened.
4. In the **Manage Route Resources** wizard, click **Add** and select *SampleXquery* from the Resources tree view in the dialog. Click **OK**.

The *SampleXquery* Route Resource is added in the table of the **Manage Route Resources** wizard.
5. Select the SampleXquery from the Route Resources list and click Copy Path. Click OK to close the wizard.

6. Double click the cMessagingEndpoint component to display its Basic settings view in the Component tab.

7. In the URI field, enter xquery: and paste the path of the Route Resource SampleXquery that we just copied in double quotation marks.

8. Click the Advanced settings tab, add the Camel component saxon in the Dependencies list. For more information about Xquery, see Apache Camel’s Website: http://camel.apache.org/xquery-endpoint.html.

9. Double-click the cProcessor component to open its Basic settings view in the Component tab.

10. In the Code area, enter the following code to display the messages intercepted on the console:

    ```java
    System.out.println(exchange.getIn().getBody(String.class));
    ```

11. Press Ctrl+S to save your Route.
Viewing code and executing the Route

Procedure

1. To have a look at the generated code, click the **Code** tab at the bottom of the design workspace.

   ```java
   public void initRoute() throws Exception {
       routeBuilder = new org.apache.camel.builder.RouteBuilder() {
           public void configure() throws Exception {
               from(uriMap.get("Message_source_cFile_1"))
                   .routeId("Message_source_cFile_1")
                   .to (uriMap
                       .get("XQueryParse_cMessagingEndpoint_1"))
                       .id("cMessagingEndpoint_1")
                       .process (new org.apache.camel.Processor()) {
                           public void process(
                               org.apache.camel.Exchange exchange)
                               throws Exception {
                               System.out
                                   .println("People in London:
                                   + exchange
                                   .getIn()
                                   .getBody(String.class));
                           }
                       }
                   .id("cProcessor_1");
       }
   }
   ```

   As shown in the code above, the message is routed from Message_source_cFile_1 to cMessagingEndpoint_1 and then processed by cProcessor_1.

2. In the **Run** view, click the **Run** button to launch the execution of your Route. You can also press **F6** to execute it.

   RESULT: The **firstName** and **lastName** of all the **person** elements of the source file is printed in the console.

![Job cMessagingEndpoint](image-url)
cMock

Simulates message generation and message endpoints for testing Routes and mediation rules.

**cMock Standard properties**

These properties are used to configure cMock running in the Standard Job framework.

The Standard cMock component belongs to the Testing family.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Validate message count</td>
<td>Select this check box to test that the correct number of messages are received on each endpoint. Specify the expected message number in the <strong>expected number</strong> field.</td>
</tr>
<tr>
<td>Header / Validate message header</td>
<td>Select this check box to test that the correct message header is received on each endpoint.</td>
</tr>
<tr>
<td>Header / Use File</td>
<td>This option appears when the <strong>Validate message header</strong> check box is selected. Select this option to specify the expected message header from a file and type in the name and path of the file between double quotes in the <strong>File name</strong> field.</td>
</tr>
<tr>
<td>Header / Use Inline Table</td>
<td>This option appears when the <strong>Validate message header</strong> check box is selected. Select this option to specify the expected message header from the table. Add as many rows as needed and enter the name and value of the header in the table.</td>
</tr>
<tr>
<td>Body / Validate message bodies</td>
<td>Select this check box to test that the correct message bodies are received on each endpoint.</td>
</tr>
<tr>
<td>Body / Use File</td>
<td>This option appears when the <strong>Validate message bodies</strong> check box is selected. Select this option to specify the expected message bodies from a file and type in the name and path of the file between double quotes in the <strong>File name</strong> field.</td>
</tr>
<tr>
<td>Body / Use Inline Table</td>
<td>This option appears when the <strong>Validate message bodies</strong> check box is selected. Select this option to specify the expected message bodies from the table. Add as many rows as needed and enter the message bodies in the table.</td>
</tr>
<tr>
<td>Simulate</td>
<td>This option appears when the <strong>cMock</strong> is used as a message producer. Select this check box to simulate the message generation, and select the <strong>cProcessor</strong> component to produce the message in the <strong>Use existing cProcessor list</strong>.</td>
</tr>
<tr>
<td>Wait time (in millis)</td>
<td>This option appears when the <strong>cMock</strong> is used to check the test output result. Specify the time in milliseconds that the <strong>cMock</strong> waits for the result to come.</td>
</tr>
</tbody>
</table>
Usage

| Usage rule | The `cMock` component is designed for testing Routes. It is not recommended to use the `cMock` in message routing. When you add `cMock` to a Route, each exchange sent to it will be stored (to allow for later validation) in memory until explicitly reset or the JVM is restarted. If you are sending high volume and/or large messages, this may cause excessive memory use. For more information about how to test Routes, see the relevant section in the `Talend Studio User Guide`. |

Related scenarios

No scenario is available for the Standard version of this component yet.
cMQConnectionFactory

Encapsulates a set of configuration parameters to connect to a MQ server. The connection can be called by multiple cJMS, cWMQ, cAMQP or cMQTT components in a Route.

Configuring connection to the WebSphere MQ native server in a properties file

The connection to the WebSphere MQ native server can also be configured in a properties file. If the Hostname, Port, and Channel is not specified in the component fields, the component loads a mq.properties file from the classloader. An example of a mq.properties shown as follows:

```plaintext
default.hostname=localhost
default.port=7777
default.channel=QM_TEST.SVRCONN
```

The mq.properties can contain multiple MQ Queue Managers definition. The format is:

```plaintext
name.hostname
name.port
name.channel
```

where the name is the queue manager name. For example, the mq.properties file can contain:

```plaintext
default.hostname=localhost
default.port=7777
default.channel=DEFAULT.SVRCONN
test.hostname=localhost
test.port=7778
test.channel=QM_TEST.SVRCONN
```

The mq.properties also supports the optional userID, password, and CCSID properties, which are required only for authentication. For example:

```plaintext
default.hostname=localhost
default.port=7777
default.channel=DEFAULT.SVRCONN
default.userID=mqm
default.password=mqm
default.CCSID=1208
```

To call the mq.properties, add it to the Dependencies table.

If the Route with this component is deployed in Runtime, the component calls the mq.properties file from <TalendRuntimePath>/container/etc folder.

For more information about how to specify the connection to the WebSphere MQ native server in the component fields, see cMQConnectionFactory on page 230.

cMQConnectionFactory Standard properties

These properties are used to configure cMQConnectionFactory running in the Standard Job framework.

The Standard cMQConnectionFactory component belongs to the Connectivity family.
## Basic settings

<table>
<thead>
<tr>
<th><strong>MQ Server</strong></th>
<th>Select an MQ server from ActiveMQ, WebSphere MQ Jms, WebSphere MQ Native, AMQP 1.0, MQTT, or Customized. You can also find out and add all missing JARs easily on the <strong>Modules</strong> tab in the <strong>Integration</strong> perspective of your studio. You can</td>
</tr>
</tbody>
</table>
To use the WebSphere MQ Native server, you need to download the com.ibm.mq.jar, com.ibm.mq.commonservices.jar, com.ibm.mq.headers.jar, com.ibm.mq.jmqi.jar and connector.jar from the IBM web site and add them to the Dependencies list.

Related scenario:

For a related scenario, see Sending and receiving a message from a JMS queue on page 163.
cMQTT

Sends messages to, or consumes messages from MQTT compliant message brokers.

**cMQTT Standard properties**

These properties are used to configure cMQTT running in the Standard Job framework.

The Standard cMQTT component belongs to the Connectivity family.

**Basic settings**

<table>
<thead>
<tr>
<th>ConnectionFactory</th>
<th>This option appears when Use Connection Factory is selected. Click [...] and select a connection factory to be used for handling messages.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Topic Name</td>
<td>Type in a name for the message topic in the message broker.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| Parameters | Set the optional parameters in the corresponding table. Click [+] as many times as required to add parameters to the table. Then click the corresponding value field and enter a value. See the site http://camel.apache.org/amqp.html for available options. |

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>cMQTT can be a start, middle or end component in a Route. It has to be used with the cMQConnectionFactory component, which creates a connection to a MQ server. For more information about cMQConnectionFactory, see cMQConnectionFactory on page 230.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limitation</td>
<td>Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
</tbody>
</table>

**Sending messages to and receiving messages from an MQTT broker**

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

This scenario will show you how to use the cMQTT component to send messages to and consume messages from an MQTT broker. To do this, two Routes are built, a message producer Route, and a
consumer Route. Messages are sent to the MQTT broker in the producer Route and then consumed in the consumer Route.

In this use case, Apache ActiveMQ is used as the message broker which supports the MQTT protocol. You need to launch the ActiveMQ server before executing the Route. For more information about installing and launching ActiveMQ server, see the site http://activemq.apache.org/index.html.

Building the producer Route

Dropping and linking the components

About this task

![Diagram showing the components and their connections]

Procedure

1. From the Palette, drag and drop a cMQConnectionFactory, a cTimer, a cSetBody, a cMQTT, and a cLog component onto the design workspace.
2. Label the components for better identification of their roles and link them with the Row > Route connection as shown above.

Configuring the components

Procedure

1. Double-click the cMQConnectionFactory component to display its Basic settings view in the Component tab.
2. From the **MQ Server** list, select **MQTT** to handle messages.

   In the **Host Name** field, keep the default value “127.0.0.1” as the local ActiveMQ server is used as the message broker in this example.

   In the **Port** field, keep the default 1883.

   Keep the default settings of the other options.

3. Double-click the **cTimer** component to open its **Basic settings** view in the **Component** tab.

4. In the **Repeat** field, enter 5 to generate the message exchange five times. Keep the default settings of the other options.

5. Double-click the **cSetBody** component to open its **Basic settings** view in the **Component** tab.
6. Select SIMPLE from the Language list box and type in "Hello world" in the Expression field as the message body.

7. Double-click the cMQTT component to open its Basic settings view in the Component tab.

![Producer(cMQTT_1)](image1)

8. In the ConnectionFactory field, click [...] and select the MQ connection factory that you have just configured to handle messages.
   In the Topic Name field, type in a name for the topic, for example "mytopic".

9. Keep the default settings of the cLog component to log the message exchanges.

![Log_message(cLog_1)](image2)

10. Press Ctrl+S to save your Route.

**Viewing the code**

**Procedure**

Click the Code tab at the bottom of the design workspace to check the generated code.

```java
public void configure() throws java.lang.Exception {
    from(uriMap.get("cTimer_1")).routeId("Starter_cTimer_1").setBody()
        .simple("Hello World!").id("cSetBody_1")
        .to(uriMap.get("cMQTT_1")).id("cMQTT_1")
        .to(uriMap.get("cLog_1")).id("cLog_1");
}
```

As shown above, the message flow from cTimer_1 is given a payload by cSetBody_1 and then sent to cMQTT_1 and cLog_1.
Building the consumer Route

Arranging the flow of the message

About this task

![Diagram showing the arrangement of components]

Procedure

1. From the Palette, drag and drop a **cMQConnectionFactory**, a **cMQTT**, and a **cLog** component onto the design workspace.
2. Label the components for better identification of their roles and link them with the **Row > Route** connection as shown above.

Configuring how the message is processed

Procedure

1. Double-click the **cMQConnectionFactory** component to display its **Basic settings** view in the **Component** tab.
   ![cMQConnectionFactory Basic settings](image)
   - MQ Server: MQTT
   - Host Name: "127.0.0.1"
   - Port: 1883
   - Use SSL
   - Connect Attempts: -1
   - Reconnect Attempts: -1
   - Reconnect Delay: 10
   - Quality of Service: At Least Once
   - Connect Wait in Seconds: 10
   - Disconnect Wait In Seconds: 5
   - Send Wait In Seconds: 5
2. Configure the **cMQConnectionFactory** component as the one in the producer Route to connect to the same MQTT broker.
3. Double-click the **cMQTT** component to display its **Basic settings** view in the **Component** tab.
4. In the **ConnectionFactory** field, click [...] and select the MQ connection factory that you have just configured to handle messages.
   Specify the same **Topic Name** in the consumer **cMQTT** component as in the producer.

5. Keep the default settings of the **cLog** component to log the message exchanges.

6. Press **Ctrl+S** to save your Route.

**Viewing the code and executing the Route**

**Procedure**

1. Click the **Code** tab at the bottom of the design workspace to check the generated code.

   ```java
   public void configure() throws java.lang.Exception {
      from(uriMap.get("cMQTT_1")).routeId("Consumer_cMQTT_1")
         .to(uriMap.get("cLog_1"))
         .id("cLog_1");
   }
   ```

   As shown above, the message flow is routed from **cMQTT_1** to **cLog_1**.

2. Press **F6** to execute the Route. In the execution console you can see that there's no message exchange yet.
3. Execute the producer Route. The logs of the message exchange are printed in the console.

4. In the consumer Route, the messages are consumed and shown in the execution console.
5. In the ActiveMQ Web Console, you can see that the topic `mytopic` has been created and the messages are consumed.
**cMulticast**

Routes messages to a number of endpoints at one go and process them in different ways.

**cMulticast Standard properties**

These properties are used to configure cMulticast running in the Standard Job framework.

The Standard cMulticast component belongs to the Routing family.

**Basic settings**

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>URIS</td>
<td>Add as many lines as needed in the URIs table to define the endpoints to route the message(s) to.</td>
</tr>
<tr>
<td>Use ParallelProcessing</td>
<td>Select this check box to multicast the message(s) to the specified endpoints simultaneously.</td>
</tr>
<tr>
<td>set timeout</td>
<td>Select this check box and set a timeout in the <strong>Timeout</strong> field, in milliseconds. If <strong>cMulticast</strong> fails to send and process all the messages within the set timeframe, it breaks out and continues. Note that this check box appears only when the <strong>Use ParallelProcessing</strong> check box is selected.</td>
</tr>
<tr>
<td>Use Aggregation Strategy</td>
<td>Select this check box to refer to a predefined Java bean as an aggregation strategy for assembling the messages from the message source into a single outgoing message. By default, the last message acts as the outgoing message.</td>
</tr>
<tr>
<td>Stop On Exception</td>
<td>Select this check box to stop the processing immediately when an exception occurred.</td>
</tr>
</tbody>
</table>

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th><strong>cMulticast</strong> can be used as a middle or end component in a Route.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connections</td>
<td><strong>Route</strong>: Select this link to route the message(s) from the sender to the next endpoint.</td>
</tr>
<tr>
<td></td>
<td><strong>EndBlock</strong>: Select this link to route the message(s) from the end block of the Route to the next endpoint.</td>
</tr>
<tr>
<td>Limitation</td>
<td>n/a</td>
</tr>
</tbody>
</table>

**Route a message to multiple endpoints and set a new body for each**

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.
In this scenario, a **cMulticast** component is used to route a message to two endpoints. The source message and the message on each endpoint is then set a new body. The **cProcessor** component is used to monitor the messages.

### Dropping and linking the components

**Procedure**

1. From the **Palette**, expand the **Connectivity** folder. Drag and drop a **cFile** and two **cMessagingEndpoint** components onto the design workspace.
2. From the **Routing** folder, drag and drop a **cMulticast** component onto the design workspace.
3. From the **Custom** folder, drag and drop four **cProcessor** components onto the design workspace.
4. From the **Core** folder, drag and drop three **cSetBody** components onto the design workspace.
5. Label the components as shown above to better identify their roles in the Route.
6. Right-click the **cMulticast** component, select **Row > EndBlock** in the context menu and click the **cProcessor** component labeled **Monitor_endblock**.
7. Right-click the **cFile** component, select **Row > Route** in the context menu and click the **cMulticast** component. Repeat this step to link the rest components in the Route as shown above using the **Row > Route** connection.

### Configuring the components

**Procedure**

1. Double-click the **cFile** component labeled **Source_file** to open its **Basic settings** view in the **Component** tab.
2. In the Path field, fill in or browse to the path where the source file Hello.txt is located. Keep the default settings for other fields.

3. Double-click the cMulticast component labeled Multicast to open its Basic settings view in the Component tab.

4. In the URIS table, click the plus button to add two lines and specify the URIs of the endpoints where the message will be sent, "direct:a" and "direct:b" in this use case.

5. Double-click the cMessagingEndpoint component labeled direct_a to open its Basic settings view in the Component tab.

6. In the URI field, enter the endpoint URI, "direct:a" in this use case. Repeat this step to set the endpoint URI for direct_b as "direct:b". 
7. Double-click the **cProcessor** component labeled **Monitor_source** to open its **Basic settings** view in the **Component** tab.

8. In the **Code** box, enter the code below to print the source message in the console.

   ```java
   System.out.println("The source message is: " + exchange.getIn().getBody(String.class));
   ```

   Repeat this step to customize the code of **Monitor_endblock**, **Monitor_direct_a**, and **Monitor_direct_b** as shown below to print the message of each endpoint.

   **Monitor_endblock**:
   ```java
   System.out.println("The endblock message is: " + exchange.getIn().getBody(String.class));
   ```

   **Monitor_direct_a**:
   ```java
   System.out.println("direct a just downloaded: "+exchange.getIn().getBody(String.class));
   ```

   **Monitor_direct_b**:
   ```java
   System.out.println("direct b just downloaded: "+exchange.getIn().getBody(String.class));
   ```

9. Double-click the **cSetBody** component labeled **Set_new_body** to open its **Basic settings** view in the **Component** tab.

10. Select **SIMPLE** in the **Language** list.

    In the **Expression** field, enter "New message" as the new message body.

    Repeat this step to set the message body for **direct:a** and **direct:b** as "message A" and "message B" respectively.

11. Press **Ctrl+S** to save your Route.
Viewing code and executing the Route

Procedure

1. Click the Code tab at the bottom of the design workspace to check the generated code.

```java
public RouteBuilder route() {
    return new RouteBuilder()
    .id("cMulticast")
    .to("direct:a", "direct:b")
    .id("cMulticast_1")
    .process(new org.apache.camel.Processor()) {
        public void process(
            org.apache.camel.Exchange exchange)
            throws Exception {
            System.out.println("The source message is: " + exchange.getIn().getBody(String.class));
        }
    } .id("cProcessor_1").setBody().simple("New message")
    .id("cSetBody_3").end()
    .process(new org.apache.camel.Processor()) {
        public void process(
            org.apache.camel.Exchange exchange)
            throws Exception {
            System.out.println("The endblock message is: " + exchange.getIn().getBody(String.class));
        }
    } .id("cProcessor_2");
}
```

In the partially shown code, the source message is routed from "Source_file_cFile_1" to direct:a and direct:b via "cMulticast_1". The message is then processed by "cProcessor_1" and given the message body "New message" by "cSetBody_3". The .end block of the route is processed by "cProcessor_2". The message from "direct_a_cMessagingEndpoint_1" is set the message body "message A" by "cSetBody_1" and processed by "cProcessor_3". The message from direct:b is processed similarly.
2. Click the **Run** view to display it and click the **Run** button to launch the execution of your Route. You can also press **F6** to execute it.

RESULT: The source file message is *Hello world!*. The message routed to *direct:a* and *direct:b* is set the message body *message A* and *message B* respectively. The end block message of this Route is *New message* that is set by the component labeled *Set_new_body*. 
cOnException

Catches the exceptions defined and triggers certain actions which are then performed on these exceptions and the message routing.

**cOnException Standard properties**

These properties are used to configure cOnException running in the Standard Job framework.

The Standard cOnException component belongs to the Exception Handling family.

**Basic settings**

<table>
<thead>
<tr>
<th>Properties</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Exceptions</td>
<td>Click the plus button to add as many lines as needed in the table to define the exceptions to be caught.</td>
</tr>
<tr>
<td>Set a redelivering tries count</td>
<td>Select this check box to set the maximum redelivering tries in the Maximum redelivering tries field.</td>
</tr>
<tr>
<td>Non blocking asynchronous behavior</td>
<td>Select this check box to enable asynchronous delayed redelivery. For details, go to <a href="http://camel.apache.org/exception-clause.html">http://camel.apache.org/exception-clause.html</a>.</td>
</tr>
<tr>
<td>Exception behavior</td>
<td>None: select this option to take no action on the original route. Handle the exceptions: select this option to handle exceptions and break out the original route. Ignore the exceptions: select this option to ignore the exceptions and continue routing in the original route.</td>
</tr>
<tr>
<td>Route the original input body instead of the current body</td>
<td>Select this check box to route the original message instead of the current message that might be changed during the routing.</td>
</tr>
</tbody>
</table>

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>cOnException is used as a separate component in a Route.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limitation</td>
<td>n/a</td>
</tr>
</tbody>
</table>

**Using cOnException to ignore exceptions and continue message routing**

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

In this scenario, a cOnException component is used to ignore an IO exception thrown by a Java bean so that the message is successfully routed to the destination in spite of the exception.
Dropping and linking the components

Procedure
1. Drag and drop these components from the Palette onto the workspace: a cOnException component, a cFile component, a cBean component, and cProcessor component.
2. Link cFile to cBean using a Row > Route connection.
3. Link cBean to cProcessor using a Row > Route connection.
4. Label the components to better identify their roles in the Route.

Configuring the components

Procedure
1. Double-click the cOnException component, which is labelled Ignore_exception, to open its Basic settings view in the Component tab.
2. Click the plus button to add a line in the Exceptions table, and define the exception to catch. In this example, enter java.io.IOException to handle IO exceptions.

In the Exception behavior area, select the Ignore the exceptions option to ignore exceptions and let message routing continue. Leave the other parameters as they are.
3. Double-click the **cFile** component, which is labelled **Source**, to open its **Basic settings** view in the **Component** tab.

4. In the **Path** field, enter the path of the message source, and leave the other parameters as they are.

5. Double-click the **cBean** component, which is labelled **Throw_exception**, to open its **Basic settings** view in the **Component** tab.

6. Select **New Instance** and in the **Bean class** field, enter the name of the bean to throw an IO exception, `beans.throwIOException.class` in this scenario.

   Note that this bean has already been defined in the **Code** node of the **Repository** and it looks like this:

   ```java
   package beans;
   import java.io.IOException;
   import org.apache.camel.Exchange;
   public class throwIOException {
       /**
        * @throws IOException
        */
       public static void helloExample(String message, Exchange exchange) throws IOException {
           throw new IOException("An IOException has been caught");
       }
   }
   ```

   For more information about creating and using Java Beans, see *Talend Studio User Guide*.

7. Double-click the **cProcessor** component, which is labelled **Monitor**, to open its **Basic settings** view in the **Component** tab.
8. In the Code area, customize the code to display the file name of the consumed message on the Run console:

```java
System.out.println("Message consumed: "+
exchange.getIn().getHeader("CamelFileName"));
```

9. Press Ctrl+S to save your Route.

### Viewing code and executing the Route

#### Procedure

1. Click the Code tab at the bottom of the design workspace to check the generated code.

```java
public void initRoute() throws Exception {
    routeBuilder = new org.apache.camel.builder.RouteBuilder() {
        public void configure() throws Exception {
            onException(java.io.IOException.class)
                .continued(true).routeId("Ignore_exception");
            from(uriMap.get("Source")).routeId("Source").bean(
                bean().throwIOException.class).id("cBean_1")
                .process(new org.apache.camel.Processor() {
                    public void process(
                        org.apache.camel.Exchange exchange)
                        throws Exception {
                    System.out.println("Message consumed: "+
                            exchange.getIn().getHeader("CamelFileName"));
                }
            ).id("cProcessor_1");
            }
        }
    }
}
```

As shown above, Ignore_exception handles any IO exception thrown by .bean(beans.throwIOException.class) invoked by cBean_1, so that messages from the endpoint Source can be successfully routed onwards (continued(true)) in spite of the exception.

2. Press F6 to execute the Route.
The route gets executed successfully and the files from the source are successfully routed to the destination.

3. Change the exception handling option in the `cOnException` component or deactivate the component and run the Route again.

The exception thrown by the Java bean prevents the messages from being routed successfully.
cPipesAndFilters

Splits message routing into a series of independent processing stages. 
cPipesAndFilters divides message processing into a sequence of independent endpoint instances, which can then be chained together.

cPipesAndFilters Standard properties

These properties are used to configure cPipesAndFilters running in the Standard Job framework. The Standard cPipesAndFilters component belongs to the Routing family.

Basic settings

| URI list | Click the plus button to add new lines for URIs that identify endpoints. |

Usage

| Usage rule | cPipesAndFilters is usually used in the middle of a Route. |
| Limitation | n/a |

Using cPipesAndFilters to process the task in sequence

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

In this scenario, a cPipesAndFilters component is used so that messages sent from the sender endpoint undergo stage A and stage B. Upon completion of both stages, the messages are routed to a file system, which is the receiver endpoint for the messages.
Dropping and linking the components

Procedure

1. From the Connectivity folder of the Palette, drop two cFile components onto the design workspace, one as the message sender and the other as the message receiver, and label them Sender and Receiver respectively to better identify their roles in the Route.
2. From the Routing folder, drop one cPipesAndFilters component onto the design workspace, between the two cFile components.
3. From the Core folder, drop two cMessagingEndpoint components onto the design workspace, one as the endpoint of stage A and the other as the endpoint of stage B, and label them Stage_A and Stage_B respectively to better identify their roles in the Route.
4. From the Custom folder, drop three cProcessor components onto the design workspace to monitor messages received on the receiver, stage A and stage B endpoints respectively, and label them Monitor_Receiver, Monitor_stage_A, and Monitor_stage_B respectively to better identify their roles in the Route.
5. Right-click the cFile component labeled Sender, select Row > Route from the contextual menu, and click the cPipesAndFilters component. Repeat this step to set up the rest Row > Route connections, as shown above.

Configuring the components

Procedure

1. Double-click the cFile component labeled Sender to open its Basic settings view in the Component tab.
2. In the Path field, fill in or browse to the path to the folder that holds the source files.
3. From the Encoding list, select the encoding type of your source files. Leave the other parameters as they are.
4. Repeat these steps to define the path to the output files and the output encoding type in the Basic settings view of the cFile component labeled Receiver.
5. Double-click the cPipesAndFilters component to open its Basic settings view in the Component tab.
6. Click the plus button to add two lines to the **URI list** table, and fill the first line with "direct:a" and the second line with "direct:b" to define the URIs of stage A and stage B that the messages will undergo.

7. Double-click the **cMessagingEndpoint** component labeled **Stage_A** to configure the component in its **Basic settings** view and define the URI of stage A.

Repeat this step to define the URI of stage B in the **Basic settings** view of the **cMessagingEndpoint** component labeled **Stage_B**.

8. Double-click the **cProcessor** component labeled **Monitor_Receiver** to open its **Basic settings** view, and customize the code in the **Code** area to display the file names of the messages received on Receiver, as follows:

```
System.out.println("Message sent to Receiver: "+
exchange.getIn().getHeader("CamelFileName"));
```

Repeat this step to customize the code in the other two **cProcessor** components to display the file names of the messages received on stage A and stage B respectively:

```
System.out.println("Message sent to stage A: "+
exchange.getIn().getHeader("CamelFileName"));
```

```
System.out.println("Message sent to stage B: "+
exchange.getIn().getHeader("CamelFileName"));
```

9. Press **Ctrl+S** to save your Route.
Viewing code and executing the Route

Procedure

1. Click the Code tab at the bottom of the design workspace to have a look at the generated code.

```java
public void initRoute() throws Exception {
    routeBuilder = new org.apache.camel.builder.RouteBuilder() {
        public void configure() throws Exception {
            from(uriMap.get("Sender")).routeId("Sender").pipeline("direct:a", "direct:b")
                .id("cPipesAndFilters_1").to()
                    .uriMap.get("Receiver").id("cFile_2")
            ...
        }
    }
}
```

As shown in the code, messages sent from Sender are redirected to endpoints identified by direct:a and direct:b by cPipesAndFilters_1 before being routed to Receiver.

2. Press F6 to run your Route.

RESULT: The message delivery goes through stage A and then stage B before reaching Receiver.
cProcessor

Implements consumers of message exchanges or implements a Message Translator.
cProcessor quickly whirls up some code. If the code in the inner class is complicated, it is recommended to refactor it into a separate class.

**cProcessor Standard properties**

These properties are used to configure cProcessor running in the Standard Job framework.
The Standard cProcessor component belongs to the Custom family.

**Basic settings**

<table>
<thead>
<tr>
<th>Imports</th>
<th>Enter the Java code that helps to import, if necessary, external libraries used in the Code box.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Code</td>
<td>Type in the Java code you want to implement.</td>
</tr>
</tbody>
</table>

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>cProcessor is used as a middle or end component in a Route.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limitation</td>
<td>n/a</td>
</tr>
</tbody>
</table>

**Related scenario:**

For a related scenario, see Intercepting several routes and redirect them in a single new route on page 157 of cIntercept on page 157.
cRecipientList

Routes messages to a number of dynamically specified recipients.

**cRecipientList** can also process the message before sending it to the recipients and assemble the replies from the sub-messages into a single outgoing message.

## cRecipientList Standard properties

These properties are used to configure cRecipientList running in the Standard Job framework.

The Standard cRecipientList component belongs to the Routing family.

### Basic settings

</tbody>
</table>

**Routing a message to multiple recipients**

This scenario applies only to **Talend Open Studio for ESB**, **Talend Data Services Platform** and **Talend Data Fabric**.

In this scenario, a **cRecipientList** component is used to route a message to a list of recipients.

![Diagram](https://via.placeholder.com/150)

To build the Route, do the following.

**Dropping and linking the components**

**Procedure**

1. Drag and drop the components from the **Palette** onto the workspace: **cFile**, **cSetHeader**, **cRecipientList**, two **cMessagingEndpoint** and two **cProcessor**. Change the label of the **cFile**
component to **Read_Input**. Change the labels of the two **cMessagingEndpoint** components to **Recipient_A** and **Recipient_B**. Change the labels of the two **cProcessor** components to **Print_File_Name_A** and **Print_File_Name_B**.

2. Link **Read_Input** to **cSetHeader** using a **Row > Route** connection.
3. Link **cSetHeader** to **cRecipientList** using a **Row > Route** connection.
4. Link **Recipient_A** to **Print_File_Name_A** using a **Row > Route** connection.
5. Link **Recipient_B** to **Print_File_Name_B** using a **Row > Route** connection.

### Configuring the components

**Procedure**

1. Double-click **cFile** to open its **Basic settings** view in the **Component** tab.

   ![cFile Settings](image)

   - **Path**: "E:/data/input"
   - Keep other default settings unchanged.

2. In the **Path** field, type in the path to the source message, for example, "E:/data/input". Keep other default settings unchanged.

3. Double-click **cSetHeader** to open its **Basic settings** view in the **Component** tab.

   ![cSetHeader Settings](image)

   - Click [+\(\)] to add a row to the **Headers** table.
   - In the **Name** field, enter the header name, for example, "ListOfRecipients".
   - In the **Language** list, select **Constant**.
   - In the **Value** field, enter the endpoint URIs, for example, "direct:a,direct:b".

4. Double-click **cRecipientList** to open its **Basic settings** view in the **Component** tab.
6. In the **Language** list, select **Header**.

In the **Expression** field, enter the name of the header that contains the recipients list, that is, "ListOfRecipients".

7. Double-click **Recipient_A** to open its **Basic settings** view in the **Component** tab and define the URI of recipient A.

Perform the same operation to **Recipient_B** to define the URI of recipient B.

8. Double-click **Print_File_Name_A** to open its **Basic settings** view in the **Component** tab and enter the code below to print out the message received by **Recipient_A**. `System.out.println("Recipient_a just downloaded:"+exchange.getIn().getHeader("CamelFileName"));`

Perform the same operation to **Print_File_Name_B** and type in the code below in its code box:

`System.out.println("Recipient_b just downloaded:"+exchange.getIn().getHeader("CamelFileName"));`

9. Press **Ctrl+S** to save your Route.
Viewing code and executing the Route

Procedure

1. Click the **Code** tab at the bottom of the design workspace to check the generated code.

```java
public void configure() throws java.lang.Exception {
    from(uriMap.get("Read Input_cFile_1"))
        .routeId("Read Input_cFile_1")
        .setHeader("ListOfRecipients").constant("direct:a,direct:b")
        .id("cSetHeader_1")

        .recipientList().header("ListOfRecipients")
            .id("cRecipientList_1")
        from(uriMap.get("Recipient A_cMessagingEndpoint_1"))
            .routeId("Recipient A_cMessagingEndpoint_1")
            .process(new org.apache.camel.Processor()) {
                public void process(org.apache.camel.Exchange exchange)
                    throws Exception {
                        System.out.println("Recipient_a just downloaded:")
                        + exchange.getIn().getHeader("CamelFileName");
                }
            }
        .id("cProcessor_1");
    from(uriMap.get("Recipient B_cMessagingEndpoint_2"))
        .routeId("Recipient B_cMessagingEndpoint_2")
        .process(new org.apache.camel.Processor()) {
            public void process(org.apache.camel.Exchange exchange)
                throws Exception {
                    System.out.println("Recipient_b just downloaded:")
                        + exchange.getIn().getHeader("CamelFileName");
            }
        }
        .id("cProcessor_2");
}
```

As shown above, the route gets the message from `Read Input_cFile_1`, and
.setHeader("ListOfRecipients") using .constant("direct:a,direct:b"). Then,
cRecipientList_1 reads .header("ListOfRecipients") and routes the message to the recipients included in it.

2. Press F6 to execute the Route.

The message is sent to recipients included in the header.

```
[statistics] connecting to socket on port 3620
[statistics] connected
Recipient_a just downloaded:File_A.txt
Recipient_b just downloaded:File_A.txt
```
cRoutingSlip

Routes the message consecutively through a series of processing steps, with the sequence of steps unknown at design time and variable for each message.

cRoutingSlip Standard properties

These properties are used to configure cRoutingSlip running in the Standard Job framework.

The Standard cRoutingSlip component belongs to the Routing family.

Basic settings

<table>
<thead>
<tr>
<th>Header name</th>
<th>Type in name of the message header as defined in the preceding cSetHeader component, mySlip by default. The header should carry a list of endpoint URIs you wish each message to be routed to.</th>
</tr>
</thead>
<tbody>
<tr>
<td>URI delimiter</td>
<td>Delimiter used to separate multiple endpoint URIs carried in the message header, comma (,) by default.</td>
</tr>
</tbody>
</table>

Usage

| Usage rule | cRoutingSlip is used as a middle or end component of a sub-route. It always follows a cSetHeader component, which sets a header to each message to carry a list of endpoint URIs. |

Routing a message consecutively to a series of endpoints

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

In this scenario, messages from a file system is routed consecutively to a series of endpoints according to the URIs carried in the message header.

Dropping and linking the components

About this task

This use case requires a cFile component as the message sender, a cSetHeader component to define a series of endpoints, a cRoutingSlip component to route messages to the endpoints consecutively, three cMessagingEndpoint components to retrieve messages routed to the endpoints, and three cProcessor components to monitor messages routed to the connected messaging endpoints.
Procedure

1. From the Palette, expand the Connectivity folder, drop one cFile and three cMessagingEndpoint components onto the design workspace, and label them to better identify their roles in the Route, as shown above.

2. From the Core folder, drop a cSetHeader component onto the design workspace, and label it to better identify its role in the Route.

3. From the Routing folder, drop a cRoutingSlip component onto the design workspace, and label it to better identify its role in the Route.

4. From the Custom folder, drop three cProcessor components onto the design workspace, and label them to better identify their roles in the Route.

5. Right-click the cFile component, select Row > Route from the contextual menu and click the cSetHeader component.

6. Right-click the cSetHeader component, select Row > Route from the contextual menu and click the cRoutingSlip component.

7. Repeat this operation to connect the cMessagingEndpoint components to the corresponding cProcessor components.

Configuring the components and connections

Procedure

1. Double-click the cFile component, which is labelled Sender, to display its Basic settings view in the Component tab.
2. In the **Path** field, fill in or browse to the path to the folder that holds the source files *Beijing.xml*, *London.xml*, *Paris.xml*, and *Washington.xml*.

   From the **Encoding** list, select the encoding type of your source files. Leave the other parameters as they are.

3. Double-click the **cSetHeader** component, which is labelled *Set_endpoints*, to display its **Basic settings** view in the **Component** tab.

4. Click [+] to add a row to the **Headers** table.

   In the **Name** field, type in the name of the header you want to add to each message.

   In this use case, we simply use *mySlip*, which is the default value filled in the **Header name** field of the **cRoutingSlip** component.

5. From the **Language** list box, select the **Constant** or **Simple**, and in the **Value** field, type in the URIs you wish the message to be routed consecutively to, separated by a comma, which is the default value of the **URI delimiter** field of the **cRoutingSlip** component.

   In this use case, we want the message to be routed first to endpoint *c*, then to endpoint *a*, and finally to endpoint *b*.

6. Double-click the **cRoutingSlip** component, which is labelled *Routing_slip*, to display its **Basic settings** view in the **Component** tab, and define the message header in the **Header name** field and the URI delimiter in the **URI delimiter** field.

   In this use case, we simply use the default settings.
7. Double-click the cMessagingEndpoint component labelled Endpoint_a to display its Basic settings view in the Component tab, and type in the URI in the URI field for the destination of your messages. Here, we want to use this component to retrieve the message routed to the URI direct:a.

Repeat this step to set the endpoint URIs in the other cMessagingEndpoint components: direct:b and direct:c respectively.

8. Double-click the cProcessor component, which is labelled Monitor_a, to display its Basic settings view in the Component tab, and customize the code so that the console will display information the way you wish. Here, we want to use this component to monitor the messages routed to the connected endpoint a and display the file name, so we customize the code accordingly, as follows:

```java
System.out.println("Message received on endpoint a: " + exchange.getIn().getHeader("CamelFileName"));
```

Repeat this step to customize the code for the other two cProcessor components, for messages routed to the connected endpoints b and c respectively.

```java
System.out.println("Message received on endpoint b: " + exchange.getIn().getHeader("CamelFileName"));

System.out.println("Message received on endpoint c: " + exchange.getIn().getHeader("CamelFileName"));
```

9. Press Ctrl+S to save your Route.

**Viewing code and executing the Route**

**Procedure**

1. Click the Code tab at the bottom of the design workspace to have a look at the generated code.
In this partially shown code, messages from the sender are given a header according to `.setHeader`, which carries a list of URIs ("direct:c,direct:a,direct:b"), and then routed in the slip pattern according by `cRoutingSlip_1`.

2. Click the Run view to display it and click the Run button to launch the execution of your Route. You can also press F6 to execute it.

RESULT: The source file messages are routed consecutively to the defined endpoints: c, then a, and then b.

**Routing each message conditionally to a series of endpoints**

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

In this scenario, which is based on the previous scenario, each message from a file system is routed consecutively to different endpoints according to the city name it contains.

All files used in this use case are named after the city name they contain. The following are the extracts of two examples:
A predefined Java Bean, *setEndpoints*, is called in this use case to return endpoint URIs according to the city name contained in each message, so that the messages will be routed as follows:

- The message containing the city name *Paris* will be routed first to endpoint *a*, then to endpoint *b*, and finally to endpoint *c*.
- The message containing the city name *Beijing* will be routed first to endpoint *c*, then to endpoint *a*, and finally to endpoint *b*.
- Any other messages will be routed to endpoint *b* and then to endpoint *c*.

For more information about creating and using Java Beans, see *Talend Studio User Guide*.

```java
package beans;
import org.w3c.dom.Document;
import org.w3c.dom.Element;
import org.w3c.dom.NodeList;

public class setEndpoints {
    public String helloExample(Document document) {
        NodeList cities = document.getDocumentElement().getElementsByTagName("city");
        Element city = (Element) cities.item(0);
        String textContent = city.getTextContent();
        if ("Paris".equals(textContent)) {
            return "direct:a,direct:b,direct:c";
        } else if ("Beijing".equals(textContent)) {
            return "direct:c,direct:a,direct:b";
        } else {
            return "direct:b,direct:c";
        }
    }
}
```

**Dropping and linking the components**

In this scenario, we will reuse the Route set up in the previous scenario, without adding or removing any components or modifying any connections.

**Configuring the components and connections**

**About this task**

In this scenario, we only need to configure the *cSetHeader* component to call the predefined Java Bean, and keep the settings of all the other components are they are in the previous scenario.

**Procedure**

1. Double-click the *cSetHeader* component to display its **Basic settings** view in the **Component** tab.
2. Select **Bean** from the **Language** list box, and in the **Value** field, specify the Java Bean that will return the endpoint URIs. In this use case, type in:

```java
beans.setEndpoints
```

3. Press **Ctrl+S** to save your Route.

**Viewing code and executing the Route**

**Procedure**

1. Click the **Code** tab at the bottom of the design workspace to have a look at the generated code.

```java
public void initRoute() throws Exception {
    routeBuilder = new org.apache.camel.builder.RouteBuilder() {
        public void configure() throws Exception {
            from(uriMap.get("Sender")).routeId("Sender").setHeader("mySlip").method(beans.setEndpoints.class).id("cSetHeader_1").routingSlip(header("mySlip"), ",,").id("cRoutingSlip_1");
        }
    };
}
```

In this partially shown code, messages from the sender are given a header according to `.setHeader`, which carries a list of URIs returned by the `beans.setEndpoints.class`, and then routed to the `cRoutingSlip_1`.

2. Click the **Run** view to display it and click the **Run** button to launch the execution of your Route. You can also press **F6** to execute it.
RESULT: The sources are routed consecutively to the defined endpoints: the message containing the city name *Beijing* is routed first to endpoint *c*, then to endpoint *a*, and finally to endpoint *b*; the message containing the city name *Paris* is routed first to endpoint *a*, then to endpoint *b*, and finally to endpoint *c*; the other messages are routed to endpoint *b* and then to endpoint *c*. 
cSEDA

Produces and consumes messages asynchronously in different threads within a single CamelContext. cSEDA provides asynchronous SEDA behavior, so that messages are exchanged on a BlockingQueue and consumers are invoked in a separate thread from the producer within a single CamelContext.

cSEDA Standard properties

These properties are used to configure cSEDA running in the Standard Job framework.

The Standard cSEDA component belongs to the Core family.

**Basic settings**

<table>
<thead>
<tr>
<th>When using as a start component in a Route:</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Name</strong></td>
<td>Type in any string that uniquely identifies the endpoint.</td>
</tr>
<tr>
<td><strong>Specify maximum capacity size</strong></td>
<td>Select this check box to set the maximum number of messages that the SEDA queue can hold. Specify the number in the <strong>Size</strong> field.</td>
</tr>
<tr>
<td><strong>Concurrent consumers</strong></td>
<td>Specify the number of concurrent threads processing exchanges.</td>
</tr>
<tr>
<td><strong>Wait for task to complete</strong></td>
<td>Specify whether the caller should wait for the asynchronous task to complete or not before continuing. Select from <strong>Always</strong>, <strong>Never</strong> or <strong>IfReplyExpected</strong>. The default option is <strong>IfReplyExpected</strong> which means the caller will only wait if the message is Request-Reply based. For more information about this option, see the site <a href="http://camel.apache.org/asynchronous.html">http://camel.apache.org/asynchronous.html</a>.</td>
</tr>
<tr>
<td><strong>Timeout</strong></td>
<td>Specify the time in milliseconds before a SEDA producer will stop waiting for an asynchronous task to complete. You can disable this option by using 0 or a negative value.</td>
</tr>
<tr>
<td><strong>Use multiple consumers</strong></td>
<td>Specifies whether multiple consumers are allowed. If enabled, you can use cSEDA for Publish-Subscribe messaging, which means you can send a message to the SEDA queue and have each consumer receive a copy of the message. When enabled, this option should be specified on every consumer endpoint.</td>
</tr>
<tr>
<td><strong>Limit concurrent consumers</strong></td>
<td>Whether to limit the number of concurrent consumers to the maximum of 500. By default, an exception will be thrown if a SEDA endpoint is configured with a greater number.</td>
</tr>
<tr>
<td><strong>Block when full</strong></td>
<td>Whether a thread that sends messages to a full SEDA queue will block until the queue’s capacity is no longer exhausted. By default, an exception will be thrown stating that the queue is full. By enabling this option, the calling thread will block instead and wait until the message can be accepted.</td>
</tr>
<tr>
<td><strong>Poll timeout</strong></td>
<td>Specify the timeout in milliseconds used when polling. When a timeout occurs, the consumer can check whether it</td>
</tr>
</tbody>
</table>
is allowed to continue running. Setting a low value allows the consumer to react more quickly upon shutdown.

When using as a middle or end component in a Route:

| Use Exist cSEDA | Click [...] and select the corresponding consumer in the dialog box. |

Advanced settings

| Arguments | This option is available only when cSEDA is used as a start component in the Route. Set the optional arguments in the corresponding table. Click [+] as many times as required to add arguments to the table. Then click the corresponding Value field and enter a value. See the site http://camel.apache.org/seda.html for available options. |

Usage

| Usage rule | cSEDA is used as a start, middle, or end component in a Route. |
| Limitation | n/a |

Using cSEDA, cVM and cDirect to produce and consume messages separately

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

In this scenario, we will use a cTimer component to trigger a message exchange. The message is routed to a cSEDA, a cVM and a cDirect sequentially with a message body set for each of them, which is then consumed in another thread.

We will create a Route Resource to define the repeat count of the message exchange (the number of times the message should be sent), which will be used by the cTimer component.

Creating a Route Resource and calling it in the Route

Procedure

1. From the repository tree view, right-click the Resources node and select Create Resource from the context menu.

2. The New Route Resource wizard opens. In the Name field, type in a name for the Resource, for example, SetRepeatCount. Click Finish to close the wizard.
3. Enter `repeat.count=2` in the design workspace to set the repeat count.

4. Press **Ctrl+S** to save your Route Resource.

5. Right-click the Route from the repository tree view and select **Manage Route Resources** from the context menu.
The Manage Route Resources wizard is opened.

6. Click Add and select SetRepeatCount from the Resources tree view in the dialog. Click OK.

The SetRepeatCount Route Resource is added in the table.
7. Click **OK** to close the wizard.
   For more information about creating and using Route Resources, see *Talend Studio User Guide*.

8. Click the **Spring** tab on the lower half of the design workspace of the Route.

9. Enter the following code in this view to call the Route Resource you just created.

```xml
<bean id="properties" class="org.apache.camel.component.properties.PropertiesComponent">
  <property name="location" value="classpath:SetRepeatCount.properties"/>
</bean>
```

For more information about using Spring configuration in a Route, see *Talend Studio User Guide*. 
Dropping and linking the components

About this task

Procedure

1. From the Palette, drag and drop a cTimer, two cSEDA, two cVM, two cDirect, three cSetbody, and three cLog components onto the design workspace.
2. Link the components using the Row > Route connection as shown above.
3. Label the components to better identify their roles in the Route.

Configuring the components and connections

Procedure

1. Double-click Starter in the design workspace to display its Basic settings view in the Component tab.

2. In the Repeat field, enter "{{{repeat.count}}}" that is defined in the Route resource.
3. Double-click Set_body_SEDA in the design workspace to display its Basic settings view in the Component tab.
4. Select **SIMPLE** in the **Language** list.
In **Expression** field, enter the "to cSEDA" as the message body.
Repeat this step to set the message body in **Set_body_VM** and **Set_body_Direct** as "to cVM" and "to cDirect" respectively.

*Set_body_VM*:

*Set_body_Direct*:

5. Double-click **SEDA_producer** to display its **Basic settings** view in the **Component** tab.

6. Click [...] and select **SEDA_consumer** in the **Select a Node** wizard, which will consume the message that is sent to **SEDA_producer**.
Repeat this step to select the node VM_consumer for VM_producer.

Select the node Direct_consumer for VM_producer.

7. Double-click SEDA_consumer to display its Basic settings view in the Component tab.

8. In the Name field, type in "seda" to identify this endpoint. Keep the default settings of the other options.
   Repeat this step to give the name "vm" to VM_consumer.
Give the name "direct" to Direct_consumer.

9. Double-click Monitor_SEDA to display its Basic settings view in the Component tab.

10. Select INFO in the Level list and select Specify output log message. In the Message field, enter "log cSEDA:${body}" to print the message body in the console.

   Repeat this step to specify the output message for Monitor_VM and Monitor_Direct as "log cVM:${body}" and "log cDirect:${body}" respectively.

11. Press Ctrl+S to save your Route.

Viewing code and executing the Route

Procedure

1. Click the Code tab at the bottom of the design workspace to have a look at the generated code.
As shown in the code, a message route is built from "Starter_cTimer_1", set the message body "to cSEDA" by "cSetBody_1", and sent to cSEDA_2, which is mapped to "SEDA_consumer_cSEDA_1". The message is then sent to cVM_2, cDirect_2 sequentially which is mapped to its corresponding consumer with a new message body. On the consumer side, the message body from each consumer is logged by the corresponding monitor.

2. Click the Run view to display it and click the Run button to launch the execution of your Route. You can also press F6 to execute it.

RESULT: The message that is sent to SEDA_producer, VM_producer, and Direct_producer is consumed by SEDA_consumer, VM_consumer, and Direct_consumer respectively. The message exchange is triggered twice as set in the Route Resource SetRepeatCount.
**cSetBody**

Sets the message body in the Route. 

*cSetBody* replaces the payload of each message sent to it.

**cSetBody Standard properties**

These properties are used to configure cSetBody running in the Standard Job framework.  
The Standard cSetBody component belongs to the Core family.

**Basic settings**

| **Language** | Select the language of the expression you use to set the content for matched messages, from None, Bean, CONSTANT, CorrelationID, EL, GROOVY, HEADER, JAVASCRIPT, JoSQL, JsonPath, JXPath, MVEL, OGNL, PHP, PROPERTY, PYTHON, RUBY, SIMPLE, SpEL, SQL, XPATH, and XQUERY.  
For more information about how to use the languages to create an expression, see the site [http://camel.apache.org/languages.html](http://camel.apache.org/languages.html). |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Expression</strong></td>
<td>Type in the expression to set the message content.</td>
</tr>
</tbody>
</table>
| **Correlation expression/Add Namespaces** | This option appears when XPath is selected in the Language list.  
Select this check box to add namespaces for the Xpath expression. Click [*] to add as many namespaces as required to the table and define the prefix and URI in the corresponding columns. |

**Usage**

| **Usage rule** | **cSetBody** is used as a middle component in a Route. |
| **Limitation** | n/a |

**Replacing the content of messages with their extracts**

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.  

In this scenario, file messages are routed from one endpoint to another, with the content of each message replaced with the information extracted from it.
The following is an example of the XML files used in this use case:

```xml
<people>
    <person>
        <firstName>Pierre</firstName>
        <lastName>Dubois</lastName>
        <city>Paris</city>
    </person>
</people>
```

**Dropping and linking the components**

_About this task_

This use case uses two _cFile_ components, one as the message sender and the other as the receiver, a _cSetBody_ component to replace the content of the messages on route, and a _cProcessor_ component to display the new content of the messages routed to the receiving endpoint.

**Procedure**

1. From the _Palette_, expand the _Connectivity_ folder, and drop two _cFile_ components onto the design workspace.
2. From the _Core_ folder, drop a _cSetBody_ component onto the design workspace, between the two _cFile_ components.
3. From the _Custom_ folder, drop a _cProcessor_ component onto the design workspace, following the second _cFile_ component.
4. Right-click the first _cFile_ select _Row > Route_ from the contextual menu and click the _cSetBody_ component.
5. Repeat this operation to connect the _cSetBody_ component to the second _cFile_ component, and the second _cFile_ component to the _cProcessor_ component.
6. Label the components to better identify their roles in the Route, as shown above.

**Configuring the components and connections**

_Procedure_ 

1. Double-click the _cFile_ component labeled _Sender_ to display its _Basic settings_ view in the _Component_ tab.
2. In the **Path** field, fill in or browse to the path to the folder that holds the source files.

3. From the **Encoding** list, select the encoding type of your source files. Leave the other parameters as they are.

4. Repeat these steps to define output file path and encoding type in the **Basic settings** view of the other **cFile** component, which is labeled **Receiver**.

5. Double-click the **cSetBody** component to display its **Basic settings** view in the **Component** tab.

6. From the **Language** list box, select the language of the expression you are going to use. Here we are handling XML files, so select **XPath** from the list box.

7. In the **Expression** field, type in the expression that will return the new message content you want. In this use case, we want **person** to be the root element of each file when routed to the receiving endpoint, so type in **"/people/person"** in the **Expression** field.

8. Double-click the **cProcessor** component to display its **Basic settings** view in the **Component** tab, and customize the code so that the console will display information the way you wish. In this use case, we want to display the file name and content of each message routed to the receiving endpoint, so we customize the code as follows:

```java
System.out.println("File received: " + exchange.getIn().getHeader("CamelFileName") + "\nContent:\n " + exchange.getIn().getBody(String.class));
```

9. Press **Ctrl+S** to save your Route.

**Viewing code and executing the Route**

**Procedure**

1. Click the **Code** tab at the bottom of the design workspace to have a look at the generated code.
In this partially shown code, a message route is built from one endpoint to another, and while in routing, the content of each message is replaced according to the condition \texttt{.xpath("/people/person")} by \texttt{"cSetBody_1"}.

2. Click the \textbf{Run} view to display it and click the \textbf{Run} button to launch the execution of your Route. You can also press \texttt{F6} to execute it.

RESULT: The XML files are sent to the receiver, where \textit{person} has become the root element of each file.
cSetHeader

Sets headers or customizes the default headers, if any, on each message sent to it for subsequent message processing.

CSetHeader Standard properties

These properties are used to configure cSetHeader running in the Standard Job framework.
The Standard cSetHeader component belongs to the Core family.

Basic settings

<table>
<thead>
<tr>
<th>Headers</th>
<th>Click [+] to add as many headers as required to the table.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Type in a name for the message header. The header name CorrelationID is reserved. The value of this header will be overridden by the correlation ID of the message if it exist.</td>
</tr>
<tr>
<td>Language</td>
<td>Select the language of the expression you use from None, Bean, Constant, CorrelationID, EL, Groovy, Header, JavaScript, JSQL, JSonPath, JXPath, MVEL, OGNL, PHP, Property, Python, Ruby, Simple, SpEL, SQL, XPath, and XQuery. Select Bean if you want to call a predefined Java Bean to return the header value. Select CorrelationID to use the existing correlation ID of the message as the header value if the correlation ID is available in the closest cSOAP connected to this component. For more information about the cSOAP component, see cSOAP on page 78.</td>
</tr>
<tr>
<td>Value</td>
<td>Type in the expression to set the value of the message header, or the Bean class that will return a value for the message header, in the form of beans.BEAN_NAME. If CorrelationID is selected in the Language list, this field is grayed out. The existing correlation ID from the closest cSOAP connected to this component will be set as the header value. For more information about the cSOAP component, see cSOAP on page 78.</td>
</tr>
</tbody>
</table>

Add Namespaces

Select this check box to add namespaces for the expression. Click [+] to add as many namespaces as required to the table and define the prefix and URI in the corresponding columns.

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>cSetHeader is used as a middle component in a Route.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limitation</td>
<td>n/a</td>
</tr>
</tbody>
</table>
Splitting a message and renaming the sub-messages according to contained information

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

In this scenario, a file message containing people information is split into sub-messages. Each sub-messages is renamed according the city name it contains, and then routed to another endpoint.

The following is the example XML file used in this use case:

```xml
<people>
  <person>
    <firstName>Pierre</firstName>
    <lastName>Dubois</lastName>
    <city>Paris</city>
  </person>
  <person>
    <firstName>Nicolas</firstName>
    <lastName>Yang</lastName>
    <city>Beijing</city>
  </person>
  <person>
    <firstName>Ellen</firstName>
    <lastName>Ripley</lastName>
    <city>Washington</city>
  </person>
</people>
```

A predefined Java Bean, `setFileNames`, is called by the `cSetHeader` component used in this use case to define a file name for each message according to the city name it contains. For more information about creating and using Java Beans, see Talend Studio User Guide.

```java
package beans;
import org.w3c.dom.Document;
import org.w3c.dom.Element;
import org.w3c.dom.NodeList;
public class setFileNames {
    public String getCityName(Document document) {
        NodeList cities = document.getDocumentElement().getElementsByTagName("city");
        Element city = (Element) cities.item(0);
        String textContent = city.getTextContent();
        return textContent + ".xml";
    }
}
```

Dropping and linking the components

About this task

This use case uses two `cFile` components, one as the message sender and the other as the receiver, a `cSplitter` component to split the source message into sub-messages, a `cSetHeader` component to rename each sub-message, and a `cProcessor` component to display the file name of each message routed to the receiver.
Procedure
1. From the **Palette**, expand the **Connectivity** folder, and drop two **cFile** components onto the design workspace.
2. From the **Routing** folder, drop a **cSplitter** component onto the design workspace, between the two **cFile** components.
3. From the **Core** folder, drop a **cSetHeader** component onto the design workspace, between the **cSplitter** component and the receiving **cFile** component.
4. Right-click the first **cFile** component, select **Row > Route** from the contextual menu and click the **cSplitter** component.
5. Right-click the **cSplitter** component, select **Row > Split** from the contextual menu and click the **cSetHeader** component.
6. Right-click the **cSetHeader** component, select **Row > Route** from the contextual menu and click the second **cFile** component.
7. Right-click the second **cFile** component, select **Row > Route** from the contextual menu and click the **cProcessor** component.
8. Label the components to better identify their roles in the Route, as shown above.

Configuring the components and connections

Procedure
1. Double-click the **cFile** component labeled **Sender** to display its **Basic settings** view in the **Component** tab.

![Sender(cFile_1)](image)

2. In the **Path** field, fill in or browse to the path to the folder that holds the source files. From the **Encoding** list, select the encoding type of your source files.
   In the **FileName** field, type in the file name of the source message. You can skip this step if the source folder contains only one file.
3. Repeat steps 1 and 2 above to define the output file path and encoding type in the **Basic settings** view of the other **cFile** component, which is labeled **Receiver**. Leave the **FileName** field blank.
4. Double-click the cSplitter component to display its Basic settings view in the Component tab. In this use case, as we want to split the message into sub-messages at each person node of the XML file. Select XPath in the Language list and type in "/people/person") in the Expression field.

5. Double-click the cSetHeader component, which is labeled Set_file_name to display its Basic settings view in the Component tab.
6. Click [+] to add a row to the Headers table.

In the Name field, type in the name of the header you want to give to the messages. Here, as we want to define the file name for each incoming message, fill in "CamelFileName" as the header name.

Select Bean in the Language field and type in the name of the predefined Java Bean in the Value field, beans.setFileNames.class in this use case.

7. Double-click the cProcessor component to display its Basic settings view in the Component tab, and customize the code so that the console will display information the way you wish.

In this use case, we want to display the file name each message routed to the receiving endpoint, so we customize the code as follows:

```java
System.out.println("File received: "+ exchange.getIn().getHeader("CamelFileName");
```

8. Press Ctrl+S to save your Route.

**Viewing code and executing the Route**

**Procedure**

1. Click the Code tab at the bottom of the design workspace to have a look at the generated code.

```java
public void configure() throws java.lang.Exception {
    from(uriMap.get("Sender_cFile_1")).routeId("Sender_cFile_1").split()
        .xpath("/people/person").id("cSplitter_1")
        .setHeader("CamelFileName").method(beans.setFileNames.class)
        .id("cSetHeader_1").to(uriMap.get("Receiver_cFile_2")).id("cFile_2")
        .process(new org.apache.camel.Processor() {
            public void process(org.apache.camel.Exchange exchange) throws Exception {
                System.out.println("File received: "+ exchange.getIn().getHeader("CamelFileName");
            }
        }).id("cProcessor_1");
}
```
As shown in the code, a message route is built from one endpoint to another, and while in routing, the source message is split according to the condition xpath("/people/person") by cSplitter_1, and each sub-message is given a header named CamelFileName, the value of which is returned by .method(beans.setFileNames.class).

2. Click the Run view to display it and click the Run button to launch the execution of your Route. You can also press F6 to execute it.

RESULT: The source file message is split into sub-messages and each sub-message is renamed after the city name it contains and routed to the receiving endpoint.

Related scenarios

For more scenarios, see:

- Using cTalendJob to call a DI Job on page 302
- Routing a message consecutively to a series of endpoints on page 263
- Routing each message conditionally to a series of endpoints on page 267
cSetProperty

Sets properties for each message sent to it for subsequent message processing.

**cSetProperty Standard properties**

These properties are used to configure cSetProperty running in the Standard Job framework.

The Standard cSetProperty component belongs to the Core family.

**Basic settings**

<table>
<thead>
<tr>

</table>
cSplitter

| Parameters/Share Unit of Work | Select this check box to share the unit of work between the parent exchange and each split exchange. For more information and an use case of this option, see the site http://camel.apache.org/splitter.html. |
| Parameters/Timeout | Specify a total timeout in millisecond. If the message is not split and processed within the given time frame, the timeout triggers and the splitter breaks out. |

**Usage**

**Usage rule**

cSplitter is used as a middle component in a Route.

**Connections**

split: Select this link to route the split messages to the next endpoint.

Route: Select this link to route all the messages from the sender to the next endpoint.

**Limitation**

n/a

### Using cSplitter to split a message and aggregate replies from sub-messages

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

In this scenario, we will use the cSplitter component to split a message and aggregate the replies from sub-messages.

A predefined Java Bean, AppendAggregator will be called to as the strategy to aggregate the replies from sub-messages. For more information about creating and using Java beans, see Talend Studio User Guide.

```java
package beans;
import org.apache.camel.Exchange;
import org.apache.camel.processor.aggregate.AggregationStrategy;

class AppendAggregator implements AggregationStrategy {

    public Exchange aggregate(Exchange oldEx, Exchange newEx) {
        if(oldEx==null) {
            return newEx;
        }
        String oldBody = oldEx.getIn().getBody(String.class);
        String newBody = newEx.getIn().getBody(String.class);
        newEx.getIn().setBody(oldBody + "\n" + newBody);
        return newEx;
    }
}
```
Dropping and linking the components

About this task

Procedure
1. From the Palette, expand the Custom folder. Drag and drop a cBeanRegister component onto the design workspace.
2. From the Orchestration folder, drag and drop a cTimer components onto the design workspace.
3. From the Core folder, drag and drop two cSetBody and two cDirect components onto the design workspace.
4. From the Routing folder, drag and drop a cSplitter component onto the design workspace.
5. From the Miscellaneous folder, drag and drop two cLog components onto the design workspace.
6. Label the components to better identify their roles in the Route as shown above.
7. Right-click the cSplitter component, select Row > Split from the contextual menu and click the cDirect component labeled directA_sender.
8. Right-click the cSplitter component again, select Row > Route from the contextual menu and click the cLog component labeled Log_Finished.
9. In the same way, link the other components in the Route using the Row > Route connection as shown above.

Configuring the components and connections

Procedure
1. Double-click the cBeanRegister component labeled appendAggregator to display its Basic settings view in the Component tab.
2. In the **Id** field, enter "appendAggregator". Select the **Simple** option and in the **Class Name** field, enter the name of the predefined Java bean, `beans.AppendAggregator` in this scenario, which will be called later by the **cSplitter** component.

3. Double-click the **cTimer** component labeled **Starter** to display its **Basic settings** view in the **Component** tab.

4. In the **Repeat** field, enter 1 to trigger the message exchange. Keep the default settings of the other options.

5. Double-click the **cSetbody** component labeled **Set_body** to display its **Basic settings** view in the **Component** tab.

6. Select **SIMPLE** in the **Language** list and enter "thing1, thing2, thing3" in the **Expression** field as the message body.

7. Configure the **cSetbody** component labeled **Set_new_body** in the same way to set new body to the sub-messages. In the **Expression** field, enter *** SPLIT: ${body} to add *** SPLIT: before the old message body.
8. Double-click the `cSplitter` component to display its **Basic settings** view in the **Component** tab.

9. In this use case, we want to split the message body into sub-messages using ``, as the separator. Select **Simple** in the **Language** list and enter `$\{\text{body}\}$` in the **Expression** field.
   Select the **Use Strategy** check box. In the **Strategy** field, enter the Id of the preregistered Java bean `appendAggregator`, which will be used to aggregate the replies from sub-messages.

10. Double-click the `cDirect` component labeled `directA_sender` to display its **Basic settings** view in the **Component** tab.

11. Click `[...]` and select the `directA_receiver` node to receive the sub-messages.

12. Double-click the `cDirect` component labeled `directA_receiver` to display its **Basic settings** view in the **Component** tab.
13. In the **Name** field, type in "directA" to identify this endpoint.

14. Keep the default settings of the **cLog** components labeled **Log_Finished** and **Log_Split**. **Log_Finished** will log the aggregated replies from sub-messages. **Log_Split** will log the sub-messages.

15. Press **Ctrl+S** to save your Route.

**Viewing code and executing the Route**

1. Click the **Code** tab at the bottom of the design workspace to have a look at the generated code.

   ```java
   public void configure() throws java.lang.Exception {
   from(uriMap.get("directA_receiver_cDirect_1")).
     .routeId("directA_receiver_cDirect_1").setBody()
     .simple("*** SPLIT: ${body}").id("cSetBody_2")
     .to(uriMap.get("Log_Split_cLog_1")).id("cLog_1")
   
   from(uriMap.get("Starter_cTimer_1")).routeId("Starter_cTimer_1")
     .setBody().simple("thing1, thing2, thing3").id("cSetBody_1")
     .split().simple("${body}"))
     .aggregationStrategyRef("appendAggregator").id("cSplitter_1")
     .to(uriMap.get("directA_receiver_cDirect_1")).id("cDirect_2")
     .end()
   
   .to(uriMap.get("Log_Finished_cLog_2")).id("cLog_2")
   }
   ```

   As shown in the code, the message route is built from one endpoint .to another. The message sent to **cSplitter_1** is split by the method .split().simple("${body}") and the replies from the sub-messages are aggregated by the method .aggregationStrategyRef("appendAggregator").

2. Click the **Run** view to display it and click the **Run** button to launch the execution of your Route. You can also press **F6** to execute it.
RESULT: The source message is split into sub-messages using , as the separator and each sub-message is given a new message body. The replies from the sub-messages are aggregated then into a single outgoing message from the cSplitter component.
cStop

Stops a message routing to which it is connected.

**cStop Standard properties**

These properties are used to configure cStop running in the Standard Job framework.

The Standard cStop component belongs to the Miscellaneous family.

**Usage**

| Usage rule | cStop is not a start component, but it can be a middle or end component in a Route. |

**Related scenario:**

For a related scenario, see *Intercepting several routes and redirect them in a single new route* on page 157 of *cIntercept* on page 157.
cTalendJob

Exchanges messages between a Data Integration Job and a Mediation Route.

**cTalendJob** calls a Data Integration Job either from the repository or exported as an OSGI Bundle For ESB. For more information on how to build a Job and how to export a Job as an OSGI Bundle for ESB, see *Talend Studio User Guide*.

**cTalendJob Standard properties**

These properties are used to configure cTalendJob running in the Standard Job framework.

The Standard cTalendJob component belongs to the Talend family.

**Basic settings**

<td><strong>Advanced settings</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Propagate Header</strong></td>
<td>Select this check box to pass the message header to the referenced Job as a context variable.</td>
</tr>
<tr>
<td><strong>Fast Job Invocation</strong></td>
<td>Select this check box to bind the life cycle of the embedded Talend Job to the start and stop state changes of the connected Talend Camel Endpoint. When the Route is started, the endpoint for the embedded Job is also started, and the Job instance is created and ready for receiving message exchanges. With this option enabled, while the Route is active, the embedded Job keeps long-living resources and refreshes short-living resources between invocations. In this case the database access objects are only kept connected while data are sent or received, which avoids overhead and performance loss with Jobs containing database assess resources that are expensive on creation.</td>
</tr>
<tr>
<td><strong>Warning:</strong></td>
<td><strong>Due to the variety of possible Jobs, there is no warranty that a specific Job will work as expected with the Fast Job Invocation option activated. Therefore, Jobs using this option need to be tested well for proper execution, and in failure case this option needs to be de-activated.</strong></td>
</tr>
</tbody>
</table>
Warning:
In combination with the Fast Job Invocation option, the Propagate Header option may not work as expected. The combination needs to be tested well for the specific Job, and in failure case the Fast Job Invocation option needs to be de-activated.

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>cTalendJob can be a start, middle or end component in a Route. It is mandatory that a tRouteInput component is used in the Data Integration Job. The reason for it is that this will prevent the referenced Job from starting automatically when deployed in Talend Runtime. Instead it will only start when it gets called by the Route.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limitation</td>
<td>n/a</td>
</tr>
</tbody>
</table>

Using cTalendJob to call a DI Job

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

In this scenario, we will build a Data Integration Job with context first. Then, we will create a Route with a cTalendJob component to call the Job and set the context variables in the Job.

Creating an Data Integration Job

In this section, we will build a Job named RouteCommunication to accept the message from a Route. For more information on how to build a Job, see Talend Studio User Guide.

Dropping and linking the components

About this task

Procedure

1. Drag and drop a tRouteInput and a tLogRow from the Palette onto the design workspace.
2. Right-click the tRouteInput component, select Row > Main from the contextual menu and click the tLogRow component.
Configuring the components

Procedure

1. Create two variables, `header` and `body` in the `Default` context group. Give the value `world` to the `body` variable. The `header` variable will receive its value propagated from the Route. For more information about context setup, see Talend Studio User Guide.

```
<table>
<thead>
<tr>
<th>Variable</th>
<th>Context</th>
<th>Prompt</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>body</td>
<td>Default</td>
<td>body?</td>
<td>world</td>
</tr>
<tr>
<td>header</td>
<td>Default</td>
<td>header?</td>
<td>null</td>
</tr>
</tbody>
</table>
```

2. Double-click the `tRouteInput` component to open its Basic settings view in the Component tab.

3. Click [...] next to Edit Schema. In the schema dialog box, click [+] to add two lines of `String` type and name them `header` and `body` respectively. Click OK to close the dialog box.
4. In the **Simple Expression** field for the **header** element, enter `context.header` to use the variable `header` in the context group which will be propagated from the Route.

   In the same field for the **body** element, enter `context.body` to use the variable `body` in the context group as the message body.

5. The **cLogRow** component will monitor the message exchanges and does not need any configuration.

6. Press **Ctrl+S** to save your Job.

**Creating a Mediation Route**

In this section, we will create a Route to send a message to the Job.

**Arranging the flow of the message**

**About this task**

![Diagram of message flow]

**Procedure**

1. Drag and drop a **cTimer**, a **cSetHeader**, and a **cTalendJob** from the **Palette** onto the design workspace.

2. Link the components with the **Row > Route** connection as shown above.

3. Label the components for better identification of their roles.

**Configuring how the message is processed**

**Procedure**

1. Double-click the **cTimer** component to open its **Basic settings** view in the **Component** tab.

   ![Component settings]

   2. Set the values for the **Period (200)**, **Repeat (1)** and **Delay (1000)** fields as shown above to trigger a message exchange after a delay of 1000 milliseconds.

2. Double-click the **cSetHeader** component to display its **Basic settings** view in the **Component** tab.
4. Click [+] to add a row to the Headers table. 
   In the Name field, type in "header" as the header name. 
   Select Constant in the Language list, and enter "FileName" in the Value field.

5. Double-click the cTalendJob component to display its Basic settings view in the Component tab.

6. Select Repository to call a Job from the repository.

7. In the Repository Job area, select Use Selected Context. 
   Click [...] next to the Job field to open the Assign Job wizard. Select Assign an existing Job to this cTalendJob component and click Next.
In the **Job selection** view, select RouteCommunication that we just created in the **Job designs** tree view and click **Finish**.

RouteCommunication is now displayed in the **Job** field. By default, the latest version and the default context of it is selected.

8. Click [+ ] under the **Context Param** to add a row to it.

The **Parameters** list contains the variables in the default context group of the referenced Job. Select body in the list.

Enter "Hello World!" in the **Values** field. It will replace the value world that is defined in the Job context.

9. Click the **Advanced settings** view. Select the **Propagate Header** check box to pass the header that is defined in **cSetHeader** to the Job as a context variable.
10. Press Ctrl+S to save your Route.

**Viewing the code and executing the Route**

**Procedure**

1. Click the Code tab at the bottom of the design workspace to check the generated code.

```java
public void configure() throws java.lang.Exception {
    org.apache.camel.Endpoint endpoint_cTalendJob_1 = endpoint("talden:"
        + esbdemos.routecommunication_0_1.RouteCommunication.class
        .getName() + "?context="
        + "Default&propagateHeader=true");

    Map<String, String> propertiesMap = new HashMap<String, String>();
    propertiesMap.put("body", propertyToString("Hello World!");
    endpoint_cTalendJob_1.getCamelContext()
        .setProperties(propertiesMap);

    from(uriMap.get("Starter_cTimer_1")).routeId("Starter_cTimer_1")
        .setHeader("header").constant("FileName").id("cSetHeader_1")
        .to(endpoint_cTalendJob_1.id("cTalendJob_1");
}
```

As shown above, a message route is built from the Starter, set a message header by the cSetHeader, and then sent to cTalendJob for the execution of the Job.

2. Press F6 to execute the Route.
As shown above, the header and body of the message is printed in the execution console by the `tLogRow`. The header value is `FileName`. It is defined by the `cSetHeader` and passed to the Job as a context variable. The body value is `Hello World!`. It is defined by `tRouteInput` using the context variable `body` of the Job. The value for this variable is set as `world` in the Job, but changed to `Hello World!` in `cTalendJob`. 
cThrottler

Limits the number of messages flowing to a specific endpoint in order to prevent it from getting overloaded.

**cThrottler Standard properties**

These properties are used to configure cThrottler running in the Standard Job framework.

The Standard cThrottler component belongs to the Routing family.

**Basic settings**

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Request per period</td>
<td>The number of messages allowed to pass cThrottler within the defined time period.</td>
</tr>
<tr>
<td>Set time period</td>
<td>Select this check box to set the value of the time period (in milliseconds) and enable throttling.</td>
</tr>
<tr>
<td>Use asynchronous delaying</td>
<td>If this check box is selected, any messages that are delayed will be routed asynchronously using a scheduled thread pool.</td>
</tr>
</tbody>
</table>

**Usage**

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Usage rule</td>
<td>Being a middle component, cThrottler allows you to limit the number of messages flowing to a specific endpoint in order to prevent it from getting overloaded.</td>
</tr>
<tr>
<td>Connections</td>
<td><strong>throttler</strong>: Select this link to route the throttled messages to the next endpoint.</td>
</tr>
<tr>
<td></td>
<td><strong>Route</strong>: Select this link to route all the messages from the sender to the next endpoint.</td>
</tr>
<tr>
<td>Limitation</td>
<td>n/a</td>
</tr>
</tbody>
</table>

**Throttling the message flow**

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

In this scenario, a cThrottler component is used to reduce the number of messages flowing out within a time period.
To build the Route, do the following.

Dropping and linking the components

Procedure
1. Drag and drop the components from the Palette onto the workspace: cThrottler, cFile and two cProcessor. Change the label of the cFile component to Read_Output. Change the labels of the two cProcessor components to Print_File_Name and Print_File_Content.
2. Link Read_Output to cThrottler using a Row > Route connection.
3. Link cThrottler to Print_File_Name using a Row > Throttler connection, and to Print_File_Content using a Row > Route connection.

Configuring the components

Procedure
1. Double-click Read_Output to open its Basic settings view in the Component tab.

![Basic settings of Read_Output](image)

2. In the Path field, type in the path to the source message, for example, "E:/data/output". Keep the default settings for other fields.
3. Double-click cThrottler to open its Basic settings view in the Component tab.
4. In the Request per period field, type in the number of messages allowed to pass the throttler per period, for example, 1.
   In the Set time period field, type in the value of the period, for example, 8000.

5. Double-click Print_File_Name to open its Basic settings view in the Component tab.

6. In the Code box, enter the code below to get the name of the message that passes the throttler.

   ```java
   System.out.println("The file that passes throttler is: "+exchange.getIn().getHeader("CamelFileName"));
   ```

7. Double-click Print_File_Content to open its Basic settings view in the Component tab.

8. In the Code box, enter the code below to get the content of the message that passes the throttler.

   ```java
   System.out.println("The content of "+exchange.getIn().getHeader("CamelFileName")+
   " is: "+exchange.getIn().getBody(String.class));
   ```

9. Press Ctrl+S to save your Route.

**Viewing the code and executing the Route**

**Procedure**

1. Click the Code tab at the bottom of the design workspace to check the generated code.
public void initRoute() throws Exception {
    routeBuilder = new org.apache.camel.builder.RouteBuilder()
    
    public void configure() throws Exception {
        from(urn:Map.get("Read_Output")|routeId("Read_Output")
            .throttle(1).timePeriodMillis(8000).id(
                "cThrottler_1").process(
            new org.apache.camel.Processor() {
                public void process(
                    org.apache.camel.Exchange exchange)
                throws Exception {
                    System.out
                    .println("The file that passes throttler is: " + exchange
                        .getIn()
                        .getHeader("CamelFileName")
                
            });
        }).id("cProcessor_2").end().process(
        new org.apache.camel.Processor() {
            public void process(
                org.apache.camel.Exchange exchange)
            throws Exception {
                System.out
                .println("The content of " + exchange
                    .getIn()
                    .getHeader("CamelFileName") + " is: " + exchange
                        .getIn()
                        .getBody("String.class")
                
            });
        };
    
    }
}

As shown above, the messages from Read_Output go through throttling at cThrottler_1, with only (1) message allowed to leave the throttler within each timePeriodMillis(8000). Meanwhile, the filename and the content of the throttled message are printed out via the two processors.

2. Press F6 to execute the Route.

As shown below, File_A.txt was delivered within the first time period while in the second period, File_B.txt was delivered as well.
cTimer

Schedules message exchanges in a Route.

**cTimer Standard properties**

These properties are used to configure cTimer running in the Standard Job framework. The Standard cTimer component belongs to the Orchestration family.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Period</td>
<td>Fill this field with an integer (in milliseconds) to generate message exchanges every period.</td>
</tr>
<tr>
<td>Repeat</td>
<td>Specifies a maximum limit of message exchange numbers. A value of zero or negative will generate message exchanges forever.</td>
</tr>
<tr>
<td>Delay</td>
<td>The number of milliseconds to wait before the first message exchange is generated. This option should not be used with the Set Schedule Time option.</td>
</tr>
<tr>
<td>Fixed Rate</td>
<td>Select this check box to generate message exchanges at regular intervals, separated by the specified period.</td>
</tr>
<tr>
<td>Daemon</td>
<td>Specify whether the thread associated with the timer endpoint runs as a daemon.</td>
</tr>
<tr>
<td>Set Schedule Time</td>
<td>Select this check box to specify the time that the first message exchange should be generated. In the Time field, enter the time using the pattern yyyy-MM-dd HH:mm:ss or yyyy-MM-dd'T'HH:mm:ss.</td>
</tr>
</tbody>
</table>

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>cTimer can only be used as a start component in a Route.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limitation</td>
<td>n/a</td>
</tr>
</tbody>
</table>

**Related Scenario:**

For a related scenario, see **Using cDataset to create messages** on page 104.
**cTry**

Offers the Java equivalent exception handling abilities by building Try/Catch/Finally blocks to isolate the part of your Route likely to generate an error, catch the errors, and execute final instructions regardless of the errors.

**cTry Standard properties**

These properties are used to configure cTry running in the Standard Job framework.

The Standard cTry component belongs to the Exception Handling family.

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>cTry is used as a middle component in a Route.</th>
</tr>
</thead>
</table>

**Connections**

**Try:** Select this link to isolate the part of your Route that is likely to throw an exception or exceptions.

**Note:**
When the Try link is followed by multiple components, a compile error may occur showing "The method doCatch() is undefined for the type ExpressionNode". In this case, use a JavaDSLProcessor component to end the Try block with the code .endDoTry() as a workaround.

**Catch:** Select this link to catch any exception thrown in the Route.

In the Exceptions field, type in an expression to filter the type of exception to catch.

**Note:**
This link can be used only when a Try link is present.

**Finally:** Select link to execute final instructions regardless of any exceptions that may occur in the Route.

**Note:**
This link can be used only when a Try link is present.

**Route:** Select this link to route all the messages from the sender to the next endpoint.

<table>
<thead>
<tr>
<th>Limitation</th>
<th>n/a</th>
</tr>
</thead>
</table>
Using cTry to build Try/Catch/Finally blocks for exception handling

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

In this scenario, the content of each file sent from the message sender to the receiver is checked and if any file does not meet the content requirement, an exception is thrown and the relevant information is displayed on the console.

Dropping and linking components

Procedure

1. From the Connectivity folder of the Palette, drop two cFile components onto the design workspace, one as the message sender and the other as the message receiver.
2. From the Exception Handling folder, drop a cTry component onto the design workspace to build Try, Catch and Finally blocks.
3. From the Custom folder, drop two cProcessor components onto the design workspace.
4. Link the cFile component serving as message sender to the cTry component using a Row > Route connection.
5. Link the cTry component to one cProcessor using a Row > Try connection. This cProcessor component will throw an exception if any file coming via this connection does not contain the required content.
6. Link the cTry component to the other cProcessor component using a Row > Catch connection to catch the exception. This cProcessor component will display the information related to the exception and the file name that does not contain the required content.
7. Link the cTry component to the receiving cFile component using a Row > Finally connection.
8. Label the components according to their roles in the Route.

Configuring the components and connections

Procedure

1. Double-click the cFile component labeled Sender to open its Basic settings view in the Component tab.
2. In the **Path** field, fill in or browse to the path to the folder that holds the source files.

3. From the **Encoding** list, select the encoding type of your source files. Leave the other parameters as they are.

4. Repeat these step to define the output file path and encoding type in the **Basic settings** view of the other **cFile** component, which is labeled **Receiver**.

5. Double-click the **cProcessor** component labeled **Throw_exception** to open its **Basic settings** view in the **Component** tab, and customize the code in the **Code** area to throw an exception and display relevant information if any file coming via the **try** connection does not meet the content requirement, as follows:

   ```java
   String body = exchange.getIn().getBody(String.class);
   System.out.println("\nTrying: "+body);
   Exception e = new Exception("Only 'Talend Integration Solutions' is acceptable. Please check the file:");
   if(!"Talend Integration Solutions".equals(body)){
     throw e;
   }else{
     System.out.println("File is good.");
   }
   ```

6. Click the **catch** connection and then the **Component** tab to open its **Basic settings** view, and fill the **Expression** field with an expression to specify the type of exception to catch.

   In this scenario, fill in **Exception.class** to catch any exception thrown.

7. Double-click **cProcessor** component labeled **Show_exception** to open its **Basic settings** view in the **Component** tab, and customize the code in the **Code** area to display the exception information and the related file name, as follows:

   ```java
   System.out.println(exchange.getProperty("CamelExceptionCaught") + " + exchange.getIn().getHeader("CamelFileName"));
   ```

8. Click **Ctrl+S** to save your Route.
Viewing code and executing the Route

Procedure

1. Click the Code tab at the bottom of the design workspace to check the generated code.

```java
public void initRoute() throws Exception {
    routeBuilder = new org.apache.camel.builder.RouteBuilder()
    .id("cTry_1")
    .doTry()
    .process(new org.apache.camel.Processor() {
        public void process(
            org.apache.camel.Exchange exchange)
            throws Exception {
                String body = exchange.getIn().getBody(
                        String.class);
                System.out.println("\nTrying: " + body);
                Exception e = new Exception("" + "Only 'Talend Integration Solutions' is acceptable. Please check the file: ");
                if ("Talend Integration Solutions" .equals(body)) {
                    throw e;
                } else {
                    System.out.println("File is good.");
                }
            }
    })
    .id("cProcessor_1")
    .doCatch(Exception.class)
    .process(new org.apache.camel.Processor() {
        public void process(
            org.apache.camel.Exchange exchange)
            throws Exception {
                System.out
                .println(exchange
                .getProperty("CamelExceptionCaught")
                + " = 
                + exchange
                .getIn()
                .getReader(
                        "CamelFileName")
                .toString());
            }
        }
    }).id("cProcessor_2")
    .doFinally().to(
        uriMap.get("Receiver").id("cFile_2"))
    ;
}
```

As shown above, while messages are routed from the sender to the receiver, .doTry(), .doCatch() and .doFinally() blocks are built by cTry_1. Thus, when any file does not meet the content requirement, an exception is thrown and caught, before each file is finally routed to the receiver.

2. Press F6 to execute the Route.

![Execution output](image-url)
RESULT: When a file that does not meet the content requirement is detected, an exception is thrown, and the exception information is displayed on the console. Regardless of the exception, all the files from the sender are sent to the receiver.
cVM

Produces and consumes messages asynchronously in different threads across CamelContext. You can use this mechanism to communicate across Web applications.

cVM provides asynchronous SEDA behavior, so that messages are exchanged on a BlockingQueue and consumers are invoked in a separate thread from the producer across CamelContext instances.

**cVM Standard properties**

These properties are used to configure cVM running in the Standard Job framework.
The Standard cVM component belongs to the Core family.

**Basic settings**

<table>
<thead>
<tr>
<th>When using as a start component in a Route:</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Name</strong></td>
<td>Type in any string that uniquely identifies the endpoint.</td>
</tr>
<tr>
<td><strong>Specify maximum capacity size</strong></td>
<td>Select this check box to set the maximum number of messages that the SEDA queue can hold. Specify the number in the Size field.</td>
</tr>
<tr>
<td><strong>Concurrent consumers</strong></td>
<td>Specify the number of concurrent threads processing exchanges.</td>
</tr>
<tr>
<td><strong>Wait for task to complete</strong></td>
<td>Specify whether the caller should wait for the asynchronous task to complete or not before continuing. Select from Always, Never or IfReplyExpected. The default option is IfReplyExpected which means the caller will only wait if the message is Request-Reply based. For more information about this option, see the site <a href="http://camel.apache.org/asynchronous.html">http://camel.apache.org/asynchronous.html</a>.</td>
</tr>
<tr>
<td><strong>Timeout</strong></td>
<td>Specify the time in milliseconds before a SEDA producer will stop waiting for an asynchronous task to complete. You can disable this option by using 0 or a negative value.</td>
</tr>
<tr>
<td><strong>Use multiple consumers</strong></td>
<td>Specifies whether multiple consumers are allowed. If enabled, you can use cVM for Publish-Subscribe messaging, which means you can send a message to the SEDA queue and have each consumer receive a copy of the message. When enabled, this option should be specified on every consumer endpoint.</td>
</tr>
<tr>
<td><strong>Limit concurrent consumers</strong></td>
<td>Whether to limit the number of concurrent consumers to the maximum of 500. By default, an exception will be thrown if a SEDA endpoint is configured with a greater number.</td>
</tr>
<tr>
<td><strong>Block when full</strong></td>
<td>Whether a thread that sends messages to a full SEDA queue will block until the queue’s capacity is no longer exhausted. By default, an exception will be thrown stating that the queue is full. By enabling this option, the calling thread will block instead and wait until the message can be accepted.</td>
</tr>
</tbody>
</table>
### Poll timeout

Specify the timeout in milliseconds used when polling. When a timeout occurs, the consumer can check whether it is allowed to continue running. Setting a lower value allows the consumer to react more quickly upon shutdown.

<table>
<thead>
<tr>
<th>When using as a middle or end component in a Route:</th>
</tr>
</thead>
</table>

### Related scenario:

For a related scenario, see Using cSEDA, cVM and cDirect to produce and consume messages separately on page 272.
**cWireTap**

Routes messages to a separate endpoint while forwarded to the ultimate destination.

cWireTap wiretaps messages to a user defined URI while they are sent to their original endpoint. It also allows you to populate a new message to this wiretap URI concurrently.

**cWireTap Standard properties**

These properties are used to configure cWireTap running in the Standard Job framework.

The Standard cWireTap component belongs to the Routing family.

**Basic settings**

<table>
<thead>
<tr>
<th>URI</th>
<th>The endpoint URI to send the wire tapped message.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Populate new exchange</td>
<td>Select this check box to populate a new message to the wiretap URI.</td>
</tr>
<tr>
<td>Populate Type</td>
<td>This option appears when the <strong>Populate new exchange</strong> check box is selected. The <strong>Populate Type</strong> is either <strong>Expression</strong> or <strong>Processor</strong>.</td>
</tr>
</tbody>
</table>

**Expression**:

- **Language**: Select the language of the expression you want to use to set the message body from `None`, `Bean`, `Constant`, `CorrelationID`, `EL`, `Groovy`, `Header`, `JavaScript`, `JoSQL`, `JsonPath`, `JXPath`, `MVEL`, `OGNL`, `PHP`, `Property`, `Python`, `Ruby`, `Simple`, `SpEL`, `SQL`, `XPath`, and `XQuery`.

For more information about how to use the languages to create an expression, see the site [http://camel.apache.org/languages.html](http://camel.apache.org/languages.html).

- **Expression TXT**: Enter the expression to set the message body.

**Processor**:

- **Using processor** gives you full power to specify how the exchange is populated as you can set properties, headers and so on to the message with a piece of Java code in the **Code** field.

**Copy the original message**

- Select this check box to create a copy of the original exchange, which will be the totally the same as the original one. If this check box is not selected, only a new exchange with the same endpoint name will be created. The message body and headers are null.

The exchange pattern is **InOnly** for both conditions.

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>cWireTap can be a middle component in a Route.</th>
</tr>

Wiretapping a message in a Route

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

In this scenario, a cWireTap component is used to route a message to a separate endpoint while it is routed to the ultimate destination.

Dropping and linking the components

Procedure

1. From the Palette, expand the Connectivity folder, and drop a cFile and two cMessagingEndpoint components onto the design workspace.
2. Expand the Routing folder, and drop a cWireTap component onto the design workspace.
3. Expand the Core folder, and drop a cJavaDSLProcessor components onto the design workspace.
4. Expand the Custom folder, and drop and two cProcessor components onto the design workspace.
5. Right-click the cFile component, select Row > Route from the contextual menu and click the cWireTap component.
6. Repeat this operation to connect the components as shown above.
7. Label the components to better identify their functionality.

Configuring the components

Procedure

1. Double-click the cFile component labeled Source to display its Basic settings view in the Component tab.
2. In the **Path** field, browse to or enter the input file path. In this use case, there is a *Hello.txt* file in the specified file path, which contains the content *Hello World!*. Leave the other parameters as they are.

3. Double-click the **cWireTap** component to display its **Basic settings** view in the **Component** tab.

4. Enter "direct:a" in the **URI** field to route the wiretapped message to this endpoint. Select the **Populate new exchange** check box, select **Processor** as the populate type, and then enter the following code in the **Code** box to display the file name of the wiretapped message and its content on the console:

   ```java
   System.out.println("\nMessage wiretapped: " + exchange.getIn().getHeader("CamelFileName"));
   System.out.println("Message content: " + exchange.getIn().getBody(String.class)+"\n");
   ```

5. Double-click the **cJavaDSLProcessor** component to display its **Basic settings** view in the **Component** tab.
6. In the **Code** field, enter the Java code `.to("direct:b")` to define the URI of the endpoint to route the original message to.

7. Double-click the **cMessagingEndpoint** component labeled **Endpoint_a** to display its **Basic settings** view in the **Component** tab. Enter "direct:a" in the **URI** field to retrieve the message routed to this endpoint.

![Endpoint_a(cMessagingEndpoint_1)](image)

Repeat this operation to set the endpoint URI for **Endpoint_b**.

8. Double-click the **cProcessor** component labeled **Monitor_a** to display its **Basic settings** view in the **Component** tab. Enter the following code in the **Code** box to display the file name of the message routed to **Endpoint_a**.

   ```java
   System.out.println("Message on endpoint a: "+
   exchange.getIn().getHeader("CamelFileName");
   ```

![Monitor_a(cProcessor_1)](image)

   Then, configure the other **cProcessor** component in the same way to display the file name of the message routed to **Endpoint_b**.

9. Press **Ctrl+S** to save your Route.

**Viewing code and executing the Route**

**Procedure**

1. Click the **Code** tab at the bottom of the design workspace to have a look at the generated code.
In this partially shown code, any message from the endpoint Source will be wiretapped by .wireTap and routed to "direct:a". The fine name and content of each wiretapped message will be displayed on the console. The original message will be routed .to an endpoint identified by the URI "direct:b", which is defined in cJavaDSLProcessor_1.

2. Click the Run view to display it and click the Run button to launch the execution of your Route. You can also press F6 to execute it.

RESULT: The source message is wiretapped and routed to endpoint a as well as being routed to endpoint b.
cWMQ

Exchanges messages between a Route and a JMS provider using WMQ.

cWMQ sends messages to, or consumes messages from, a JMS Queue or Topic using the WebSphere broker.

**cWMQ Standard properties**

These properties are used to configure cWMQ running in the Standard Job framework.
The Standard cWMQ component belongs to the Connectivity family.

**Basic settings**

<table>
<thead>
<tr>
<th>URI/Type</th>
<th>Select the messaging type, either queue or topic.</th>
</tr>
</thead>
<tbody>
<tr>
<td>URI/Destination</td>
<td>Type in a name for the message queue or topic in the message broker.</td>
</tr>
<tr>
<td>ConnectionFactory</td>
<td>Select a WMQ connection factory to be used for handling messages from the drop-down list.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| MQ Properties | Set the optional parameters in the corresponding table. Click [+] as many times as required to add parameters to the table. Then click the corresponding value field and enter a value. See the site [http://camel.apache.org/jms.html](http://camel.apache.org/jms.html) for available options. |

**Usage**

| Usage rule | cWMQ can be a start, middle or end component in a Route. It has to be used with the cMQConnectionFactory component, which creates a connection to a MQ server. For more information about cMQConnectionFactory, see cMQConnectionFactory on page 230. |
| Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center ([https://help.talend.com](https://help.talend.com)). To run the Route using the cWMQ component in the studio, you need to download the com.ibm.mq.jar, com.ibm.mq.comemonservices.jar, com.ibm.mq.headers.jar, com.ibm.mq.jmqi.jar and connector.jar from the IBM web site and add them to the Dependencies list of the cMQConnectionFactory. For more information about cMQConnectionFactory, see cMQConnectionFactory on page 230. |
To run the Route using the cWMQ component in Talend Runtime, before deploy the Route, you need to download com.ibm.mq.osgi.java_7.5.0.5.jar from the IBM web site and add it to the <TalendRuntime Path>/container/deploy folder. Alternatively, copy the com.ibm.mq.jar, com.ibm.mq.commonservices.jar, com.ibm.mq.headers.jar, com.ibm.mq.jmqi.jar and connector.jar to the <TalendRuntimePath>/container/lib/ext folder and change <TalendRuntimePath>/container/etc/custom.properties by adding the MQ packages to org.osgi.framework.system.packages.extra:

```properties
org.osgi.framework.system.packages.extra = \
  com.ibm.mq; \
  com.ibm.mq.constants; \
  com.ibm.mq.exits; \
  com.ibm.mq.headers; \
  com.ibm.mq.headers.pcf; \
  com.ibm.mq.jmqi; \
  com.ibm.mq.pcf; \
  ...
```

Related scenario

For a related scenario, see Sending and receiving a message from a JMS queue on page 163.
**cMap**

Executes transformations (called maps) between different sources and destinations by harnessing the capabilities of *Talend Data Mapper*, available in the **Mapping** perspective.

**cMap** transforms data from a wide range of sources to a wide range of destinations. If you want to use multiple inputs and/or outputs, you must use *Talend Data Mapper* I/O functions. For more information, see *Talend Data Mapper User Guide*.

**cMap Standard properties**

These properties are used to configure cMap running in the Standard Job framework.

The Standard cMap component belongs to the Transformation family.

The component in this framework is available in *Talend Data Management Platform*, *Talend Big Data Platform*, *Talend Real Time Big Data Platform*, *Talend Data Services Platform*, *Talend MDM Platform* and in *Talend Data Fabric*.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Open Map Editor</strong></td>
<td>Click the [...] button to open the map specified in the Map Path in the Mapping perspective.</td>
</tr>
<tr>
<td><strong>Map Path</strong></td>
<td>Specifies the map to be executed. Click the [...] button next to the Map Path field to open a dialog box in which you can select the map you want to use, then click the [...] button next to Open Map Editor to work with the map selected. Note that this map must have previously been created in the Mapping perspective.</td>
</tr>
<tr>
<td><strong>Output Type</strong></td>
<td>From the drop-down list, select how you want the output to be written.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Default</strong>: The default output is the same as the input, or Java if the map outputs Java.</td>
</tr>
<tr>
<td></td>
<td>• <strong>String</strong>: Use this option if the data in the output column is to be a String.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Byte Array</strong>: Use this option if the data in the output column is to be a Byte array.</td>
</tr>
<tr>
<td></td>
<td>• <strong>InputStream</strong>: Use this option if you are working with Talend Data Mapper metadata and the input is a stream.</td>
</tr>
</tbody>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Log Level</strong></td>
<td>From the drop-down list, select how often you want events to be logged.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Infrequent</strong>: Logs only events related to startup, shutdown and exceptions.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Frequent</strong> (default): Logs events related to startup, shutdown and exceptions, and once per map execution.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Info</strong>: Logs all events at an informational level or higher.</td>
</tr>
<tr>
<td></td>
<td>• <strong>All</strong>: Logs all events.</td>
</tr>
</tbody>
</table>
cMap

Exception Threshold

Talend Data Mapper returns an execution status with an severity value which can be OK, Info, Warning, Error or Fatal. By setting the exception threshold, you can specify the severity level at which an exception is thrown, thus enabling downstream components to detect the error in cases other than the default value of Fatal.

From the drop-down list, select the severity level at which an exception may be thrown during the execution of a map.

- **Fatal** (default): An exception is thrown when a fatal error occurs.
- **Error**: An exception is thrown when an error (or higher) occurs.
- **Warning**: An exception is thrown when a warning (or higher) occurs.

Usage

Usage rule

**cMap** is used for Routes that require data mapping.

Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

This limitation applies to maps that reference databases.

Note:

- For further information about performing transformations using Talend Data Mapper, see Talend Data Mapper User Guide.
- For cMap using representations other than Hashmap, CSV, Avro, XML, and Cobol: Running cMap may create temporary folders, which are not automatically removed after completing the Eclipse runtime. If you frequently run Talend Data Mapper, these files may pile up ad eventually lead to a disk full error. When the error occurs, the runtime fails. To avoid such scenario, ensure that you perform periodical cleaning.

Mapping data with cMap

This scenario applies only to Talend Data Management Platform, Talend Big Data Platform, Talend Real Time Big Data Platform, Talend Data Services Platform, Talend MDM Platform and Talend Data Fabric.

The following scenario creates a three-component Route, in which a **cFile** component visits a local file directory to copy its contents, performs a transformation using a **cMap** component, and then sends the files in the input directory to an output **cFile** component that writes the files in another directory.
Copying an editable version of the example files

Procedure
1. In the Mapping perspective, in the Data Mapper view, expand the Hierarchical Mapper node and the Other Projects folder, right-click Examples and then select Copy in the contextual menu.
2. In the Data Mapper view, right-click at the root of the Hierarchical Mapper node, and then select Paste in the contextual menu.

This copies an editable version of all the read-only example files to your local workspace.

Adding and linking the components

Procedure
1. Click the point in the design workspace where you want to add the first component, start typing cFile, and then click the name of the component when it appears in the list proposed in order to select it.
2. Do the same to add a cMap component and a second cFile component as well.
3. Connect the cFile_1 component to the cMap component using a Row > Route link, then connect the cMap component to the cFile_2 component using a second Row > Route link.

Defining the properties of cFile_1

Procedure
1. Select the cFile_1 component to define its properties.
2. In the Path field, browse to or enter the path to where the input file is located.
3. In the fileName field, enter the name of the input file: PayPalPO.csv in this example.
4. Leave the other parameters unchanged.
Defining the properties of cMap

Procedure

1. Select the **cMap** component to define its properties.

![Image of cMap component]

2. Click the [...] button next to the **Map Path** field to open the picker and select the map to use, **Maps/CSV/POPayPalCsv_PO2**, then click **OK**. This map transforms a CSV file into an XML file.

Defining the properties of cFile_2

Procedure

1. Select the **cFile_2** component to define its properties.

![Image of cFile_2 component]

2. In the **Path** field, browse to or enter the path to where the output file is to be located.

3. In the **fileName** field, enter a name for the output file with the extension `.xml`.

4. Leave the other parameters unchanged.
Saving and executing the Route

Procedure

1. Press Ctrl+S to save your Route.
2. In the Run tab, click Run to execute the Route.
3. Browse to the output directory on your file system to check that the input files have been transformed and written in the output directory.
