<th>Enter the name of the bucket in which the files to be used are stored. A bucket of GridFS is similar to a folder.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th><strong>Schema and Edit schema</strong></th>
<th>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <strong>line</strong> when naming the fields.</th>
</tr>
</thead>
</table>
The columns of the predefined schema of **tMongoDBGridFSProperties** represent the default attributes of a GridFS file and the column names are already identical with the attribute names.

- If you want to exclude some attributes from the data flow to be processed in your Job, you can remove the columns corresponding to those attributes from this schema.
- Do not change the names of the columns to be used, because the names of each column must be identical with the name of the file attribute it represents.
- If the files to be processed contain some custom attributes you want to extract, you need to add their representative columns accordingly and ensure that these columns and these custom attributes are using identical names.

### Query type

Select the type of the query you want **tMongoDBGridFSProperties** to perform to select the files from which you need to extract the attributes.

- **Filename**: you need to enter the name of the file to be used. This name is the value of the *filename* attribute of this file. Note that only one name is allowed.

  In GridFS, a file is identified only by its unique identifier (its object ID); its file name is not necessarily unique.

- **Mongo Query**: enter the query to be used to select the files to be used.

  The example query, `{}` within double quotation marks provided with **tMongoDBGridFSProperties**, means to select all of the files in a bucket. You can put `{filename: {'$regex': 'REGEX_PATTERN'}` to apply a regular expression to defining the file names to be used.

### Advanced settings

**tStatCatcher Statistics**

Select this check box to collect the log data at the component level.

**No query timeout**

Select this check box to prevent MongoDB servers from stopping idle cursors at the end of 10-minute inactivity of these cursors. In this situation, an idle cursor will stay open until either the results of this cursor are exhausted or you manually close it using the `cursor.close()` method.

A cursor for MongoDB is a pointer to the result set of a query. By default, that is to say, with this check box being clear, a MongoDB server automatically stops idle cursors after a given inactivity period to avoid excess memory use. For further information about MongoDB cursors, see [https://docs.mongodb.org/manual/core/cursors/](https://docs.mongodb.org/manual/core/cursors/).
Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NB_FILE</td>
<td>the number of files processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>ERROR_MESSAGE</td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>This component combines MongoDB GridFS connection and data extraction and needs to use a Main link to connect to its following component in order to send data to this component.</td>
</tr>
</tbody>
</table>

Related scenario

For a scenario using tMongoDBGridFSProperties, see Managing files using MongoDB GridFS on page 2340.
tMongoDBGridFSPut

Connects to a MongoDB GridFS system to load files into it.

`tMongoDBGridFSPut` copies files from a local directory, pastes them into a given MongoDB GridFS system and if needs be, renames these files.

**tMongoDBGridFSPut Standard properties**

These properties are used to configure `tMongoDBGridFSPut` running in the Standard Job framework. The Standard `tMongoDBGridFSPut` component belongs to the Big Data and the Databases families. The component in this framework is available when you are using one of the *Talend* solutions with Big Data.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-In or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Built-In: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file where the properties are stored.</td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined.

Note that when a Job contains the parent Job and the child Job, **Component List** presents only the connection components in the same Job level.

**Use replica set address or multiple query routers**

Select this check box to show the **Server addresses** table.

In the **Server addresses** table, define the sharded MongoDB databases or the MongoDB replica sets you want to connect to.

**Server and Port**

IP address and listening port of the database server.

Available when the **Use replica set address** check box is not selected.

Note that if you use the authentication mechanisms to connect to this MongoDB database, you must enter the name, rather than the IP address, of the host of the database server.

**Database**

Name of the database.

**Use SSL connection**

Select this check box to enable the SSL or TLS encrypted connection.

Then you need to use the `tSetKeystore` component in the same Job to specify the encryption information.

For further information about `tSetKeystore`, see `tSetKeystore` on page 3532.
### Set read preference
Select this check box and from the **Read preference** drop-down list that is displayed, select the member to which you need to direct the read operations.

If you leave this check box clear, the Job uses the default Read preference, that is to say, uses the primary member in a replica set.

For further information, see MongoDB’s documentation about Replication and its Read preferences.

### Required authentication
Select this check box to enable the database authentication.

Among the mechanisms listed on the **Authentication mechanism** drop-down list, the **NEGOTIATE** one is recommended if you are not using Kerberos, because it automatically select the authentication mechanism the most adapted to the MongoDB version you are using.

For details about the other mechanisms in this list, see [MongoDB Authentication](https://docs.mongodb.com/v3.2/configservers/kerberos/) from the MongoDB documentation.

### Set Authentication database
If the username to be used to connect to MongoDB has been created in a specific Authentication database of MongoDB, select this check box to enter the name of this Authentication database in the **Authentication database** field that is displayed.

For further information about the MongoDB Authentication database, see [User Authentication database](https://docs.mongodb.com/v3.2/core/security/authentication/#using-mongodb-user-authentication).

### Username and Password
DB user authentication data.

To enter the password, click the `[...]` button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

Available when the **Required authentication** check box is selected.

If the security system you have selected from the Authentication mechanism drop-down list is Kerberos, you need to enter the **User principal**, the **Realm** and the **KDC server** fields instead of the **Username** and the **Password** fields.

### Bucket
Enter the name of the bucket you need to write files in. A bucket of GridFS is similar to a folder.

### Local Folder
Browse to, or enter the path to the folder in which the files to be copied and written to GridFS are stored.

### Use Perl5 Regex Expression as Filemask
Select this check box if you want to use Perl5 regular expressions in the **Files** field as file filters. This is useful when the name of the file to be used contains special characters such as parentheses.

Note that the SSL connection is available only for the version 2.4 + of MongoDB.
**Files**

In the **Files** area, the fields to be completed are:
- **File mask**: type in the file name to be selected from the local directory. Regular expression is available.
- **New name**: give a new name to the loaded file.

**Advanced settings**

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
<th>Select this check box to collect the log data at the component level.</th>
</tr>
</thead>
</table>
| **No query timeout**    | Select this check box to prevent MongoDB servers from stopping idle cursors at the end of 10-minute inactivity of these cursors. In this situation, an idle cursor will stay open until either the results of this cursor are exhausted or you manually close it using the `cursor.close()` method.  
A cursor for MongoDB is a pointer to the result set of a query. By default, that is to say, with this check box being clear, a MongoDB server automatically stops idle cursors after a given inactivity period to avoid excess memory use. For further information about MongoDB cursors, see [https://docs.mongodb.org/manual/core/cursors/](https://docs.mongodb.org/manual/core/cursors/). |

**Global Variables**

| Global Variables | **NB_FILE**: the number of files processed. This is an After variable and it returns an integer.  
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
For further information about variables, see [Talend Studio User Guide](#). |

**Usage**

| Usage rule | This component combines MongoDB GridFS connection and data extraction, thus usually used as a single-component subjob to copy data from a user-defined local directory to GridFS. |
Managing files using MongoDB GridFS

This scenario applies only to a Talend solution with Big Data.

In this scenario, the MongoDB GridFS components are used to create a Job to manage video files in MongoDB GridFS.

For further information about the GridFS system of MongoDB, see When to use GridFS.

For demonstration purposes, only one video file, called custom_hadoop.mp4, is used; you can use any of your own video files to replicate this scenario.

Linking the components

Procedure

1. In the Integration perspective of the Studio, create an empty Job, named FS_video for example, from the Job Designs node in the Repository tree view. For further information about how to create a Job, see Talend Studio User Guide.

2. In the workspace, enter the name of the component to be used and select this component from the list that appears. In this scenario, the components are tMongoDBConnection, tMongoDBGridFSPut,
tMongoDBGridFSPut

tMongoDBGridFSList, tMongoDBGridFSProperties, tFilterColumns, tLogRow, tMongoDBGridFSGet and tMongoDBGridFSDelete.

3. Connect tMongoDBConnection to tMongoDBGridFSPut using the Trigger > On Subjob Ok link.
4. Repeat this operation to connect tMongoDBGridFSPut to tMongoDBGridFSList, tMongoDBGridFSList to tMongoDBGridFSGet, and then tMongoDBGridFSGet to tMongoDBGridFSDelete.
5. Connect tMongoDBGridFSList to tMongoDBGridFSProperties using the Row > Iterate link. This link allows tMongoDBGridFSList to send data to tMongoDBGridFSProperties iteratively.
6. Connect tMongoDBGridFSProperties to tFilterColumns using the Row > Main link.
7. Do the same to connect tFilterColumns to tLogRow.

**Connecting to MongoDB**

**Procedure**

1. Double-click tMongoDBConnection to open its Component view.

2. From the DB version list, select the MongoDB version you are using.
3. In the Server and Port fields, enter the authentication information required for the connection to MongoDB.
   
   If you use the host name of the MongoDB server, ensure that you have added the mapping between this host name and its IP address in the hosts file of the operating system in which the current Job is executed.
4. In the Database field, enter the name of the database hosting GridFS. This database is created on the fly if it does not exist.

**Copying data to MongoDB GridFS**

**Procedure**

1. Double-click tMongoDBGridFSPut to open its Component view.
2. Select the **Use existing connection** check box and from the **Connection** list, select the component in which the MongoDB connection to be used is defined.

3. In the **Bucket** field, enter the bucket to be used to store files in GridFS. In this example, it is `talend_channel/61`.

4. In the **Local folder** field, enter the path, or browse to the folder where the files to be uploaded to GridFS are stored. As explained previously, it is a video file called `custom_hadoop.mp4`.

5. In the **Files** table, add one row by clicking the `[+]` button and in the **Filemask** column, enter `*.mp4` within the double quotation marks. This allows **tMongoDBGridFSPut** to copy all the files with the `.mp4` extension from the local folder you have specified to the bucket to be used in GridFS.

6. Leave the **New name** column empty, that is to say, leave the double quotation marks in this column as is, so as to keep the name of this video unchanged after being copied to GridFS.

**Listing files stored in MongoDB GridFS**

**Iterating on the files**

**Procedure**

1. Double-click **tMongoDBGridFSList** to open its **Component** view.
2. Select the **Use existing connection** check box and from the **Connection** list, select the component in which the MongoDB connection to be used is defined.

3. In the **Bucket** field, enter the bucket in which the files to be listed are stored. In this example, it is `talend_channel/61`.

4. In the **Query** field, enter the query to select the files you want `tMongoDBGridFSList` to iterate on to generate different file lists. In this example, leave the default one in order to iterate on all of the files stored in this `talend_channel/61` bucket.

As explained previously, only one file, `custom_hadoop.mp4`, is expected.

### Extracting file metadata

#### Procedure

1. Double-click `tMongoDBGridFSProperties` to open its **Component** view.

#### tMongoDBGridFSProperties 1

2. Select the **Use existing connection** check box and from the **Connection** list, select the component in which the MongoDB connection to be used is defined.
3. In the **Bucket** field, enter the bucket in which the files to be used are stored. In this example, it is `talend_channel/61`.

4. From the **Query type** list, select the approach you want to use to select the files about which you need to extract the metadata. In this example, select **Filename** to use the `filename` attribute of each GridFS file for query.

5. In the **Filename** field, press **Ctrl + Space** to display the variable list and choose the variable to be used. In this example, select `tMongoDBGridFSList.CURRENT_FILENAME` from the list. Then the expression to use the `CURRENT_FILENAME` variable is automatically added.

   This allows **tMongoDBGridFSProperties** to read each file name returned by **tMongoDBGridFSList**.

### Filtering attributes

#### Procedure

1. Double-click **tFilterColumns** to open its **Component** view.

2. Click the [...] button next to **Edit schema** to open the schema editor.

3. On the left side (the input side), select the column to be used and click the button to move this column to the right side (the output side). In this example, move every column to the right side except the `contentType` column.

   Each column represents a file attribute and the pre-defined schema of **tMongoDBGridFSProperties** automatically contains these columns.

4. Click **OK** to validate these changes and accept the propagation prompted by the pop-up dialog box.
Downloading files from MongoDB GridFS

Procedure

1. Double-click tMongoDBGridFSGet to open its Component view.

   ![tMongoDBGridFSGet Component View]

2. Select the **Use existing connection** check box and from the **Connection** list, select the component in which the MongoDB connection to be used is defined.

3. In the **Bucket** field, enter the bucket in which the files to be retrieved are stored. In this example, it is `talend_channel/61`.

4. In the **Local folder** field, enter the path to the local folder in which you want to store the downloaded files. In this scenario, it is `C:/tmp/output`.

5. Select the **Use Document ID as output filename** check box to rename each downloaded file using the value of its `ObjectId` attribute.

   Since a file in GridFS is distinct by ID rather than by name, it is possible that several files are using the same file name. For this reason, when downloading this kind of files into the same directory without renaming them differently, an exception is returned to alert that the file being downloaded already exists. In order to avoid this error, you can either select the **Overwrite local files** check box to replace the existing one with the latest downloaded file or rename these files on the fly using their IDs. In this example, the strategy of renaming these files is adopted.

Remove files from MongoDB GridFS

Procedure

1. Double-click tMongoDBGridFSDelete to open its Component view.
2. Select the **Use existing connection** check box and from the **Connection** list, select the component in which the MongoDB connection to be used is defined.

3. In the **Bucket** field, enter the bucket in which the files to be deleted are stored. In this example, it is `talend_channel/61`.

4. From the **Query type** list, select the approach you want to use to select the files to be deleted. In this example, select **Filename** to use the `filename` attribute of each GridFS file for query.

5. In the **Filename** field, enter the name of the file to be deleted.

### Executing the Job

**About this task**

Then you can run this Job.

The **tLogRow** component is used to present the execution result of the Job.

**Procedure**

1. If you want to configure the presentation mode on its **Component** view, double-click the **tLogRow** component to open the **Component** view and in the **Mode** area, then, select the **Table (print values in cells of a table)** radio box.

2. Press **F6** to run this Job.

**Results**

Once done, the **Run** view is opened automatically, where the metadata of the video `custom_hadoop.mp4` in GridFS is displayed.

```
Starting job FS_video at 15:00 06-04-2016.
[statistics] connecting to socket on port 3799

Job FS_video ended at 15:01 06-04-2016. [exit code=0]
The downloaded file can be found in the directory `C:/tmp/output`, using its ID as its file name.
tMongoDBInput

Retrieves records from a collection in the MongoDB database and transfers them to the following component for display or storage.

`tMongoDBInput` retrieves certain documents from a MongoDB database collection by supplying a query document containing the fields the desired documents should match.

**tMongoDBInput Standard properties**

These properties are used to configure `tMongoDBInput` running in the Standard Job framework.

The `tMongoDBInput` component belongs to the Big Data and the Databases families.

The component in this framework is available when you are using one of the *Talend* solutions with Big Data.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Use existing connection</strong></td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td><strong>DB Version</strong></td>
<td>List of the database versions. Available when the <code>Use existing connection</code> check box is not selected.</td>
</tr>

</thead>
</table>

| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
  • View schema: choose this option to view the schema only.  
  • Change to built-in property: choose this option to change the schema to Built-in for local changes.  
  • Update repository connection: choose this option to change the schema stored in the repository and |
|-------------------|-----------------------------------------------------------------------------------------------------|
decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

If a column in the database is a JSON document and you need to read the entire document, put an asterisk (*) in the DB column column, without quotation marks around.

<table>
<thead>
<tr>
<th><strong>Query</strong></th>
<th>Specify the query condition. This field is available only when you have selected <strong>Find query</strong> from the <strong>Query type</strong> drop-down list. For example, type in &quot;(id:4)&quot; to retrieve the record whose id is 4 from the collection specified in the Collection field.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Note:</strong></td>
<td>Different from the query statements required in the MongoDB client software, the query here refers to the contents inside <code>find()</code>, such as the query here <code>{id:4}</code> versus the MongoDB client query <code>db.blog.find({id:4})</code>.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Aggregation stages</strong></th>
<th>Create a MongoDB aggregation pipeline by adding the stages you want the documents to pass through so as to obtain aggregated results from these documents. This table is available only when you have selected <strong>Aggregation pipeline query</strong> from the <strong>Query type</strong> drop-down list. Only one stage is allowed per row in this Aggregation stages table and the stages are executed one by one in the order you place them in this table. For example, if you want to aggregate documents about your customers using the <code>$match</code> and the <code>$group</code> stages, you need to add two rows to this Aggregation stages table and define the two stages as follows:</th>
</tr>
</thead>
</table>
| | "{$match : {status : 'A'}}"
"{$group : { _id : '$cust_id',
  total : {$sum : '$amount'}}}" |
| | In this aggregation, the customer documents with status A are selected; then among the selected customers, those using the same customer id are grouped and the values from the amount fields of the same customer are summed up. For a full list of the stages you can use and their related operators, see **Aggregation pipeline operators**. For further information about MongoDB aggregation pipeline, see **Aggregation pipeline**. |

<table>
<thead>
<tr>
<th><strong>Mapping</strong></th>
<th>Each column of the schema defined for this component represents a field of the documents to be read. In this table, you need to specify the parent nodes of these fields, if any. For example, in the document reading as follows</th>
</tr>
</thead>
</table>
The *first* and the *last* fields have *person* as their parent node but the *id* field does not have any parent node. So once completed, this Mapping table should read as follows:

<table>
<thead>
<tr>
<th>Column</th>
<th>Parent node path</th>
</tr>
</thead>
<tbody>
<tr>
<td>_id</td>
<td></td>
</tr>
<tr>
<td>first</td>
<td>&quot;person&quot;</td>
</tr>
<tr>
<td>last</td>
<td>&quot;person&quot;</td>
</tr>
</tbody>
</table>

### Advanced settings

<table>
<thead>

Global Variables

**Global Variables**

<table>
<thead>
<tr>
<th>Variable Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NB_LINE</td>
<td>the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>ERROR_MESSAGE</td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

**Usage rule**

As a start component, tMongoDBInput allows you to retrieve records from a collection in the MongoDB database and transfer them to the following component for display or storage.

Scenario: Retrieving data from a collection by advanced queries

This scenario applies only to a Talend solution with Big Data.

In this scenario, advanced MongoDB queries are used to retrieve the post by the author Anderson.

There are such posts in the collection blog of the MongoDB database talend:

```javascript
> db.blog.find()
{ "id" : ObjectId("5226d25e675f26b4a2876888"), "id" : 1, "post" : { "author" : "Andy", "title" : "Open Source Outlook", "keywords" : "Open Source,Talend", "contents" : "Talend, the leader of the open source world..." } }
{ "id" : ObjectId("5226d25e675f26b4a2876889"), "id" : 2, "post" : { "author" : "Andy", "title" : "Data Integration Overview", "keywords" : "Data Integration,Talend", "contents" : "Talend, the leading player in the DI field..." } }
{ "id" : ObjectId("5226d25e675f26b4a287688a"), "id" : 3, "post" : { "author" : "Anderson", "title" : "ELT Overview", "keywords" : "ELT,Talend", "contents" : "Talend, the big name in the ELT circle..." } }
{ "id" : ObjectId("5226d25e675f26b4a287688b"), "id" : 4, "post" : { "author" : "Andy", "title" : "Big Data Bang", "keywords" : "Big Data,Talend", "contents" : "Talend, the driving force for Big Data applications..." } }
```

To insert data into the database, see Scenario 1: Creating a collection and writing data to it on page 2361.
Linking the components

Procedure
1. Drop tMongoDBConnection, tMongoDBClose, tMongoDBInput and tLogRow onto the workspace.
2. Link tMongoDBConnection to tMongoDBInput using the OnSubjobOk trigger.
3. Link tMongoDBInput to tMongoDBClose using the OnSubjobOk trigger.
4. Link tMongoDBInput to tLogRow using a Row > Main connection.

Configuring the components

Procedure
1. Double-click tMongoDBConnection to open its Basic settings view.
2. From the DB Version list, select the MongoDB version you are using.
3. In the Server and Port fields, enter the connection details.
4. In the Database field, enter the name of the MongoDB database.
5. Double-click tMongoDBInput to open its Basic settings view.
6. Select the **Use existing connection** option.

7. In the **Collection** field, enter the name of the collection, namely *blog*.

8. Click the [*...*] button next to **Edit schema** to open the schema editor.

9. Click the [+ ] button to add five columns, namely *id, author, title, keywords* and *contents*, with the type as *Integer* and *String* respectively.

10. Click **OK** to close the editor.

11. The columns now appear in the left part of the **Mapping** area.

12. For columns *author, title, keywords* and *contents*, enter their parent node *post* so that the data can be retrieved from the correct positions.
13. In the **Query** box, enter the advanced query statement to retrieve the posts whose author is Anderson:

```
"{post.author : 'Anderson'}"
```

This statement requires that the sub-node of `post`, the node `author`, should have the value "Anderson".

14. Double-click **tLogRow** to open its **Basic settings** view. Select **Table (print values in cells of a table)** for a better display of the results.

**Executing the Job**

**Procedure**

1. Press **Ctrl+S** to save the Job.
2. Press **F6** to run the Job.

```
<table>
<thead>
<tr>
<th>id</th>
<th>author</th>
<th>title</th>
<th>keywords</th>
<th>contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>Anderson</td>
<td>ELT Overview</td>
<td>ELT, Talend</td>
<td>the big name in the ELT circle...</td>
</tr>
</tbody>
</table>
```

As shown above, the post by Anderson is retrieved.

**Related scenarios**

For related scenarios, see:

- **Scenario 1: Creating a collection and writing data to it** on page 2361
- **Scenario: Using MongoDB functions to create a collection and write data to it** on page 2376
tMongoDBOutput

Executes the action defined on the collection in the MongoDB database. tMongoDBOutput inserts, updates, upserts or deletes documents in a MongoDB database collection based on the incoming flow from the preceding component in the Job.

### tMongoDBOutput Standard properties

These properties are used to configure tMongoDBOutput running in the Standard Job framework. The Standard tMongoDBOutput component belongs to the Big Data and the Databases families. The component in this framework is available when you are using one of the Talend solutions with Big Data.

#### Basic settings

<table>
<thead>
<tr>
<th>Use existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB Version</td>
<td>List of the database versions. Available when the Use existing connection check box is not selected.</td>
</tr>
<tr>
<td>Use replica set address</td>
<td>Select this check box to show the Replica address table. In the Replica address table, you can define multiple MongoDB database servers for failover. Available when the Use existing connection check box is not selected.</td>
</tr>
<tr>
<td>Server and Port</td>
<td>IP address and listening port of the database server. Available when the Use existing connection or Use replica set address check box is not selected.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database.</td>
</tr>
<tr>
<td>Use SSL connection</td>
<td>Select this check box to enable the SSL or TLS encrypted connection. Then you need to use the tSetKeystore component in the same Job to specify the encryption information. For further information about tSetKeystore, see tSetKeystore on page 3532. Note that the SSL connection is available only for the version 2.4 + of MongoDB.</td>
</tr>
<tr>
<td>Set write concern</td>
<td>Select this check box to set the level of acknowledgement requested from for write operations. Then you need to select the level of this operation.</td>
</tr>
</tbody>
</table>
For further information, see the related MongoDB documentation on [http://docs.mongodb.org/manual/core/write-concern/](http://docs.mongodb.org/manual/core/write-concern/).

### Bulk write

Select this check box to insert, update or remove data in bulk. Note this feature is available only when the version of MongoDB you are using is 2.6+.

Then you need to select **Ordered** or **Unordered** to define how the MongoDB database processes the data sent by the Studio.

- If you select **Ordered**, MongoDB processes the queries sequentially.
- If you select **Unordered**, MongoDB optimizes the bulk write operations without keeping the order in which the individual operations were inserted in the bulk write.

In the **Bulk write size** field, enter the size of each query group to be processed by MongoDB. In the documentation of MongoDB, some restrictions and expected behaviors as to this size are explained. You can find the details on [http://docs.mongodb.org/manual/core/bulk-write-operations/](http://docs.mongodb.org/manual/core/bulk-write-operations/).

### Required authentication

Select this check box to enable the database authentication.

Among the mechanisms listed on the **Authentication mechanism** drop-down list, the **NEGOTIATE** one is recommended if you are not using Kerberos, because it automatically select the authentication mechanism the most adapted to the MongoDB version you are using.

For details about the other mechanisms in this list, see **MongoDB Authentication** from the MongoDB documentation.

### Set Authentication database

If the username to be used to connect to MongoDB has been created in a specific Authentication database of MongoDB, select this check box to enter the name of this Authentication database in the **Authentication database** field that is displayed.

For further information about the MongoDB Authentication database, see **User Authentication database**.

### Username and Password

DB user authentication data.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

Available when the **Required authentication** check box is selected.

If the security system you have selected from the **Authentication mechanism** drop-down list is Kerberos, you need to enter the **User principal**, the **Realm** and
<table>
<thead>
<tr>
<th><strong>Collection</strong></th>
<th>Name of the collection in the MongoDB database.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Drop collection if exist</strong></td>
<td>Select this check box to drop the collection if it already exists.</td>
</tr>
<tr>
<td><strong>Action on data</strong></td>
<td>The following operations are available:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Insert</strong>: insert documents.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Set</strong>: modifies the existing fields of an existing document and appends a field if it does not exist in this document. If you need to apply this action on all the documents in the collection to be used, select the <strong>Update all document</strong> check box that is displayed; otherwise, only the first document is updated.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Update</strong>: replaces the existing documents with the incoming data but keeps the technical ID of these documents.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Upsert</strong>: inserts a document if it does not exist otherwise it applies the same rules as <strong>Update</strong>.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Upsert with set</strong>: inserts a document if it does not exist otherwise it applies the same rules as <strong>Set</strong>. If you need to apply this action on all the documents in the collection to be used, select the <strong>Update all document</strong> check box that is displayed; otherwise, only the first document is updated.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Delete</strong>: delete documents.</td>
</tr>
<tr>
<td><strong>Schema and Edit Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <code>line</code> when naming the fields. Click <strong>Edit schema</strong> to make changes to the schema. If the current schema is of the <strong>Repository</strong> type, three options are available:</td>
</tr>
<tr>
<td></td>
<td>• <strong>View schema</strong>: choose this option to view the schema only.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Change to built-in property</strong>: choose this option to change the schema to <strong>Built-in</strong> for local changes.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Update repository connection</strong>: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select <strong>No</strong> upon completion and choose this schema metadata again in the [Repository Content] window. Click <strong>Sync columns</strong> to retrieve the schema from the previous component connected in the Job.</td>
</tr>
</tbody>
</table>
**Built-In:** You create and store the schema locally for this component only. Related topic: see *Talend Studio User Guide*.

**Repository:** You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see *Talend Studio User Guide*.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

**Mapping**

Each column of the schema defined for this component represents a field of the documents to be read. In this table, you need to specify the parent nodes of these fields, if any.

For example, in the document reading as follows

```json
{  
    _id: ObjectId("5099803df3f4948bd2f98391"),
    person: { first: "Joe", last: "Walker" }
}
```

The `first` and the `last` fields have `person` as their parent node but the `_id` field does not have any parent node.

So once completed, this **Mapping** table should read as follows:

<table>
<thead>
<tr>
<th>Column</th>
<th>Parent node path</th>
</tr>
</thead>
<tbody>
<tr>
<td>_id</td>
<td></td>
</tr>
<tr>
<td>first</td>
<td>&quot;person&quot;</td>
</tr>
<tr>
<td>last</td>
<td>&quot;person&quot;</td>
</tr>
</tbody>
</table>

Not available when the **Generate JSON Document** check box is selected in **Advanced settings**.

**Die on error**

This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

**Advanced settings**

**Generate JSON Document**

Select this check box for JSON configuration:

**Configure JSON Tree:** click the [...] button to open the interface for JSON tree configuration. For more information, see **Configuring a JSON Tree** on page 4040.

**Group by:** click the [+] button to add lines and choose the input columns for grouping the records.

**Remove root node:** select this check box to remove the root node.
Data node and Query node (available for update and upsert actions): type in the name of data node and query node configured on the JSON tree.

**Warning:**
These nodes are mandatory for update and upsert actions. They are intended to enable the update and upsert actions though will not be stored in the database.

<table>
<thead>
<tr>
<th>No query timeout</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select this check box to prevent MongoDB servers from stopping idle cursors at the end of 10-minute inactivity of these cursors. In this situation, an idle cursor will stay open until either the results of this cursor are exhausted or you manually close it using the cursor.close() method. A cursor for MongoDB is a pointer to the result set of a query. By default, that is to say, with this check box being clear, a MongoDB server automatically stops idle cursors after a given inactivity period to avoid excess memory use. For further information about MongoDB cursors, see <a href="https://docs.mongodb.org/manual/core/cursors/">https://docs.mongodb.org/manual/core/cursors/</a>.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select this check box to collect the log data at the component level.</td>
</tr>
</tbody>
</table>

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
</tr>
</thead>
</table>
| **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.  
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
For further information about variables, see *Talend Studio User Guide*. |

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>tMongoDBOutput</strong> executes the action defined on the collection in the MongoDB database based on the flow incoming from the preceding component in the Job.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Limitation</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Note:</strong></td>
</tr>
</tbody>
</table>
• The "multi" parameter, which allows to update multiple documents at a time, is not supported. Therefore, if two documents have the same key, the first is always updated, but the second never will.

• For the update operation, the key cannot be a JSON array.

Scenario 1: Creating a collection and writing data to it

This scenario applies only to a Talend solution with Big Data.

This scenario creates the collection blog and writes post data to it.

Linking the components

Procedure

1. Drop tMongoDBConnection, tFixedFlowInput, tMongoDBOutput, tMongoDBClose, tMongoDBInput and tLogRow onto the workspace.
2. Rename tFixedFlowInput as blog_post_data, tMongoDBOutput as write_data_to_collection, tMongoDBInput as read_data_from_collection and tLogRow as show_data_from_collection.
3. Link tMongoDBConnection to tFixedFlowInput using the OnSubjobOk trigger.
4. Link tFixedFlowInput to tMongoDBOutput using a Row > Main connection.
5. Link tFixedFlowInput to tMongoDBInput using the OnSubjobOk trigger.
7. Link tMongoDBInput to tLogRow using a Row > Main connection.

Configuring the components

Procedure

1. Double-click tMongoDBConnection to open its Basic settings view.
2. From the **DB Version** list, select the MongoDB version you are using.

3. In the **Server** and **Port** fields, enter the connection details.
   
   In the **Database** field, enter the name of the MongoDB database.

4. Double-click **tFixedFlowInput** to open its **Basic settings** view.

Select **Use Inline Content (delimited file)** in the **Mode** area.

In the **Content** field, enter the data to write to the MongoDB database, for example:

```
1;Andy;Open Source Outlook;Open Source,Talend;Talend, the leader of the open source world...
3;Andy;ELT Overview;ELT,Talend;Talend, the big name in the ELT circle...
2;Andy;Data Integration Overview;Data Integration,Talend;Talend, the leading player in the DI field...
```

5. Double-click **tMongoDBOutput** to open its **Basic settings** view.
Select the **Use existing connection** and **Drop collection if exist** check boxes.

In the **Collection** field, enter the name of the collection, namely *blog*.

6. Click the [...] button next to **Edit schema** to open the schema editor.

7. Click the [+] button to add five columns in the right part, namely *id, author, title, keywords and contents*, with the type as *Integer* and *String* respectively.

   - Click **→** to copy all the columns to the input table.
   - Click **Ok** to close the editor.

8. The columns now appear in the left part of the **Mapping** area.

   - For columns *author, title, keywords and contents*, enter their parent node *post*. By doing so, those nodes reside under the node *post* in the MongoDB collection.

9. Double-click **tMongoDBInput** to open its **Basic settings** view.
Select the **Use existing connection** check box.

In the **Collection** field, enter the name of the collection, namely *blog*.

10. Click the [...] button next to **Edit schema** to open the schema editor.

11. Click the [+] button to add five columns, namely *id*, *author*, *title*, *keywords* and *contents*, with the type as *Integer* and *String* respectively.

   Click **OK** to close the editor.

12. The columns now appear in the left part of the **Mapping** area.
For columns author, title, keywords and contents, enter their parent node post so that the data can be retrieved from the correct positions.

13. In the Sort by area, click the [+] button to add one line and enter id under Column. Select asc from the Order asc or desc? column to the right of the id column. This way, the retrieved records will appear in ascending order of the id column.

**Executing the Job**

**Procedure**

1. Press Ctrl+S to save the Job.
2. Press F6 to run the Job.

```
    | statistics] connecting to socket on port 27017
    | show_data_from_collection
    | id  | author     | title               | keywords       | contents                                 |
    +----+------------+---------------------+-------------------+------------------------------------------|
    | 1   | Andy       | Open Source Outlook | Open Source, Talend | Talend, the leader of the open source world... |
    | 2   | Andy       | Data Integration Overview | Data Integration, Talend | Talend, the leading player in the DI field... |
    | 3   | Andy       | ELT Overview | ELT, Talend | Talend, the big name in the ELT circle... |

    | statistics] disconnected
```

3. Switch to the database talend and read data from the collection blog in the MongoDB command line client. You can find that author, title, keywords and contents all reside under the node post. Meanwhile, the records are stored in the same order as the source input.

**Scenario 2: Upserting records in a collection**

This scenario applies only to a Talend solution with Big Data.

This scenario upserts the collection blog as an existing record has its author changed and a new record is added. Before the upsert, the collection blog looks like:

```
1;Andy;Open Source Outlook;Open Source,Talend;Talend, the leader of the open source world...
2;Andy;Data Integration Overview;Data Integration,Talend;Talend, the leading player in the DI field...
3;Andy;ELT Overview;ELT,Talend;Talend, the big name in the ELT circle...
```
Such records can be inserted to the database following the instructions of Scenario 1: Creating a collection and writing data to it on page 2361.

**Linking the components**

**Procedure**

1. Drop tMongoDBConnection, tFixedFlowInput, tMongoDBOutput, tMongoDBClose, tMongoDBInput and tLogRow from the Palette onto the design workspace.
2. Rename tFixedFlowInput as blog_post_data, tMongoDBOutput as write_data_to_collection, tMongoDBInput as read_data_from_collection and tLogRow as show_data_from_collection.
3. Link tMongoDBConnection to tFixedFlowInput using the OnSubjobOk trigger.
4. Link tFixedFlowInput to tMongoDBOutput using a Row > Main connection.
5. Link tFixedFlowInput to tMongoDBInput using the OnSubjobOk trigger.
7. Link tMongoDBInput to tLogRow using a Row > Main connection.

**Configuring the components**

**Procedure**

1. Double-click tMongoDBConnection to open its Basic settings view.

   ![tMongoDBConnection](image)

2. From the DB Version list, select the MongoDB version you are using.
3. In the Server and Port fields, enter the connection details.
In the **Database** field, enter the name of the MongoDB database.

4. Double-click **tFixedFlowInput** to open its **Basic settings** view.

   ![Basic settings view](image)

   Select **Use Inline Content (delimited file)** in the **Mode** area.

   In the **Content** field, enter the data for upserting the MongoDB database, for example:

   ```
   1;Andy;Open Source Outlook;Open Source,Talend,Talend, the leader of the open source world...
   2;Andy;Data Integration Overview;Data Integration,Talend,Talend, the leading player in the DI field...
   3;Anderson;ELT Overview;ELT,Talend,Talend, the big name in the ELT circle...
   4;Andy;Big Data Bang;Big Data,Talend,Talend, the driving force for Big Data applications...
   ```

   As shown above, the 3rd record has its author changed and the 4th record is new.

5. Double-click **tMongoDBOutput** to open its **Basic settings** view.

   ![Basic settings view](image)

   Select the **Use existing connection** and **Die on error** check boxes.

   In the **Collection** field, enter the name of the collection, namely **blog**.

   Select **Upsert** from the **Action on data** list.
6. Click the [...] button next to **Edit schema** to open the schema editor.

![Schema of write_data_to_collection](image)

7. Click the [+] button to add five columns in the right part, namely *id*, *author*, *title*, *keywords* and *contents*, with the type as *Integer* and *String* respectively.

   Click ![copy button](image) to copy all the columns to the input table.

   Click **Ok** to close the editor.

8. In the **Advanced Settings** view, select the **Generate JSON Document** check box.

   Select the **Remove root node** check box.

   In the **Data node** and **Query node** fields, enter "*data*" and "*query*".

![write_data_to_collection(tMongoDBOutput_4)](image)

9. Click the [...] button next to **Configure JSON Tree** to open the configuration interface.
10. Right-click the node `rootTag` and select **Add Sub-element** from the contextual menu. In the dialog box that appears, type in `data` for the **Data node**:

![Input element's label](image1)

Click **OK** to close the window.

Repeat this operation to define `query` as the **Query node**.

Right-click the node `data` and select **Set As Loop Element** from the contextual menu.

**Warning:**

These nodes are mandatory for update and upsert actions. They are intended to enable the update and upsert actions though will not be stored in the database.

11. Select all the columns under the **Schema list** and drop them to the `data` node.

In the window that appears, select **Create as sub-element of target node**.
Click OK to close the window.
Repeat this operation to drop the id column from the Schema list under the Query node.

12. Right-click the node id under data and select Add Attribute from the contextual menu.
In the dialog box that appears, type in type as the attribute name:

Click OK to close the window.
Right-click the node @type under id and select Set A Fix Value from the contextual menu.
In the dialog box that appears, type in integer as the attribute value, ensuring the id values are stored as integers in the database.

Click OK to close the window.
Repeat this operation to set this attribute for the id node under Query.
Click OK to close the JSON Tree configuration interface.

Select the **Use existing connection** check box.

In the **Collection** field, enter the name of the collection, namely *blog*.

Click the [...] button next to **Edit schema** to open the schema editor.

Click the [*+] button to add five columns, namely *id, author, title, keywords and contents*, with the type as *Integer* and *String* respectively.

Click **OK** to close the editor.

The columns now appear in the left part of the **Mapping** area.

For columns *author, title, keywords and contents*, enter their parent node *post* so that the data can be retrieved from the correct positions.

14. Double-click **tLogRow** to open its **Basic settings** view.
In the **Mode** area, select **Table (print values in cells of a table)** for better display.

### Executing the Job

**Procedure**

1. Press **Ctrl+S** to save the Job.
2. Press **F6** to run the Job.

```
<table>
<thead>
<tr>
<th>id</th>
<th>author</th>
<th>title</th>
<th>keywords</th>
<th>contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Andy</td>
<td>Open Source Outlook</td>
<td>Open Source Talend</td>
<td>Talend: the leader of the open source world...</td>
</tr>
<tr>
<td>2</td>
<td>Andy</td>
<td>Data Integration Overview</td>
<td>Data Integration Talend</td>
<td>Talend: the leading player in the DI field...</td>
</tr>
<tr>
<td>3</td>
<td>Anderson</td>
<td>ELT Overview</td>
<td>ELT Talend</td>
<td>Talend: the big name in the ELT circle...</td>
</tr>
<tr>
<td>4</td>
<td>Andy</td>
<td>Big Data Magic</td>
<td>Big Data Talend</td>
<td>Talend: the driving force for Big Data applications...</td>
</tr>
</tbody>
</table>
```

As shown above, the 3rd record has its author updated and the 4th record is inserted.
tMongoDBRow

Executes the commands and functions of the MongoDB database.

### tMongoDBRow Standard properties

These properties are used to configure tMongoDBRow running in the Standard Job framework.

The Standard tMongoDBRow component belongs to the Big Data and the Databases families.

The component in this framework is available when you are using one of the Talend solutions with Big Data.

#### Basic settings

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Use existing connection</strong></td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td><strong>DB Version</strong></td>
<td>List of the database versions. Available when the Use existing connection check box is not selected.</td>
</tr>
<tr>
<td><strong>Use replica set address</strong></td>
<td>Select this check box to show the Replica address table. In the Replica address table, you can define multiple MongoDB database servers for failover. Available when the Use existing connection check box is not selected.</td>
</tr>
<tr>
<td><strong>Server and Port</strong></td>
<td>Address and listening port of the database server. Available when the Use existing connection or Use replica set address check box is not selected.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database.</td>
</tr>
<tr>
<td><strong>Use SSL connection</strong></td>
<td>Select this check box to enable the SSL or TLS encrypted connection. Then you need to use the tSetKeystore component in the same Job to specify the encryption information. For further information about tSetKeystore, see tSetKeystore on page 3532. Note that the SSL connection is available only for the version 2.4 + of MongoDB.</td>
</tr>
<tr>
<td><strong>Required authentication</strong></td>
<td>Select this check box to enable the database authentication. Among the mechanisms listed on the Authentication mechanism drop-down list, the NEGOTIATE one is recommended if you are not using Kerberos, because it automatically select the authentication mechanism the most adapted to the MongoDB version you are using.</td>
</tr>
</tbody>
</table>
For details about the other mechanisms in this list, see [MongoDB Authentication](https://docs.mongodb.com/manual/reference/auth/) from the MongoDB documentation.

### Set Authentication database
If the username to be used to connect to MongoDB has been created in a specific Authentication database of MongoDB, select this check box to enter the name of this Authentication database in the **Authentication database** field that is displayed.

For further information about the MongoDB Authentication database, see [User Authentication database](https://docs.mongodb.com/manual/reference/auth/).

### Username and Password
DB user authentication data.

To enter the password, click the `...` button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

Available when the **Required authentication** check box is selected.

If the security system you have selected from the **Authentication mechanism** drop-down list is Kerberos, you need to enter the **User principal**, the **Realm** and the **KDC server** fields instead of the **Username** and the **Password** fields.

### Schema and Edit Schema
A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word *line* when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

Click **Sync columns** to retrieve the schema from the previous component connected in the Job.

### Execute command
Select this check box to enter MongoDB commands in the **Command** field for execution.

- **Command**: in this field, enter the command to be executed, if this command contains one single variable.
For example, if you need to construct the command

```json
{"isMaster": 1}
```

You need simply enter `isMaster` within quotation marks.

- **Construct command from keys and values**: if the command to be executed contains multiple variables, select this check box and in the **Command keys and values** table, add the variables and their respective values to be used.

  For example, if you need to construct the following command

  ```json
  { renameCollection : 
    "<source_namespace>" ,
    to : "<target_namespace>" ,
    dropTarget : < true | false > }
  ```

  You need to add three rows to the **Command keys and values** table and enter one variable-value pair to each row within quotation marks:

  ```json
  "renameCollection"
  "old_name"
  "to"
  "new_name"
  "dropTarget"            "false"
  ```

- **Construct command from a JSON string**: if you want to directly enter the command to be used, select this check box and enter this command in the **JSON string command** field that is displayed. Only one command is allowed per **tMongoDBRow**.

  For example:

  ```json
  "{createIndexes: 'restaurants',
  indexes : [{key : {
  restaurant_id: 1}, name:
  'id_index_2', unique: true}]}"
  ```

  Note that you must use single quotation marks to surround the string values used in the command and double quotation marks to surround the command itself.

  For further information about the MongoDB commands you can use in this field, see [https://docs.mongodb.org/manual/reference/command/](https://docs.mongodb.org/manual/reference/command/).

<table>
<thead>
<tr>
<th>Function</th>
<th>Enter MongoDB functions in the <strong>Function</strong> field for execution. Not available when the <strong>Execute command</strong> check box is selected.</th>
</tr>
</thead>
<tbody>

<td>Click the [*] button to add lines as needed and then define the parameter values in the form of variables or <strong>tMongoDBRow</strong>.</td>
</tr>
</tbody>
</table>
constant values, for example `row1.author` or "Andy". Note that the parameter values correspond to the parameters defined in the Function field, in the same order.

Not available when the **Execute command** check box is selected.

**Die on error**

This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect the log data at the component level. |

**Global Variables**

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it. For further information about variables, see **Talend Studio User Guide**. |

**Usage**

| Usage rule | **tMongoDBRow** allows you to manipulate the MongoDB database through the MongoDB commands and functions. |

**Scenario: Using MongoDB functions to create a collection and write data to it**

This scenario applies only to a Talend solution with Big Data.

This scenario creates the collection *blog* and writes post data to it through the MongoDB functions.

**Linking the components**

**Procedure**

1. Drop **tMongoDBConnection**, **tFixedFlowInput**, **tMongoDBRow**, **tMongoDBClose**, **tMongoDBInput** and **tLogRow** onto the workspace.
2. Rename `tFixedFlowInput` as `blog_post_data`, `tMongoDBRow` as `write_data_to_collection`, `tMongoDBInput` as `read_data_from_collection` and `tLogRow` as `show_data_from_collection`.

3. Link `tMongoDBConnection` to `tFixedFlowInput` using the OnSubjobOk trigger.

4. Link `tFixedFlowInput` to `tMongoDBRow` using a Row > Main connection.

5. Link `tFixedFlowInput` to `tMongoDBInput` using the OnSubjobOk trigger.

7. Link `tMongoDBInput` to `tLogRow` using a Row > Main connection.

### Configuring the components

**Procedure**

1. Double-click `tMongoDBConnection` to open its Basic settings view.

![tMongoDBConnection_1](image)

2. From the DB Version list, select the MongoDB version you are using.

3. In the Server and Port fields, enter the connection details.

   In the Database field, enter the name of the MongoDB database.

4. Double-click `tFixedFlowInput` to open its Basic settings view.
Select **Use Inline Content (delimited file)** in the **Mode** area.

In the **Content** field, enter the data to write to the MongoDB database, for example:

Andy;Open Source Outlook;Open Source,Talend,Talend, the leader of the open source world...
Andy;Data Integration Overview;Data Integration,Talend,Talend, the leading player in the DI field...
Andy;ELT Overview;ELT,Talend,Talend, the big name in the ELT circle...

5. Double-click **tMongoDBRow** to open its **Basic settings** view.
Select the **Use existing connection** check box.

In the **Function** field, enter the MongoDB function to create the collection `blog` and insert data to it:

```javascript
"function(author,title,keywords,contents){
    return db.blog.save(
        {author:author,title:title,keywords:keywords,contents:contents}
    );
}
"
```

6. Click the [...] button next to **Edit schema** to open the schema editor.
7. Click the [+ ] button to add four columns in the right part, namely author, title, keywords and contents, with the type of String.

Click to copy all the columns to the input table.

Click OK to close the editor.

8. In the Parameters value table, click the [+ ] button to add four lines and enter the values in sequence: row1.author, row1.title, row1.keywords and row1.contents. By doing so, data of row1 will be transferred to the parameters defined in the function.

Select the Use existing connection check box.

In the Collection field, enter the name of the collection, namely blog.

10. Click the [...] button next to Edit schema to open the schema editor.

11. Click the [+ ] button to add four columns, namely author, title, keywords and contents, with the type as String.
Click **OK** to close the editor.

12. Double-click **tLogRow** to open its **Basic settings** view.

In the **Mode** area, select **Table (print values in cells of a table)** for better display.

**Executing the Job**

**Procedure**

1. Press **Ctrl+S** to save the Job.
2. Press **F6** to run the Job.

<table>
<thead>
<tr>

**Related scenarios**

No scenario is available for the Standard version of this component yet.
tMSAXOutput

Writes data in a Microsoft AX server.

**tMSAXOutput Standard properties**

These properties are used to configure tMSAXOutput running in the Standard Job framework.

The Standard tMSAXOutput component belongs to the Business family.

The component in this framework is generally available.

### Basic settings

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-in or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the Repository file where properties are stored. The fields that come after are pre-filled in using the fetched data.</td>
</tr>
</tbody>
</table>

**Version**

Select the type of the business connector to be used. The type may be:

- Dynamics AX 4.0
- Dynamics AX 2012

### Advanced settings

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

### Global Variables

**Global Variables**

- **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.
- **NB_LINE_UPDATED**: the number of rows updated. This is an After variable and it returns an integer.
- **NB_LINE_INSERTED**: the number of rows inserted. This is an After variable and it returns an integer.
- **NB_LINE_DELETED**: the number of rows deleted. This is an After variable and it returns an integer.
- **NB_LINE_REJECTED**: the number of rows rejected. This is an After variable and it returns an integer.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions...
only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

</tbody>
</table>
Scenario 1: Inserting data in a defined table in a MicrosoftAX server

Warning:
Before being able to use this component, make sure that you install and launch the MicrosoftAX server correctly.

This Java scenario describes a two-component Job that uses tMSAXOutput to insert four columns in a defined table in a MicrosoftAX server after it alters values in one of the inserted columns.

Setting up the Job

Procedure

1. Drop tFixedFlowInput and tMSAXOutput from the Palette to the design workspace.
2. Connect the two components together using a Row > Main connection.

Configuring tFixedFlowInput

Procedure

1. Double-click tFixedFlowInput to display its Basic settings view and define the component properties.
2. Set Schema type to Built-in and click the three-dot button next to Edit schema to display a dialog box where you can define the input schema.
3. Click the plus button and add the input schema columns, three in this example: name, city and street.
4. Click **OK** to close the dialog box and accept propagating the changes when prompted by the system.

The three schema columns display automatically in the **Values** list.

5. Click in the **Value** column and enter a value for each of the input columns.

**Configuring tMSAXOutput**

**Procedure**

1. Double-click **tMSAXOutput** to open its **Basic settings** view and define the component properties.

2. Set **Property type** to **Built-in**.

3. In the **Host** field, type in the IP address of the MicrosoftAX server and type in the domain name on which the MicrosoftAX server is hosted in the **Domain** field.

4. Enter your username and password for the server in the corresponding fields and enter the name of the table you want to write data in the **Table Name** field, ADDRESS in this example.

5. In the **Action on data** list, select the action you want to carry on, **Insert** in this example.

6. Click **Sync columns** to retrieve the schema from the preceding component.

   In this example, we want to retrieve the three input columns: *name*, *city* and *street* and write the data included in the three input columns in the MicrosoftAX server without any changes.

   If needed, click the three-dot button next to **Edit Schema** to verify the retrieved schema.

7. In the **Additional columns** list, click the plus button to add one line where you can define parameters for the new column to add to the row you want to write in the ADDRESS table.

8. Set a name, a data type, a position and a reference column in the corresponding columns for the line you added.

   In this example, we want to add a new column we call "address" after the *street* column.

9. Click in the **Local expression** column and press **Ctrl + space** on your keyboard to open the context variable list and select: `StringHandling.UPCASE(row2.city)+"-"+row2.street`. This expression will write the city name initially capped followed by the street name to form the address of Bryant park. Thus the address column in this example will contain the string: *New York-Midtown Manhattan*. 
Job execution

Procedure

Save your Job and press F6 to execute it.

`tMSAXOutput` inserts in the `ADDRESS` table in the MicrosoftAX server a row that holds the three input columns, `name`, `city` and `street` in addition to the new `address` column that combines the city name and the street name.

Scenario 2: Deleting data from a defined table in a MicrosoftAX server

Warning:

Before being able to use this component, make sure that you install and launch the MicrosoftAX server correctly.

This Java scenario describes a two-component Job that uses `tMSAXOutput` to delete from a defined table in a MicrosoftAX server all rows that do not match the data included in a key column.

In this example, the input schema we use is an `address` column that holds the following data: *New York-Midtown Manhattan*. We want to delete from the MicrosoftAX server all addresses that are not identical with this one.

Setting up the Job

Procedure

1. Drop `tFixedFlowInput` and `tMSAXOutput` from the Palette to the design workspace.
2. Connect the two components together using a Row > Main connection.

Configuring `tFixedFlowInput`

Procedure

1. Double-click `tFixedFlowInput` to display its Basic settings view and define the component properties.
2. Set Schema type to Built-in and click the three-dot button next to Edit schema to display a dialog box where you can define the input schema.

3. Click the plus button and add the input schema columns, address in this example.

4. Click OK to close the dialog box. The schema column displays automatically in the Values list.

5. Click in the Value column and enter a value for the input column.

**Setting up the connection to the MicrosoftAX server**

**Procedure**

1. Double-click tMSAXOutput to open its Basic settings view and define the component properties.

2. Set Property type to Built-in.

3. In the Host field, type in the IP address of the MicrosoftAX server.

4. In the Domain field, type in the domain name on which the MicrosoftAX server is hosted.

5. Enter your username and password for the server in the corresponding fields.

6. In the Table Name field, enter the name of the table you want to delete data from, ADDRESS in this example.
Defining the action on data

Procedure

1. In the Action on data list, select the action you want to carry on, **Delete** in this example.
2. Click **Sync columns** to retrieve the schema from the preceding component. In this example, we want to retrieve the input column: *address*.
3. Click the three-dot button next to **Edit Schema** to open a dialog box where you can verify the retrieved schema.

4. In the output schema, select the Key check box next to the column name you want to define as a key column, and then click **OK** to validate your changes and close the dialog box.

   ![Schema dialog box](image)

   **Note:**
   When you select **Delete** as an action on data, you must always define the Reference column as a key column in order for **tMSAXOutput** to delete rows based on this key column.

5. In the Additional columns list, click the plus button to add one line and define the parameters the component will use as basis for the delete operation.
6. Set a name, an operator, a data type, a local expression, a position and a reference column in the corresponding columns for the line you added.

   In this example, we want to delete from the *ADDRESS* table in the MicrosoftAX server all rows in which the address column is not equal to the address in the key *address* column and that reads as the following: New York-Midtown Manhattan.

   **Note:**
   When you select **Delete** as an action on data, you must always set Position to Replace. Otherwise, all settings in the Additional columns will not be taken into account when executing your Job.

Job execution

Procedure

Save your Job and press **F6** to execute it.

**tMSAXOutput** deletes from the *ADDRESS* table in the MicrosoftAX server all rows where the address string is not equal to the address in the key column.
tMsgBox

Opens a dialog box with an OK button requiring action from the user.
tMsgBox is a graphical break in the Job execution progress.

**tMsgBox Standard properties**

These properties are used to configure tMsgBox running in the Standard Job framework.
The Standard tMsgBox component belongs to the Misc family.
The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>Title</th>
<th>Text entered shows on the title bar of the dialog box created.</th>
</tr>
</thead>
</table>
| Buttons | Listbox of buttons you want to include in the dialog box. The button combinations are restricted and cannot be changed.  
The **Question** button displays the **Mask Answer** check box. Select this check box if you want to mask the answer you type in the pop-up window that opens when you run the Job. |
| Icon | Icon shows on the title bar of the dialog box. |
| Message | Free text to display as message on the dialog box. Text can be dynamic (for example: retrieve and show a file name). |

**Global Variables**

| Global Variables | RESULT: the return value of the component. This is an After variable and it returns a string.  
ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.  
For further information about variables, see Talend Studio User Guide. |

<td>n/a</td>
</tr>
</tbody>
</table>

Scenario: 'Hello world!' type test

The following scenario creates a single-component Job, where tMsgBox is used to display the pid (process id) in place of the traditional “Hello World!” message.

Setting up the Job

Procedure

1. Drop a tMsgBox component from the Palette to the design workspace.

2. Define the dialog box display properties:

   - **Title**: "Talend Open Studio"
   - **Buttons**: OK
   - **Icon**: Icon Information
   - **Message**: "Current date is: "+(TalendDate.getCurrentDate())

   ‘Title’ is the message box title, it can be any variable.

3. In the Message field, enter "Current date is: " between double quotation marks. Then click CTRL+Space to display the autocompletion list and select the following system routine, TalendDate.getCurrentDate. Put brackets around this routine.

Executing the Job

Procedure

- Switch to the Run tab to execute the Job defined.

Results

The Message box displays the message and requires the user to click **OK** to go to the next component or end the Job.
After the user clicked **OK**, the **Run** log is updated accordingly.

Related topic: see *Talend Studio User Guide*. 
tMSSqlBulkExec

 Offers gains in performance while executing the Insert operations to a Microsoft SQL Server database.

The tMSSqlOutputBulk and tMSSqlBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tMSSqlOutputBulkExec component, detailed in a separate section. The advantage of using a two step process is that the data can be transformed before it is loaded in the database.

**tMSSqlBulkExec Standard properties**

These properties are used to configure tMSSqlBulkExec running in the Standard Job framework.

The Standard tMSSqlBulkExec component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Options</th>
</tr>
</thead>

<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-in</strong>: No property data is stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

**JDBC Provider**

Select the provider of the JDBC driver to be used, either Microsoft (recommended) or **Open source JTDS**.

When using this component with Datasource in Talend Runtime, you need to use the **Open source JTDS** driver.

Note that when Microsoft is selected, you need to download the Microsoft JDBC Driver for SQL Server on Microsoft Download Center, unpack the downloaded zip file, choose a jar in the unzipped folder based on your JRE version, rename the jar to *mssql-jdbc.jar* and install it manually. For more information about choosing the jar, see the System Requirements information on Microsoft Download Center.

<table>

<th>Use an existing connection</th>
<th>Options</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
### Note:

When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.

2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see [Talend Studio User Guide](#).

<table>
<thead>
<tr>
<th>Field</th>

<tr>
<td><strong>Schema and Edit Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the</td>
</tr>
</tbody>
</table>
next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

| **Built-In** | You create and store the schema locally for this component only. Related topic: see *Talend Studio User Guide*. |
| **Repository** | You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see *Talend Studio User Guide*. When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually. You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)). |

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-In** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **[Repository Content]** window.

**Remote File Name**

Name of the file to be loaded.

**Warning:**

This file is located on the machine specified by the URI in the **Host** field so it should be on the same machine as the database server.

**Advanced settings**

| **Action** | Select the action to be carried out

**Bulk insert**  **Bulk update**  **Bcp query out** Depending on the action selected, the required information varies. |
| **Fire Triggers** | Select this check box to execute any insert trigger defined on the table into which data will be loaded during the bulk insert operation. This property is available when **Bulk insert** is selected from the **Action** drop-down list. |
Usage

<table>

**Dynamic settings**

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.
**Limitation**

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

---

### Related scenarios

For use cases in relation with **tMSSqlBulkExec**, see the following scenarios:

- **Scenario: Inserting transformed data in MySQL database** on page 2537.
- **Scenario: Inserting data in bulk in MySQL database** on page 2544.
# tMSSqlClose

Closes a transaction in the MSSql databases.

## tMSSqlClose Standard properties

These properties are used to configure tMSSqlClose running in the Standard Job framework.

The Standard tMSSqlClose component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see [Dynamic database components](#) on page 598.

## Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the <strong>tMssqlConnection</strong> component in the list if more than one connection are planned for the current Job.</td>
</tr>
</tbody>
</table>

## Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

## Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is to be used along with tMssql components, especially with <strong>tMssqlConnection</strong> and <strong>tMssqlCommit</strong>.</th>
</tr>
</thead>
</table>

## Dynamic settings

Click the `[+]` button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see [Scenario: Reading data from databases through context-](#).
Related scenarios

No scenario is available for the Standard version of this component yet.
tMSSqlColumnList

Lists all column names of a given MSSql table.
tMSSqlColumnList iterates on all columns of a given table through a defined MS SQL connection.

**tMSSqlColumnList Standard properties**

These properties are used to configure tMSSqlColumnList running in the Standard Job framework.
The Standard tMSSqlColumnList component belongs to the Databases family.
The component in this framework is generally available.

![Note:](image)

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tMSSqlConnection component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Table name</td>
<td>Enter the name of the table.</td>
</tr>
</tbody>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
<th>Select this check box to collect log data at the component level.</th>
</tr>
</thead>
</table>

**Global Variables**

**Global Variables**

<table>
<thead>
<tr>
<th>COLUMN_NAME: the name of the column currently iterated upon. This is a Flow variable and it returns a string.</th>
</tr>
</thead>
<tbody>
<tr>
<td>COLUMN_DEFAULT: the default value of the column currently iterated upon. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td>IS_NULLABLE: nullability of the column currently iterated upon. This is a Flow variable and it returns YES if the column allows NULL; otherwise, NO.</td>
</tr>
<tr>
<td>DATA_TYPE: the data type of the column currently iterated upon. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td>CHARACTER_MAXIMUM_LENGTH: the maximum length in number of characters of the column currently iterated</td>
</tr>
</tbody>
</table>
upon. This is a Flow variable, and it returns a numeric string for binary or character data types and NULL for other types.

**CHARACTER_OCTET_LENGTH**: the maximum length in bytes of the column currently iterated upon. This is a Flow variable, and it returns a numeric string for binary or character data types and NULL for other types.

**NUMERIC_PRECISION**: the data precision of the column currently iterated upon. This is a Flow variable, and it returns a numeric string for approximate numeric data, exact numeric data, integer data, or monetary data and NULL for other data types.

**NUMERIC_PRECISION_RADIX**: the data precision radix of the column currently iterated upon. This is a Flow variable, and it returns a numeric string for approximate numeric data, exact numeric data, integer data, or monetary data and NULL for other data types.

**NUMERIC_SCALE**: the scale in digits allowed in the column currently iterated upon. This is a Flow variable, and it returns a numeric string for approximate numeric data, exact numeric data, integer data, or monetary data and NULL for other data types.

**DATETIME_PRECISION**: the datetime precision in fractional seconds of the column currently iterated upon. This is a Flow variable, and it returns a numeric string if the data type is datetime or smalldatetime; otherwise, it returns NULL.

**COLUMN_KEY**: the key indicator of the column currently iterated upon. This is a Flow variable and it returns a string if the column is set to Key; otherwise it returns nothing.

**NB_COLUMN**: the number of columns iterated upon so far. This is an After variable and it returns an integer.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

| Usage rule | This component is to be used along with MSSql components, especially with tMSSqlConnection. |
## Dynamic settings

Click the [+](https://example.com) button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

### Related scenario

For **tMSSqlColumnList** related scenario, see Scenario: Iterating on a DB table and listing its column names on page 2470.
**tMSSqlCommit**

Commits in one go, using a unique connection, a global transaction instead of doing that on every row or every batch and thus provides gain in performance.

*tMSSqlCommit* validates the data processed through the job into the connected DB.

**tMSSqlCommit Standard properties**

These properties are used to configure *tMSSqlCommit* running in the Standard Job framework. The component in this framework is generally available.

**Note:**
This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the <em>tMSSqlConnection</em> component in the list if more than one connection are planned for the current Job.</td>
</tr>
<tr>
<td>Close connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task. <strong>Warning:</strong> If you want to use a <em>Row &gt; Main</em> connection to link <em>tMSSqlCommit</em> to your Job, your data will be committed row by row. In this case, do not select the <em>Close connection</em> check box or your connection will be closed before the end of your first row commit.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the job processing metadata at a job level as well as at each component level. |
### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>This component is more commonly used with other tMSSql* components, especially with the tMSSqlConnection and tMSSqlRollback components.</td>

<td></td>
</tr>
</tbody>
</table>

### Related scenarios

For a tMSSqlCommit related scenario, see Scenario: Inserting data in mother/daughter tables on page 2476.
tMSSqlConnection

Opens a connection to the specified database that can then be reused in the subsequent subjob or subjobs.

tMSSqlConnection opens a connection to a Microsoft SQL Server database or a Microsoft Azure SQL database.

**tMSSqlConnection Standard properties**

These properties are used to configure tMSSqlConnection running in the Standard Job framework.

The Standard tMSSqlConnection component belongs to the Databases and the ELT families.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>

<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><strong>JDBC Provider</strong></td>
<td>Select the provider of the JDBC driver to be used, either <strong>Microsoft</strong> (recommended) or <strong>Open source JTDS</strong>.</td>
</tr>
<tr>
<td></td>
<td>When using this component with Datasource in Talend Runtime, you need to use the <strong>Open source JTDS</strong> driver.</td>
</tr>
<tr>
<td></td>
<td>Note that when <strong>Microsoft</strong> is selected, you need to download the Microsoft JDBC Driver for SQL Server on Microsoft Download Center, unpack the downloaded zip file, choose a jar in the unzipped folder based on your JRE version, rename the jar to mssql-jdbc.jar and install it manually. For more information about choosing the jar, see the System Requirements information on Microsoft Download Center.</td>
</tr>
<tr>
<td><strong>Host</strong></td>
<td>Database server IP address.</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>Schema name.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database.</td>
</tr>
<tr>
<td>----------</td>
<td>-----------------------</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Additional JDBC parameters</strong></td>
<td>Specify additional connection properties for the database connection you are creating. The properties are separated by semicolon and each property is a key-value pair. For example, <code>encrypt=true;trustServerCertificate=false;hostNameInCertificate=*.database.windows.net;loginTimeout=30;</code> for Azure SQL database connection.</td>
</tr>
<tr>
<td><strong>Use or register a shared DB Connection</strong></td>
<td>Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the <strong>Shared DB Connection Name</strong> field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child. This option is incompatible with the <strong>Use dynamic job</strong> and <strong>Use an independent process to run sub job</strong> options of the tRunJob component. Using a shared connection together with a tRunJob component with either of these two options enabled will cause your Job to fail. This check box is not available when the <strong>Specify a data source alias</strong> check box is selected.</td>
</tr>
<tr>
<td><strong>Specify a data source alias</strong></td>
<td>Select this check box and specify the alias of a data source created on the Talend Runtime side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in Talend Runtime. For a related use case, see Scenario: Deploying your Job on Talend Runtime to retrieve data from a MySQL database on page 2503. This check box is not visible when the <strong>Use or register a shared DB Connection</strong> check box is selected.</td>
</tr>
<tr>
<td><strong>Data source alias</strong></td>
<td>Enter the alias of the data source created on the Talend Runtime side. This field is available only when the <strong>Specify a data source alias</strong> check box is selected.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| **Auto Commit** | Select this check box to commit any changes to the database automatically upon the transaction. With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. |
By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component.

Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component.

**tStatCatcher Statistics**

Select this check box to gather the job processing metadata at a Job level as well as at each component level.

**Usage**

**Usage rule**

This component is more commonly used with other tMSSql* components, especially with the tMSSqlCommit and tMSSqlRollback components.

**Limitation**

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

**Scenario: Inserting data into a database table and extracting useful information from it**

The scenario describes a Job that reads the employee data from a text file, inserts the data into a table of an MSSQL database, then extracts useful data from the table, and displays the information on the console.
This scenario involves the following components:

- **tMSSqlConnection**: establishes a connection to the MSSQL server.
- **tFileInputDelimited**: reads the input file, defines the data structure and sends it to the next component.
- **tMSSqlOutput**: writes data it receives from the preceding component into a table of an MSSQL database.
- **tMSSqlInput**: extracts data from the table based on an SQL query.
- **tLogRow**: displays the information it receives from the preceding component on the console.
- **tMSSqlCommit**: commits the transaction in the connected MSSQL server.

**Setting up the Job**

**Procedure**

1. Drop the following components from the Palette onto the design workspace: **tMSSqlConnection**, **tFileInputDelimited**, **tMSSqlOutput**, **tMSSqlInput**, **tLogRow**, and **tMSSqlCommit**.
2. Connect **tMSSqlConnection** to **tFileInputDelimited** using a Trigger > OnSubjobOk link.
3. Do the same to connect **tFileInputDelimited** to **tMSSqlInput** and **tMSSqlCommit**.
4. Connect **tFileInputDelimited** to **tMSSqlOutput** using a Row > Main link.
5. Do the same to connect **tMSSqlInput** to **tLogRow**.
Configuring the components

Opening a connection to the MSSQL server

Procedure

1. Double-click the tMSSqlConnection component to open its Basic settings view in the Component tab.

   ![tMSSqlConnection](image)

   - **Host** field: Type in the IP address or hostname of the MSSQL server, 192.168.30.47 in this example.
   - **Port** field: Type in the port number of the database server, 1433 in this example.
   - **Schema** field: Type in the schema name, dbo in this example.
   - **Database** field: Type in the database name, talend in this example.
   - **Username** and **Password** fields: Enter the credentials for the MSSQL connection.

2. In the **Host** field, type in the IP address or hostname of the MSSQL server, 192.168.30.47 in this example.
3. In the **Port** field, type in the port number of the database server, 1433 in this example.
4. In the **Schema** field, type in the schema name, dbo in this example.
5. In the **Database** field, type in the database name, talend in this example.
6. In the **Username** and **Password** fields, enter the credentials for the MSSQL connection.

Reading the input data

Procedure

1. Double-click the tFileInputDelimited component to open its Component view.

   ![tFileInputDelimited](image)

   - **File Name/Stream** field: Click the [...] button next to the File Name/Stream field to browse to the input file. In this example, it is D:/Input/Employee_Wage.txt. This text file holds three columns: id, name and wage. id;name;wage 51;Harry;2300 40;Ronald;3796 17;Theodore;2174 21;James;1986
3. In the **Header** field, type in 1 to skip the first row of the input file.

4. Click **Edit schema** to define the data to pass on to the `tMSSqlOutput` component. In this example, we define `id` as the key, and specify the length and precision for each column respectively.

Click **OK** to close the schema editor. A dialog box opens, and you can choose to propagate the schema to the next component.

Related topic: `tFileInputDelimited` on page 1010.

**Writing the data into the database table**

**Procedure**

1. Double-click the `tMSSqlOutput` component to open its **Basic settings** view in the **Component** tab.

2. Type in required information for the connection or use the existing connection you have configured before. In this example, we select the **Use an existing connection** check box. If multiple connections are available, select the connection you want to use from the **Component List** drop-down list.

3. In the **Table** field, type in the name of the table you want to write the data to: `Wage_Info` in this example. You can also click the `[...]` button next to the **Table** field to open a dialog box and select a proper table.

4. Select **Create table if not exists** from the **Action on table** drop-down list.

5. Select **Insert if not exists** from the **Action on data** drop-down list.

6. Click **Sync columns** to retrieve the schema from the preceding component.
Extracting useful information from the table

Procedure

1. Double-click the **tMSSqlInput** component to open its **Basic settings** view in the **Component** tab.

![tMSSqlInput component with Basic settings](image)

2. Select the **Use an existing connection** check box. If multiple connections are available, select the connection you want to use from the **Component List** drop-down list.

3. Click **Edit schema** to define the data structure to be read from the table. In this example, we need to read all three columns from the table.

![Schema of tMSSqlInput component](image)

4. In the **Table Name** field, type in the name of the table you want to read the data from: *Wage_Info* in this example.

5. In the **Query** field, fill in the SQL query to be executed on the table specified. To obtain the data of employees whose wages are above the average value and order them by id, enter the SQL query as

```sql
SELECT * 
FROM Wage_Info 
WHERE wage > (SELECT avg(wage) FROM Wage_Info) 
ORDER BY id
```
follows:

```
SELECT * FROM Wage_Info WHERE wage > (SELECT avg(wage) FROM Wage_Info) ORDER BY id
```

**Displaying information on the console**

**Procedure**

1. Double-click the `tLogRow` component to open its **Basic settings** view.
2. In the **Mode** area, select **Table (print values in cells of a table)**.

**Committing the transaction and closing the connection**

**Procedure**

1. Double-click the `tMSSqlCommit` component to open its **Basic settings** view.
   - 2. Select the **Close Connection** check box.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl+S** to save your Job.
2. Execute the Job by pressing **F6** or clicking **Run** on the **Run** tab.

The information of employees whose wages are above the average value ordered by id is displayed on the console.
tMSSqlInput

Executes a DB query with a strictly defined order which must correspond to the schema definition.

tMSSqlInput reads data and extracts fields based on a query from a Microsoft SQL Server database or a Microsoft Azure SQL database. Then it passes on the field list to the next component via a Main row link.

**tMSSqlInput Standard properties**

These properties are used to configure tMSSqlInput running in the Standard Job framework.

The Standard tMSSqlInput component belongs to the Databases family.

The component in this framework is generally available.

<i>Note:</i>

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
<tr>
<td><strong>Property type</strong></td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><strong>JDBC Provider</strong></td>
<td>Select the provider of the JDBC driver to be used, either Microsoft (recommended) or Open source JTDS.</td>
</tr>
<tr>
<td></td>
<td>When using this component with Datasource in Talend Runtime, you need to use the Open source JTDS driver.</td>
</tr>
<tr>
<td></td>
<td>Note that when Microsoft is selected, you need to download the Microsoft JDBC Driver for SQL Server on Microsoft Download Center, unpack the downloaded zip file, choose a jar in the unzipped folder based on your JRE version, rename the jar to mssql-jdbc.jar and install it manually. For more information about choosing the jar,</td>
</tr>
</tbody>
</table>
Use an existing connection

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

Note:

When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.

2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>Host</th>
<th>Database server IP address.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database.</td>
</tr>
<tr>
<td>Schema</td>
<td>Name of the schema.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
</tbody>
</table>

- **Built-In**: You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available.
- **View schema**: choose this option to view the schema only.

- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.

- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.

**Query type and Query**

Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.

**Specify a data source alias**

Select this check box and specify the alias of a data source created on the *Talend Runtime* side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in *Talend Runtime*. For a related use case, see Scenario: Deploying your Job on Talend Runtime to retrieve data from a MySQL database on page 2503.

This check box is not available when the **Use an existing connection** check box is selected.

**Data source alias**

Enter the alias of the data source created on the *Talend Runtime* side.

This field is available only when the **Specify a data source alias** check box is selected.

**Advanced settings**

**Additional JDBC parameters**

Specify additional connection properties for the database connection you are creating. The properties are separated by semicolon and each property is a key-value pair. For example, `encrypt=true;trustServerCertificate=false;hostNameInCertificate=*.database.windows.net;loginTimeout=30;` for Azure SQL database connection.

This field is not available if the **Use an existing connection** check box is selected.

**Trim all the String/Char columns**

Select this check box to remove leading and trailing whitespace from all the String/Char columns.

**Trim column**

Remove leading and trailing whitespace from defined columns.

**tStat Catcher Statistics**

Select this check box to collect log data at the component level.
### Global Variables

<table>
<thead>

Related scenarios

For related topics, see:

- tMSSqlConnection on page 2406

For related topic in tContextLoad, see Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489.
**tMSSqlLastInsertId**

Retrieves the last primary keys added by a user to a MSSql table.

`tMSSqlLastInsertId` displays the last IDs added to a table from a MSSql specified connection.

### tMSSqlLastInsertId Standard properties

These properties are used to configure `tMSSqlLastInsertId` running in the Standard Job framework.

The Standard `tMSSqlLastInsertId` component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see [Dynamic database components](#) on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Schema</strong> and <strong>Edit Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <code>line</code> when naming the fields.</td>
</tr>
<tr>
<td><strong>Built-In:</strong></td>
<td>You create and store the schema locally for this component only. Related topic: see <a href="#">Talend Studio User Guide</a>.</td>
</tr>
<tr>
<td><strong>Repository:</strong></td>
<td>You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see <a href="#">Talend Studio User Guide</a>.</td>
</tr>
</tbody>
</table>

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema:** choose this option to view the schema only.
- **Change to built-in property:** choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection:** choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.
<table>
<thead>

**Related scenario**

For a related scenario, see *Scenario: Get the ID for the last inserted record with tMysqlLastInsertId* on page 2510
tMSSqlOutput

Executes the action defined on the table and/or on the data contained in the table, based on the flow incoming from the preceding component in the Job.

tMSSqlOutput writes, updates, makes changes or suppresses entries in a Microsoft SQL Server database or a Microsoft Azure SQL database.

**tMSSqlOutput Standard properties**

These properties are used to configure tMSSqlOutput running in the Standard Job framework.

The Standard tMSSqlOutput component belongs to the Databases family.

The component in this framework is generally available.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>

<td>For more information about setting up and storing database connection parameters, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

| Use an existing connection | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. |
| | Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to: |
| | 1. In the parent level, register the database connection to be shared in the Basic |
settings view of the connection component which creates that very database connection.

2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

| JDBC Provider | Select the provider of the JDBC driver to be used, either **Microsoft** (recommended) or **Open source JTDS**.  
When using this component with Datasource in Talend Runtime, you need to use the **Open source JTDS** driver.  
Note that when **Microsoft** is selected, you need to download the Microsoft JDBC Driver for SQL Server on [Microsoft Download Center](https://www.microsoft.com/download), unpack the downloaded zip file, choose a jar in the unzipped folder based on your JRE version, rename the jar to `mssql-jdbc.jar` and install it manually. For more information about choosing the jar, see the System Requirements information on [Microsoft Download Center](https://www.microsoft.com/download). |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>Database server IP address.</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Schema</td>
<td>Name of the schema.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database.</td>
</tr>
</tbody>
</table>
| Username and Password | DB user authentication data.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings. |
| Table | Name of the table to be written. Note that only one table can be written at a time. |
| Action on table | On the table defined, you can perform one of the following operations:  
**Default**: No operation is carried out.  
**Drop and create table**: The table is removed and created again.  
**Create table**: The table does not exist and gets created.  
**Create table if not exists**: The table is created if it does not exist.  
**Drop table if exists and create**: The table is removed if it already exists and created again.  
**Clear table**: The table content is deleted.  
**Truncate table**: The table content is deleted. You do not have the possibility to rollback the operation. |
<table>
<thead>
<tr>
<th>Turn on identity insert</th>
<th>Select this check box to use your own sequence for the identity value of the inserted records (instead of having the SQL Server pick the next sequential value).</th>
</tr>
</thead>
</table>
| Action on data | On the data of the table defined, you can perform:  
- **Insert**: Add new entries to the table. If duplicates are found, job stops.  
- **Single Insert Query**: Add entries to the table in a batch  
- **Update**: Make changes to existing entries  
- **Insert or update**: Insert a new record. If the record with the given reference already exists, an update would be made.  
- **Update or insert**: Update the record with the given reference. If the record does not exist, a new record would be inserted.  
- **Delete**: Remove entries corresponding to the input flow.  
- **Insert if not exist**: Add new entries to the table if they do not exist.  

**Warning:**  
It is necessary to specify at least one column as a primary key on which the **Update** and **Delete** operations are based. You can do that by clicking **Edit Schema** and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the **Advanced settings** view where you can simultaneously define primary keys for the **Update** and **Delete** operations. To do that: Select the **Use field options** check box and then in the **Key in update column**, select the check boxes next to the column names you want to use as a base for the Update operation. Do the same in the **Key in delete column** for the Delete operation. |
| Specify identity field | Select this check box to specify the identity field, which is made up of an automatically incrementing identification number.  
When this check box is selected, three other fields are displayed:  
- **Identity field**: select the column you want to define as the identity field from the list.  
- **Start value**: type in a start value, used for the very first row loaded into the table.  
- **Step**: type in an incremental value, added to the value of the previous row that was loaded.  

This check box is available only when you select **Drop and create table**, **Create table**, **Create table if not exists**, or **Drop table if exists and create** from the **Action on table** list, and will disappear if you select the **Enable parallel execution** check box in the **Advanced settings** view. If you select this check box with the **Turn on identity insert** check box cleared and the **Create table if
The `not exists` option selected from the **Action on table** list and if the specified table does not exist, only a table will be created without inserting data into it.

### Note:
You can also specify the identity field from the schema of the component. To do so, set the **DB Type** of the relevant column to **INT IDENTITY**.

### Note:
When the **Specify identity field** check box is selected, the **INT IDENTITY DB Type** in the schema is ignored.

#### Schema and Edit schema
A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word *line* when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.

#### Built-In
You create and store the schema locally for this component only. Related topic: see [Talend Studio User Guide](https://help.talend.com).

#### Repository
You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see [Talend Studio User Guide](https://help.talend.com).

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in [Talend Help Center](https://help.talend.com).

#### Specify a data source alias
Select this check box and specify the alias of a data source created on the **Talend Runtime** side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in **Talend Runtime**. For a related use case, see [Scenario: Deploying your Job on Talend](https://help.talend.com).
### Advanced settings

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Data source alias</strong></td>
<td>Enter the alias of the data source created on the Talend Runtime side. This field is available only when the Specify a data source alias check box is selected.</td>
</tr>
<tr>
<td><strong>Die on error</strong></td>
<td>This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a Row &gt; Rejects link.</td>
</tr>
<tr>
<td><strong>Additional JDBC parameters</strong></td>
<td>Specify additional connection properties for the database connection you are creating. The properties are separated by semicolon and each property is a key-value pair. For example, <code>encrypt=true;trustServerCertificate=false;hostNameInCertificate=*.database.windows.net;loginTimeout=30;</code> for Azure SQL database connection. This field is not available if the Use an existing connection check box is selected.</td>
</tr>
<tr>
<td><strong>Commit every</strong></td>
<td>Enter the number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and, above all, better performance at execution.</td>
</tr>
<tr>
<td><strong>Additional Columns</strong></td>
<td>This option is not offered if you create (with or without drop) the DB table. This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing.</td>
</tr>

</tr>
<tr>
<td></td>
<td><strong>NB_LINE_UPDATED</strong>: the number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td><strong>NB_LINE_INSERTED</strong>: the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td><strong>NB_LINE_DELETED</strong>: the number of rows deleted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td><strong>NB_LINE_REJECTED</strong>: the number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td><strong>QUERY</strong>: the query statement processed. This is an After variable and it returns a string.</td>
</tr>
<tr>
<td></td>
<td><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions</td>
</tr>
</tbody>
</table>
only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide.*

---

**Usage**

**Usage rule**

This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible.

This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in a MSSql database. It also allows you to create a reject flow using a **Row > Rejects** link to filter data in error. For an example of the use of `tMysqlOutput` in use, see *Scenario: Retrieving data in error with a Reject link* on page 2529.

**Dynamic settings**

Click the `[*]` button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see *Scenario: Reading data from databases through context-based dynamic connections* on page 2497 and *Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters* on page 489. For more information on **Dynamic settings** and context variables, see *Talend Studio User Guide.*

**Limitation**

When the **Single Insert Query** option is selected in the **Action on data** list, an SQL Prepared Statement is generated, for example, `INSERT INTO table (col1, col2, col3) VALUES (?,?,?) , (?,?,?) , (?,?,?) , (?,?,?)`. Within brackets are the groups of parameters the number of which cannot exceed 2000, generally, depending on the JDBC driver. Therefore, the batch size should be set so that this limit is respected.
Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

**Related scenarios**

For **tMSSqlOutput** related topics, see:

- **tMSSqlConnection** on page 2406.
- **Scenario: Inserting a column and altering data using tMysqlOutput** on page 2521.
**tMSSqlOutputBulk**

 Prepares the file to be used as parameter in the INSERT query to feed the MSSql database.

 The tMSSqlOutputBulk and tMSSqlBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tMSSqlOutputBulkExec component, detailed in a separate section. The advantage of using a two step process is that the data can be transformed before it is loaded in the database.

 tMSSqlOutputBulk writes a file with columns based on the defined delimiter and the MSSql standards.

**tMSSqlOutputBulk Standard properties**

 These properties are used to configure tMSSqlOutputBulk running in the Standard Job framework. The Standard tMSSqlOutputBulk component belongs to the Databases family.

 The component in this framework is generally available.

 _Note:_

 This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

 For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>

<td></td>
</tr>
<tr>
<td>This file is generated on the local machine or a shared folder on the LAN.</td>
<td></td>
</tr>
<tr>
<td>Append</td>
<td>Select this check box to add the new rows at the end of the records.</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <strong>line</strong> when naming the fields.</td>
</tr>
</tbody>
</table>
Built-In: You create and store the schema locally for this component only. Related topic: see *Talend Studio User Guide*.

Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see *Talend Studio User Guide*.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.

### Advanced settings

<table>
<thead>
<tr>
<th>Row separator</th>
<th>String (ex: &quot;\n&quot; on Unix) to distinguish rows.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Field separator</td>
<td>Character, string or regular expression to separate fields.</td>
</tr>
<tr>
<td>Include header</td>
<td>Select this check to include the column header.</td>
</tr>
<tr>
<td>Encoding</td>
<td>Select the encoding from the list or select <strong>Custom</strong> and define it manually. This field is compulsory for DB data handling.</td>
</tr>
<tr>
<td>tStaCatcher statistics</td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

### Global Variables

**Global Variables**

- **NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions
only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is to be used along with <em>tMSSqlBulkExec</em> component. Used together they offer gains in performance while feeding a MSSql database.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component family</td>
<td>Databases/MS SQL Server</td>
</tr>
</tbody>
</table>

## Related scenarios

For use cases in relation with *tMSSqlOutputBulk*, see the following scenarios:

- **Scenario: Inserting transformed data in MySQL database** on page 2537.
- **Scenario: Inserting data in bulk in MySQL database** on page 2544.
tMSSqlOutputBulkExec

Gains in performance during Insert operations to a Microsoft SQL Server database.

The tMSSqlOutputBulk and tMSSqlBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tMSSqlOutputBulkExec component.

**tMSSqlOutputBulkExec Standard properties**

These properties are used to configure tMSSqlOutputBulkExec running in the Standard Job framework. The Standard tMSSqlOutputBulkExec component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see [Dynamic database components on page 598](#).

**Basic settings**

<table>
<thead>
<tr>

<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Action</td>
<td>Select the action to be carried out</td>
</tr>
<tr>
<td></td>
<td>Bulk insert  Bulk update</td>
</tr>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository .</td>
</tr>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

**Note:**

When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection. For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

| **JDBC Provider** | Select the provider of the JDBC driver to be used, either **Microsoft** (recommended) or **Open source JTDS**. When using this component with Datasource in Talend Runtime, you need to use the **Open source JTDS** driver. Note that when **Microsoft** is selected, you need to download the Microsoft JDBC Driver for SQL Server on Microsoft Download Center, unpack the downloaded zip file, choose a jar in the unzipped folder based on your JRE version, rename the jar to *mssql-jdbc.jar* and install it manually. For more information about choosing the jar, see the System Requirements information on Microsoft Download Center. |
| **Host** | Database server IP address. Currently, only *localhost, 127.0.0.1* or the exact IP address of the local machine is allowed for proper functioning. In other words, the database server must be installed on the same machine where the Studio is installed or where the Job using *tMSSqlOutputBulkExec* is deployed. |
| **Port** | Listening port number of DB server. |
| **DB name** | Name of the database |
| **Schema** | Name of the schema. |
| **Username** and **Password** | DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| **Table** | Name of the table to be written. Note that only one table can be written at a time and that the table must exist for the insert operation to succeed. |
| **Action on table** | On the table defined, you can perform one of the following operations: **None**: No operation is carried out. **Drop and create a table**: The table is removed and created again. **Create a table**: The table does not exist and gets created. **Create a table if not exists**: The table is created if it does not exist. |
### Truncate table
The table content is deleted. You do not have the possibility to rollback the operation.

### Clear a table
The table content is deleted. You have the possibility to rollback the operation.

### Schema and Edit schema
A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

#### Built-In
You create and store the schema locally for this component only. Related topic: see [Talend Studio User Guide](https://help.talend.com).

#### Repository
You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see [Talend Studio User Guide](https://help.talend.com).

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content](https://help.talend.com) window.

### File Name
Name of the file to be generated and loaded.

**Warning:**
This file is generated on the machine specified by the URI in the **Host** field so it should be on the same machine as the database server.

### Append
Select this check box to add the new rows at the end of the records.

### Advanced settings

#### Additional JDBC parameters
Specify additional connection properties for the database connection you are creating. The properties
are separated by semicolon and each property is a key-value pair. For example, `encrypt=true;trustServerCertificate=false; hostNameInCertificate=*.database.windows.net;loginTimeout=30;` for Azure SQL database connection.

This field is not available if the **Use an existing connection** check box is selected.

<table>
<thead>
<tr>
<th>Field separator</th>
<th>Character, string or regular expression to separate fields.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Row separator</td>
<td>String (ex: <code>\n</code> on Unix) to distinguish rows.</td>
</tr>
<tr>
<td>First row</td>
<td>Type in the number of the row where the action should start.</td>
</tr>
<tr>
<td>Include header</td>
<td>Select this check box to include the column header.</td>
</tr>
<tr>
<td>Code page</td>
<td><strong>OEM</strong> code pages used to map a specific set of characters to numerical code point values.</td>
</tr>
<tr>
<td>Data file type</td>
<td>Select the type of data being handled.</td>
</tr>
<tr>
<td>Encoding</td>
<td>Select the encoding from the list or select Custom and define it manually. This field is compulsory for DB data handling.</td>
</tr>
<tr>
<td><strong>tStatCatcher statistics</strong></td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

### Usage

#### Usage rule

This component is mainly used when no particular transformation is required on the data to be loaded onto the database.

#### Dynamic settings

Click the `[+]` button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see **Scenario: Reading data from databases through context-based dynamic connections** on page 2497 and **Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters** on page 489.

For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.
**Limitation**

The database server must be installed on the same machine where the Studio is installed or where the Job using `tMSSqlOutputBulkExec` is deployed, so that the component functions properly.

---

**Related scenarios**

For use cases in relation with `tMSSqlOutputBulkExec`, see the following scenarios:

- **Scenario: Inserting transformed data in MySQL database** on page 2537
- **Scenario: Inserting data in bulk in MySQL database** on page 2544
tMSSqlRollback

Cancels the transaction commit in the MSSql database and thus avoids to commit part of a transaction involuntarily.

**tMSSqlRollback Standard properties**

These properties are used to configure tMSSqlRollback running in the Standard Job framework. The Standard tMSSqlRollback component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tMSSqlConnection component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is more commonly used with other tMSSql components, especially with the tMSSqlConnection and tMSSqlCommit components. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. |
Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenario

For tMSSqlRollback related scenario, see Scenario: Rollback from inserting data in mother/daughter tables on page 2480.
tMSSqlRow

Acts on the actual DB structure or on the data (although without handling data).

`tMSSqlRow` executes the SQL query stated onto the specified Microsoft SQL Server or Azure SQL database, depending on the nature of the query and the database. The row suffix means the component implements a flow in the job design although it doesn’t provide output.

The `SQLBuilder` tool helps you write easily your SQL statements.

**tMSSqlRow Standard properties**

These properties are used to configure `tMSSqlRow` running in the Standard Job framework.

The Standard `tMSSqlRow` component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

**Note:**

When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.

2. In the child level, use a dedicated connection component to read that registered database connection.
For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

**JDBC Provider**
Select the provider of the JDBC driver to be used, either Microsoft (recommended) or Open source JTDS.
When using this component with Datasource in Talend Runtime, you need to use the Open source JTDS driver.
Note that when Microsoft is selected, you need to download the Microsoft JDBC Driver for SQL Server on Microsoft Download Center, unpack the downloaded zip file, choose a jar in the unzipped folder based on your JRE version, rename the jar to mssql-jdbc.jar and install it manually. For more information about choosing the jar, see the System Requirements information on Microsoft Download Center.

<table>
<thead>
<tr>

</tr>
<tr>
<td><strong>Repository:</strong> You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.</td>
<td></td>
</tr>
<tr>
<td>Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:</td>
<td></td>
</tr>
<tr>
<td>• View schema: choose this option to view the schema only.</td>
<td></td>
</tr>
<tr>
<td>• Change to built-in property: choose this option to change the schema to Built-in for local changes.</td>
<td></td>
</tr>
<tr>
<td>• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate</td>
<td></td>
</tr>
</tbody>
</table>
the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.

<table>
<thead>
<tr>
<th>Table name</th>
<th>Name of the table to be used.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Turn on identity insert</td>
<td>Select this check box to use your own sequence for the identity value of the inserted records (instead of having the SQL Server pick the next sequential value).</td>
</tr>
<tr>
<td>Query type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td>Built-in</td>
<td>Fill in manually the query statement or build it graphically using SQLBuilder.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the relevant query stored in the Repository. The Query field gets accordingly filled in.</td>
</tr>
<tr>
<td>Guess Query</td>
<td>Click the <strong>Guess Query</strong> button to generate the query which corresponds to your table schema in the Query field.</td>
</tr>
<tr>
<td>Query</td>
<td>Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.</td>
</tr>
<tr>
<td>Specify a data source alias</td>
<td>Select this check box and specify the alias of a data source created on the <strong>Talend Runtime</strong> side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in <strong>Talend Runtime</strong>. For a related use case, see Scenario: Deploying your Job on Talend Runtime to retrieve data from a MySQL database on page 2503. This check box is not available when the <strong>Use an existing connection</strong> check box is selected.</td>
</tr>
<tr>
<td>Data source alias</td>
<td>Enter the alias of the data source created on the <strong>Talend Runtime</strong> side. This field is available only when the <strong>Specify a data source alias</strong> check box is selected.</td>
</tr>
<tr>
<td>Die on error</td>
<td>This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a <strong>Row &gt; Rejects</strong> link.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| Additional JDBC parameters | Specify additional connection properties for the database connection you are creating. The properties are separated by semicolon and each property is a key-value pair. For example, `encrypt=true;trustServerCertificate=false;hostNameInCertificate=*.database.windows.net;loginTimeout=30` for Azure SQL database connection. |
This field is not available if the **Use an existing connection** check box is selected.

| Propagate QUERY's recordset | Select this check box to insert the result of the query into a COLUMN of the current flow. Select this column from the **use column** list.  
| Note: | This option allows the component to have a different schema from that of the preceding component. Moreover, the column that holds the QUERY's recordset should be set to the type of **Object** and this component is usually followed by **tParseRecordSet**. |

| Use PreparedStatement | Select this check box if you want to query the database using a PreparedStatement. In the **Set PreparedStatement Parameter** table, define the parameters represented by "?" in the SQL instruction of the **Query** field in the **Basic Settings** tab.  
| Parameter Index: | Enter the parameter position in the SQL instruction.  
| Parameter Type: | Enter the parameter type.  
| Parameter Value: | Enter the parameter value.  
| Note: | This option is very useful if you need to execute the same query several times. Performance levels are increased |

| Commit every | Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions. |

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

### Global Variables

| Global Variables | **QUERY**: the query statement being processed. This is a Flow variable and it returns a string.  
| **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
| A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
| To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it. |

| Global Variables | **QUERY**: the query statement being processed. This is a Flow variable and it returns a string.  
| **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
| A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
| To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it. |
Usage

Usage rule
This component offers the flexibility of the DB query and covers all possible SQL queries.

Dynamic settings
Click the [+ ] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Limitation
Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

Related scenarios

For related topics, see:

- Scenario: Combining two flows for selective output on page 2558
- Procedure on page 625.
- Scenario: Removing and regenerating a MySQL table index on page 2552.
tMSSqlSCD

Tracks and reflects changes in a dedicated SCD table in a Microsoft SQL Server or Azure SQL database. tMSSqlSCD addresses Slowly Changing Dimension needs, reading regularly a source of data and logging the changes into a dedicated SCD table.

**tMSSqlSCD Standard properties**

These properties are used to configure tMSSqlSCD running in the Standard Job framework. The Standard tMSSqlSCD component belongs to the Business Intelligence and the Databases families. The component in this framework is generally available.

**Note:**
This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>

</tbody>
</table>
| **Schema and Edit schema** | **A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the **Repository** type, three options are available:**
| | • **View schema**: choose this option to view the schema only.
| | • **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
| | • **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window. |
| **Built-in:** | The schema is created and stored locally for this component only. Related topic: see *Talend Studio User Guide*. |
| **Repository:** | The schema already exists and is stored in the Repository, hence can be reused. Related topic: see *Talend Studio User Guide*. |

**SCD Editor**
The SCD editor helps to build and configure the data flow for slowly changing dimension outputs.
For more information, see *SCD management methodology* on page 2566.

**Use memory saving Mode**
Select this check box to maximize system performance.

**Source keys include Null**
Select this check box to allow the source key columns to have Null values.

**Warning:**
Special attention should be paid to the uniqueness of the source key(s) values when this option is selected.

**Die on error**
This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

**Advanced settings**

**Additional JDBC parameters**
Specify additional connection properties for the database connection you are creating. The properties are separated by semicolon and each property is a key-value pair. For example, `encrypt=true;trustServerCertificate=false;hostNameInCertificate=*.database.windows.net;loginTimeout=30;` for Azure SQL database connection.
This field is not available if the **Use an existing connection** check box is selected.

**End date time details**
Specify the time value of the SCD end date time setting in the format of `HH:mm:ss`. The default value for this field is `12:00:00`.
This field appears only when SCD Type 2 is used and **Fixed year value** is selected for creating the SCD end date.

**tStatCatcher Statistics**
Select this check box to collect log data at the component level.

**Debug mode**
Select this check box to display each step during processing entries in a database.

**Global Variables**

| **Global Variables** | **NB_LINE_UPDATED**: the number of rows updated. This is an After variable and it returns an integer. |
**NB_LINE_INSERTED**: the number of rows inserted. This is an After variable and it returns an integer.

**NB_LINE_REJECTED**: the number of rows rejected. This is an After variable and it returns an integer.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

---

**Usage**

**Usage rule**

This component is used as Output component. It requires an Input component and Row main link as input.

**Dynamic settings**

Click the **[+]** button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see *Scenario: Reading data from databases through context-based dynamic connections on page 2497* and *Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489*. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

**Limitation**

This component does not support using SCD type 0 together with other SCD types.

---

**Related scenario**

For related topics, see *tMysqlSCD on page 2563*. 
tMSSqlSP

Offers a convenient way to centralize multiple or complex queries in a database and calls them easily. tMSSqlSP calls the stored procedure in a Microsoft SQL Server or Azure SQL database.

**tMSSqlSP Standard properties**

These properties are used to configure tMSSqlSP running in the Standard Job framework.

The Standard tMSSqlSP component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td><strong>Property type</strong></td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>. <strong>Built-in</strong>: No property data stored centrally. <strong>Repository</strong>: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><strong>Use an existing connection</strong></td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined. <strong>Note:</strong> When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to: 1. In the parent level, register the database connection to be shared in the <strong>Basic settings</strong> view of the connection component which creates that very database connection. 2. In the child level, use a dedicated connection component to read that registered database connection. For an example about how to share a database connection across Job levels, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>
| **JDBC Provider** | Select the provider of the JDBC driver to be used, either **Microsoft** (recommended) or **Open source JTDS**.  
When using this component with Datasource in Talend Runtime, you need to use the **Open source JTDS** driver.  
Note that when **Microsoft** is selected, you need to download the Microsoft JDBC Driver for SQL Server on Microsoft Download Center, unpack the downloaded zip file, choose a jar in the unzipped folder based on your JRE version, rename the jar to *mssql-jdbc.jar* and install it manually. For more information about choosing the jar, see the System Requirements information on Microsoft Download Center. |
<table>
<thead>
<tr>
<th></th>
<th></th>

</thead>
<tbody>
<tr>
<td><strong>Host</strong></td>
<td>Database server IP address</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database.</td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>Name of the schema.</td>
</tr>
</tbody>
</table>
| **Username and Password** | DB user authentication data.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| **Schema and Edit Schema** | In SP principle, the schema is an input parameter.  
A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. |
| **Built-In**: You create and store the schema locally for this component only. Related topic: see *Talend Studio User Guide*. | |
| **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see *Talend Studio User Guide*. | |
| Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
- **View schema**: choose this option to view the schema only.  
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** |
upon completion and choose this schema metadata again in the [Repository Content] window.

<table>
<thead>
<tr>
<th>SP Name</th>
<th>Type in the exact name of the Stored Procedure</th>

<tbody>
<tr>
<td>Is Function / Return result</td>
<td>Select this box, if only a value is to be returned. Select on the list the schema column, the value to be returned is based on.</td>
</tr>
<tr>
<td>Parameters</td>
<td>Click the Plus button and select the various <strong>Schema Columns</strong> that will be required by the procedures. Note that the SP schema can hold more columns than there are parameters used in the procedure. Select the <strong>Type</strong> of parameter: <strong>IN</strong>: Input parameter <strong>OUT</strong>: Output parameter/return value <strong>IN OUT</strong>: Input parameters is to be returned as value, likely after modification through the procedure (function). <strong>RECORDSET</strong>: Input parameters is to be returned as a set of values, rather than single value.</td>
</tr>
<tr>
<td>Specify a data source alias</td>
<td>Select this box and specify the alias of a data source created on the <strong>Talend Runtime</strong> side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in <strong>Talend Runtime</strong>. For a related use case, see Scenario: Deploying your Job on Talend Runtime to retrieve data from a MySQL database on page 2503. This check box is not available when the <strong>Use an existing connection</strong> check box is selected.</td>
</tr>
<tr>
<td>Data source alias</td>
<td>Enter the alias of the data source created on the <strong>Talend Runtime</strong> side. This field is available only when the <strong>Specify a data source alias</strong> check box is selected.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| Additional JDBC parameters | Specify additional connection properties for the database connection you are creating. The properties are separated by semicolon and each property is a key-value pair. For example, `encrypt=true;trustServerCertificate=false;hostNameInCertificate=*.database.windows.net;loginTimeout=30;` for Azure SQL database connection. |
| tMSSqlSP | This field is not available if the **Use an existing connection** check box is selected. |
| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

### Usage rule

This component is used as intermediary component. It can be used as start component but only input parameters are thus allowed.

### Dynamic settings

Click the `[+]` button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see [Scenario: Reading data from databases through context-based dynamic connections](#) on page 2497 and [Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters](#) on page 489. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

### Limitation

The Stored Procedures syntax should match the Database syntax.

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

---

**Scenario: Retrieving personal information using a stored procedure**

This scenario describes a Job that retrieves a personal information record from a specified table using a stored procedure according to the **id** value defined in the input flow.
In this scenario, the table to retrieve data from contains the personal information. To reproduce this scenario, you can write the data into the table from a CSV file like the following. For how to write data into a MS SQL table, see Scenario: Inserting data into a database table and extracting useful information from it on page 2408.

id;name;sex;age
1;Ford;Male;25
2;Rose;Female;30
3;Sabrina;Female;28
4;Teddy;Male;32
5;Kate;Male;35

In this scenario, the stored procedure used to retrieve the personal information is as follows:

```
CREATE PROCEDURE [dbo].[QueryPerson]
@id int,
@name varchar(50)
AS
BEGIN
SET NOCOUNT ON
SELECT * FROM dbo.person where id=@id
END
```

### Dropping and linking the components

**Procedure**

1. Create a new Job and add the following components by typing their names in the design workspace or dropping them from the Palette: a tFixedFlowInput component, a tMSSqlSP component, a tParseRecordSet component, and two tLogRow components.

2. Connect tFixedFlowInput to tMSSqlSP using a Row > Main link.

3. Do the same to connect tMSSqlSP to the first tLogRow, the first tLogRow to tParseRecordSet, and tParseRecordSet to the second tLogRow.

### Configuring the components

**Configuring the input component**

**Procedure**

1. Double-click tFixedFlowInput to open its Basic settings view.
2. Click the [...] button next to Edit schema to open the schema editor.

Click the [+] button to add two columns: id of the integer type and name of the string type. Click OK to close the schema editor.

3. In the Mode area, fill each column with respective value. In this example, the id value is set to 4, and the name value is null since it is not used in the select SQL statement in the stored procedure.

Configuring the tMSSqlSP component

Procedure

1. Double-click tMSSqlSP to open its Basic settings view.
2. Fill in the **Host**, **Port**, **Schema**, **Database**, **Username**, and **Password** fields with your MS SQL Server connection details.

3. In the **SP Name** field, enter the name of the stored procedure to be used. In this example, it is `QueryPerson`.

4. Click the `[...]` button next to **Edit schema** to open the schema editor.

Click the button to copy all columns from the input schema to the output schema, and then click the `[+]` button in the right panel to add a new column `person` of the object type to hold the personal information to be retrieved from the database.

Click **OK** to close the schema editor and accept the propagation prompted by the pop-up dialog box.
5. In the **Parameters** area, click the `[+]` button to add three rows and select a schema column and its type for each row. In this example, the *id* and *name* columns are of type IN, and the *person* column is of type RECORD SET.

**Configuring the tParseRecordSet component**

**Procedure**

1. Double-click **tParseRecordSet** to open its **Basic settings** view.

   ![Image of tParseRecordSet component](image)

   - **Prev. Comp. Column list** drop-down list, select the column that holds the personal information to be parsed. In this example, it is *person*.

   - Click the `[...]` button next to **Edit schema** to open the schema editor.

   ![Image of schema editor](image)

   - Click the `[+]` button in the right panel to add four columns: *id* and *age* of the integer type, and *name* and *sex* of the string type.

   - Click **OK** to close the schema editor and accept the propagation prompted by the pop-up dialog box.

2. In the **Attribute table** area, fill in each **Value** column with the corresponding column name in the MS SQL Server table that holds the personal information.
Configuring the output components

Procedure

1. Double-click the first tLogRow to open its Basic settings view.

   ![tLogRow_1 settings](image)

   In the Mode area, select **Vertical (each row is a key/value list)** for a better display of the result.

2. Do the same to configure the second tLogRow.

Saving and executing the Job

Procedure

1. Press **Ctrl + S** to save the Job.

2. Press **F6** to run the Job.

```
Starting job tMSSqlSP_Demo at 16:16 29/09/2014.
[statistics] connecting to socket on port 3560
[statistics] connected

<table>
<thead>
<tr>
<th>key</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>4</td>
</tr>
<tr>
<td>name</td>
<td>null</td>
</tr>
<tr>
<td>person</td>
<td>net.sourceforge.jtde.jdbc.CachedResultSet$22e6b6b0</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>key</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>4</td>
</tr>
<tr>
<td>name</td>
<td>Teddy</td>
</tr>
<tr>
<td>sex</td>

<tr>
<td>age</td>
<td>32</td>
</tr>
</tbody>
</table>

[statistics] disconnected
Job tMSSqlSP_Demo ended at 16:16 29/09/2014. [exit code=0]
```

The personal information with the id of 4 in the MS SQL table is displayed in the lower table on the console. Note that the values of the **id** and **name** columns shown in the upper table are the input data.
Related scenarios

For related scenarios, see:

- **Scenario: Using tMysqlSP to find a State Label using a stored procedure** on page 2583.
- **Scenario: Checking number format using a stored procedure** on page 2809.
- **Executing a stored procedure using tMDMSP** on page 2190.

Check as well **Scenario: Inserting data in mother/daughter tables** on page 2476 to analyze a set of records from a database table or DB query and return single records.
**tMSSqlTableList**

Lists the names of a given set of MSSql tables using a select statement based on a Where clause.

**tMSSqlTableList Standard properties**

These properties are used to configure tMSSqlTableList running in the Standard Job framework.

The Standard tMSSqlTableList component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>

</tr>
</tbody>
</table>

### Related scenario

For tMSSqlTableList related scenario, see Scenario: Iterating on a DB table and listing its column names on page 2470.
tMysqlBulkExec

Offers gains in performance while executing the Insert operations on a Mysql database.

The tMysqlOutputBulk and tMysqlBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT statement used to feed a database. These two steps are fused together in the tMysqlOutputBulkExec component, detailed in a separate section. The advantage of using two separate steps is that the data can be transformed before it is loaded in the database.

tMysqlBulkExec Standard properties

These properties are used to configure tMysqlBulkExec running in the Standard Job framework.

The Standard tMysqlBulkExec component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td>Built-in: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
<td></td>
</tr>
<tr>
<td>DB Version</td>
<td>Select the version of Mysql that you are using.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

**Note:**

When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection. For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>Host</th>
<th>Database server IP address</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database</td>
</tr>
</tbody>
</table>

**Username and Password**

DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

**Action on table**

On the table defined, you can perform one of the following operations:

- **None**: No operation is carried out.
- **Drop and create table**: The table is removed and created again.
- **Create table**: The table does not exist and gets created.
- **Create table if not exists**: The table is created if it does not exist.
- **Drop table if exists and create**: The table is removed if it already exists and created again.
- **Clear table**: The table content is deleted. You have the possibility to rollback the operation.
- **Truncate table**: The table content is deleted. You do not have the possibility to rollback the operation.

**Table**

Name of the table to be written. Note that only one table can be written at a time and that the table must exist for the insert operation to succeed.

**Local file Name**

Name of the file to be loaded. This file should be located on the same machine where the Studio is installed or where the Job using tMysqlBulkExec is deployed.

**Schema and Edit Schema**

A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either Built-in or stored remotely in the Repository.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
### Advanced settings

<table>
<thead>

<td><strong>Update records in table</strong>: Make changes to existing records.</td>
</tr>
<tr>
<td></td>
<td><strong>Replace records in table</strong>: Replace existing records with new ones. <strong>Ignore records in table</strong>: Ignore the existing records, or insert the new ones.</td>
</tr>
<tr>
<td><strong>Records contain NULL value</strong></td>
<td>Check this box if you want to retrieve the null values from the input data flow. If you do not check this box, the null values from the input data flow will be considered as empty fields in the output data flow.</td>
</tr>
</tbody>
</table>
Encoding

Select the encoding from the list or select Custom and define it manually. This field is compulsory for DB data handling.

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

Usage

Usage rule

This component is to be used along with tMysqlOutputBulk component. Used together, they can offer gains in performance while feeding a Mysql database.

Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

Related scenarios

For use cases in relation with tMysqlBulkExec, see the following scenarios:

- Scenario: Inserting transformed data in MySQL database on page 2537.
- Scenario: Inserting data in bulk in MySQL database on page 2544.
• Scenario: Truncating and inserting file data into an Oracle database on page 2752.
tMysqlClose

Closes the transaction committed in a Mysql database.

**tMysqlClose Standard properties**

These properties are used to configure tMysqlClose running in the Standard Job framework.

The Standard tMysqlClose component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>COLUMN_NAME: the name of the column currently iterated upon. This is a Flow variable and it returns a string.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>DATA_TYPE: the data type of the column currently iterated upon. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td></td>
<td>COLUMN_DEFAULT: the default value of the column currently iterated upon. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td></td>
<td>IS_NULLABLE: nullability of the column currently iterated upon. This is a Flow variable and it returns YES if the column allows NULL; otherwise, NO.</td>
</tr>
<tr>
<td></td>
<td>COLUMN_KEY: the key indicator of the column currently iterated upon. This is a Flow variable and it returns a string.</td>
</tr>
</tbody>
</table>
**tMysqlColumnList**

- **string if the column is set to Key; otherwise it returns nothing.**

**CHARACTER_MAXIMUM_LENGTH**: the maximum length in number of characters of the column currently iterated upon. This is a Flow variable, and it returns a numeric string for binary or character data types and NULL for other types.

**NUMERIC_PRECISION**: the data precision of the column currently iterated upon. This is a Flow variable, and it returns a numeric string for approximate numeric data, exact numeric data, integer data, or monetary data and NULL for other data types.

**NUMERIC_SCALE**: the scale in digits allowed in the column currently iterated upon. This is a Flow variable, and it returns a numeric string for approximate numeric data, exact numeric data, integer data, or monetary data and NULL for other data types.

**NB_COLUMN**: the number of columns iterated upon so far. This is an After variable and it returns an integer.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is to be used along with Mysql components, especially with tMysqlConnection.</th>
</tr>
</thead>
</table>

| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using... |
Scenario: Iterating on a DB table and listing its column names

The following Java scenario creates a five-component job that iterates on a given table name from a Mysql database using a Where clause and lists all column names present in the table.

- Drop the following components from the Palette onto the design workspace: tMysqlConnection, tMysqlTableList, tMysqlColumnList, tFixedFlowInput, and tLogRow.
- Connect tMysqlConnection to tMysqlTableList using an OnSubjobOk link.
- Connect tMysqlTableList, tMysqlColumnList, and tFixedFlowInput using Iterate links.
- Connect tFixedFlowInput to tLogRow using a Row Main link.

- In the design workspace, select tMysqlConnection and click the Component tab to define its basic settings.
- In the Basic settings view, set the database connection details manually or select them from the context variable list, through a Ctrl+Space click in the corresponding field if you have stored them locally as Metadata DB connection entries.

For more information about Metadata, see Talend Studio User Guide.

In this example, we want to connect to a Mysql database called customers.
• In the design workspace, select tMysqlTableList and click the Component tab to define its basic settings.

• On the Component list, select the relevant Mysql connection component if more than one connection is used.

• Enter a Where clause using the right syntax in the corresponding field to iterate on the table name(s) you want to list on the console.

  In this scenario, the table we want to iterate on is called customer.

• In the design workspace, select tMysqlColumnList and click the Component tab to define its basic settings.

• On the Component list, select the relevant Mysql connection component if more than one connection is used.

• In the Table name field, enter the name of the DB table you want to list its column names.

  In this scenario, we want to list the columns present in the DB table called customer.

• In the design workspace, select tFixedFlowInput and click the Component tab to define its basic settings.

• Set the Schema to Built-In and click the three-dot [...] button next to Edit Schema to define the data you want to use as input. In this scenario, the schema is made of two columns, the first for the table name and the second for the column name.
• Click **OK** to close the dialog box, and accept propagating the changes when prompted by the system. The defined columns display in the **Values** panel of the **Basic settings** view.

• Click in the **Value** cell for each of the two defined columns and press **Ctrl+Space** to access the global variable list.

• From the global variable list, select `((String)globalMap.get("tMysqlTableList_1_CURRENT_TABLE"))` and `((String)globalMap.get("tMysqlColumnList_1_COLUMN_NAME"))` for the **TableName** and **ColumnName** respectively.

• In the design workspace, select **tLogRow**.

• Click the **Component** tab and define the basic settings for **tLogRow** as needed.

• Save your job and press **F6** to execute it.

```
Starting job Column_Table_List at 00:55 17/11/2008
customer|id
customer|FirstName
customer|LastName
customer|Address
customer|id_State
Job Column_Table_List ended at 00:55 17/11/2008. [exit code=0]
```

The name of the DB table is displayed on the console along with all its column names.
tMysqlCommit

Commits in one go, using a unique connection, a global transaction instead of doing that on every row or every batch and thus provides gain in performance.

`tMysqlCommit` validates the data processed through the Job into the connected DB.

**tMysqlCommit Standard properties**

These properties are used to configure `tMysqlCommit` running in the Standard Job framework.

The Standard `tMysqlCommit` component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the <code>tMysqlConnection</code> component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Warning:**

*If you want to use a Row > Main connection to link `tMysqlCommit` to your Job, your data will be committed row by row. In this case, do not select the Close connection check box or your connection will be closed before the end of your first row commit.*

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Global Variables**

| Global Variables | `ERROR_MESSAGE`: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions |
only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

---

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is more commonly used with other tMysql* components, especially with the tMysqlConnecti on and tMysqlRollback components.</th>
</tr>
</thead>
</table>

| Dynamic settings | Click the [+ ] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide. |

---

### Related scenario

For tMysqlCommit related scenario, see Scenario: Inserting data in mother/daughter tables on page 2476.
**tMysqlConnection**

Opens a connection to the specified MySQL database for reuse in the subsequent subjob or subjobs.

**tMysqlConnection Standard properties**

These properties are used to configure tMysqlConnection running in the Standard Job framework.

The Standard tMysqlConnection component belongs to the Databases and the ELT families.

The component in this framework is generally available.

ℹ️ **Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td><strong>Property type</strong></td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the repository file in which the properties are stored.</td>
</tr>
<tr>
<td></td>
<td>The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><strong>Host</strong></td>
<td>Database server IP address.</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database.</td>
</tr>
<tr>
<td><strong>Additional JDBC parameters</strong></td>
<td>Specify additional connection properties for the DB connection you are creating.</td>
</tr>
<tr>
<td><strong>Username</strong> and <strong>Password</strong></td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td><strong>Use or register a shared DB Connection</strong></td>
<td>Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the <strong>Shared DB Connection Name</strong> field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child.</td>
</tr>
</tbody>
</table>
This option is incompatible with the **Use dynamic job** and **Use an independent process to run subjob** options of the `tRunJob` component. Using a shared connection together with a `tRunJob` component with either of these two options enabled will cause your Job to fail.

This check box is not available when the **Specify a data source alias** check box is selected.

### Specify a data source alias

Select this check box and specify the alias of a data source created on the **Talend Runtime** side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in **Talend Runtime**. For a related use case, see Scenario: Deploying your Job on Talend Runtime to retrieve data from a MySQL database on page 2503.

### Advanced settings

#### Auto Commit

Select this check box to commit any changes to the database automatically upon the transaction.

With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component.

Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component.

#### tStatCatcher Statistics

Select this check box to gather the job processing metadata at a Job level as well as at each component level.

### Usage

#### Usage rule

This component is more commonly used with other `tMysql*` components, especially with the `tMysqlCommit` and `tMysqlRollback` components.

### Scenario: Inserting data in mother/daughter tables

The following Job is dedicated to advanced database users, who want to carry out multiple table insertions using a parent table id to feed a child table.

As a prerequisite to this Job, follow the steps described below to create the relevant tables using an engine such as **innodb**:

---

**tMysqlConnection**

This option is incompatible with the **Use dynamic job** and **Use an independent process to run subjob** options of the `tRunJob` component. Using a shared connection together with a `tRunJob` component with either of these two options enabled will cause your Job to fail.

This check box is not available when the **Specify a data source alias** check box is selected.

**Specify a data source alias**

Select this check box and specify the alias of a data source created on the **Talend Runtime** side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in **Talend Runtime**. For a related use case, see Scenario: Deploying your Job on Talend Runtime to retrieve data from a MySQL database on page 2503.

### Advanced settings

#### Auto Commit

Select this check box to commit any changes to the database automatically upon the transaction.

With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component.

Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component.

#### tStatCatcher Statistics

Select this check box to gather the job processing metadata at a Job level as well as at each component level.

### Usage

#### Usage rule

This component is more commonly used with other `tMysql*` components, especially with the `tMysqlCommit` and `tMysqlRollback` components.

### Scenario: Inserting data in mother/daughter tables

The following Job is dedicated to advanced database users, who want to carry out multiple table insertions using a parent table id to feed a child table.

As a prerequisite to this Job, follow the steps described below to create the relevant tables using an engine such as **innodb**:

---

**tMysqlConnection**

This option is incompatible with the **Use dynamic job** and **Use an independent process to run subjob** options of the `tRunJob` component. Using a shared connection together with a `tRunJob` component with either of these two options enabled will cause your Job to fail.

This check box is not available when the **Specify a data source alias** check box is selected.

**Specify a data source alias**

Select this check box and specify the alias of a data source created on the **Talend Runtime** side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in **Talend Runtime**. For a related use case, see Scenario: Deploying your Job on Talend Runtime to retrieve data from a MySQL database on page 2503.

### Advanced settings

#### Auto Commit

Select this check box to commit any changes to the database automatically upon the transaction.

With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component.

Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component.

#### tStatCatcher Statistics

Select this check box to gather the job processing metadata at a Job level as well as at each component level.

### Usage

#### Usage rule

This component is more commonly used with other `tMysql*` components, especially with the `tMysqlCommit` and `tMysqlRollback` components.

### Scenario: Inserting data in mother/daughter tables

The following Job is dedicated to advanced database users, who want to carry out multiple table insertions using a parent table id to feed a child table.

As a prerequisite to this Job, follow the steps described below to create the relevant tables using an engine such as **innodb**:
1. In a command line editor, connect to your Mysql server.

2. Once connected to the relevant database, type in the following command to create the parent table:
   
   ```sql
   create table f1090_mum(id int not null auto_increment, name varchar(10), primary key(id)) engine=innodb;
   ```

3. Then create the second table:
   
   ```sql
   create table f1090_baby (id_baby int not null, years int) engine=innodb;
   ```

Back in *Talend Studio*, the Job requires seven components including *tMysqlConnection* and *tMysqlCommit*.

**Linking the components**

**Procedure**

1. Drag and drop the following components from the Palette: a *tFileList*, a *tFileInputDelimited*, a *tMap*, a *tMysqlConnection*, a *tMysqlCommit* and two *tMysqlOutput*.

2. Connect *tMysqlConnection* to *tFileList* using an *OnComponentOk* link.

3. Connect *tFileList* to *tMysqlCommit* using an *OnComponentOk* link.

4. Connect the *tFileList* component to the input file component using an *Iterate* link as the name of the file to be processed will be dynamically filled in from the *tFileList* directory using a global variable.

5. Connect the *tFileInputDelimited* component to the *tMap* and dispatch the flow between the two output Mysql DB components. Use a *Row* link for each for these connections representing the main data flow.

**Configuring the components**

**Procedure**

1. Set the *tFileList* component properties, such as the directory name where files will be fetched from.
2. In the **tMysqlConnection** Component view, set the connection details manually or fetch them from the Repository if you centrally stored them as a Metadata DB connection entry. For more information about Metadata, see *Talend Studio User Guide*.

3. On the **tFileInputDelimited** component’s **Basic settings** panel, press Ctrl+Space bar to access the variable list. Set the **File Name** field to the global variable: `tFileList_1.CURRENT_FILEPATH`

4. Set the rest of the fields as usual, defining the row and field separators according to your file structure.

5. Then set the schema manually through the **Edit schema** feature or select the schema from the Repository. In Java version, make sure the data type is correctly set, in accordance with the nature of the data processed.

6. In the **tMap** Output area, add two output tables, one called mum for the parent table, the second called baby, for the child table.
   - Drag the **Name** column from the **Input** area, and drop it to the mum table.
   - Drag the **Years** column from the **Input** area and drop it to the baby table.

7. Make sure the mum table is on the top of the baby table as the order is determining for the flow sequence hence the DB insert to perform correctly.
   - Connect the output row link to distribute correctly the flow to the relevant DB output component.

8. In each of the **tMysqlOutput** components’ **Basic settings** panel, select the **Use an existing connection** check box to retrieve the **tMysqlConnection** details.
9. Set the Table name making sure it corresponds to the correct table, in this example either f1090_mum or f1090_baby.

There is no action on the table as they are already created.

Select Insert as Action on data for both output components.

Click on Sync columns to retrieve the schema set in the tMap.

10. In the Additional columns area of the DB output component corresponding to the child table (f1090_baby), set the id_baby column so that it reuses the id from the parent table.

11. In the SQL expression field type in: "(Select Last_Insert_id())"

The position is Before and the Reference column is years.

In the Advanced settings panel, clear the Extend insert check box.

**Executing the Job**

**Procedure**

1. Press Ctrl + S to save your Job.
2. Press F6 to execute it.

The parent table id has been reused to feed the id_baby column.
Scenario: Rollback from inserting data in mother/daughter tables

About this task

Based on Scenario: Inserting data in mother/daughter tables on page 2476, insert a rollback function in order to prevent unwanted commit.

Procedure

1. Drag and drop tMysqlRollback to the design workspace. tMysqlRollback ensures that the transaction will not be partly committed.
2. Connect tFileList to tMysqlRollback with an OnSubjobError trigger.
3. Double-click tMysqlRollback to enter its Basic settings view.
4. From the Component List, select the connection component.

Scenario: Sharing a database connection between a parent Job and child Job

This scenario shows how a database connection is shared between a parent Job and a child Job. The parent Job first calls the child Job to write some randomly generated data to a MySQL database, and then reads the data from the MySQL database and displays it on the console. A connection to the MySQL database is set up only once and used in both Jobs.

Setting up the child Job

Adding and linking components

Procedure

1. Add the following components by typing the component names on the design workspace or dropping them from the Palette:
   - a tMysqlConnection component, to open a connection to the MySQL database,
   - a tRowGenerator, to generate random input data,
• a tMysqlOutput component, to write data to the MySQL database.

2. Connect the tRowGenerator component to the tMysqlOutput component using a Row > Main connection.

3. Connect the tMysqlConnection component to the tRowGenerator using a Trigger > OnSubjobOk connection.

Configuring the database connection

Procedure

1. Double-click the tMysqlConnection component to open its Basic settings view.

2. With the Property Type set to Built-In, specify the connection details in the relevant fields, including:
   • the host name or IP address of your database server
   • the listening port number
   • the database name
   • the user name and password for your database authentication.

   If you have stored your connection details under the Metadata node in the Repository tree view, you can simply drop your centralized metadata item onto the tMysqlConnection component. For
information on how to centralize a database connection, see the chapter on managing metadata of the *Talend Studio User Guide*.

3. Select the **Use or register a shared DB Connection** check box so that the database connection open by this component can be shared across different Jobs. Then, enter a name for the shared connection between double quotes in the **Shared DB Connection Name** field, *shared_mysql_connection* in this example.

### Configuring the input data

**Procedure**

1. Double-click the **tRowGenerator** component to open the Row Generator editor.

2. Click the [+ ] button to add four columns and set their properties:
   - **id**, type Integer, 2 characters long.
   - **firstName**, type String, 15 characters long
   - **lastName**, type String, 15 characters long
   - **city**, type String, 15 characters long

3. Define the function for each column:
   - For the **id** column, select **Numeric.sequence** from the **Function** list to generate sequence numbers.
   - For the **firstName** column, select **TalendDataGenerator.getFirstName** from the **Function** list to generate random first names.
   - For the **lastName** column, select **TalendDataGenerator.getLastName** from the **Function** list to generate random family names.
• For the city column, select `TalendDataGenerator.getUsCity` from the Function list to generate random city names.

4. In the Number of Rows for RowGenerator field, specify the number of data rows you want to generate, 10 in this example.

5. Click the Preview button on the Preview tab to validate the generator settings.

6. When done, click OK to close the editor and click Yes when prompted to propagate the schema to the next component.

Configuring the database output

Procedure

1. Double-click the tMysqlOutput component to open its Basic settings view.

   ![tMysqlOutput component settings](image)

   - Select the Use an existing connection check box and, in case you have more than one connection component in the Job, select the connection component to be used from the Component List dropdown list.
   - In the Table field, enter the name of the database table you are going to write data to, customers in this example.
   - From the Action on table list, select the Drop table if exists and create option to ensure a clean table is created.
   - From the Action on data list, select Insert.
   - Click the [...] button next to Edit schema to check the output schema. If needed, click Sync columns to retrieve the schema from the preceding component.
   - Press Ctrl+S to save the Job.

Setting up the parent Job

Arranging data flow for the parent Job

Procedure

1. Add the following components by typing the component names on the design workspace or dropping them from the Palette:
   - a tRunJob component, to call the child Job,
   - a tMysqlConnection component, to open the MySQL database connection,
   - a tMysqlInput component, to read the data written to the MySQL database by the child Job.
   - a tLogRow component to display the data on the console,
• a **tMysqlCommit** component to commit data upon transation and close the database connection.

2. Connect the **tRunJob** component to the **tMysqlConnection** component using a **Trigger > OnSubjobOk** connection.

3. Connect the **tMysqlConnection** component to the **tMysqlInput** component using a **Trigger > OnSubjobOk** connection.

4. Connect the **tMysqlInput** component to the **tLogRow** component using a **Row > Main** connection.

5. Connect the **tMysqlInput** component to the **tMysqlCommit** component using a **Trigger > OnSubjobOk** connection.

---

### Configuring the components

#### Procedure

1. Double-click the **tRunJob** component to open its **Basic settings** view.
   
   If a child Job has been already specified in the component, you can open its **Basic settings** view by right-clicking it and selecting **Settings** from the contextual menu, or by clicking the component and then selecting the **Component** tab.

   ![tRunJob component settings](image)

2. Click the [...] button next to the **Job** field and select the child Job from the [Repository Content] dialog box. Leave all the other parameters as default.
3. In the Basic settings view of the tMysqlConnection component, select the **Use or register a shared DB Connection** check box. Then, in the **Shared DB Connection Name** field, enter the name of the shared connection defined in the child Job, `shared_mysql_connection` in this example. Leave all the other parameters blank or as default.

![tMysqlConnection Component](image)

4. Double-click the tMysqlInput component to open its Basic settings view.

![tMysqlInput Component](image)

5. Select the **Use an existing connection** check box and, in case you have more than one connection component in the Job, select the connection component to be used from the **Component List** drop-down list.

6. Click the [...] button next to **Edit schema** to open the [Schema] editor, and define the same data structure as in the child Job.

![Schema Editor](image)
When done, click **OK** to close the dialog and click **Yes** when prompted to propagate the schema to the next component.

7. Specify the table name in the **Table Name** list, and click **Guess Query** to get the query statement automatically filled in the **Query** field.

8. In the **Basic settings** view of the **tLogRow** component, select the **Table** mode to display the execution result in table cells.

   Leave the settings of the **tMysqlCommit** component unchanged.

**Execute the Job**

**Procedure**

1. Press **Ctrl+S** to save the Job.
2. Press **F6** or click the **Run** button on the **Run** console to execute the Job.
The Job first calls the child Job to write data to the database and then reads the data from the database and displays it on the console.
tMysqlInput

Executes a DB query with a strictly defined order which must correspond to the schema definition. tMysqlInput reads a database and extracts fields based on a query. Then it passes on the field list to the next component via a Main row link.

tMysqlInput Standard properties

These properties are used to configure tMysqlInput running in the Standard Job framework. The Standard tMysqlInput component belongs to the Databases family. The component in this framework is generally available.

Note:
This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-In or Repository.</td>
</tr>
<tr>
<td>Built-In: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td>Repository: Select the repository file where the properties are stored.</td>
<td></td>
</tr>
</tbody>
</table>

Click this icon to open a database connection wizard and store the database connection parameters you set in the component Basic settings view.

For more information about setting up and storing database connection parameters, see Talend Studio User Guide.

| DB version | Select the version of the database to be used. |
| Use an existing connection | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. |

Note:
When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component.
which creates that very database connection.

2. In the child level, use a dedicated connection component to read that registered database connection. For an example about how to share a database connection across Job levels, see *Talend Studio User Guide.*

<table>
<thead>
<tr>
<th>Host</th>
<th>Database server IP address.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Schema and Edit Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td><strong>Built-In</strong>: You create and store the schema locally for this component only. Related topic: see <em>Talend Studio User Guide.</em></td>
<td><strong>Repository</strong>: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see <em>Talend Studio User Guide.</em></td>
</tr>
<tr>
<td>Click <strong>Edit schema</strong> to make changes to the schema. If the current schema is of the <strong>Repository</strong> type, three options are available:</td>
<td></td>
</tr>
<tr>
<td>• <strong>View schema</strong>: choose this option to view the schema only.</td>
<td></td>
</tr>
<tr>
<td>• <strong>Change to built-in property</strong>: choose this option to change the schema to <strong>Built-in</strong> for local changes.</td>
<td></td>
</tr>
<tr>
<td>• <strong>Update repository connection</strong>: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select <strong>No</strong> upon completion and choose this schema metadata again in the <strong>[Repository Content]</strong> window.</td>
<td></td>
</tr>
<tr>
<td><strong>Table Name</strong></td>
<td>Name of the table to be read.</td>
</tr>
<tr>
<td><strong>Query type and Query</strong></td>
<td>Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.</td>
</tr>
</tbody>
</table>
### Specify a data source alias

Select this check box and specify the alias of a data source created on the *Talend Runtime* side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in *Talend Runtime*. For a related use case, see Scenario: Deploying your Job on Talend Runtime to retrieve data from a MySQL database on page 2503.

**Warning:**

If you use the component’s own DB configuration, your data source connection will be closed at the end of the component. To prevent this from happening, use a shared DB connection with the data source alias specified.

This check box is not available when the *Use an existing connection* check box is selected.

### Advanced settings

<table>
<thead>
<tr>
<th><strong>Advanced settings</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Specify a data source alias</strong></td>
<td>Select this check box and specify the alias of a data source created on the <em>Talend Runtime</em> side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in <em>Talend Runtime</em>. For a related use case, see Scenario: Deploying your Job on Talend Runtime to retrieve data from a MySQL database on page 2503. <strong>Warning:</strong> If you use the component’s own DB configuration, your data source connection will be closed at the end of the component. </thead>
<tbody>
<tr>
<td></td>
<td>QUERY: the query statement being processed. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td></td>
<td>For further information about variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component covers all possible SQL queries for Mysql databases.</th>
</tr>
</thead>
</table>

#### Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.
Scenario: Writing columns from a MySQL database to an output file using tMysqlInput

In this scenario we will read certain columns from a MySQL database, and then write them to a table in a local output file.

Dragging and dropping components and linking them together

Procedure
1. Drop tMysqlInput and tFileOutputDelimited from the Palette onto the workspace.
2. Link tMysqlInput to tFileOutputDelimited using a Row > Main connection.

Configuring the components

Procedure
1. Double-click tMysqlInput to open its Basic Settings view in the Component tab.

2. From the Property Type list, select Repository if you have already stored the connection to database in the Metadata node of the Repository tree view. The property fields that follow are automatically filled in.

For more information about how to store a database connection, see Talend Studio User Guide.

If you have not defined the database connection locally in the Repository, fill in the details manually after selecting Built-in from the Property Type list.

3. Set the Schema as Built-in and click Edit schema to define the desired schema.

The schema editor opens:
4. Click the [+] button to add the rows that you will use to define the schema, four columns in this example: id, first_name, city and salary.
   Under Column, click in the fields to enter the corresponding column names.
   Click the field under Type to define the type of data.
   Click OK to close the schema editor.

5. Next to the Table Name field, click the [...] button to select the database table of interest.
   A dialog box displays a tree diagram of all the tables in the selected database:

6. Click the table of interest and then click OK to close the dialog box.

7. Set the Query Type as Built-In.

8. In the Query box, enter the query required to retrieve the desired columns from the table.

9. Double-click tFileOutputDelimited to set its Basic settings in the Component tab.
Next to the **File Name** field, click the [...] button to browse your directory to where you want to save the output file, then enter a name for the file.

Select the **Include Header** check box to retrieve the column names as well as the data.

**Save the Job.**

**Executing the Job**

The results below can be found after **F6** is pressed to run the Job.

<table>
<thead>
<tr>
<th></th>
<th>id;first_name;city;salary</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1;Martin;Sacramento;9011</td>
</tr>
<tr>
<td>2</td>
<td>2;Zachary;Atlanta;8118</td>
</tr>
<tr>
<td>3</td>
<td>3;James;Hartford;5087</td>
</tr>
<tr>
<td>4</td>
<td>4;Herbert;Charleston;9233</td>
</tr>
<tr>
<td>5</td>
<td>5;Herbert;Hartford;5289</td>
</tr>
<tr>
<td>6</td>
<td>6;Ulysses;Nashville;6269</td>
</tr>
</tbody>
</table>

As shown above, the output file is written with the desired column names and corresponding data, retrieved from the database:

**Note:**

The Job can also be run in the **Traces Debug** mode, which allows you to view the rows as they are being written to the output file, in the workspace.

**Scenario: Using context parameters when reading a table from a database**

In this scenario, MySQL is used for demonstration purposes. We will read a table from a MySQL database, using a context parameter to refer to the table name.

**Dragging and dropping components and linking them together**

**Procedure**

1. Drop **tMysqlInput** and **tLogRow** from the **Palette** onto the workspace.
2. Link **tMysqlInput** to **tLogRow** using a **Row > Main** connection.
Configuring the components

Procedure

1. Double-click tMysqlInput to open its Basic Settings view in the Component tab.

2. From the Property Type list, select Repository if you have already stored the connection to database in the Metadata node of the Repository tree view. The property fields that follow are automatically filled in.

   For more information about how to store a database connection, see Talend Studio User Guide.

   If you have not defined the database connection in the Repository, fill in the details manually after selecting Built-in from the Property Type list.

3. Set the Schema as Built-In and click Edit schema to define the desired schema.

   The schema editor opens:
4. Click the [+ ] button to add the rows that you will use to define the schema, seven columns in this example:  \textit{id, first\_name, last\_name, city, state, date\_of\_birth and salary}. 
Under Column, click the fields to enter the corresponding column names. 
Click the fields under Type to define the type of data. 
Click OK to close the schema editor.

5. Put the cursor in the Table Name field and press F5 for context parameter setting.

![Context Parameter](image)

For more information about context settings, see \textit{Talend Studio User Guide}.

6. Keep the default setting in the Name field and type in the name of the database table in the Default value field, employees in this case.

7. Click Finish to validate the setting. 
The context parameter context\_TABLE automatically appears in the Table Name field.

8. In the Query type list, select Built-In. Then, click Guess Query to get the query statement.
In this use case, we want to read the records with the salary above 8000. Therefore, we add a Where clause and the final query statement is as follows:

```
"SELECT  
"+context.TABLE+".`id`,  
"+context.TABLE+".`first\_name`,  
"+context.TABLE+".`last\_name`,  
"+context.TABLE+".`city`,  
"+context.TABLE+".`state`,  
"+context.TABLE+".`date\_of\_birth`,  
"+context.TABLE+".`salary`  
FROM "+context.TABLE+"  
WHERE  
"+context.TABLE+".`salary` > 8000"
```

9. Double-click tLogRow to set its Basic Settings in the Component tab.
10. In the **Mode** area, select **Table (print values in cells of a table)** for a better display of the results.

11. Save the Job.

**Executing the Job**

The results below can be found after **F6** is pressed to run the Job.

<table>
<thead>
<tr>
<th>id</th>
<th>first_name</th>
<th>last_name</th>
<th>city</th>
<th>state</th>
<th>date_of_birth</th>
<th>salary</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Martin</td>
<td>Roosevelt</td>
<td>Sacramento</td>
<td>ND</td>
<td>19-10-1950</td>
<td>9011</td>
</tr>
<tr>
<td>2</td>
<td>Zachary</td>
<td>Johnson</td>
<td>Atlanta</td>
<td>ND</td>
<td>14-11-1978</td>
<td>8118</td>
</tr>
<tr>
<td>4</td>
<td>Herbert</td>
<td>Harrison</td>
<td>Charleston</td>
<td>AE</td>
<td>15-08-1963</td>
<td>9233</td>
</tr>
</tbody>
</table>

As shown above, the records with the salary greater than 8000 are retrieved.

**Scenario: Reading data from databases through context-based dynamic connections**

In this scenario, MySQL is used for demonstration purposes. We will read data from database tables with the same data structure but in two different MySQL databases named **project_q1** and **project_q2** respectively. We will specify the connections to these databases dynamically at runtime, without making any modification to the Job.

**Dropping and linking the components**

**Procedure**

1. Drop two **tMysqlConnection**, a **tMysqlInput**, a **tLogRow**, and a **tMysqlClose** components onto the design workspace.

2. Link the first **tMysqlConnection** to the second **tMysqlConnection** and the second **tMysqlConnection** to **tMysqlInput** using **Trigger > On Subjob Ok** connections.

3. Link **tMysqlInput** to **tLogRow** using a **Row > Main** connection.

4. Link **tMysqlInput** to **tMysqlClose** using a **Trigger > On Subjob Ok** connection.
Creating a context variable

About this task

To be able to choose a database connection dynamically at runtime, we need to define a context variable, which will then be configure it in the Dynamic settings of the database input component.

Procedure

1. In the Contexts view, click the `[+]` button to add a row in the table, click in the Name field and enter a name for the variable, myConnection in this example.

2. From the Type list field, select List Of Value.
3. Click in the Value field and then click the button that appears in the field to open the [Configure value of list] dialog box.
4. In the [Configure value of list] dialog box, click the New... button to open the [New Value] dialog box, and enter the name of one of the connection components in the text field, tMysqlConnection_1 in this example. Then click OK to close the dialog box.

Repeat this step to specify the other connection component name as another list item, tMysqlConnection_2 in this example.

When done, click OK to close the [Configure Values] dialog box.

5. Select the check box next to the variable value field, and fill the Prompt field with the message you want to display at runtime, Select a connection component: in this example.
Configuring the components

Procedure

1. Double-click the first tMysqlConnection component to show its Basic settings view, and set the connection details. For more information on the configuration of tMysqlConnection, see tMysqlConnection on page 2475.

   Note that we use this component to open a connection to a MySQL database named project_q1.

2. Configure the second tMysqlConnection component in the same way, but fill the Database field with project_q2 because we want to use this component to open a connection to another MySQL database, project_q2.

3. Double-click the tMysqlInput component to show its Basic settings view.
4. Select the **Use an existing connection** check box, and leave the **Component List** box as it is.

5. Click the [...] button next to **Edit schema** to open the **[Schema]** dialog box and define the data structure of the database table to read data from.

![Schema of tMysqlInput_1](image)

In this example, the database table structure is made of four columns, *id* (type Integer, 2 characters long), *firstName* (type String, 15 characters long), *lastName* (type String, 15 characters long), and *city* (type String, 15 characters long). When done, click **OK** to close the dialog box and propagate the schema settings to the next component.

6. Fill the **Table** field with the database table name, *customers* in this example, and click **Guess Query** to generate the query statement corresponding to your table schema in the **Query** field.

7. In the **Dynamic settings** view, click the [+ ] button to add a row in the table, and fill the **Code** field with the code script of the context variable you just created, " + context.myConnection + " in this example.

![tMysqlInput_1](image)

8. In the **Basic settings** view of the **tLogRow** component, select the **Table** option for better display effect of the Job execution result.
9. In the **Dynamic settings** view of the **tMysqlClose** component, do exactly the same as in the **Dynamic settings** view of the **tMysqlInput** component.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl+S** to save your Job and press **F6** or click **Run** to launch it.

   A dialog box appears prompting you to specify the connection component you want to use.

2. Select the connection component, **tMysqlConnection_1**, and click **OK**.

   The data read from database *project_q1* is displayed in the **Run** console.
3. Press F6 or click Run to launch your Job again. When prompted, select the other connection component, **tMysqlConnection_2**, to read data from the other database, **project_q2**.

The data read from database **project_q2** is displayed in the Run console.

---

**Scenario: Deploying your Job on Talend Runtime to retrieve data from a MySQL database**

This scenario describes a two-component Job that retrieves data from a MySQL database table and displays the data on the console. The Job will be deployed in Talend Runtime and will use the data source created on Talend Runtime to connect to the database defined in a Runtime configuration file.

**Creating a MySQL data source in Talend Runtime Container**

To be able to retrieve data from a MySQL database table and displays the data on the console, you must have created a MySQL data source in Talend Runtime Container.

**Before you begin**

You must have properly installed Talend Runtime in the machine in which you want to execute your Job. For further information, search for installing Talend Runtime on Talend Help Center (https://help.talend.com).

**Procedure**

1. Install the MySQL JDBC driver by running the following `bundle:install` command in Talend Runtime Container:
2. Install the database connection pool by running the following `bundle:install` command in Talend Runtime Container:

```
karaf@trun()> bundle:install mvn:mysql/mysql-connector-java/5.1.18
```

3. Copy the data source configuration file `datasource-mysql.xml` under the folder `<TalendRuntimePath>/add-ons/datasources/dataservice` to the folder `<TalendRuntimePath>/container/deploy` and then in the file update the username and password property values required to connect to your database.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<blueprint xmlns="http://www.osgi.org/xmlns/blueprint/v1.0.0"
  default-activation="lazy">
  <bean id="mysqlDataSource" class="com.mysql.jdbc.jdbc2.optional.MysqlConnectionPoolDataSource">
    <property name="url" value="jdbc:mysql://localhost:3306/test"/>
    <property name="user" value="root"/>
    <property name="password" value="talend"/>
  </bean>

  <bean id="dataSource" class="org.apache.commons.dbcp.datasources.SharedPoolDataSource" destroy-method="close">
    <property name="connectionPoolDataSource" ref="mysqlDataSource"/>
    <property name="maxActive" value="20"/>
    <property name="maxIdle" value="5"/>
    <property name="maxWait" value="-1"/>
  </bean>

  <service ref="dataSource" interface="javax.sql.DataSource">
    <service-properties>
      <entry key="osgi.jndi.service.name" value="jdbc/sample"/>
    </service-properties>
  </service>
</blueprint>
```

**Note:** The property `osgi.jndi.service.name` in the data source configuration file defines the data source alias, `jdbc/sample`, in this example. The alias will be used in the database component to connect to the database defined in the data source configuration file when the Job is deployed in Talend Runtime.

For more information about how to use the data source in Talend Runtime Container, see *Talend ESB Container Administration Guide* and *Talend ESB Studio User Guide*.

### Adding and linking the components

**Procedure**

1. Create a new Job and add a `tMysqlInput` component and a `tLogRow` component by typing their names in the design workspace or dropping them from the Palette.

2. Link the `tMysqlInput` component to the `tLogRow` component using a `Row > Main` connection.
Configuring the components

Procedure

1. Double-click tMysqlInput to open its Basic Settings view in the Component tab.

![tMysqlInput settings](image)

- **Property Type**: Built-In
- **DB Version**: Mysql 5
- **Use an existing connection**: unchecked
- **Host**: unspecified
- **Port**: 3306
- **Database**: unspecified
- **Username**: unspecified
- **Password**: unspecified
- **Scheme**: Built-In
- **Table Name**: student
- **Query Type**: `SELECT
student.sid, 
student.sname
FROM student`
- **Data source alias**: jdbc/sample

2. In the Table Name field, enter the name of the table from which the data will be retrieved. In this example, it is student.

3. Click the [...] button next to Edit schema to open the Schema dialog box and define the schema of the table student by adding two columns: sid of Integer type and sname of String type.

![Schema dialog box](image)

4. Click the Guess Query button to fill the Query field with the SQL query statement to be used to retrieve data from the specified table.

5. Select the Specify a data source alias check box and in the Data source alias field displayed enter the data source alias specified in the data source configuration file datasource-mysql.xml on Talend Runtime side. In this example, it is jdbc/sample.

6. Double-click the tLogRow component to open its Basic settings view.
7. In the Mode area, select **Table (print values in cells of a table)** for better readability of the result.

**Building the Job and deploying it in Talend Runtime Container**

**Procedure**

1. Press **Ctrl + S** to save the Job.
2. Start the Talend Runtime Container.
3. In the Repository tree view of your Talend Studio, right-click the Job and from the contextual menu select **Build Job** to open the [Build Job] dialog box.

4. Select **OSGI Bundle For ESB** from the **Select the build type** drop-down list.
5. Click the **Browse** button next to the *To archive file* field to specify where you will store the Job archive file. In this example, we will export the Job directly to the deploy folder `<TalendRuntime Path>/container/deploy` so that the Job can be run immediately in Talend Runtime after being exported.

For more information about how to build a Job, see *Talend Studio User Guide*.

6. Click **Finish** to close the [Build Job] dialog box.

As you can see on the Talend Runtime Container console, the Job starts to run immediately after being deployed and the data in the *student* table is retrieved and displayed on the console.
tMysqlLastInsertId

Obtains the primary key value of the record that was last inserted in a Mysql table by a user.
tMysqlLastInsertId fetches the last inserted ID from a selected MySQL Connection.

**tMysqlLastInsertId Standard properties**

These properties are used to configure tMysqlLastInsertId running in the Standard Job framework.
The Standard tMysqlLastInsertId component belongs to the Databases family.
The component in this framework is generally available.

**Note:**
This component is a specific version of a dynamic database connector. The properties related
to database settings vary depending on your database type selection.
For more information about dynamic database connectors, see Dynamic database components
on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Schema</strong> and <strong>Edit Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
</tbody>
</table>

**Built-In**: You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.
Component list

Select the relevant **tMysqlConnection** component in the list if more than one connection is planned for the current job.

### Advanced settings

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

### Global Variables

#### Global Variables

**NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

#### Usage rule

This component is to be used as an intermediary component.

**Warning:**

*If you use this component with **tMySqlOutput**, verify that the **Extend Insert** check box in the **Advanced Settings** tab is not selected. **Extend Insert** allows you to make a batch insertion, however, if the check box is selected, only the ID of the last line in the last batch will be returned.*

#### Dynamic settings

Click the [*] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.
Scenario: Get the ID for the last inserted record with tMysqlLastInsertId

The following Java scenario creates a job that opens a connection to Mysql database, writes the defined data into the database, and finally fetches the last inserted ID on the existing connection.

- Drop the following components from the Palette onto the design workspace: tMySqlConnection, tMySqlCommit, tFileInputDelimited, tMySqlOutput, tMysqlLastInsertId, and tLogRow.

- Connect tMySqlConnection to tFileInputDelimited using an OnSubjobOk link.

- Connect tFileInputDelimited to tMySqlCommit using an OnSubjobOk link.

- Connect tFileInputDelimited to the three other components using Row Main links.

- In the design workspace, select tMysqlConnection.

- Click the Component tab to define the basic settings for tMysqlConnection.

- In the Basic settings view, set the connection details manually or select them from the context variable list, through a Ctrl+Space click in the corresponding field if you stored them locally as Metadata DB connection entries. For more information about Metadata, see Talend Studio User Guide.
In the design workspace, select **tMysqlCommit** and click the **Component** tab to define its basic settings.

On the **Component List**, select the relevant **tMysqlConnection** if more than one connection is used.

In the design workspace, select **tFileInputDelimited**.

Click the **Component** tab to define the basic settings of **tFileInputDelimited**.

- Fill in a path to the processed file in the **File Name** field. The file used in this example is **Customers**.
- Define the **Row separator** that allow to identify the end of a row. Then define the **Field separator** used to delimit fields in a row.
- Set the header, the footer and the number of processed rows as necessary. In this scenario, we have one header.
- Click the three-dot button next to **Edit Schema** to define the data to pass on to the next component.

In this scenario, the schema consists of two columns, *name* and *age*. The first holds three employees’ names and the second holds the corresponding age for each.

- In the design workspace, select **tMySqlOutput**.
- Click the **Component** tab to define the basic settings of **tMySqlOutput**.
  - Select the **Use an existing connection** check box.
  - In the **Table** field, enter the name of the table where to write the employees’ list, in this example: *employee*.
  - Select relevant actions on the **Action on table** and **Action on data** lists. In this example, no action is carried out on table, and the action carried out on data is **Insert**.
  - Click **Sync columns** to synchronize columns with the previous component. In this example, the schema to be inserted into the MySql database table consists of the two columns *name* and *age*.

- In the design workspace, select **tMySqlLastInsertId**.
• Click the **Component** tab to define the basic settings of **tMysqlLastInsertId**.

![Image of tMysqlLastInsertId_1 component]

- **Basic settings**
- **Advanced settings**
- **Dynamics settings**
- **View**
- **Documentation**

- **Schema of tMysqlLastInsertId_1**

<table>
<thead>
<tr>
<th>Column</th>
<th>Db Column</th>
<th>Key</th>
<th>Type</th>
<th>Nulla</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>name</td>
<td></td>
<td>String</td>
<td></td>
</tr>
<tr>
<td>age</td>
<td>age</td>
<td></td>
<td>Integer</td>
<td></td>
</tr>
</tbody>
</table>

You can select the data type **Long** from the **Type** drop-down list in case of a huge number of entries.

- In the design workspace, select **tLogRow** and click the **Component** tab to define its basic settings. For more information, see **tLogRow** on page 1988.

- Save your job and press **F6** to execute it.

```plaintext
Starting job lastinserted at 11:12 01/09/2008.
<table>
<thead>
<tr>
<th>tLogRow_1</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
</tr>
<tr>
<td>Marie</td>
</tr>
<tr>
<td>Patrick</td>
</tr>
<tr>
<td>Pierrick</td>
</tr>
</tbody>
</table>
```

**Job lastinserted ended at 11:12 01/09/2008. [exit code=0]**

**tMysqlLastInsertId** fetched the last inserted ID for each line on the existing connection.
tMysqlLookupInput

Reads a MySQL database and extracts fields based on a query.

tMysqllookupInput executes a database query with a strictly defined order which must correspond to the schema definition.

This component also allows you to connect and read data from a RDS Aurora or a RDS MySQL database.
tMysqlOutput

Writes, updates, makes changes or suppresses entries in a database.

tMysqlOutput executes the action defined on the table and/or on the data contained in the table, based on the flow incoming from the preceding component in the Job.

**tMysqlOutput Standard properties**

These properties are used to configure tMysqlOutput running in the Standard Job framework. The Standard tMysqlOutput component belongs to the Databases family.

The component in this framework is generally available.

ℹ️ **Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>

<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Property type</strong></td>
<td>Either Built-In or Repository.</td>
</tr>
<tr>
<td></td>
<td>Built-In: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file where the</td>
</tr>
<tr>
<td></td>
<td>properties are stored.</td>
</tr>
<tr>
<td><strong>DB Version</strong></td>
<td>Select the MySQL version you are using.</td>
</tr>
</tbody>
</table>

🔍 Click this icon to open a database connection wizard and store the database connection parameters you set in the component Basic settings view.

For more information about setting up and storing database connection parameters, see Talend Studio User Guide.

**Use an existing connection**

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

ℹ️ **Note:**

When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component.
which creates that very database connection.

2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see [Talend Studio User Guide](#).

<table>
<thead>
<tr>
<th>Host</th>
<th>Database server IP address.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Table</td>
<td>Name of the table to be written. Note that only one table can be written at a time</td>
</tr>
</tbody>
</table>
| Action on table | On the table defined, you can perform one of the following operations:  
| Default: No operation is carried out.  
| Drop and create a table: The table is removed and created again.  
| Create a table: The table does not exist and gets created.  
| Create a table if not exists: The table is created if it does not exist.  
| Drop a table if exists and create: The table is removed if it already exists and created again.  
| Clear a table: The table content is deleted.  
| Truncate table: The table content is quickly deleted. However, you will not be able to rollback the operation. |
| Action on data | On the data of the table defined, you can perform:  
| Insert: Add new entries to the table. If duplicates are found, the job stops.  
| Update: Make changes to existing entries.  
| Insert or update: Insert a new record. If the record with the given reference already exists, an update would be made.  
| Update or insert: Update the record with the given reference. If the record does not exist, a new record would be inserted.  
| Delete: Remove entries corresponding to the input flow.  
| Replace: Add new entries to the table. If an old row in the table has the same value as a new row for a |
**Insert or update on duplicate key or unique index:** Add entries if the inserted value does not exist or update entries if the inserted value already exists and there is a risk of violating a unique index or primary key.

**Insert Ignore:** Add only new rows to prevent duplicate key errors.

**Warning:**

You must specify at least one column as a primary key on which the **Update** and **Delete** operations are based. You can do that by clicking **Edit Schema** and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the **Advanced settings** view where you can simultaneously define primary keys for the update and delete operations. To do that: Select the **Use field options** check box and then in the **Key in update** column, select the check boxes next to the column name on which you want to base the update operation. Do the same in the **Key in delete** column for the deletion operation.

---

### Schema and Edit schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word **line** when naming the fields.

### Built-In

You create and store the schema locally for this component only. Related topic: see **Talend Studio User Guide**.

### Repository

You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see **Talend Studio User Guide**.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in **Talend Help Center** ([https://help.talend.com](https://help.talend.com)).

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the
Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.

<table>
<thead>
<tr>
<th>Die on error</th>
</tr>
</thead>
<tbody>
<tr>
<td>This check box is selected by default. Clear the check box to skip the row in error and complete the process for error-free rows. If needed, you can retrieve the rows in error via a Row &gt; Rejects link.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Specify a data source alias</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select this check box and specify the alias of a data source created on the Talend Runtime side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in Talend Runtime. For a related use case, see Scenario: Deploying your Job on Talend Runtime to retrieve data from a MySQL database on page 2503.</td>
</tr>
</tbody>
</table>

**Warning:**

If you use the component’s own DB configuration, your data source connection will be closed at the end of the component. To prevent this from happening, use a shared DB connection with the data source alias specified.

This check box is not available when the **Use an existing connection** check box is selected.

---

### Advanced settings

<table>
<thead>
<tr>
<th>Additional JDBC parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the <strong>Use an existing connection</strong> check box in the Basic settings.</td>
</tr>
</tbody>
</table>

**Note:**

You can press **Ctrl+Space** to access a list of predefined global variables.

<table>
<thead>
<tr>
<th>Extend Insert</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select this check box to carry out a bulk insert of a defined set of lines instead of inserting lines one by one. The gain in system performance is considerable.</td>
</tr>
</tbody>
</table>

**Number of rows per insert:** enter the number of rows to be inserted per operation. Note that the higher the value specified, the lower performance levels shall be due to the increase in memory demands.

**Note:**

This option is not compatible with the Reject link. You should therefore clear the check box if you are using a Row > Rejects link with this component.

**Warning:**

*If you are using this component with tMysqlLastInsertID, ensure that the Extend Insert check box in Advanced Settings is not selected.*
**Extend Insert** allows for batch loading, however, if the check box is selected, only the ID of the last line of the last batch will be returned.

| **Use Batch** | Select this check box to activate the batch mode for data processing.  
**Note:**  
This check box is available only when you have selected, the Update or the Delete option in the Action on data field. |
| **Batch Size** | Specify the number of records to be processed in each batch.  
This field appears only when the **Use batch mode** check box is selected. |
| **Commit every** | Number of rows to be included in the batch before it is committed to the DB. This option ensures transaction quality (but not rollback) and, above all, a higher performance level. |
| **Additional Columns** | This option is not available if you have just created the DB table (even if you delete it beforehand). This option allows you to call SQL functions to perform actions on columns, provided that these are not insert, update or delete actions, or actions that require pre-processing.  
**Name:** Type in the name of the schema column to be altered or inserted.  
**SQL expression:** Type in the SQL statement to be executed in order to alter or insert the data in the corresponding column.  
**Position:** Select Before, Replace or After, depending on the action to be performed on the reference column.  
**Reference column:** Type in a reference column that tMySqlOutput can use to locate or replace the new column, or the column to be modified. |
| **Use field options** | Select this check box to customize a request, particularly if multiple actions are being carried out on the data. |
| **Use Hint Options** | Select this check box to activate the hint configuration area which helps you optimize a query’s execution. In this area, parameters are:  
- **HINT:** specify the hint you need, using the syntax /*+ */.  
- **POSITION:** specify where you put the hint in a SQL statement.  
- **SQL STMT:** select the SQL statement you need to use. |
| **Enable debug mode** | Select this check box to display each step involved in the process of writing data in the database. |
Use duplicate key update mode insert

| Use duplicate key update mode insert | Updates the values of the columns specified, in the event of duplicate primary keys:
| | **Column**: Between double quotation marks, enter the name of the column to be updated.
| | **Value**: Enter the action you want to carry out on the column.
| | ![Note]
| | To use this option you must first of all select the Insert mode in the Action on data list found in the Basic Settings view.

**tStatCatcher Statistics**

| tStatCatcher Statistics | Select this check box to collect log data at the component level.

**Global Variables**

| Global Variables | 
| | **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.
| | **NB_LINE_UPDATED**: the number of rows updated. This is an After variable and it returns an integer.
| | **NB_LINE_INSERTED**: the number of rows inserted. This is an After variable and it returns an integer.
| | **NB_LINE_DELETED**: the number of rows deleted. This is an After variable and it returns an integer.
| | **NB_LINE_REJECTED**: the number of rows rejected. This is an After variable and it returns an integer.
| | **QUERY**: the query statement processed. This is an After variable and it returns a string.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

**Usage**

| Usage rule | This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible.
| | This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in a MySQL database. It also allows you to create a reject flow using a Row > Rejects link to filter data in error. For an example of tMySqlOutput in use, see Scenario: Retrieving data in error with a Reject link on page 2529.

---

2520
Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Scenario: Inserting a column and altering data using tMysqlOutput

This Java scenario is a three-component job that aims at creating random data using a tRowGenerator, duplicating a column to be altered using the tMap component, and eventually altering the data to be inserted based on an SQL expression using the tMysqlOutput component.

- Drop the following components from the Palette onto the design workspace: tRowGenerator, tMap and tMySQLOutput.
- Connect tRowGenerator, tMap, and tMysqlOutput using the Row Main link.
- In the design workspace, select tRowGenerator to display its Basic settings view.
• Click the **Edit schema** three-dot button to define the data to pass on to the **tMap** component, two columns in this scenario, *name* and *random_date*.

![tRowGenerator_1](image1)

• Click **OK** to close the dialog box.

• Click the **RowGenerator Editor** three-dot button to open the editor and define the data to be generated.

![Schema of tRowGenerator_1](image2)

• Click in the corresponding **Functions** fields and select a function for each of the two columns, *getFirstName* for the first column and *getrandomDate* for the second column.

• In the **Number of Rows for Rowgenerator** field, enter 10 to generate ten first name rows and click **Ok** to close the editor.

• Double-click the **tMap** component to open the Map editor. The Map editor opens displaying the input metadata of the **tRowGenerator** component.
In the Schema editor panel of the Map editor, click the plus button of the output table to add two rows and define the first as `random_date` and the second as `random_date1`.

In this scenario, we want to duplicate the `random_date` column and adapt the schema in order to alter the data in the output component.

- In the Map editor, drag the `random_date` row from the input table to the `random_date` and `random_date1` rows in the output table.
• Click **OK** to close the editor.

• In the design workspace, double-click the **tMysqlOutput** component to display its **Basic settings** view and set its parameters.

  ![tMysqlOutput component](image)

  **Dates(tMysqlOutput_1)**

  **Basic settings**
  - **Property Type**: Repository
  - **DB Version**: Mysql
  - **Use an existing connection**
  - **Host**: localhost
  - **Port**: 3306
  - **Database**: test
  - **Username**: root
  - **Password**: ********
  - **Table**: Dates
  - **Action on table**: Drop table if exists and create
  - **Action on data**: Insert
  - **Schema**: Built-In
  - **Data source**: Built-In
  - **This option only applies when deploying and running in the Talend Runtime**
  - **Specify a data source alias**
  - **Die on error**

  ![Schema editor](image)

• Set **Property Type** to Repository and then click the three-dot button to open the [Repository content] dialog box and select the correct DB connection. The connection details display automatically in the corresponding fields.

  **Note:**
  
  If you have not stored the DB connection details in the Metadata entry in the Repository, select **Built-in** on the property type list and set the connection detail manually.

• Click the three-dot button next to the **Table** field and select the table to be altered, Dates in this scenario.
• On the **Action on table** list, select **Drop table if exists and create**, select **Insert** on the **Action on data** list.

• If needed, click **Sync columns** to synchronize with the columns coming from the **tMap** component.

• Click the **Advanced settings** tab to display the corresponding view and set the advanced parameters.

![Image of Dates(tMysqlOutput_1) window](image)

- In the **Additional Columns** area, set the alteration to be performed on columns.

  In this scenario, the *One_month_later* column replaces *random_date_1*. Also, the data itself gets altered using an SQL expression that adds one month to the randomly picked-up date of the *random_date_1* column. ex: 2007-08-12 becomes 2007-09-12.

  - Enter *One_Month_Later* in the **Name** cell.
  - In the **SQL expression** cell, enter the relevant addition script to be performed, "adddate(Rando m_date, interval 1 month)" in this scenario.
  - Select **Replace** on the **Position** list.
  - Enter *Random_date1* on the **Reference column** list.

**Note:**

For this job we duplicated the *random_date_1* column in the DB table before replacing one instance of it with the *One_Month_Later* column. The aim of this workaround was to be able to view upfront the modification performed.

• Save your job and press **F6** to execute it.

The new *One_month_later* column replaces the *random_date1* column in the DB table and adds one month to each of the randomly generated dates.
Scenario: Updating data using tMysqlOutput

This Java scenario describes a two-component Job that updates data in a MySQL table according to that in a delimited file.

- Drop tFileInputDelimited and tMysqlOutput from the Palette onto the design workspace.
- Connect the two components together using a Row Main link.

- Double-click tFileInputDelimited to display its Basic settings view and define the component properties.
- From the Property Type list, select Repository if you have already stored the metadata of the delimited file in the Metadata node in the Repository tree view. Otherwise, select Built-In to define manually the metadata of the delimited file.

For more information about storing metadata, see Talend Studio User Guide.
• In the **File Name** field, click the three-dot button and browse to the source delimited file that contains the modifications to propagate in the MySQL table.

In this example, we use the *customer_update* file that holds four columns: `id`, `CustomerName`, `CustomerAddress` and `idState`. Some of the data in these four columns is different from that in the MySQL table.

<table>
<thead>
<tr>
<th>id</th>
<th>CustomerName</th>
<th>CustomerAddress</th>
<th>idState</th>
</tr>
</thead>
<tbody>
<tr>
<td>858</td>
<td>Froggy's Gourmet Catering</td>
<td>1831 Beverly #9D</td>
<td>4</td>
</tr>
<tr>
<td>859</td>
<td>Dependable Plumbing and Sewer</td>
<td>1550 Ridge Rd.</td>
<td>25</td>
</tr>
<tr>
<td>860</td>
<td>Lockman Restoration</td>
<td>1235 Easton Rd.</td>
<td>40</td>
</tr>
<tr>
<td>861</td>
<td>Actuarial Enterprises Ltd.</td>
<td>3148 cottonwood Ct.</td>
<td>18</td>
</tr>
<tr>
<td>862</td>
<td>Rythmics Ltd.</td>
<td>857 Woodbine Rd.</td>
<td>30</td>
</tr>
<tr>
<td>863</td>
<td>Actuarial Enterprises Ltd.</td>
<td>1482 Concorde Circle</td>
<td>48</td>
</tr>
<tr>
<td>864</td>
<td>Crosstracks Car Wash</td>
<td>218 Oakridge Ave.</td>
<td>39</td>
</tr>
<tr>
<td>865</td>
<td>Meonis &amp; Mogoni Inc.</td>
<td>616 Cobblestone Cir.</td>
<td>17</td>
</tr>
<tr>
<td>866</td>
<td>Foley Aviation</td>
<td>2220 Grant Blvd.</td>
<td>50</td>
</tr>
<tr>
<td>867</td>
<td>Ebert Music Center</td>
<td>12 Broadview Lane</td>
<td>29</td>
</tr>
<tr>

<td>2922 Twin Oaks Drive</td>
<td>40</td>
</tr>
<tr>
<td>870</td>
<td>Corbins, Rodriguez, &amp; Savocchi</td>
<td>115 Pleasant Ave.</td>
<td>18</td>
</tr>
<tr>
<td>871</td>
<td>Nina's Snow Plowing</td>
<td>3385 University Ave.</td>
<td>20</td>
</tr>
<tr>
<td>872</td>
<td>Darcy Frame and Matting Servic</td>
<td>1101 Deffield Place</td>
<td>47</td>
</tr>
<tr>
<td>873</td>
<td>Marks, Marks, and Kaplan Ltd.</td>
<td>1949 Cleaverdale Rd.</td>
<td>9</td>
</tr>
</tbody>
</table>

• Define the row and field separators used in the source file in the corresponding fields.

• If needed, set **Header**, **Footer** and **Limit**.

In this example, **Header** is set to 1 since the first row holds the names of columns, therefore it should be ignored. Also, the number of processed lines is limited to 2000.

• Click the three-dot button next to **Edit Schema** to open a dialog box where you can describe the data structure of the source delimited file that you want to pass to the component that follows.

<table>
<thead>
<tr>
<th>Column</th>
<th>Key</th>
<th>Type</th>
<th>Nullable</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>✓</td>
<td>Integer</td>
<td>✓</td>
</tr>
<tr>
<td>CustomerName</td>
<td></td>
<td>String</td>
<td>✓</td>
</tr>
<tr>
<td>CustomerAddress</td>
<td></td>
<td>String</td>
<td>✓</td>
</tr>
<tr>
<td>idState</td>
<td></td>
<td>Integer</td>
<td>✓</td>
</tr>
</tbody>
</table>

• Select the **Key** check box(es) next to the column name(s) you want to define as key column(s).

**Note:**

It is necessary to define at least one column as a key column for the Job to be executed correctly. Otherwise, the Job is automatically interrupted and an error message displays on the console.

• In the design workspace, double-click **tMysqlOutput** to open its **Basic settings** view where you can define its properties.
Click **Sync columns** to retrieve the schema of the preceding component. If needed, click the three-dot button next to **Edit schema** to open a dialog box where you can check the retrieved schema.

From the **Property Type** list, select **Repository** if you have already stored the connection metadata in the **Metadata** node in the **Repository** tree view. Otherwise, select **Built-In** to define manually the connection information.

For more information about storing metadata, see *Talend Studio User Guide*.

Fill in the database connection information in the corresponding fields.

In the **Table** field, enter the name of the table to update.

From the **Action on table** list, select the operation you want to perform, **Default** in this example since the table already exists.

From the **Action on data** list, select the operation you want to perform on the data, **Update** in this example.

Save your Job and press **F6** to execute it.
Using your DB browser, you can verify if the MySQL table, customers, has been modified according to the delimited file.

In the above example, the database table has always the four columns id, CustomerName, CustomerAddress and idState, but certain fields have been modified according to the data in the delimited file used.

**Scenario: Retrieving data in error with a Reject link**

This scenario describes a four-component Job that carries out migration from a customer file to a MySQL database table and redirects data in error towards a CSV file using a Reject link.
• In the Repository, select the customer file metadata that you want to migrate and drop it onto the workspace. In the [Components] dialog box, select tFileInputDelimited and click OK. The component properties will be filled in automatically.

• If you have not stored the information about your customer file under the Metadata node in the Repository, drop a tFileInputDelimited component from the family File > Input, in the Palette, and fill in its properties manually in the Component tab.

• From the Palette, drop a tMap from the Processing family onto the workspace.

• In the Repository, expand the Metadata node, followed by the Db Connections node and select the connection required to migrate your data to the appropriate database. Drop it onto the workspace. In the [Components] dialog box, select tMysqlOutput and click OK. The database connection properties will be automatically filled in.

• If you have not stored the database connection details under the Db Connections node in the Repository, drop a tMysqlOutput from the Databases family in the Palette and fill in its properties manually in the Component tab.

For more information, see Talend Studio User Guide.

• From the Palette, select a tFileOutputDelimited from the File > Output family, and drop it onto the workspace.

• Link the customers component to the tMap component, and the tMap and Localhost with a Row Main link. Name this second link out.

• Link the Localhost to the tFileOutputDelimited using a Row > Reject link.

• Double-click the customers component to display the Component view.

• In the Property Type list, select Repository and click the [...] button in order to select the metadata containing the connection to your file. You can also select the Built-in mode and fill in the fields manually.

• Click the [...] button next to the File Name field, and fill in the path and the name of the file you want to use.

• In the Row and Field Separator fields, type in between inverted commas the row and field separator used in the file.

• In the Header, Footer and Limit fields, type in the number of headers and footers to ignore, and the number of rows to which processing should be limited.
In the **Schema** list, select **Repository** and click the [...] button in order to select the schema of your file, if it is stored under the **Metadata** node in the **Repository**. You can also click the [...] button next to the **Edit schema** field, and set the schema manually.

The schema is as follows:

![Schema of customers](image)

- Double-click the **tMap** component to open its editor.

![tMap component](image)

- Select the `id`, `CustomerName`, `CustomerAddress`, `idState`, `id2`, `RegTime` and `RegisterTime` columns on the table on the left and drop them on the **out** table, on the right.
• In the **Schema editor** area, at the bottom of the **tMap** editor, in the right table, change the length of the **CustomerName** column to 28 to create an error. Thus, any data for which the length is greater than 28 will create errors, retrieved with the **Reject** link.

• Click **OK**.

• In the workspace, double-click the output **Localhost** component to display its **Component** view.

• In the **Property Type** list, select **Repository** and click the [...] button to select the connection to the database metadata. The connection details will be automatically filled in. You can also select the **Built-in** mode and set the fields manually.

• In the **Table** field, type in the name of the table to be created. In this scenario, we call it **customers_data**.

• In the **Action on data** list, select the **Create table** option.

• Click the **Sync columns** button to retrieve the schema from the previous component.

• Make sure the **Die on error** check box isn’t selected, so that the Job can be executed despite the error you just created.
• Click the **Advanced settings** tab of the **Component** view to set the advanced parameters of the component.

![mysqloutput](image)

- Deselect the **Extend Insert** check box which enables you to insert rows in batch, because this option is not compatible with the **Reject** link.

- Double-click the **tFileOutputDelimited** component to set its properties in the **Component** view.

![fileoutputdelimited](image)

• Click the [...] button next to the **File Name** field to fill in the path and name of the output file.

• Click the **Sync columns** button to retrieve the schema of the previous component.

• Save your Job and press **F6** to execute it.

</tbody>
</table>

The data in error are sent to the delimited file, as well as the error type met. Here, we have: Data truncation.
tMysqlOutputBulk

Writes a file with columns based on the defined delimiter and the MySQL standards.

The tMysqlOutputBulk and tMysqlBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT statement used to feed a database. These two steps are fused together in the tMysqlOutputBulkExec component, detailed in a separate section. The advantage of using two separate steps is that the data can be transformed before it is loaded in the database.

**tMysqlOutputBulk Standard properties**

These properties are used to configure tMysqlOutputBulk running in the Standard Job framework.

The Standard tMysqlOutputBulk component belongs to the Databases family.

The component in this framework is generally available.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td>Built-in: No property data stored centrally.</td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>File Name</td>
<td>Name of the file to be generated. This file is generated on the same machine where the Studio is installed or where the Job using tMysqlOutputBulk is deployed.</td>
</tr>
<tr>
<td>Append</td>
<td>Select this check box to add the new rows at the end of the file.</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td>Built-In: You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.</td>
<td></td>
</tr>
</tbody>
</table>
Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the [Repository Content] window.

### Advanced settings

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Row separator</strong></td>
<td>String (ex: “\n” on Unix) to distinguish rows.</td>
</tr>
<tr>
<td><strong>Field separator</strong></td>
<td>Character, string or regular expression to separate fields.</td>
</tr>
<tr>
<td><strong>Text enclosure</strong></td>
<td>Character used to enclose the text.</td>
</tr>
<tr>
<td><strong>Create directory if does not exist</strong></td>
<td>This check box is selected by default. It creates a directory to hold the output table if required.</td>
</tr>
<tr>
<td><strong>Custom the flush buffer size</strong></td>
<td>Customize the amount of memory used to temporarily store output data. In the Row number field, enter the number of rows after which the memory is to be freed again.</td>
</tr>
<tr>
<td><strong>Records contain NULL value</strong></td>
<td>This check box is selected by default. It allows you to take account of NULL value fields. If you clear the check box, the NULL values will automatically be replaced with empty values.</td>
</tr>
<tr>
<td><strong>Check disk space</strong></td>
<td>Select the this check box to throw an exception during execution if the disk is full.</td>
</tr>
<tr>
<td><strong>Encoding</strong></td>
<td>Select the encoding from the list or select Custom and define it manually. This field is compulsory for DB data handling.</td>
</tr>
</tbody>
</table>
### Global Variables

**Global Variables**

**NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

### Usage

**Usage rule**

This component is to be used along with **tMySQlBulkExec** component. Used together they offer gains in performance while feeding a MySQL database.

**Component family**

Databases/MySQL

**Limitation**

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

### Scenario: Inserting transformed data in MySQL database

This scenario describes a four-component job which aims at fueling a database with data contained in a file, including transformed data. Two steps are required in this job, first step is to create the file, that will then be used in the second step. The first step includes a tranformation phase of the data included in the file.
Dropping and linking components

Procedure
1. Drag and drop a tRowGenerator, a tMap, a tMysqlOutputBulk as well as a tMysqlBulkExec component.
2. Connect the main flow using row Main links.
3. And connect the start component (tRowGenerator in this example) to the tMysqlBulkExec using a trigger connection, of type OnComponentOk.

Configuring the components

Procedure
1. A tRowGenerator is used to generate random data. Double-click on the tRowGenerator component to launch the editor.
2. Define the schema of the rows to be generated and the nature of data to generate. In this example, the clients file to be produced will contain the following columns: ID, First Name, Last Name, Address, City which all are defined as string data but the ID that is of integer type.
Some schema information don’t necessarily need to be displayed. To hide them away, click on **Columns** list button next to the toolbar, and uncheck the relevant entries, such as **Precision** or **Parameters**.

Use the plus button to add as many columns to your schema definition. Click the Refresh button to preview the first generated row of your output.

3. Then select the **tMap** component to set the transformation.
4. Drag and drop all columns from the input table to the output table.

5. Apply the transformation on the **LastName** column by adding `.toUpperCase()` in its expression field. Then, click **OK** to validate the transformation.
6. Double-click on the **tMysqlOutputBulk** component.
7. Define the name of the file to be produced in **File Name** field. If the delimited file information is stored in the **Repository**, select it in **Property Type** field, to retrieve relevant data. In this use case the file name is **clients.txt**.
   
   The schema is propagated from the **tMap** component, if you accepted it when prompted.
8. In this example, don’t include the header information as the table should already contain it.
9. Click OK to validate the output.
10. Then double-click on the **tMysqlBulkExec** component to set the INSERT query to be executed.
11. Define the database connection details. We recommend you to store this type of information in the Repository, so that you can retrieve them at any time for any Job.

12. Set the table to be filled in with the collected data, in the Table field.

13. Fill in the column delimiters in the Field terminated by area.

14. Make sure the encoding corresponds to the data encoding.

Saving and executing the Job

Procedure

1. Press Ctrl+S to save your Job.

2. Press F6 or click Run on the Run tab to execute the Job.

The clients database table is filled with data from the file including upper-case last name as transformed in the job.

Results

For simple Insert operations that don’t include any transformations, the use of tMysqlOutputBulkExec allows you to skip a step in the process and thus improves performance.

Related topic: tMysqlOutputBulkExec Standard properties on page 2541
tMysqlOutputBulkExec

Executes the Insert action in the specified MySQL database.

As a dedicated component, tMysqlBulkExec improves performance during Insert operations to a MySQL database.

The tMysqlOutputBulk and tMysqlBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT statement used to feed a database. These two steps are fused together in the tMysqlOutputBulkExec component.

tMysqlOutputBulkExec Standard properties

These properties are used to configure tMysqlOutputBulkExec running in the Standard Job framework. The Standard tMysqlOutputBulkExec component belongs to the Databases family.

The component in this framework is generally available.

Note:

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>

<tr>
<td></td>
<td>the password field, and then in the pop-up dialog box</td>
</tr>
<tr>
<td></td>
<td>enter the password between double quotes and click OK to</td>
</tr>
<tr>
<td></td>
<td>save the settings.</td>
</tr>
<tr>
<td>Action on table</td>
<td>On the table defined, you can perform one of the following operations:</td>
</tr>
</tbody>
</table>
## None: No operation is carried out.

**Drop and create table:** The table is removed and created again.

**Create table:** The table does not exist and gets created.

**Create table if not exists:** The table is created if it does not already exist.

**Drop table if exists and create:** The table is removed if it already exists and created again.

**Clear table:** The table content is deleted.

### Table

Name of the table to be written.

**Note:**

Note that only one table can be written at a time and that the table must already exist for the insert operation to succeed.

### Local FileName

Name of the file to be generated and loaded.

This file is generated on the same machine where the Studio is installed or where the Job using tMysqlOutputBulkExec is deployed. Then it is loaded to the database specified by Host field.

### Append

Select the check box for this option to append new rows to the end of the file.

### Schema and Edit Schema

A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either **Built-in** or stored remotely in the **Repository**.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema:** choose this option to view the schema only.
- **Change to built-in property:** choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection:** choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.

**Built-In:** You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.

**Repository:** You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.
When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually. You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

### Advanced settings

<table>
<thead>
<tr>
<th><strong>Additional JDBC parameters</strong></th>
<th>Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the <strong>Use an existing connection</strong> check box in the Basic settings.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Note:</strong></td>
<td>You can press <strong>Ctrl+Space</strong> to access a list of predefined global variables.</td>
</tr>
<tr>
<td><strong>Row separator</strong></td>
<td>String (ex: <code>\n</code> on Unix) to distinguish rows.</td>
</tr>
<tr>
<td><strong>Field separator</strong></td>
<td>Character, string or regular expression to separate fields.</td>
</tr>
<tr>
<td><strong>Escape char</strong></td>
<td>Character of the row to be escaped</td>
</tr>
<tr>
<td><strong>Text enclosure</strong></td>
<td>Character used to enclose the text.</td>
</tr>
<tr>
<td><strong>Create directory if does not exist</strong></td>
<td>This check box is selected by default. It creates a directory to hold the output table if required.</td>
</tr>
<tr>
<td><strong>Custom the flush buffer size</strong></td>
<td>Customize the amount of memory used to temporarily store output data. In the <strong>Row number field</strong>, enter the number of rows after which the memory is to be freed again.</td>
</tr>
<tr>
<td><strong>Action on data</strong></td>
<td>On the data of the table defined, you can carry out the following operations:</td>
</tr>
<tr>
<td></td>
<td><strong>Insert records in table:</strong> Add new records to the table.</td>
</tr>
<tr>
<td></td>
<td><strong>Update records in table:</strong> Make changes to existing records.</td>
</tr>
<tr>
<td></td>
<td><strong>Replace records in table:</strong> Replace existing records with new one. <strong>Ignore records in table:</strong> Ignore existing records or insert the new ones.</td>
</tr>
<tr>
<td><strong>Records contain NULL value</strong></td>
<td>This check box is selected by default. It allows you to take account of NULL value fields. If you clear the check box, the NULL values will automatically be replaced with empty values.</td>
</tr>
<tr>
<td><strong>Encoding</strong></td>
<td>Select the encoding from the list or select <strong>Custom</strong> and define it manually. This field is compulsory for DB data handling.</td>
</tr>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to collect the log data at the component level.</td>
</tr>
</tbody>
</table>
Usage

Usage rule

This component is mainly used when no particular transformation is required on the data to be loaded onto the database.

Scenario: Inserting data in bulk in MySQL database

This scenario describes a two-component Job which carries out the same operation as the one described for tMysqlOutputBulk Standard properties on page 2535 and tMysqlBulkExec Standard properties on page 2461, although no data is transformed.

- Drop a tRowGenerator and a tMysqlOutputBulkExec component from the Palette to the design workspace.
- Connect the components using a link such as Row > Main.
- Set the tRowGenerator parameters the same way as in Scenario: Inserting transformed data in MySQL database on page 2537. The schema is made of four columns including: ID, First Name, Last Name, Address and City.
- In the workspace, double-click the tMysqlOutputBulkExec to display the Component view and set the properties.

- In the Action on table field, select the None option as you want to insert the data into a table which already exists.

For further information, see Talend Studio User Guide.
In the **Table** field, enter the name of the table you want to populate, the name being *clients* in this example.

In the **Local filename** field, indicate the access path and the name of the file which contains the data to be added to the table. In this example, the file is *clients.txt*.

Click on the **Advanced settings** tab to define the component’s advanced parameters.

- In the **Action on data** list, select the **Insert records in table** to insert the new data in the table.

Press **F6** to run the Job.

The result should be pretty much the same as in **Scenario: Inserting transformed data in MySQL database** on page 2537, but the data might differ as these are regenerated randomly everytime the Job is run.
tMysqlRollback

Cancels the transaction commit in the connected MySQL database to avoid committing part of a transaction involuntarily.

**tMysqlRollback Standard properties**

These properties are used to configure tMysqlRollback running in the Standard Job framework.

The Standard tMysqlRollback component belongs to the Databases family.

The component in this framework is generally available.

**i Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the <strong>tMysqlConnection</strong> component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

### Advanced settings

| tStat Catcher Statistics                         | Select this check box to collect log data at the component level. |

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is more commonly used with other tMysql* components, especially with the <strong>tMysqlConnection</strong> and <strong>tMysqlCommit</strong> components.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic settings</td>
<td>Click the <code>[+]</code> button to add a row in the table and fill the <strong>Code</strong> field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.</td>
</tr>
</tbody>
</table>
Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see **Scenario: Reading data from databases through context-based dynamic connections** on page 2497 and **Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters** on page 489. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.
tMysqlRow

Executes the stated SQL query on the specified MySQL database.

Depending on the nature of the query and the database, tMysqlRow acts on the actual DB structure or on the data (although without handling data). The SQLBuilder tool helps you write easily your SQL statements.

tMysqlRow is the specific component for MySQL database query. It implements a flow in the Job design although it doesn’t provide output.

### tMysqlRow Standard properties

These properties are used to configure tMysqlRow running in the Standard Job framework.

The Standard tMysqlRow component belongs to the Databases family.

The component in this framework is generally available.

#### Note:

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see [Dynamic database components](#) on page 598.

#### Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
<tr>
<td><strong>Property type</strong></td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td><strong>Built-in</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><strong>DB Version</strong></td>
<td>Select the MySQL version that you are using.</td>
</tr>
<tr>
<td><strong>Use an existing connection</strong></td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

#### Note:

When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection. For an example about how to share a database connection across Job levels, see **Talend Studio User Guide**.

<table>
<thead>
<tr>
<th><strong>Host</strong></th>
<th>Database server IP address</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td><strong>Schema and Edit Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <strong>line</strong> when naming the fields.</td>
</tr>
<tr>
<td><strong>Built-In</strong>: You create and store the schema locally for this component only. Related topic: see <strong>Talend Studio User Guide</strong>.</td>
<td></td>
</tr>
<tr>
<td><strong>Repository</strong>: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see <strong>Talend Studio User Guide</strong>. When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually. You can find more details about how to verify default values in retrieved schema in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
<td></td>
</tr>
</tbody>
</table>

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.
<table>
<thead>
<tr>
<th>Table Name</th>
<th>Name of the table to be processed.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Query type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-in</strong>: Fill in manually the query statement or build it graphically using SQLBuilder.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: Select the relevant query stored in the Repository. The Query field gets accordingly filled in.</td>
</tr>
<tr>
<td>Guess Query</td>
<td>Click the Guess Query button to generate the query which corresponds to your table schema in the Query field.</td>
</tr>
<tr>
<td>Query</td>
<td>Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.</td>
</tr>
<tr>
<td>Die on error</td>
<td>This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a Row &gt; Rejects link.</td>
</tr>
<tr>
<td>Specify a data source alias</td>
<td>Select this check box and specify the alias of a data source created on the Talend Runtime side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in Talend Runtime. For a related use case, see Scenario: Deploying your Job on Talend Runtime to retrieve data from a MySQL database on page 2503. If you use the component's own DB configuration, your data source connection will be closed at the end of the component. To prevent this from happening, use a shared DB connection with the data source alias specified. This check box is not available when the Use an existing connection check box is selected.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| Additional JDBC parameters       | Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the Use an existing connection check box in the Basic settings. |
| Propagate QUERY’s recordset     | Select this check box to insert the result of the query in a COLUMN of the current flow. Select this column from the use column list.  

**Note:**  
This option allows the component to have a different schema from that of the preceding component. Moreover, the column that holds the QUERY’s recordset should be set to the
type of Object and this component is usually followed by tParseRecordSet.

Use PreparedStatement

Select this check box if you want to query the database using a PreparedStatement. In the Set PreparedStatement Parameter table, define the parameters represented by "?" in the SQL instruction of the Query field in the Basic Settings tab.

Parameter Index: Enter the parameter position in the SQL instruction.
Parameter Type: Enter the parameter type.
Parameter Value: Enter the parameter value.

Note:
This option is very useful if you need to execute the same query several times. Performance levels are increased.

Commit every

Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions.

tStatCatcher Statistics

Select this check box to collect log data at the component level.

Global Variables

QUERY: the query statement being processed. This is a Flow variable and it returns a string.

ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule

This component offers the flexibility of the DB query and covers all possible SQL queries.

Dynamic settings

Click the [+ ] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful.
when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

### Scenario: Removing and regenerating a MySQL table index

This scenario describes a four-component job that removes a table index, applies a select insert action onto a table then regenerates the index.

#### Linking the components

**Procedure**

1. Select and drop the following components onto the design workspace: **tMysqlRow** (x2), **tRowGenerator**, and **tMysqlOutput**.
2. Link the first **tMysqlRow** to **tRowGenerator** using an OnComponentOk connection.
3. Link **tRowGenerator** to **tMysqlOutput** using a Row > Main connection.
4. Link **tRowGenerator** to the second **tMysqlRow** using an OnSubjobOk connection.
Configuring the components

Procedure

1. Select the tMysqlRow to fill in the DB Basic settings.
2. In Property type as well in Schema, select the relevant DB entry in the list.
   The DB connection details and the table schema are accordingly filled in.
3. Propagate the properties and schema details onto the other components of the Job.
   The query being stored in the Metadata area of the Repository, you can also select Repository in the Query type field and the relevant query entry.
4. If you didn’t store your query in the Repository, type in the following SQL statement to alter the database entries: drop index <index_name> on <table_name>
5. Select the second tMysqlRow component, check the DB properties and schema.
6. Type in the SQL statement to recreate an index on the table using the following statement: create index <index_name> on <table_name> (<column_name>)
   The tRowGenerator component is used to generate automatically the columns to be added to the DB output table defined.
7. Select the tMysqlOutput component and fill in the DB connection properties either from the Repository or manually the DB connection details are specific for this use only. The table to be fed is named: comprehensive.
8. The schema should be automatically inherited from the data flow coming from the tLogRow. Edit the schema to check its structure and check that it corresponds to the schema expected on the DB table specified.
   The Action on table is None and the Action on data is Insert.
   No additional Columns is required for this job.

Executing the Job

Procedure

1. Press Ctrl+S to save the Job.
2. Press F6 to run the job.
   If you manage to watch the action on DB data, you can notice that the index is dropped at the start of the job and recreated at the end of the insert action.
   Related topics: tDBSQLRow Standard properties on page 622.

Scenario: Using PreparedStatement objects to query data

This scenario describes a four component job which allows you to link a table column with a client file. The MySQL table contains a list of all the American States along with the State ID, while the file contains the customer information including the ID of the State in which they live. We want to retrieve the name of the State for each client, using an SQL query. In order to process a large volume of data quickly, we use a PreparedStatement object which means that the query is executed only once rather than against each row in turn. Then each row is sent as a parameter. Note that PreparedStatement object can also be used in avoiding SQL injection.

For this scenario, we use a file and a database for which we have already stored the connection and properties in the Repository metadata. For further information concerning the creation of metadata in
delimited files, the creation of database connection metadata and the usage of metadata, see *Talend Studio User Guide*.

### Linking the components

**Procedure**

1. In the **Repository**, expand the **Metadata** and **File delimited** nodes.
2. Select the metadata which corresponds to the client file and slide the metadata onto the workspace. Here, we are using the `customers` metadata.
3. Double-click **tFileInputDelimited** in the **Components** dialog box to add **tFileInputDelimited** to the workspace, with the relevant fields filled by the metadata file.
4. Drop **tMysqlRow**, **tParseRecordSet** and **tFileOutputDelimited** onto the workspace.
5. Link **tFileInputDelimited** to **tMysqlRow** using a **Row > Main** connection.
6. Link **tMysqlRow** to **tParseRecordSet** using a **Row > Main** connection.
7. Link **tParseRecordSet** to **tFileOutputDelimited** using a **Row > Main** connection.

### Configuring the components

**Procedure**

1. Double-click **tFileInputDelimited** to open its **Basic settings** view.

   ![Basic settings view](image)

   **Basic settings**
   - **Property/Type**: Repository, DELIM:customers
   - **File name/Stream**: `D:/04_cobs/Files/customer.csv`
   - **Row Separator**: `|`
   - **Field Separator**: `;`
   - **Header**: 6
   - **Footer**: 0
   - **Limit**: 0
   - **Schema**: Repository, DELIM:customers - metadata

2. In the **Schema** list, select **Built-in** so that you can modify the component's schema. Then click on **[...]** next to the **Edit schema** field to add a column into which the name of the State will be inserted.
3. Click on the [+] button to add a column to the schema. Rename this column `LabelStateRecordSet` and select `Object` from the `Type` list. Click `OK` to save your modifications.

4. From the Palette, select the `tMysqlRow`, `tParseRecordSet` and `tFileOutputDelimited` components and drop them onto the workspace.

5. Double click `tMysqlRow` to set its properties in the `Basic settings` tab of the `Component` view.
6. In the **Property Type** list, select **Repository** and click on the [...] button to select a database connection from the metadata in the Repository. The **DB Version**, **Host**, **Port**, **Database**, **Username** and **Password** fields are completed automatically. If you are using the **Built-in** mode, complete these fields manually.

7. From the **Schema** list, select **Built-in** to set the schema properties manually and add the **LabelStateRecordSet** column, or click directly on the **Sync columns** button to retrieve the schema from the preceding component.

8. In the **Query** field, enter the SQL query you want to use. Here, we want to retrieve the names of the American States from the **LabelState** column of the MySQL table, **us_state**: "SELECT LabelState FROM us_state WHERE idState=?". The question mark, "?", represents the parameter to be set in the **Advanced settings** tab.

9. Click **Advanced settings** to set the components advanced properties.

10. Select the **Propagate QUERY's recordset** check box and select the **LabelStateRecordSet** column from the **use column** list to insert the query results in that column.

11. Select the **Use PreparedStatement** check box and define the parameter used in the query in the **Set PreparedStatement Parameters** table.

12. Click on the [+] button to add a parameter.

   a) In the **Parameter Index** cell, enter the parameter position in the SQL instruction. Enter "1" as we are only using one parameter in this example.

   b) In the **Parameter Type** cell, enter the type of parameter. Here, the parameter is a whole number, hence, select **Int** from the list.

   c) In the **Parameter Value** cell, enter the parameter value. Here, we want to retrieve the name of the State based on the State ID for every client in the input file. Hence, enter "row1.idState".

13. Double click **tParseRecordSet** to set its properties in the **Basic settings** tab of the **Component** view.
a) From the **Prev. Comp. Column list**, select the preceding components column for analysis. In this example, select *LabelStateRecordSet*.

b) Click on the **Sync columns** button to retrieve the schema from the preceding component. The **Attribute table** is automatically completed with the schema columns.

c) In the **Attribute table**, in the **Value** field which corresponds to the *LabelStateRecordSet*, enter the name of the column containing the State names to be retrieved and matched with each client, within double quotation marks. In this example, enter "*LabelState*".

14. Double click **tFileOutputDelimited** to set its properties in the **Basic settings** tab of the **Component** view.

a) In the **File Name field**, enter the access path and name of the output file.

b) Click **Sync columns** to enter the schema from the preceding component.

### Executing the Job

**Procedure**

1. Press **Ctrl+S** to save the Job.
2. Press **F6** to run it.
Results

A column containing the name of the American State corresponding to each client is added to the file.

Scenario: Combining two flows for selective output

In this scenario, a flow generated by tFixedFlowInput is combined with a flow from the Mysql database. The source flow contains id and age fields while the Mysql table contains id and name. We want to retrieve the age data of the source flow and combine it with the id and name records from the Mysql table based on id matching. One thing that is worth noting is that the input schema is different from the output one at tMysqlRow in the Job.

Linking the components

Procedure

1. Drop tFixedFlowInput, tMysqlRow, tParseRecordSet and tLogRow onto the workspace.
2. Rename tFixedFlowInput as source_flow, tMysqlRow as insert_recordset, tParseRecordSet as parse_recordset and tLogRow as show_combined_flow.
3. Link tFixedFlowInput to tMysqlRow using a Row > Main connection.
4. Link tMysqlRow to tParseRecordSet using a Row > Main connection.
5. Link tParseRecordSet to tLogRow using a Row > Main connection.

Configuring the components

Procedure

1. Double-click tFixedFlowInput to open its Basic settings view.
2. Select **Use Inline Content (delimited file)** in the **Mode** area. In the **Content** field, enter the data to be transferred:

```
1;30
2;20
```

3. Double-click the [...] button next to **Edit schema** to open the schema editor.

Click the [+] button to add two columns, namely *id* and *age*, with the type of *Integer*. Click **Ok** to close the editor.

4. Double-click **tMysqlRow** to open its **Basic settings** view.
5. In the Host and Port fields, enter the connection details.
   In the Database field, enter the database name.
   In the Username and Password fields, enter the authentication details.
   In the Query field, enter the SQL query to retrieve the id and name data from the Mysql table employee: "select id, name from employee WHERE id=?". The question mark, ",\?", represents the parameter to be set in the Advanced settings tab.

6. Click the [...] button next to Edit schema to open the schema editor.

7. Click the [+] button to add two columns in the right part, namely recordset and age, with the type of Object and Integer. Note that recordset is intended to hold the query results of the Mysql table, namely the id and name fields.
   Click OK to close the editor.

8. Click the Advanced settings tab for further setup.
9. Select the Propagate QUERY's recordset check box and choose recordset from the use column list to insert the query results in that column.

Select the Use PreparedStatement check box and define the parameter used in the query in the Set PreparedStatement Parameters table.

10. Click on the [+] button to add a line.

In the Parameter Index cell, enter the parameter position in the SQL instruction. Enter "1" as we are only using one parameter in this example.

In the Parameter Type cell, enter the type of parameter. Here, the parameter is an integer. Hence, select Int from the list.

In the Parameter Value cell, enter the parameter value. Here, we want to retrieve the id and name from the employee table based on the id value from the source flow. Hence, enter row3.id.

11. Double-click tParseRecordSet to open its Basic settings view.

From the Prev. Comp. Column list, select the column to parse, namely recordset.

12. Click the [...] button next to Edit schema to open the schema editor.
Click the [+] button to add three columns in the right part, namely *id*, *name* and *age*, with the type of *Integer*, *String* and *Integer*. Note that the *id* and *name* fields are intended to hold the parsed data of *recordset*.

Click OK to close the editor.

In the **Attribute table**, in the **Value** fields which correspond to *id* and *name*, enter the name of the column in the Mysql table to be retrieved, namely “*id*” and “*name*”.

13. Double-click **tLogRow** to open its **Basic settings** view.

In the **Mode** area, select **Table (print values in cells of a table)** for better display.

**Executing the Job**

**Procedure**

1. Press **Ctrl+S** to save the Job.
2. Press **F6** to run the Job.

```

tMysqlSCD

Reflects and tracks changes in a dedicated MySQL SCD table.
tMysqlSCD addresses Slowly Changing Dimension needs, reading regularly a source of data and logging the changes into a dedicated SCD table.

**tMysqlSCD Standard properties**

These properties are used to configure tMysqlSCD running in the Standard Job framework.
The Standard tMysqlSCD component belongs to the Business Intelligence and the Databases families.
The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-in or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Built-in: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td>Repository: Select the Repository file where properties are stored. The following fields are pre-filled in using fetched data.</td>
<td></td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

**Note:**

When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.

2. In the child level, use a dedicated connection component to read that registered database connection.
For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

| **DB Version** | Select the Mysql version you are using. |
| **Host** | Database server IP address. |
| **Port** | Listening port number of DB server. |
| **Database** | Name of the database. |
| **Username and Password** | DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| **Table** | Name of the table to be written. Note that only one table can be written at a time. |
| **Action on table** | On the table defined, you can perform one of the following operations:  
| None: No operation is carried out.  
| Create a table: The table does not exist and gets created.  
| Create a table if not exists: The table is created if it does not exist. |
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.  
| Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
| • View schema: choose this option to view the schema only.  
| • Change to built-in property: choose this option to change the schema to Built-in for local changes.  
| • Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the [Repository Content] window.  
| Built-in: The schema is created and stored locally for this component only. Related topic: see *Talend Studio User Guide*.  
<p>| Repository: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see <em>Talend Studio User Guide</em>. |</p>
<table>
<thead>
<tr>
<th><strong>SCD Editor</strong></th>
<th>The SCD editor helps to build and configure the data flow for slowly changing dimension outputs. For more information, see SCD management methodology on page 2566.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Use memory saving mode</strong></td>
<td>Select this check box to maximize system performance.</td>
</tr>
</tbody>
</table>
| **Source keys include Null** | Select this check box to allow the source key columns to have Null values.  

⚠️ **Warning:**  
Special attention should be paid to the uniqueness of the source key(s) values when this option is selected. |
| **Die on error** | This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows. |

### Advanced settings

<table>
<thead>
<tr>
<th><strong>Additional JDBC Parameters</strong></th>
<th>Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the <strong>Use an existing connection</strong> check box in the Basic settings.</th>
</tr>
</thead>
</table>
| **End date time details** | Specify the time value of the SCD end date time setting in the format of **HH:mm:ss**. The default value for this field is **12:00:00**.  
This field appears only when SCD Type 2 is used and Fixed year value is selected for creating the SCD end date. |
| **tStatCatcher Statistics** | Select this check box to collect log data at the component level. |
| **Debug mode** | Select this check box to display each step during processing entries in a database. |

### Global Variables

| **Global Variables** | **NB_LINE_UPDATED**: the number of rows updated. This is an After variable and it returns an integer.  
**NB_LINE_INSERTED**: the number of rows inserted. This is an After variable and it returns an integer.  
**NB_LINE_REJECTED**: the number of rows rejected. This is an After variable and it returns an integer.  
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. |
<table>
<thead>
<tr>
<th></th>

<td>--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
# SCD management methodology

Slowly Changing Dimensions (SCDs) are dimensions that change slowly over time.

The SCD editor offers the simplest method of building the data flow for the SCD outputs. In the SCD editor, you can map columns, select surrogate key columns, and set column change attributes through combining SCD types. The following figure illustrates an example of the SCD editor.

## Usage

### Usage rule

This component is used as Output component. It requires an Input component and Row main link as input.

### Dynamic settings

Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see **Scenario: Reading data from databases through context-based dynamic connections** on page 2497 and **Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters** on page 489. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

### Limitation

This component does not support using SCD type 0 together with other SCD types.
**SCD keys**

You must choose one or more source keys columns from the incoming data to ensure its unicity.

You must set one surrogate key column in the dimension table and map it to an input column in the source table. The value of the surrogate key links a record in the source to a record in the dimension table. The editor uses this mapping to locate the record in the dimension table and to determine whether a record is new or changing. The surrogate key is typically the primary key in the source, but it can be an alternate key as long as it uniquely identifies a record and its value does not change.

**Source keys**: Drag one or more columns from the **Unused** panel to the **Source keys** panel to be used as the key(s) that ensure the unicity of the incoming data.

**Surrogate keys**: Set the column where the generated surrogate key will be stored. A surrogate key can be generated based on a method selected on the **Creation** list.

**Creation**: Select any of the below methods to be used for the key generation.

- **Auto increment**: auto-incremental key.
- **Input field**: key is provided in an input field.
When selected, you can drag the appropriate field from the **Unused** panel to the **complement** field.

- **Routine**: from the **complement** field, you can press **Ctrl+Space** to display the autocompletion list and select the appropriate routine.

- **Table max +1**: the maximum value from the SCD table is incremented to create a surrogate key.

- **DB Sequence**: from the **complement** field, you can enter the name of the existing database sequence that will automatically increment the column indicated in the **name** field.

Note that this option is only available through the **SCD Editor** of the **tOracleSCD**.

### Slowly Changing Dimensions types

The Slowly Changing Dimensions support four types of changes: **Type 0** through **Type 3**. You can apply any of the SCD types to any column in a source table by a simple drag-and-drop operation.

- **Type 0**: is not used frequently. Some dimension data may be overwritten and other may stay unchanged over time. This is most appropriate when no effort has been made to deal with the changing dimension issues.

- **Type 1**: no history is kept in the database. New data overwrites old data. Use this type if tracking changes is not necessary. this is most appropriate when correcting certain typos, for example the spelling of a name.

- **Type 2**: the whole history is stored in the database. This type tracks historical data by inserting a new record in the dimensional table with a separate key each time a change is made. This is most appropriate to track updates, for example.

- **Type 3**: only the information about a previous value of a dimension is written into the database. This type tracks changes using separate columns. This is most appropriate to track only the previous value of a changing column.

SCD **Type 2** principle lies in the fact that a new record is added to the SCD table when changes are detected on the columns defined. Note that although several changes may be made to the same record on various columns defined as SCD **Type 2**, only one additional line tracks these changes in the SCD table.

The SCD schema in this type should include SCD-specific extra columns that hold standard log information such as:

- **start**: adds a column to your SCD schema to hold the start date. You can select one of the input schema columns as a start date in the SCD table.

- **end**: adds a column to your SCD schema to hold the end date value for a record. When the record is currently active, the end date is **NULL** or you can select **Fixed Year Value** and fill in a fictive year to avoid having a null value in the end date field.

- **version**: adds a column to your SCD schema to hold the version number of the record.

- **active**: adds a column to your SCD schema to hold the **true** or **false** status value. This column helps to easily spot the active record.
Tracking data changes using Slowly Changing Dimensions (type 0 through type 3)

This scenario describes a Job that stores and manages both the current and historical employee data in a MySQL table using SCD (Slowly Changing Dimensions).

The input data contains various employee details including name, age, role, and salary, and another id column is added to help ensuring the unicity of the input data.

At first, the following employee data is inserted to a new MySQL table using SCD:

```
1;Mark Smith;30;tester;11000.00
2;Thomas Johnson;32;developer;12000.00
3;Teddy Brown;33;tester;13000.00
```

Then the table is updated using SCD with the following renewed employee data.

```
1;Mark Smith;31;tester;11000.00
2;Thomas Johnson;32;developer;12000.00
3;Teddy Brown;33;writer;13500.00
```

You can see the age of Mark Smith is updated from 30 to 31, the role of Teddy Brown is changed from tester to writer, and his salary is raised from 13000.00 to 13500.00. In this scenario,

- we don’t want to track the data changes for the name field, so we will perform Type 0 SCD on it,
- we want the new age data to overwrite the existing data, so we will perform Type 1 SCD on it,
- we want to retain the full history of the role data, and always create a new record with the changed data and close the previous record, so we will perform Type 2 SCD on it,
- we want to keep the current and previous dimension values for the salary field, so we will perform Type 3 SCD on it.

For more information about SCD types, see SCD management methodology on page 2566.

Creating a Job for tracking data changes in MySQL using SCD

Create a Job to open a connection to a MySQL database, insert the employee data into a MySQL database table using SCD (Slowly Changing Dimensions)

This Job retrieves and displays the inserted data on the console, then updates the employee data in MySQL using SCD, retrieves and displays the updated data on the console, finally closes the connection to the MySQL database.
Procedure

1. Create a new Job and add a **tMysqlConnection** component, two **tFixedFlowInput** components, two **tMysqlSCD** components, two **tMysqlInput** components, two **tLogRow** components, and a **tMysqlClose** component by typing their names in the design workspace or dropping them from the Palette.

2. Link the first **tFixedFlowInput** component to the first **tMysqlSCD** component using a **Row > Main** connection.

3. Do the same to link the first **tMysqlInput** component to the first **tLogRow** component, the second **tFixedFlowInput** component to the second **tMysqlSCD** component, and the second **tMysqlInput** component to the second **tLogRow** component.

4. Link the **tMysqlConnection** component to the first **tFixedFlowInput** component using a **Trigger > OnSubjobOk** connection.

5. Do the same to link the first **tFixedFlowInput** component to the first **tMysqlInput** component, the first **tMysqlInput** component to the second **tFixedFlowInput** component, the second **tFixedFlowInput** component to the second **tMysqlInput** component, and the second **tMysqlInput** component to the **tMysqlClose** component.
Opening a connection to a MySQL database

Configure the `tMysqlConnection` component to open a connection to a MySQL database.

**Procedure**

1. Double-click the `tMysqlConnection` component to open its **Basic settings** view.

```
<table>
<thead>
<tr>
<th>Property Type</th>
<th>DB Version</th>
<th>Host</th>
<th>Port</th>
<th>Database</th>
<th>Username</th>
<th>Password</th>
</tr>
</thead>
<tbody>
<tr>
<td>Built-In</td>
<td>Mysql 5</td>
<td>&quot;192.168.32.68&quot;</td>
<td>&quot;3306&quot;</td>
<td>&quot;talend&quot;</td>
<td>&quot;root&quot;</td>
<td>**********</td>
</tr>
</tbody>
</table>
```

2. In the **Host**, **Port**, **Database**, **Username**, and **Password** fields, enter the information required for the connection to the MySQL database.

Inserting the employee data into a MySQL table using SCD

Configure the first `tFixedFlowInput` component and the first `tMysqlSCD` component to insert the employee data into a MySQL database table using SCD (Slowly Changing Dimensions).

**Procedure**

1. Double-click the first `tFixedFlowInput` component to open its **Basic settings** view.

```
[Content]
1: Mark Smith, 30; tester; 11000.00
2: Thomas Johnson, 32; developer; 12000.00
3: Teddy Brown, 33; tester; 13000.00
```

2. Click the button next to **Edit schema** and in the pop-up window define the schema by adding five columns: `id` and `age` of Integer type, `name` and `role` of String type, and `salary` of Double type.
When done, click OK to save the changes. In the pop-up dialog box, click Yes to propagate the schema to the next component.

3. In the Mode area, select Use Inline Content (delimited file). Then in the Content field displayed, enter the following input employee data.

1;Mark Smith;30;tester;11000.00
2;Thomas Johnson;32;developer;12000.00
3;Teddy Brown;33;tester;13000.00

4. Click the first tMysqlSCD component to open its Basic settings view.

5. Select the Use an existing connection check box and from the Component List drop-down list displayed, select the connection component you have configured.

6. In the Table field, enter the name of employee_scd.

7. Click the button next to SCD Editor to open the SCD editor. All schema columns are listed on the Unused panel.

8. In the name field on the Surrogate keys panel, enter the name for the surrogate key, SK in this example.

9. From the Unused panel, drag and drop
   - id to the Source keys panel to use it as the key to ensure the unicity of the input data,
• **name** to the **Type 0 fields** panel and no special action will be performed upon dimension changes of it,

• **age** to the **Type 1 fields** panel to perform Type 1 SCD on it,

• **role** to the **Type 2 fields** panel to perform Type 2 SCD on it, and

• **salary** to the **Type 3 fields** panel to perform Type 3 SCD on it.

10. In the **Versioning** panel, select the **version** check box to hold the version numbers for the historical and current records in the SCD table, and select also the **active** check box to add the column that will hold the **True** value for the current active record or the **False** value for the historical records in the SCD table.

   When done, click **OK** to save the changes and close the SCD editor.

**Retrieving the inserted employee data from MySQL**

Configure the first **tMysqlInput** component and the first **tLogRow** component to retrieve the inserted employee data from the MySQL SCD table and display it on the console.

**Procedure**

1. Double-click the **tMysqlInput** component to open its **Basic settings** view.
2. Select the **Use an existing connection** check box and from the **Component List** drop-down list displayed, select the connection component you have configured.

3. In the **Table Name** field, enter the name of the table from which the employee data will be retrieved. In this example, it is `employee_scd`.

4. Open the schema editor of the **tMysqlSCD** component, select and copy all its schema columns, then open the schema editor of the **tMysqlInput** component, define its schema by pasting those schema columns you have copied from the **tMysqlSCD** component.

When done, click **OK** to save the changes. In the pop-up dialog box, click **Yes** to propagate the schema to the next component.

5. Click the **Guess Query** button to fill the **Query** field with the automatically generated SQL query that will extract data of all columns from the specified table.
6. Double-click the first `tLogRow` component to open its Basic settings view. In the Mode area, select Table (print values in cells of a table) for better readability of the result displayed on the console.

**Updating the employee data in MySQL using SCD**

Configure the second `tFixedFlowInput` component and the second `tMysqlSCD` component to update the employee data in MySQL using SCD (Slowly Changing Dimensions).

**Procedure**

1. Double-click the second `tFixedFlowInput` component to open its Basic settings view.
2. Click the button next to Edit schema and in the pop-up window define the schema by copying and pasting the schema of the first `tFixedFlowInput` component.
3. In the Mode area, select Use Inline Content (delimited file). Then in the Content field displayed, enter the following updated employee data.

   1;Mark Smith;31;tester;11000.00
   2;Thomas Johnson;32;developer;12000.00
   3;Teddy Brown;33;writer;13500.00

4. Repeat 4 on page 2572 through 10 on page 2573 in the procedure Inserting the employee data into a MySQL table using SCD on page 2571 to configure the second `tMysqlSCD` component.

**Retrieving the updated employee data from MySQL**

Configure the second `tMysqlInput` component and the second `tLogRow` component to retrieve the updated employee data from the MySQL SCD table and display it on the console.

**Procedure**

1. Repeat 1 on page 2573 through 5 on page 2574 in the procedure Retrieving the inserted employee data from MySQL on page 2573 to configure the second `tMysqlInput` component.
2. Repeat 6 on page 2575 in the procedure Retrieving the inserted employee data from MySQL on page 2573 to configure the second `tLogRow` component.

**Closing the connection to the MySQL database**

Configure the `tMysqlClose` component to close the connection to the MySQL database.

**Procedure**

1. Double-click the `tMysqlClose` component to open its Basic settings view.
2. From the Component List drop-down list, select the connection component that opens the connection you want to close. In this example, it is `tMysqlConnection_1`.

**Executing the Job to track data changes in MySQL using SCD**

After setting up the Job and configuring the components used in the Job for tracking data changes in MySQL using SCD, you can then execute the Job and verify the Job execution result.

**Procedure**

1. Press Ctrl + S to save the Job.
2. Press F6 to execute the Job.

As shown above, the new age data 31 for Mark Smith the old age data 30, a new record with the SK value set to 4 is created for the role change for Teddy Brown from tester to writer, and the values of the previous salary and the current salary for Teddy Brown are both kept in the newly created record.
tMysqlSCDELT

Reflects and tracks changes in a dedicated MySQL SCD table through SQL queries.

tMysqlSCDELT addresses Slowly Changing Dimension needs through SQL queries (server-side processing mode), and logs the changes into a dedicated MySQL SCD table.

tMysqlSCDELT Standard properties

These properties are used to configure tMysqlSCDELT running in the Standard Job framework.
The Standard tMysqlSCDELT component belongs to the Business Intelligence and the Databases families.
The component in this framework is generally available.

Note:
This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.
For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally. Enter properties manually.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file where Properties are stored. The fields that come after are pre-filled in using the fetched data.</td>
</tr>
<tr>
<td>DB Version</td>
<td>Select the Mysql version you are using.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>

<td>User authentication data for a dedicated database. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td><strong>Source table</strong></td>
<td>Name of the input MySQL SCD table.</td>
</tr>
<tr>
<td><strong>Table</strong></td>
<td>Name of the table to be written. Note that only one table can be written at a time</td>
</tr>
</tbody>
</table>
| **Action on table** | Select to perform one of the following operations on the table defined:  
**None**: No action carried out on the table.  
**Drop and create the table**: The table is removed and created again  
**Create a table**: A new table gets created.  
**Create a table if not exists**: A table gets created if it does not exist.  
**Clear a table**: The table content is deleted. You have the possibility to rollback the operation.  
**Truncate a table**: The table content is deleted. You don't have the possibility to rollback the operation. |
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.  
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
- **View schema**: choose this option to view the schema only.  
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No**. |
upon completion and choose this schema metadata again in the [Repository Content] window.

**Built-in**: The schema is created and stored locally for this component only. Related topic: see [Talend Studio User Guide](#).

**Repository**: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see [Talend Studio User Guide](#).

### Surrogate Key
Select the surrogate key column from the list.

### Creation
Select the method to be used for the surrogate key generation.

For more information regarding the creation methods, see [SCD management methodology](#) on page 2566.

### Source Keys
Select one or more columns to be used as keys, to ensure the unicity of incoming data.

### Use SCD Type 1 fields
Use type 1 if tracking changes is not necessary. SCD Type 1 should be used for typos corrections for example. Select the columns of the schema that will be checked for changes.

### Use SCD Type 2 fields
Use type 2 if changes need to be tracked down. SCD Type 2 should be used to trace updates for example. Select the columns of the schema that will be checked for changes.

- **Start date**: Adds a column to your SCD schema to hold the start date value. You can select one of the input schema columns as Start Date in the SCD table.
- **End Date**: Adds a column to your SCD schema to hold the end date value for the record. When the record is currently active, the End Date column shows a null value, or you can select [Fixed Year value](#) and fill it in with a fictive year to avoid having a null value in the End Date field.
- **Log Active Status**: Adds a column to your SCD schema to hold the true or false status value. This column helps to easily spot the active record.
- **Log versions**: Adds a column to your SCD schema to hold the version number of the record.

### Advanced settings

<table>
<thead>
<tr>
<th><strong>Debug mode</strong></th>
<th>Select this check box to display each step during processing entries in a database.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>tStat Catcher Statistics</strong></td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>
## Global Variables

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide.* |

## Usage

| Usage rule | This component is used as an output component. It requires an input component and Row main link as input. |

| Dynamic settings | Click the [+ ] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see *Scenario: Reading data from databases through context-based dynamic connections* on page 2497 and *Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters* on page 489. For more information on **Dynamic settings** and context variables, see *Talend Studio User Guide.* |

## Related Scenario

For related topics, see: *tMysqlSCD* on page 2563 and *Tracking data changes using Slowly Changing Dimensions (type 0 through type 3)* on page 2569.
tMysqlSP

Calls a MySQL database stored procedure.

tMysqlSP offers a convenient way to centralize multiple or complex queries in a database and call them easily.

**tMysqlSP Standard properties**

These properties are used to configure tMysqlSP running in the Standard Job framework.

The Standard tMysqlSP component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
<tr>
<td><strong>Property type</strong></td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td><strong>Built-in</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><strong>Host</strong></td>
<td>Database server IP address</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database</td>
</tr>
</tbody>
</table>
| **Username** and **Password** | DB user authentication data.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| **Schema** and **Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. |
| **Built-In**              | You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide. |
Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.

<table>
<thead>
<tr>
<th>SP Name</th>
<th>Type in the exact name of the Stored Procedure</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Is Function / Return result in</strong></td>
<td>Select this check box, if a value only is to be returned. Select on the list the schema column, the value to be returned is based on.</td>
</tr>
</tbody>
</table>

**Parameters**

Click the Plus button and select the various **Schema Columns** that will be required by the procedures. Note that the SP schema can hold more columns than there are parameters used in the procedure.

Select the **Type** of parameter:

- **IN**: Input parameter.
- **OUT**: Output parameter/return value.
- **IN OUT**: Input parameters is to be returned as value, likely after modification through the procedure (function).
- **RECORDSET**: Input parameters is to be returned as a set of values, rather than single value.

**Note:**

Check [Scenario: Inserting data in mother/daughter tables](#) on page 2476 if you want to analyze a set of records from a database table or DB query and return single records.

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is used as intermediary component. It can be used as start component but only input parameters are thus allowed.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Dynamic settings</strong></td>
<td>Click the [+] button to add a row in the table and fill the <strong>Code</strong> field with a context variable to choose</td>
</tr>
</tbody>
</table>
your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

| Limitation | The Stored Procedures syntax should match the Database syntax. |

**Scenario: Using tMysqlSP to find a State Label using a stored procedure**

The following job aims at finding the State labels matching the odd State IDs in a Mysql two-column table. A stored procedure is used to carry out this operation.

- Drag and drop the following components used in this example: tRowGenerator, tMysqlSP, tLogRow.
- Connect the components using the Row Main link.
- The tRowGenerator is used to generate the odd id number. Double-click on the component to launch the editor.
Click on the **Plus** button to add a column to the schema to generate.

Select the **Key** check box and define the **Type** to **Int**.

The **Length** equals to 2 digits max.

Use the preset function called **sequence** but customize the Parameters in the lower part of the window.

- Change the **Value** of **step** from 1 to 2 for this example, still starting from 1.
- Set the **Number of generated rows** to 25 in order for all the odd State id (of 50 states) to be generated.
- **Click OK** to validate the configuration.
- Then select the **tMysqlSP** component and define its properties.
Set the **Property type** field to **Repository** and select the relevant entry on the list. The connection details get filled in automatically.

Else, set manually the connection information.

Click **Sync Column** to retrieve the generated schema from the preceding component.

Then click **Edit Schema** and add an extra column to hold the State Label to be output, in addition to the ID.

Type in the name of the procedure in the **SP Name** field as it is called in the Database. In this example, **getstate**. The procedure to be executed states as follows:

```
DROP PROCEDURE IF EXISTS `talend`.`getstate` $$
CREATE DEFINER=`root`@`localhost` PROCEDURE `getstate`(IN pid INT, OUT pstate VARCHAR(50))
BEGIN
    SELECT LabelState INTO pstate FROM us_states WHERE idState = pid;
END $$
```

In the **Parameters** area, click the plus button to add a line to the table.

Set the **Column** field to **ID**, and the **Type** field to **IN** as it will be given as input parameter to the procedure.

Add a second line and set the **Column** field to **State** and the **Type** to **Out** as this is the output parameter to be returned.

Eventually, set the **tLogRow** component properties.
Synchronize the schema with the preceding component.

- And select the **Print values in cells of a table** check box for reading convenience.

- Then save your Job and execute it.

The output shows the state labels corresponding to the odd state ids as defined in the procedure.

**Note:**

Check *Scenario: Inserting data in mother/daughter tables* on page 2476 if you want to analyze a set of records from a database table or DB query and return single records.

**Related scenarios**

For related scenarios, see:

- *Scenario: Retrieving personal information using a stored procedure* on page 2452.
- *Scenario: Checking number format using a stored procedure* on page 2809.
- *Executing a stored procedure using tMDMSP* on page 2190.
tMysqlTableList

Lists the names of a given set of Mysql tables using a select statement based on a Where clause. tMysqlTableList iterates on a set of table names through a defined Mysql connection.

**tMysqlTableList Standard properties**

These properties are used to configure tMysqlTableList running in the Standard Job framework.

The Standard tMysqlTableList component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see [Dynamic database components](#) on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <a href="#">Apply</a>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tMysqlConnection component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Where clause for table name selection</td>
<td>Enter the Where clause to identify the tables to iterate on.</td>
</tr>
</tbody>
</table>

### Advanced settings

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
<th>Select this check box to collect log data at the component level.</th>
</tr>
</thead>
</table>

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>tMysqlTableList properties</th>
</tr>
</thead>
<tbody>
<tr>
<td>CURRENT_TABLE: the name of the table currently iterated upon. This is a Flow variable and it returns a string.</td>
<td></td>
</tr>
<tr>
<td>NB_TABLE: the number of tables iterated upon so far. This is a Flow variable and it returns an integer.</td>
<td></td>
</tr>
<tr>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
<td></td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is to be used along with Mysql components, especially with tMysqlConnection.</th>
</tr>
</thead>
</table>
| Dynamic settings | Click the [+ ] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. 

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |

---

**Scenario: Iterating on DB tables and deleting their content using a user-defined SQL template**

The following Java scenario creates a three-component job that iterates on given table names from a MySQL database using a WHERE clause. It then deletes the content of the tables directly on the DBMS using a user-defined SQL template.

For advanced use, start with creating a connection to the database that contains the tables you want to empty of their content.

- In the Repository tree view, expand Metadata and right click DB Connections to create a connection to the relevant database and to store the connection information locally.

  For more information about Metadata, see Talend Studio User Guide.

  Otherwise, drop a tMySQLConnection component in the design workspace and fill the connection details manually.

- Drop the database connection you created from the Repository onto the design workspace.

  The [Components] dialog box displays.

- Select tMysqlTableList and click OK.
The `tMysqlConnection` component displays on the design workspace with all connection details automatically filled in its **Basic settings** view.

- Drop the following two components from the Palette onto the design workspace: `tMysqlTableList` and `tELT`.
- Connect `tMysqlConnection` to `tMysqlTableList` using an **OnSubjobOk** link.

![Design Workspace Diagram](image)

- Connect `tMysqlTableList` to `tELT` using an **Iterate** link.
- If needed, double-click `tMysqlConnection` to display its **Basic settings** view and verify the connection details.

![Basic Settings](image)

In this example, we want to connect to a MySQL database called `examples`.

- In the design workspace, double-click `tMysqlTableList` to display its **Basic settings** view and define its settings.

![Basic Settings](image)

- On the **Component list**, select the relevant MySQL connection component if more than one connection is used.
- Enter a WHERE clause using the right syntax in the corresponding field to iterate on the table name(s) you want to delete the content of.

  In this scenario, we want the job to iterate on all the tables which names start with "ex".

  ![Basic Settings](image)

- In the design workspace, double-click `tELT` to display its **Basic settings** view and define its settings.
In **Database Name**, enter the name of the database containing the tables you want to process.

On the **Component list**, select the relevant MySQL connection component if more than one connection is used.

Click in the **Table name** field and press **Ctrl+Space** to access the global variable list.

From the global variable list, select `((String)globalMap.get("tMysqlTableList_1_CURRENT_TABLE"))`.

**To create the user-defined SQL template:**

- In the **Repository** tree view, expand **SQL Templates** and **MySQL** in succession.

- Right-click **UserDefined** and select **Create SQLTemplate** from the drop-down list.

The **[New SQLTemplate]** wizard opens.
• Enter a name for the new SQL template and fill in the other fields if needed and then click **Finish** to close the wizard.

An SQL pattern editor opens on the design workspace.

• Delete the existing code and enter the code necessary to carry out the desired action, deleting the content of all tables which names start with "ex" in this example.

```
1 DELETE FROM `<% = __TABLE_NAME__ %>`;
```

**Note:**

In the SQL template code, you must use the correct variable name attached to the table name parameter ("__TABLE_NAME__" in this example). To display the variable name used, put your pointer in the **Table Name** field in the basic settings of the tELT component.

```java
Database Name: "examples"
Table Name: (String)globalsMap.get("mysqlTableList_1_CURRENT_TABLE")
Schema: The variable attached to this parameter is: __TABLE_NAME__
```

• Press **Ctrl+S** to save the new user-defined SQL template.

The next step is to add the new user-defined SQL template to the SQL template list in the tELT component.

**To add the user-defined SQL template to the SQL template list:**
• In the Component view of tELT, click the SQL Templates tab to display the SQLTemplate List.

  ![SQL Template List](image)

  • Click the Add button and add two SQL template lines.
  • Click in the first line to display a drop-down arrow and then click the arrow to display the SQL template list.

  ![SQL Template List](image)

  • Select in the list the user-defined SQL template you already created.
  • Make sure that the SQL template in the second line is Commit.
  • Save your job and press F6 to execute it.

All tables in the MySQL examples database which names begin with "ex" are emptied from their content.

**Related scenario**

For tMysqlTableList related scenario, see Scenario: Iterating on a DB table and listing its column names on page 2470.
tNamedPipeClose

Closes a named-pipe at the end of a process.

tNamedPipeClose closes a named-pipe opened with tNamedPipeOpen at the end of a process.

**tNamedPipeClose Standard properties**

These properties are used to configure tNamedPipeClose running in the Standard Job framework.
The Standard tNamedPipeClose component belongs to the File family.
The component in this framework is generally available.

**Basic settings**

| Pipe | Select an existing named-pipe from the list to close. |

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

**Global Variables**

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

**Usage**

| Usage rule | This component is usually used to close a named-pipe at the end of a Job. |
| Dynamic settings | Click the [+ ] button to add a row in the table and fill the Code field with a context variable to choose your pipe connection dynamically from multiple connections planned in your Job. When a dynamic parameter is defined, the Pipe box in the Basic settings view becomes unusable. |
For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

**Limitation**

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

**Related scenario**

For a related scenario, see Scenario: Writing and loading data through a named-pipe on page 2599.
tNamedPipeOpen

Opens a named-pipe for writing data into it.
Used in inner-process communication, tNamedPipeOpen opens a named-pipe for writing data into it.

**tNamedPipeOpen Standard properties**

These properties are used to configure tNamedPipeOpen running in the Standard Job framework.
The Standard tNamedPipeOpen component belongs to the File family.
The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>Name</th>
<th>Fill in the field with the name of the named-pipe.</th>

<th>This component is usually used as the starting component in an inner-process communication Job.</th>
</tr>
</thead>
</table>

Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

Related scenario

For a related scenario, see Scenario: Writing and loading data through a named-pipe on page 2599.
tNamedPipeOutput

Writes data into an existing open named-pipe.
tNamedPipeOutput writes data into a named-pipe opened with tNamedPipeOpen.

**tNamedPipeOutput Standard properties**

These properties are used to configure tNamedPipeOutput running in the Standard Job framework.
The Standard tNamedPipeOutput component belongs to the File family.
The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>Use existing pipe connection</th>
<th>Select this check box to use an existing named-pipe in the Pipe component list, or clear this check box to specify a named-pipe in Pipe name field.</th>
</tr>
</thead>
</table>
| Pipe component                | Select an existing named-pipe component from the list.  
                                 **Note:**  
                                 This check box will display only when you select Use existing pipe connection. |
| Pipe name                     | Fill in the field with the name of an existing named-pipe.  
                                 **Note:**  
                                 This check box will display only when you clear Use existing pipe connection. |
| Row separator                 | String (ex: "\n" on Unix) to distinguish rows in the output file.  
                                 **Note:**  
                                 This check box will display only when you clear Use existing pipe connection. |
| Field separator               | Character, string or regular expression to separate fields of the output file.  
| CSV options                   | Select this check box to take into account all parameters specific to CSV files, in particular Escape char and Text enclosure parameters. |
| Schema and Edit Schema        | A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either Built-in or stored remotely in the Repository.  
                                 Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
                                 • View schema: choose this option to view the schema only.  
                                 • Change to built-in property: choose this option to change the schema to Built-in for local changes. |
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.

Click **Sync columns** to retrieve the schema from the previous component connected in the Job.

**Built-in**: The schema will be created and stored locally for this component only. Related topic: see *Talend Studio User Guide*.

**Repository**: The schema already exists and is stored in the Repository, hence can be reused in various projects and Job flowcharts. Related topic: see *Talend Studio User Guide*.

**Delete pipe if it exists**

Select this check box to avoid duplicate named-pipe.

## Advanced settings

<table>
<thead>
<tr>
<th>Boolean type</th>
<th>Select a boolean type from the list.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to gather the Job processing metadata at a Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

## Global Variables

**Global Variables**

- **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is a Flow variable and it returns an integer.
- **PIPE_NAME**: the name of the named-pipe. This is a Flow variable and it returns a string.
- **PIPE_NATIVE_NAME**: the native name of the named-pipe. This is a Flow variable and it returns a string.
- **PIPE_OUTPUTSTREAM**: the output stream of the named-pipe. This is a Flow variable and it returns an object.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*. 
Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is usually connected to another component in a subjob that reads data from a source.</th>
</tr>
</thead>
</table>

Dynamic settings

Click the [+ ] button to add a row in the table and fill the Code field with a context variable to choose your pipe connection dynamically from multiple connections planned in your Job.

The Dynamic settings table is available only when the Use existing pipe connection check box is selected in the Basic settings view. When a dynamic parameter is defined, the Pipe component list box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

Scenario: Writing and loading data through a named-pipe

The following scenario creates a multi-component Job, which writes data into an open named-pipe and displays the data onto the console.
Dropping and linking the components

Procedure
1. Drop the following components from the Palette to the design workspace: **tNamedPipeOpen**, **tParallelize**, **tNamedPipeClose**, **tFileInputDelimited**, **tSleep**, **tLogRow**, **tRowGenerator** and **tNamedPipeOutput**.
2. Connect **tNamedPipeOpen** to **tParallelize** using a **Trigger > OnSubjobOk** connection.
3. Connect **tParallelize** to **tFileInputDelimited** using a **Trigger > Parallelize** connection.
4. Connect **tParallelize** to **tSleep** using a **Trigger > Parallelize** connection.
5. Connect **tFileInputDelimited** to **tLogRow** using a **Row > Main** connection.
6. Connect **tParallelize** to **tNamedPipeClose** using a **Trigger > Synchronize (Wait for all)** connection.
7. Connect **tSleep** to **tRowGenerator** using a **Trigger > OnComponentOk** connection.
8. Connect **tRowGenerator** to **tNamedPipeOutput** using a **Row > Main** connection.

Configuring the components

Configuring the input component

Procedure
1. Double-click **tNamedPipeOpen** to define its properties in its **Basic settings** view.
   Fill in the **Name** field with the name of a named-pipe and select **Delete if already exist** to avoid duplicate named-pipe.
2. Double-click **tParallelize** to define its properties in its **Basic settings** view.
Select **end of all subjobs** from the **Wait for** list.
Fill in the **Sleep Duration** field with **100** to set the sleep duration.

3. Double-click **tFileInputDelimited** to define its properties in its **Basic settings** view.
Fill in the **File name/Stream** field with the following expression to use the name of the existing named-pipe defined in the **Basic settings** view of **tNamedPipeOpen**:

```
((String)globalMap.get("tNamedPipeOpen_1_PIPE_NATIVE_NAME"))
```

4. Click the three-dot button next to **Edit schema**.
5. Click the plus button to add three columns for `tFileInputDelimited`. Fill the three Column fields with `id`, `first_name` and `last_name` and set the Type of `id` to `Integer`. Keep the rest of the settings as default.

6. Click **OK** to save the settings for the schema.

7. Keep the rest of the settings in the **Basic settings** view of `tFileInputDelimited` as default.

8. Double-click `tSleep` and fill the **Pause (in seconds)** field with 1.

9. Double-click `tRowGenerator` to define its properties in its **Basic settings** view.

10. Click **RowGenerator Editor** to define the schema.

11. Click the plus button to add three columns for `tRowGenerator`. Fill the three Column fields with `id`, `first_name` and `last_name` and set the Type of `id` to `Integer`. Keep the rest of the settings of Type as default.

12. Select `sequence` from the list in the Functions field for `id`.

13. Select `getFirstName` from the list in the Functions field for Column `first_name`. 
14. Select `TalendDataGenerator.getLastName` from the list in the **Functions** field for Column `last_name`.

15. Select `id`, fill the **Value** field under **Function parameters** tab with `s1` for **sequence identifier**, `1001` for **start value** and `1` for **step**.

16. Click **OK** to save the settings.

**Configuring the output component**

**Procedure**

1. Double-click **tNamedPipeOutput** to define its properties in its **Basic settings** view.

2. Select the **Use existing pipe connection** check box and select **tNamedPipeOpen_1** from the **Pipe component** list.

3. Select **Delete pipe if it exists** to avoid duplicate named-pipe.

4. Click **Sync columns** to retrieve the schema from the preceding component.

5. Leave the rest of the settings as they are.

6. Double-click **tLogRow** to define its properties in its **Basic settings** view.

7. Click **Sync columns** to retrieve the schema from the preceding component.

8. Select **Table** in the **Mode** area.
9. Double-click **tNamedPipeClose** to define its properties in its **Basic settings** view.

10. Select **tNamedPipeOpen_1** from the **Pipe** list.

## Saving and executing the Job

### Procedure

Press **F6** to execute the Job.

```
Starting job namedPipe_Sample_01 at 18:13 19/05/2011.
[statistics] connecting to socket on port 3042
[statistics] connected
[----------------------]
<table>
<thead>
<tr>
<th>id</th>
<th>first_name</th>
<th>last_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1001</td>
<td>Bill</td>
<td>Cleveland</td>
</tr>
</tbody>
</table>
[----------------------]
[statistics] disconnected
Job namedPipe_Sample_01 ended at 18:13 19/05/2011. [exit code=0]
```

### Results

The data written into the named-pipe is displayed onto the console.
tNeo4jBatchOutput

Receives data from the preceding component and writes the data into a local Neo4j database.
tNeo4jBatchOutput is used to write nodes in a Neo4j database based on the defined index.

**tNeo4jBatchOutput Standard properties**

These properties are used to configure tNeo4jBatchOutput running in the Standard Job framework.
The Standard tNeo4jBatchOutput component belongs to the Big Data and the Databases families.
The component in this framework is available when you are using one of the Talend solutions with Big Data.

**Basic settings**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Use an existing connection</strong></td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. This component supports Neo4j version V3.2.X only and does not support the remote mode. Therefore, do not reuse the connection to versions other than V3.2.X defined in a tNeo4jConnection component and do not select the Remote server check box in tNeo4jConnection. Do not use a 2.X.X version and a 3.X.X version in the same Job. Otherwise, class conflict issues occur.</td>
</tr>
<tr>
<td><strong>Database path</strong></td>
<td>Specify the directory to hold your data files. If the specified directory does not exist, it will be created. This field appears only if you do not select the Use an existing connection check box.</td>
</tr>
<tr>
<td><strong>Shutdown after job</strong></td>
<td>Select this check box to shutdown the Neo4j database connection when no more operations on Neo4j are going to be performed after the current component. Alternatively, you can use tNeo4jClose to shutdown the database. This avoids errors such as “Id file not properly shutdown” at next execution of Jobs involving Neo4j. This check box is available only if the Use an existing connection check box is not selected.</td>
</tr>
<tr>
<td><strong>Field that contains the label list</strong></td>
<td>Select the column from the input schema you have defined in the preceding components to provide labels for the nodes to be created. When the input data provides multiple labels for a node, separate those labels by semi-colons (;) in the preceding components.</td>
</tr>
<tr>
<td><strong>Index name</strong></td>
<td>Enter, within double quotation marks, the name of the index to be created for the nodes. This index is used</td>
</tr>
</tbody>
</table>
to store the identifiers of the nodes and help create relationships.

**Import identifier**
Select the column from the input schema you have defined in the preceding components to provide identifiers for the nodes to be created. These identifiers are stored in the index to be created and must be unique across the index.

Therefore, ensure that the column to be used contains only unique values.

**Save the identifier**
Select this check box to save the technical identifiers (native graph ids).

For further information about the different types of Neo4j entity identifiers, see Neo4j documentation: Entity identifier.

**Number of index elements in memory**
Enter, without double quotation marks, the cache size used to keep the index elements in memory. This value must be enough to keep all of the index elements in memory.

For further information, see Neo4j documentation: Memory tuning.

---

### Advanced settings

**Neo4j configuration**
Add parameters to the table to configure the database to be created.

For further information, see Neo4j documentation: Configuration settings.

When entering values, use the syntax demonstrated by the examples given alongside the column names of this Nodes files table.

**tStatCatcher Statistics**
Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

---

### Global Variables

**Global Variables**

**NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

| Usage rule | This component is used as an output component and it always needs an incoming link. |
tNeo4jBatchOutputRelationship

Receives data from the preceding component and writes relationships in bulk into a local Neo4j database.

tNeo4jBatchOutputRelationship Standard properties

These properties are used to configure tNeo4jBatchOutputRelationship running in the Standard Job framework.

The Standard tNeo4jBatchOutputRelationship component belongs to the Big Data and the Databases families.

The component in this framework is available when you are using one of the Talend solutions with Big Data.

Basic settings

| Use existing connection | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. This component supports Neo4j version V3.2.X only and does not support the remote mode. Therefore, do not reuse the connection to versions other than V3.2.X defined in a tNeo4jConnection component and do not select the Remote server check box in tNeo4jConnection. Do not use a 2.X.X version and a 3.X.X version in the same Job. Otherwise, class conflict issues occur. |
| Database path | Specify the directory to hold your data files. This field appears only if you do not select the Use an existing connection check box. |
| Shutdown after job | Select this check box to shutdown the Neo4j database connection when no more operations on Neo4j are going to be performed after the current component. Alternatively, you can use tNeo4jClose to shutdown the database. This avoids errors such as “Id file not properly shutdown” at next execution of Jobs involving Neo4j. This check box is available only if the Use an existing connection check box is not selected. |
| Field for relationship types | Select the column from the input schema you have defined in the preceding components to provide types for the relationships to be created. |
| Direction of the relationship | Select the direction of the relationships to be created: • Outgoing: The relationship starts from the start node to the end node. |
### Start node of the relationship
Defining the start node of each relationship using the node identifier:
- **Name of the batch index:** select the tNeo4jBatchOutput component used to create the start nodes. The name of the index for these nodes are retrieved from that component.
- **Field name for the batch index:** select the column from the input schema you have defined in the preceding components to provide the name of the start node of each relationship to be created.

### End node of the relationship
Defining the end node of each relationship using the node identifier:
- **Name of the batch index:** select the tNeo4jBatchOutput component used to create the end nodes. The name of the index for these nodes are retrieved from that component.
- **Field name for the batch index:** select the column from the input schema you have defined in the preceding components to provide the name of the end node of each relationship to be created.

### Die on error
Select the check box to stop the execution of the Job when an error occurs.
Clear the check box to skip any rows on error and complete the process for error-free rows.

### Advanced settings

#### Neo4j configuration
Add parameters to the table to configure the database to be created.
For further information, see Neo4j documentation: Configuration settings.
When entering values, use the syntax demonstrated by the examples given alongside the column names of this Nodes files table.

#### tStatCatcher Statistics
Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

#### Global Variables
**NB_LINE:** the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.

**ERROR_MESSAGE:** the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions...
only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

## Usage

| Usage rule | This component is used as an output component and it always needs an incoming link. |

## Writing information of actors and movies to Neo4j with hierarchical relationship using Neo4j Batch components

In this scenario, Neo4j Batch components are used to import data about actors and movies from two CSV files in a local Neo4j database and create relationship for the data based on another CSV file that describes the actors' roles in the movies.

This scenario applies only to a Talend solution with Big Data.

The Neo4j Batch components provided by Talend supports bulk writing to a local Neo4j database only. They can be used neither with Neo4j versions prior to V3.2.X nor alongside Neo4j components that are using one of those Neo4j versions.

The components to be used are:

- One tNeo4jConnection component: it opens the connection to Neo4j to be reused.
- Three tFileInputDelimited components: they read the input information of actors and movies.
- Two tNeo4jBatchOutput components: they write information of movies and actors to the connected Neo4j database.
- One tNeo4jBatchOutputRelationship component: it creates relationship between actors and movies.
- One tNeo4jBatchSchema component: it creates an uniqueness constraint on the nodes in the database.
Creating the Neo4j Batch Job

Procedure

1. Ensure that the status of your Neo4j service and Neo4j console is stop.
   
   If you are using command-line to manage Neo4j, you can use `neo4j status` to check the status; if you have installed the Neo4j desktop application, you can check it directly in this application.

2. From the Repository on the Integration perspective, create a Job and add the components to be used by typing their names in the design workspace or dropping them from the Palette.

3. Connect the first `tFileInputDelimited` component to the first `tNeo4jBatchOutput` component using a Row > Main link. This Subjob imports the actors data in the Neo4j database.

4. Connect the second `tFileInputDelimited` component to the second `tNeo4jBatchOutput` component using a Row > Main link. This Subjob imports the movies data in the Neo4j database.

5. Connect the third `tFileInputDelimited` component to the `tNeo4jBatchOutputRelationship` component using a Row > Main link. This Subjob creates relationship between actors and movies.

Configuring the Neo4j connection to be reused

Procedure

1. Double-click the `tNeo4jConnection` component to open its Basic settings view.
2. From the DB Version list, select Neo4J 3.2.X.

3. Ensure that the Use a remote server check box is clear because the Neo4j Batch components work only on the local mode.

4. In the Database path field, enter the path or browse to the database file.

**Bulk-writing the actors data in Neo4j**

**Procedure**

1. Double-click the first tFileInputDelimited component to open its Component view.

2. In the File name/Stream field, enter the path or browse to the CSV file that describes the actors' IDs, names and their labels to be used in Neo4j.

   The input CSV file used in this example reads as follows:

   ```
   keanu,"Keanu Reeves",Actor
   laurence,"Laurence Fishburne",Actor
   carrieanne,"Carrie-Anne Moss",Actor
   ```

   The double quotation marks on the actor names are not mandatory.

3. Click the [...] button next to Edit schema to open the schema editor, and define the input schema based on the structure of the input file.

   In this example, the columns are id, name and label, all of type String.
4. Click OK to close this editor and accept the propagation of the schema to the next component.
5. In the Field separator field, enter a comma (,) to replace the default semicolon (;).
6. Double-click the first tNeo4jBatchOutput component to open its Component view.

7. Select the Use an existing connection check box to reuse the Neo4j database connection opened by the tNeo4jConnection component.
8. Verify that the Shutdown after Job check box is clear.
9. From the Field that contains the label list drop-down list, select the column that provides labels.
10. In the Index name field, enter the name of the index to be created for the nodes.
11. From Import identifier drop-down list, select the column that provides IDs.

**Bulk-writing the movies data into Neo4j**

**Procedure**

1. Double-click the second tFileInputDelimited component to open its Component view.
2. In the **File name/Stream** field, enter the path or browse to the CSV file that describes the movies’ IDs, names, release years and their labels to be used in Neo4j.

The input CSV file used in this example reads as follows:

```
tt0133093,"The Matrix",1999,Movie
tt0234215,"The Matrix Reloaded",2003,Movie;Sequel
tt0242653,"The Matrix Revolutions",2003,Movie;Sequel
```

The double quotation marks on the movie names are not mandate.

3. Click the [...] button next to **Edit schema** to open the schema editor, and define the input schema based on the structure of the input file.

In this example, the columns are id, title, released and label.

4. Click **OK** to close this editor and accept the propagation of the schema to the next component.

5. In the **Field separator** field, enter a comma (,) to replace the default semicolon (;).

6. Double-click the second **tNeo4jBatchOutput** component to open its **Component** view.
7. Select the **Use an existing connection** check box to reuse the Neo4j database connection opened by the tNeo4jConnection component.

8. Verify that the **Shutdown after Job** check box is clear.

9. From the **Field that contains the label list** drop-down list, select the column that provides labels.

10. In the **Index name** field, enter the name of the index to be created for the nodes.

11. From **Import identifier** drop-down list, select the column that provides IDs.

### Creating relationships in bulk

**Procedure**

1. Double-click the third **tFileInputDelimited** component to open its **Component** view.

2. In the **File name/Stream** field, enter the path or browse to the CSV file that describes the actor-movie relationships.
The input CSV file used in this example reads as follows:

```
keanu,"Neo",tt0133093,ACTED_IN
keanu,"Neo",tt0234215,ACTED_IN
keanu,"Neo",tt0242653,ACTED_IN
laurence,"Morpheus",tt0133093,ACTED_IN
laurence,"Morpheus",tt0234215,ACTED_IN
laurence,"Morpheus",tt0242653,ACTED_IN
carrieanne,"Trinity",tt0133093,ACTED_IN
carrieanne,"Trinity",tt0234215,ACTED_IN
carrieanne,"Trinity",tt0242653,ACTED_IN
```

The double quotation marks on the role names are not mandatory. The value `ACTED_IN` is an user-defined relationship type that explains the relationship between the actors and the movies.

3. Click the [...] button next to **Edit schema** to open the schema editor, and define the input schema based on the structure of the input file.

In this example, the columns are **from**, **role**, **to** and **type**.

4. Click **OK** to close this editor and accept the propagation of the schema to the next component.

5. In the **Field separator** field, enter a comma (,) to replace the default semicolon (;).

6. Double-click the **tNeo4jBatchOutputRelationship** component to open its **Component** view.
7. Select the **Use an existing connection** check box to reuse the Neo4j database connection opened by the tNeo4jConnection component.

8. Verify that the **Shutdown after Job** check box is clear.

9. From the **Field for relationship type** drop-down list, select the column that provides the relationship types.

10. From the **Direction of the relationship** drop-down list, select **Outgoing**.

11. In the **Start node of the relationship** area, select the **tNeo4jBatchOutput** component that provides the index of the start nodes, which is the `asActors` index in this example from the first tNeo4jBatchOutput. Then from the **Field name for the batch index** drop-down list, select the column that provides the actor names as the start nodes.

12. Repeat this action in the **End node of the relationship** area to select the `asMovie` index from the second tNeo4jBatchOutput and then select the column that provides the movie names as the end nodes.

**Adding uniqueness constraints on the nodes**

**Procedure**

1. Double-click the **tNeo4jBatchSchema** component to open its **Component** view.
2. Select the **Use an existing connection** check box to reuse the Neo4j database connection opened by the tNeo4jConnection component.

3. Select the **Shutdown after Job** check box to properly close the connection after the execution.

4. In the **Schema definition** table, add two rows by clicking the [+] button twice:
   a) In the **Schema type** column, select **Node property is unique** for both of the rows to add uniqueness constraints to nodes in Neo4j.

   b) In the **For node with Label** column, enter, within double quotation marks, **Actor** and **Movie** respectively, which are the labels used by the actor nodes and the movie nodes. Therefore, what you enter here must be identical with the labels previously used when creating those nodes.

   c) In the **On property** column, enter, within double quotation marks, the node properties to which you need to add uniqueness constraints. For the actor nodes, enter **name** and for the movie nodes, enter **title**. The values you enter here must be identical with the column names previously defined to provide actor names and movie names for the nodes to be created by the tNeo4jBatchOutput components.

5. Press **Ctrl+S** to save the Job, and press **F6** or click **Run** on the **Run** tab to execute the Job.

**Results**

Once the Job runs successfully to the end, check the result in your Neo4j browser:
tNeo4jBatchSchema

Defines the schema of a local Neo4j database.

**tNeo4jBatchSchema Standard properties**

These properties are used to configure tNeo4jBatchSchema running in the Standard Job framework. The Standard tNeo4jBatchSchema component belongs to the Big Data and the Databases families. The component in this framework is available when you are using one of the Talend solutions with Big Data.

**Basic settings**

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Use an existing connection</strong></td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. This component supports Neo4j version V3.2.X only and does not support the remote mode. Therefore, do not reuse the connection to versions other than V3.2.X defined in a tNeo4jConnection component and do not select the Remote server check box in tNeo4jConnection. Do not use a 2.X.X version and a 3.X.X version in the same Job. Otherwise, class conflict issues occur.</td>

This check box is available only if the <strong>Use an existing connection</strong> check box is not selected.</td>
</tr>
</tbody>
</table>
| **Schema definition**        | Add indexes and unique property constraints to define the schema:  
  - **Schema type**: select whether it is an index (Index on node property) or a constraint (Node property is unique) to be defined.  
  - **For node with label**: enter, within double quotation marks, the label of a node.  
  - **On property**: enter, within double quotation marks, the property of a node. |
Advanced settings

| Neo4j configuration | Add parameters to the table to configure the database to be created.  
|                     | For further information, see Neo4j documentation: Configuration settings.  
|                     | When entering values, use the syntax demonstrated by the examples given alongside the column names of this Nodes files table. |

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

Global Variables

| Global Variables | NB_LINE: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.  
|                  | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  
|                  | A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
|                  | To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.  
|                  | For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | This component is used standalone in a Subjob to write a Neo4j graph schema. |
tNeo4jClose

Close an active connection to an Neo4j database in embedded mode.

**tNeo4jClose Standard properties**

These properties are used to configure tNeo4jClose running in the Standard Job framework.

The Standard tNeo4jClose component belongs to the Big Data and the Databases families.

The component in this framework is available when you are using one of the Talend solutions with Big Data.

**Basic settings**

| Connection | Select an active Neo4j database connection to be closed. |

**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

**Global Variables**

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

**Usage**

| Usage rule | This component is to be used along with other Neo4j components, especially with tNeo4jConnection. |

| Limitation | n/a |

**Related scenarios**

For scenario in which tNeo4jClose is used, see:
• Scenario: Writing information of actors and movies to Neo4j with hierarchical relationship on page 2648,

• Scenario 1: Creating nodes with a label using a Cypher query on page 2660, and

• Scenario 2: Importing data from a CSV file to Neo4j using a Cypher query on page 2664.
tNeo4jConnection

Opens a connection to a Neo4j database to be reuse by other Neo4j components.
tNeo4jConnection starts the database in embedded mode, and checks the server availability in REST mode.

**tNeo4jConnection Standard properties**

These properties are used to configure tNeo4jConnection running in the Standard Job framework.
The Standard tNeo4jConnection component belongs to the Big Data and the Databases families.
The component in this framework is available when you are using one of the Talend solutions with Big Data.

Advanced settings

| tStatCatcher Statistics | Select this check box to collect the log data at a component level. |

Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | This component is generally used with other Neo4j components, particularly tNeo4jClose. |
| Limitation | n/a |

Related scenarios

For scenario in which tNeo4jConnection is used, see:

- Scenario: Writing information of actors and movies to Neo4j with hierarchical relationship on page 2648,
- Scenario 1: Creating nodes with a label using a Cypher query on page 2660, and
- Scenario 2: Importing data from a CSV file to Neo4j using a Cypher query on page 2664.
tNeo4jImportTool

Uses Neo4j Import Tool to create a Neo4j database and import large amounts of data in bulk from CSV files to this database.

**tNeo4jImportTool Standard properties**

These properties are used to configure tNeo4jImportTool running in the Standard Job framework. The Standard tNeo4jImportTool component belongs to the Big Data and the Databases families. The component in this framework is available when you are using one of the *Talend* solutions with Big Data.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Neo4j database folder</td>
<td>Enter, or browse to the directory you want tNeo4jImportTool to create a Neo4j database. The name you put in the path is used to name this database.</td>
</tr>
<tr>
<td>Nodes files</td>
<td>Complete this table to provide the CSV files that contain the information about the nodes to be imported.</td>
</tr>
<tr>
<td>Path to CSV file</td>
<td>enter, within double quotation marks, the path to the CSV file to be read.</td>
</tr>
<tr>
<td>CSV headers</td>
<td>enter, within double quotation marks, the headers used in this CSV file.</td>

</tbody>
</table>
### Import configuration
Add parameters to the table to configure Neo4j Import Tool.
For further information, see Neo4j documentation: Import Tool usage.
When entering values, use the syntax demonstrated by the examples given alongside the column names of this Nodes files table.

### tStatCatcher Statistics
Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables
**Global Variables**
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.
- A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.
- To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.
- For further information about variables, see *Talend Studio User Guide*.

### Usage
**Usage rule**
This component is to be used standalone in a Subjob to load data in bulk from given CSV files that have been created with specific structure.
For further information about the CSV structure required by Neo4j Import Tool, see Import.
You can use tFileOutputDelimited to create the CSV files to be used. If so, bear the following configuration in mind:
- **Line separator**: "\n"
- **Field separator**: "," 
- Do not include headers.
- File encoding: UTF-8.
tNeo4jInput

Reads data from Neo4j and sends data in the output Talend flow.

tNeo4jInput reads data from Neo4j based on Cypher query allowing any further transformation or processing of the data in the rest of the Job.

**tNeo4jInput Standard properties**

These properties are used to configure tNeo4jInput running in the Standard Job framework.
The Standard tNeo4jInput component belongs to the Big Data and the Databases families.
The component in this framework is available when you are using one of the Talend solutions with Big Data.

**Basic settings**

**Related scenarios**

For a related scenario, see Scenario 1: Writing data to a Neo4j database and reading specific data from it on page 2635.
tNeo4jOutput

Receives data from the preceding component and writes the data into Neo4j.

tNeo4jOutput is used to write data into a Neo4j database, and/or update or delete entries in the database based on the index defined.

**tNeo4jOutput Standard properties**

These properties are used to configure tNeo4jOutput running in the Standard Job framework.

The Standard tNeo4jOutput component belongs to the Big Data and the Databases families.

The component in this framework is available when you are using one of the Talend solutions with Big Data.

**Basic settings**

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB version</td>
<td>Select the Neo4j version you are using. This list is not shown if the Use an existing connection check box is selected. Upon selecting a database version, you will be prompted to install the corresponding database driver JAR files if not yet installed. You can find more details about how to install external modules in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
<tr>
<td>Remote server</td>
<td>Select this check box if you use a Neo4j remote server, and specify the root URL in the Server URL field.</td>
</tr>
<tr>
<td>Database path</td>
<td>If you use Neo4j in embedded mode, specify the directory to hold your data files. If the specified directory does not exist, it will be created. This field appears only if you do not select the Use an existing connection check box or the Remote server check box.</td>
</tr>
<tr>
<td>Shutdown after job</td>
<td>Select this check box to shutdown the Neo4j database connection when no more operations on Neo4j are going to be performed after the current component. </tr>
</tbody>
</table>
relationships mapping editor. Use it to index node or create relationships during the node insertion.

- Select the **Auto indexed** check box for a column to automatically index nodes with this property.

- **Index creation**: With a column selected, click the [+] button to create as many indexes as you want on nodes with the property corresponding to the selected column.
  - **Name**: Specify an index name in double quotes.
  - **Key**: Specify an index key in double quotes.
  - **Value (empty for current row)**: Specify an index value in double quotes. If you leave this field empty, the default value of the index added on each node will be the value of this property of the current node.
  - **Unique**: Select this check box if you want the defined index to be created only once within the graph, rather than on each node.

- **Relationship creation**: With a column selected, click the [+] button to create as many relationships as you want for nodes with the property corresponding to the selected column.
  - **Type**: Specify a relationship type in double quotes.
  - **Direction**: Select a relationship direction, between **Outgoing** and **Incoming**.
  - **Index name**: Specify an index name for the relationship, in double quotes.
  - **Index key**: Specify an index key for the relationship, in double quotes.
  - **Value (empty for current row)**: Specify an index value for the relationship, in double quotes. If you leave this field empty, the default value of the index added on the relationship will be the value of this property of the current node.

### Use label (Neo4j > 2.0)

Select this check box to create nodes with a label. Enter your label name in the **Label name** field.

This check box is not shown if Neo4j 1.X.X is selected from the **DB Version** list or Delete is selected from the **Data action** list.

Note that this option works only with Neo4j 2.0 onwards and Java 7.

### Data action

On the data of the node, you can perform:

- **Insert**: Add new node to the database.
- **Update**: Make changes to existing entries.
- **Update or insert**: Search the node with an index to update and make changes. If the node doesn’t exist, a new node will be inserted.
- **Delete**: Remove nodes fetched by the index according to the input flow.

| **Index name** | Specify the index name to query. This field is available only if the action selected in **Data action** is other than **Insert**. |
| **Index key** | Specify the index key to query. This field is available only if the action selected in **Data action** is other than **Insert**. |
| **Index value** | Select the index value to query. This field is available only if the action selected in **Data action** is other than **Insert**. |

**Schema and Edit schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **[Repository Content]** window.

**Built-In**: You create and store the schema locally for this component only. Related topic: see **Talend Studio User Guide**.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see **Talend Studio User Guide**.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center [https://help.talend.com](https://help.talend.com).
## Advanced settings

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
</table>
| **Commit every**                             | Enter the number of rows to be completed before committing batches of nodes to the DB. This option ensures transaction quality (but not rollback) and, above all, better performance at execution.  
**Warning:**  
This option is only supported by the embedded mode of the database. You can’t make transactions in REST mode. |
| **Batch import**                             | Select this check box to activate the batch mode.  
**Warning:**  
This option is only supported by the embedded mode of the database.  
It is recommended that you perform a backup operation before executing the Job to prevent data corruption.  
**Note:**  
If you have configured index creation on multiple columns in the Mapping table, it is recommended that you select the Unique check box in the index setting for the last column to avoid creating unwanted redundant indexes that may cause batch load issues.  
If you want more explanations about memory mapping configuration of batch import, please refer to Neo4j documentation at: http://neo4j.com/docs/stable/batchinsert-examples.html. |
| **Node store mapped memory**                 | Type in the memory size in MB allocated to nodes.                                                                                                                                                           |
| **Relationship store mapped memory**         | Type in the memory size in MB allocated to relationships.                                                                                                                                                   |
| **Property store mapped memory**             | Type in the memory size in MB allocated to property.                                                                                                                                                        |
| **String store mapped memory**               | Type in the memory size in MB allocated to strings.                                                                                                                                                         |
| **Array store mapped memory**                | Type in the memory size in MB allocated to arrays.                                                                                                                                                           |
| **tStatCatcher Statistics**                  | Select this check box to gather the Job processing metadata at the Job level as well as at each component level.                                                                                             |

Scenario 1: Writing data to a Neo4j database and reading specific data from it

This scenario applies only to a Talend solution with Big Data.

This basic scenario describes a Job composed of two subjobs: the first subjob reads employees data from a CSV file and writes it to a Neo4j database, and then triggers the second subjob, which reads the employees data based on certain query conditions from the Neo4j database and displays the data on the Run console.

Adding and linking components

Procedure
1. Create a Job and add the following components to the Job by typing theirs names in the design workspace or dropping them from the Palette:
   - a tFileInputDelimited component, to read the employees data from a CSV file,
   - a tNeo4jOutput component to write the employees data to a Neo4j database,
   - a tNeo4jInput component to read the employees data from the Neo4j database based on given conditions, and
   - a tLogRow component to display the data on the Run console.
2. Link the tFileInputDelimited component to the tNeo4jOutput component using a Row > Main connection.
3. Link the tNeo4jInput component to the tLogRow component using a Row > Main connection.
4. Link the tFileInputDelimited component to the tNeo4jInput component using a Trigger > On Subjob Ok connection.
5. Label the components to better identify their roles in the Job.
Configuring the components

Importing data to the Neo4j database

Procedure

1. Double-click the tFileInputDelimited component to open its Basic settings view on the Components tab.

2. In the File name/Stream field, specify the path to the CSV file that contains the employees data to read.

The input CSV file used in this example is as follows:

```
employeeID;employeeName;age;hireDate;salary;managerID
1;Rutherford Roosevelt;38;06-10-2008;13336.58;m5
2;Warren Adams;43;05-22-2008;11626.68;m6
3;Andrew Roosevelt;55;04-01-2007;10052.95;m4
4;Herbert Quincy;54;06-14-2007;10694.71;m6
5;Woodrow Polk;33;08-14-2007;13751.50;m4
6;Theodore Johnson;47;01-26-2008;12426.87;m6
7;Benjamin Adams;32;02-25-2008;10438.65;m4
8;Woodrow Harrison;51;10-11-2008;11188.27;m5
9;George Truman;40;04-28-2008;14254.49;m5
10;Harry Jackson;38;04-01-2008;12798.78;m6
```
3. In the **Header** field, specify the number of rows to skip as header rows. In this example, the first row of the CSV file is the header row.

4. Click the [...] button next to **Edit schema** to open the [Schema] dialog box, and define the input schema based on the structure of the input file. In this example, the input schema is composed of six columns: **employeeID** (integer), **employeeName** (String), **age** (Integer), **hireDate** (Date), **salary** (Float), and **managerID** (String).

When done, click **OK** to close the [Schema] dialog box and propagate the schema to the next component.

5. Click the tNeo4jOutput component and select the **Component** tab to open its **Basic settings** view.

6. Define a Neo4j database connection. In this example, the Neo4j database is accessible in REST mode, so select the **Remote server** check box and specify the URL of the Neo4j server in the **Server URL** field, “http://localhost:7474/db/data” in this example.

7. If needed, click the **Sync columns** button to ensure the component has the same schema as the preceding component.

Keep the rest of the parameters as they are.
Reading data from the Neo4j database

Procedure

1. Double-click the tNeo4jInput component to open its Basic settings view.

   ![Basic settings view](image)

   - Connection: Use an existing connection
   - DB Version: Neo4j 1.X.X
   - Server URL: "http://localhost:7474/db/data"

2. As in the tNeo4jOutput component, specify the URL of the Neo4j server to connect to, "http://localhost:7474/db/data" in this example.

3. Click the [...] button next to Edit schema and define the schema for employees information display. When done, click OK to close the [Schema] dialog box and propagate the schema to the next component.

   ![Schema dialog box](image)

   - The defined schema columns automatically appear in the Mapping table.
4. In the **Query** field, type in the Cypher query to match the data to read from the Neo4j database. In this example, use the following Cypher query to find employees who are more than 40 years old and are under the manager *m6*.

   "MATCH (n) WHERE n.age > 40 AND n.managerID = 'm6' RETURN n;"

5. Fill the **Return parameter** field for each schema column with a return parameter in double quotes to map the node properties in the Neo4j database with the schema columns.

6. Double-click the **tLogRow** component to open its **Basic settings** view, and select the **Table (print values in cells of a table)** option to display the retrieved information in a table.

### Executing the Job

**Procedure**

1. Press **Ctrl+S** to save the Job.
2. Press **F6** or click **Run** on the **Run** tab to run the Job.

The employees data of the CSV file is written to the Neo4j database and then the information of employees matching the set conditions is retrieved from the Neo4j database and displayed on the console.

### Scenario 2: Writing family information to Neo4j and creating relationships

This scenario applies only to a Talend solution with Big Data.

This scenario describes a Job that will write family information to labeled nodes in a remote Neo4j database and create relationships based on the family names.

### Adding and linking components

**Procedure**

1. Create a Job and add the following components to the Job by typing theirs names in the design workspace or dropping them from the **Palette**:
• a **tFileInputDelimited** component, to read the family data from a CSV file,

• a **tNeo4jOutput** component to write the family data to a Neo4j database and create relationships between husband and wife.

2. Link the **tFileInputDelimited** component to the **tNeo4jOutput** component using a **Row > Main** connection.

3. Label the components to better identify their roles in the Job.

![Diagram showing the connection between tFileInputDelimited and tNeo4jOutput components]

**Configuring the components**

**Configuring the data source**

**Procedure**

1. Double-click the **tFileInputDelimited** component to open its **Basic settings** view on the **Components** tab.

![Screenshot of the tFileInputDelimited component settings]

2. In the **File name/Stream** field, specify the path to the CSV file that contains the family data to read. The input CSV file used in this example is as follows:

   Name;Gender;Age;Family
   Jenny;Female;24;the Johnsons
   Jack;Male;26;the Johnsons
   Richard;Male;35;the Blacks
   Anne;Female;36;the Whites
   Helen;Female;28;the Blacks
   Tom;Male;38;the Whites

3. In the **Header** field, specify the number of rows to skip as header rows. In this example, the first row of the CSV file is the header row.

4. Click the [...] button next to **Edit schema** to open the [Schema] dialog box, and define the input schema based on the structure of the input file. In this example, the input schema is composed of six columns: *name* (integer), *gender* (String), *age* (Integer), and *family* (String).
When done, click **OK** to close the [Schema] dialog box and propagate the schema to the next component.

Writing data to Neo4j and creating indexes and relationships

Procedure

1. Click the **tNeo4jOutput** component and select the **Component** tab to open its **Basic settings** view.

2. From the **DB Version** list, select **Neo4J 2.X.X** to enable node labeling.

3. Define a Neo4j database connection. In this example, the Neo4j database is accessible in REST mode, so select the **Remote server** check box and specify the URL of the Neo4j server in the **Server URL** field, "http://localhost:7474/db/data" in this example.
4. Double-click the tNeo4jOutput component or click the Mapping button on the component’s Basic settings view to open the index and relationship mapping editor.

5. With the name column selected from the schema panel, click the Index creation tab, click the [+] button to add a row in the table, and create an index named first_name on this column:
   - In the Name field, enter first_name between double quotation marks.
   - In the Key field, enter first_name between double quotation marks to give the index a key.
   Then click in the schema panel to validate your index creation.

6. With the family column selected from the schema panel, click the Index creation tab, click the [+] button to add a row in the table, and create an index named family on this column:
   - In the Name field, enter family between double quotation marks.
   - In the Key field, enter family_name between double quotation marks to give the index a key.
   Then click in the schema panel to validate your index creation.

7. With the family column selected from the schema panel, click the Relationship creation tab, click the [+] button to add a row in the table, and create a relationship named Spouse on this column based on the index named family:
   - In the Type field, enter Spouse between double quotation marks.
   - From the Direction list field, select either Outgoing or Incoming.
   - In the Index Name field, enter family between double quotation marks.
   - In the Index Key field, enter family_name between double quotation marks.
Then click in the schema panel to validate your relationship creation, and click OK to close the mapping editor.

8. Select the Use label (Neo4j > 2.0) check box and enter Families between double quotation marks in the Label name field so that the nodes to be created will be labeled Families.

9. From the Data action list, select Insert or update, and set a reference key in the Index area that appears:
   - In Index name field, enter first_name between double quotation marks.
   - In Index key field, enter first_name between double quotation marks.
   - From Index value field, select name. As the Value field is left blank in index creation, the index value will be the value of the name column for each row.

   This way, when the Job is executed, nodes will be inserted or updated in the Neo4j database based on the first_name index: for each data row, if a node containing the same first name already exists in the database, the node will be updated; otherwise, a new node will be created.

**Executing the Job and checking the result**

**Procedure**

1. Press Ctrl+S to save the Job, and press F6 or click Run on the Run tab to run the Job.
2. In the address bar of your Web browser, enter the URL of the Neo4j database browser, `http://localhost:7474/` in this example, and enter the following Cypher query in the command line to view the nodes.

MATCH (n:`Families`) RETURN n;

As shown in the graphic view, three pairs of nodes labeled *Families* have been created and those with the same family name are linked together via the relationship *Spouse*. 
tNeo4jOutputRelationship

Receives data from the preceding component and writes relationships into Neo4j.

**tNeo4jOutputRelationship Standard properties**

These properties are used to configure tNeo4jOutputRelationship running in the Standard Job framework.

The Standard tNeo4jOutputRelationship component belongs to the Big Data and the Databases families.

The component in this framework is available when you are using one of the Talend solutions with Big Data.

**Basic settings**

<table>
<thead>
<tr>
<th><strong>Use existing connection</strong></th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>DB version</strong></td>
<td>Select the Neo4j version you are using. This list is not shown if the Use an existing connection check box is selected. Upon selecting a database version, you will be prompted to install the corresponding database driver JAR files if not yet installed. You can find more details about how to install external modules in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
<tr>
<td><strong>Remote server</strong></td>
<td>Select this check box if you use a Neo4j remote server, and specify the root URL in the Server URL field.</td>
</tr>
<tr>
<td><strong>Database path</strong></td>
<td>If you use Neo4j in embedded mode, specify the path of the data file. This field appears only if you do not select the Use an existing connection check box.</td>
</tr>
</tbody>
</table>
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
  • View schema: choose this option to view the schema only.  
  • Change to built-in property: choose this option to change the schema to Built-in for local changes.  
  • Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the...
Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the [Repository Content] window.

**Built-In**: You create and store the schema locally for this component only. Related topic: see *Talend Studio User Guide*.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see *Talend Studio User Guide*.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

<table>
<thead>
<tr>
<th>Server url</th>
<th>If you use Neo4j in REST mode, specify the root URL. This field appears only if you select the Remote server check box.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Shutdown after job</strong></td>
<td>Select this check box to shutdown the Neo4j database connection when no more operations on Neo4j are going to be performed after the current component. Alternatively, you can use tNeo4jClose to shutdown the database. This avoids errors such as &quot;Id file not properly shutdown&quot; at next execution of Jobs involving Neo4j. This check box is available only if the Use an existing connection check box is not selected.</td>
</tr>
<tr>
<td><strong>Relationship type</strong></td>
<td>Specify the relationship type to create for each row.</td>
</tr>
<tr>
<td><strong>Start node / Index name</strong></td>
<td>Specify the index name to query the starting node of the newest relationship.</td>
</tr>
<tr>
<td><strong>Start node / Index key</strong></td>
<td>Specify the index key to query the starting node.</td>
</tr>
<tr>
<td><strong>Start node / Index value</strong></td>
<td>Select the index value to query the starting node.</td>
</tr>
</tbody>
</table>
| **Relationship direction** | Select a relationship direction.  
  - **Outgoing**: The relationship starts from the start node to the end node.  
  - **Incoming**: The relationship starts from the end node to the start node. |
| **End node / Index name** | Specify the index name to query the ending node of the newest relationship. |
| **End node / Index key** | Specify the index key to query the ending node. |
End node / Index value | Select the index value to query the ending node.
---|---
Mapping | Use this table to map relationship properties with the input schema columns.

**Advanced settings**

**Commit every** | Enter the number of rows to be completed before committing batches of nodes together the DB. This option ensures transaction quality (but not rollback) and, above all, better performance at execution.
| This option is only supported by the embedded mode of the database. You can't make transactions in REST mode.

**Batch import** | Select this check to activate the batch mode
| This option is only supported by the embedded mode of the database. **Be very careful with the batch import mode. Because this option is unsafe, perform a backup before Job execution.**
| If you want more explanations about memory mapping configuration of batch import, please refer to Neo4j documentation at: [http://neo4j.com/docs/stable/batchinsert-examples.html](http://neo4j.com/docs/stable/batchinsert-examples.html)

**Node store mapped memory** | Type in the memory size in MB allocated to nodes.

**Relationship store mapped memory** | Type in the memory size in MB allocated to relationships.

**Property store mapped memory** | Type in the memory size in MB allocated to property.

**String store mapped memory** | Type in the memory size in MB in Mo allocated to strings.

**Array store mapped memory** | Type in the memory size in MB allocated to arrays.

**tStatCatcher Statistics** | Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

**Global Variables**

Global Variables | **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.
| **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.
| A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>

Scenario: Writing information of actors and movies to Neo4j with hierarchical relationship

This scenario applies only to a Talend solution with Big Data.

This scenario describes a Job that will import information about actors and movies from two CSV files into a remote Neo4j database and then create relationship between the actors and the movies based on another CSV file that describes the actors’ roles in the movies.

Adding and linking components

Procedure

1. Create a Job and add the following components to the Job by typing theirs names in the design workspace or dropping them from the Palette:
   - a tNeo4jConnection component, to open a connection to a Neo4j database,
   - three tFileInputDelimited components, to read the input information of actors and movies,
   - two tNeo4jOutput components, to write information of movies and actors to the connected Neo4j database,
   - a tNeo4jOutputRelationship component, to create relationship between actors and movies, and
   - a tNeo4jClose component, to close the previous opened Neo4j connection at the end of Job execution.

2. Link the first tFileInputDelimited to the first tNeo4jOutput component using a Row > Main connection. This sub-job will import the actors data into the Neo4j database.

3. Link the second tFileInputDelimited component to the second tNeo4jOutput component using a Row > Main connection. This sub-job will import the movies data into the Neo4j database.

4. Link the third tFileInputDelimited component to the tNeo4jOutputRelationship component using a Row > Main connection. This sub-job will create relationship between actors and movies.

5. Link the sub-jobs using Trigger > On Subjob Ok connections.

6. Label the components to better identify their roles in the Job.
Configuring the components

Opening a Neo4j database connection

Procedure

1. Double-click the tNeo4jConnection component to open its Basic settings view on the Component tab.
2. From the DB Version list, select Neo4J 2.X.X to enable node labeling.
3. Select the **Use a remote server** check box and specify the URL of the Neo4j server in the Server URL field, "http://localhost:7474/db/data" in this example.

### Importing the actors data into Neo4j

#### Procedure

1. Double-click the first tFileInputDelimited component to open its Basic settings view on the Component tab.

2. In the File name/Stream field, specify the path to the CSV file that describes the actors' names, the years they were born in, and their roles in the movies.

   The input CSV file used in this example is as follows:
   
<table>
<thead>
<tr>
<th>Name</th>
<th>Born</th>
</tr>
</thead>
<tbody>
<tr>
<td>Keanu Reeves</td>
<td>1964</td>
</tr>
<tr>
<td>Laurence Fishburne</td>
<td>1961</td>
</tr>
<tr>
<td>Carrie-Anne Moss</td>
<td>1967</td>
</tr>
</tbody>
</table>

3. In the **Header** field, specify the number of rows to skip as header rows. In this example, the first row of the CSV file is the header row.

4. Click the [...] button next to Edit schema to open the [Schema] dialog box, and define the input schema based on the structure of the input file. In this example, the input schema is composed of two columns, **name** and **born**, both of type String.

   When done, click **OK** to close the [Schema] dialog box and propagate the schema to the next component.
5. Click the first **tNeo4jOutput** component and select the **Component** tab to open its **Basic settings** view.

6. Select the **Use an existing connection** check box to reuse the Neo4j database connection opened by the **tNeo4jConnection** component, which is the only connection component used in this example.

7. Double-click the **tNeo4jOutput** component or click the **Mapping** button on the component’s **Basic settings** view to open the index and relationship mapping editor.

8. With the **name** column selected from the schema panel, click the **Index creation** tab, click the [+] button to add a row in the table, and create an index named **name** on this column:
   - In the **Name** field, enter *name* between double quotation marks.
   - In the **Key** field, enter *name* between double quotation marks to give the index a key *name*.

Then click in the schema panel to validate your index creation, and click **OK** to close the mapping editor.
9. Select the **Use label (Neo4j > 2.0)** check box and enter *Actors* between double quotation marks in the **Label name** field so that the nodes to be created will be labeled *Actors*.

**Importing the movies data into Neo4j**

**Procedure**

1. Double-click the second **tFileInputDelimited** component to open its **Basic settings** view on the **Component** tab.

2. In the **File name/Stream** field, specify the path to the CSV file that contains the information of the movies.

   The input CSV file used in this example is as follows:

   ```
   Title;Released;Tagline
   ```
3. In the Header field, specify the number of rows to skip as header rows. In this example, the first row of the CSV file is the header row.

4. Click the [...] button next to Edit schema to open the [Schema] dialog box, and define the input schema based on the structure of the input file. In this example, the input schema is composed of three columns, title (type String), released (type Date), and tagline (type String). When done, click OK to close the [Schema] dialog box and propagate the schema to the next component.

5. Click the second tNeo4jOutput component and select the Component tab to open its Basic settings view.

6. Select the Use an existing connection check box to reuse the Neo4j database connection opened by the tNeo4jConnection component, which is the only connection component used in this example.

7. Double-click the tNeo4jOutput component or click the Mapping button on the component's Basic settings view to open the index and relationship mapping editor.

8. With the title column selected from the schema panel, click the Index creation tab, click the [+] button to add a row in the table, and create an index named title on this column:
   - In the Name field, enter title between double quotation marks.
   - In the Key field, enter title between double quotation marks to give the index a key.

Then click in the schema panel to validate your index creation, and click OK to close the mapping editor.
9. Select the **Use label (Neo4j > 2.0)** check box and enter *Movies* between double quotation marks in the **Label name** field so that the nodes to be created will be labeled *Movies*.

**Creating actor-movie relationship in Neo4j**

**Procedure**

1. Double-click the third **tFileInputDelimited** component to open its **Basic settings** view on the **Component** tab.

2. In the **File name/Stream** field, specify the path to the CSV file that describes the actors' roles in the movies.

The input CSV file used in this example is as follows:

```
Actor;Movie;Role
Keanu Reeves;The Matrix;Neo
```
3. In the **Header** field, specify the number of rows to skip as header rows. In this example, the first row of the CSV file is the header row.

4. Click the [...] button next to **Edit schema** to open the [Schema] dialog box, and define the input schema based on the structure of the input file. In this example, the input schema is composed of three columns, **actor**, **movie**, and **role**, all of type String.

When done, click **OK** to close the [Schema] dialog box and propagate the schema to the next component.

5. Double-click the **tNeo4jOutputRelationship** component to open its **Basic settings** view.

6. Select the **Use an existing connection** check box to reuse the Neo4j database connection opened by the **tNeo4jConnection** component, which is the only connection component used in this example.

7. In the **Relationship type** field, enter the type of relationship to be created, between double quotation marks. In this example, the relationship type is **ACTED_IN**, which will appear as the label of the relationship between nodes.

8. Define the start and end nodes and the direction of the relationship to be created. In this example, the relationship will be created from **Actors** nodes, on which an index called **name** has been defined, to **Movies** nodes, on which an index called **title** has been defined.

   - **Start node**: enter **name** between double quotation marks in the **Index name** and **Index key** fields, and select the schema column **name** from the **Index value** list. As the **Value** field is left blank in index creation, the index value will be the value of column **name** for each row.
• From the **Relationship direction** list, select **Outgoing**.
• **End node**: enter *title* between double quotation marks in the **Index name** and **Index key** fields, and select the schema column *title* from the **Index value** list. As the **Value** field is left blank in index creation, the index value will be the value of column *title* for each row.

9. Click the [+ ] button three times to add three rows in the **Mapping** table to define three properties of the relationship:

<table>
<thead>
<tr>
<th>Property</th>
<th>Value taken from...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Actor</td>
<td>actor column of the schema</td>
</tr>
<tr>
<td>Movie</td>
<td>movie column of the schema</td>
</tr>
<tr>
<td>Role</td>
<td>role column of the schema</td>
</tr>
</tbody>
</table>

**Executing the Job and checking the result**

**Procedure**

1. Press **Ctrl+S** to save the Job, and press **F6** or click **Run** on the **Run** tab to run the Job.
2. In the address bar of your Web browser, enter the URL of the Neo4j database browser, *http://localhost:7474/* in this example, and enter the following Cypher query in the command line to view the nodes with the specified relationship between them.

   ```cypher
   MATCH (a)-[:`ACTED_IN`]->(b) RETURN a,b;
   ```

   As shown in the graphic view, *Actors* nodes are linked with *Movies* nodes via the relationship *ACTED_IN*, with properties as defined in the Job.
tNeo4jRow

Executes the stated Cypher query onto the specified Neo4j database.

Depending on the nature of the query, tNeo4jRow acts on the data (although without handling data).
tNeo4jRow is the specific component for Neo4J database query. It implements a flow in the Job design although it doesn't provide output.

**tNeo4jRow Standard properties**

These properties are used to configure tNeo4jRow running in the Standard Job framework.

The Standard tNeo4jRow component belongs to the Big Data and the Databases families.

The component in this framework is available when you are using one of the Talend solutions with Big Data.

**Basic settings**

<table>
<thead>
<tr>
<th><strong>Use an existing connection</strong></th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>DB version</strong></td>
<td>Select the Neo4j version you are using.</td>
</tr>
<tr>
<td></td>
<td>This list is not shown if the <strong>Use an existing connection</strong> check box is selected.</td>
</tr>
<tr>
<td></td>
<td>Upon selecting a database version, you will be prompted to install the corresponding database driver JAR files if not yet installed. You can find more details about how to install external modules in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
<tr>
<td><strong>Remote server</strong></td>
<td>Select this check box if you use a Neo4j remote server, and specify the root URL in the <strong>Server URL</strong> field.</td>
</tr>
<tr>
<td><strong>Database path</strong></td>
<td>If you use Neo4j in embedded mode, specify the directory to hold your data files. If the specified directory does not exist, it will be created.</td>
</tr>
<tr>
<td></td>
<td>This field appears only if you do not select the <strong>Use an existing connection</strong> check box or the <strong>Remote server</strong> check box.</td>
</tr>
<tr>
<td><strong>Shutdown after job</strong></td>
<td>Select this check box to shutdown the Neo4j database connection when no more operations on Neo4j are going to be performed after the current component.</td>
</tr>
<tr>

<td></td>
<td>This check box is available only if the <strong>Use an existing connection</strong> check box is not selected.</td>
</tr>
</tbody>
</table>
**Schema and Edit schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **[Repository Content]** window.

**Built-In**: You create and store the schema locally for this component only. Related topic: see **Talend Studio User Guide**.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see **Talend Studio User Guide**.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

**Query**
Enter your Cypher query in double quotes. If you have some parameters corresponding to the input schema columns, declare them with curly brackets ({}) and map them in the **Parameters** table.

**Parameters**
Click the `[+]` button to add parameters corresponding to your Cypher query and map them with the input schema columns.

- **Parameter name**: Type in the name of your parameter, in double quotes.
- **Parameter value**: Select the schema column you want to map your parameter with.

**Die on error**
This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows.
### Advanced settings

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
<th>Select this check box to gather the Job processing metadata at the Job level as well as at each component level.</th>

<th>This component can be used as a standalone component or as an output component in a process.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limitation</td>
<td>n/a</td>
</tr>
</tbody>
</table>
Scenario 1: Creating nodes with a label using a Cypher query

This scenario applies only to a Talend solution with Big Data.

This scenario describes a Job that creates nodes with a label in an embedded Neo4j database using a Cypher query, and then displays some properties of the specified node on the console.

Adding and linking components

Procedure

1. Create a Job and add the following components to the Job by typing theirs names in the design workspace or dropping them from the Palette:
   - a `tNeo4jConnection` component, to open a connection to a Neo4j database,
   - a `tNeo4jRow` component, to create nodes in the Neo4j database with a Cypher query,
   - a `tNeo4jIntput` component, to read the specified properties of the created nodes,
   - a `tLogRow` component, to display the data on the Run console, and
   - a `tNeo4jClose` component, to close the Neo4j database connection established by the `tNeo4jConnection` component.

2. Link the `tNeo4jConnection` component to the `tNeo4jRow` component using a Trigger > On Subjob Ok connection.

3. Link the `tNeo4jRow` component to the `tNeo4jIntput` component using a Trigger > On Subjob Ok connection.

4. Link the `tNeo4jIntput` component to the `tLogRow` component using a Row > Main connection.

5. Link the `tNeo4jIntput` component to the `tNeo4jClose` component using a Trigger > On Subjob Ok connection.
Configuring the components

Configuring a Neo4j database connection and nodes creation

Procedure

1. Double-click the tNeo4jConnection component to open its Basic settings view on the Component tab.

2. From the DB Version list, select Neo4j 2.X.X to enable node labeling support.

3. In the Database path field, specify the directory for your data files, “E:/Talend/DB/Neo4j/data” in this example.

In this example, you will use Neo4j in embedded mode; to connect to a remote Neo4j server via REST, click the Use a remote server check box and specify the URL of the Neo4j server.
4. Double-click the **tNeo4jRow** component to open its **Basic settings** view on the **Component** tab.

5. Select the **Use an existing connection** check box to reuse the Neo4j database connection opened by the **tNeo4jConnection** component, which is the only connection component used in this example.

6. In the **Query** field, type in the Cypher query to be executed by the component.

   In this example, type in the following query to create two nodes with the label *Managers* and three properties - *id*, *name*, and *position*:

   ```cypher
   CREATE (a:Managers { id: 1, name: 'Gerald White', position: 'HR directory'})
   CREATE (b:Managers { id: 2, name: 'Jimmy Black', position: 'Sales manager'})
   ```

   As this component does not have an input flow, leave the schema and the parameter settings blank.

Configuring data retrieving and display

**Procedure**

1. Double-click the **tNeo4jInput** component to open its **Basic settings** view.

2. Select the **Use an existing connection** check box to reuse the connection opened by the **tNeo4jConnection** component.
3. Click the [...] button next to **Edit schema** and define the schema corresponding to the node properties you want to retrieve and display. In this example, the schema is composed of two columns, *name* and *position*, both of type String.

When done, click **OK** to close the [Schema] dialog box and propagate the schema to the next component.

![Schema of tNeo4jInput_1](image)

The defined schema columns automatically appear in the **Mapping** table.

4. In the **Query** field, type in the Cypher query to match the data to read from the Neo4j database. In this example, use the following Cypher query to find the name and position of the manager whose ID is 2.

   ```cypher
   "MATCH (ee:Managers{id:2}) RETURN ee.name, ee.position;"
   ```

   or

   ```cypher
   "MATCH (ee:Managers) WHERE ee.id = 2 RETURN ee.name, ee.position;"
   ```

5. Fill the **Return parameter** field for each schema column with a return parameter in double quotes to map the node properties in the Neo4j database with the schema columns.

6. Double-click the **tLogRow** component to open its **Basic settings** view, and select the **Table (print values in cells of a table)** option to display the retrieved information in a table.

**Executing the Job**

**Procedure**

1. Press **Ctrl+S** to save the Job.
2. Press **F6** or click **Run** on the **Run** tab to run the Job.
Two nodes are created in the Neo4j database based on the Cypher query, with the data files written in the specified directory, and the defined information is retrieved and displayed on the console.

Scenario 2: Importing data from a CSV file to Neo4j using a Cypher query

This scenario applies only to a Talend solution with Big Data.

This scenario describes a Job that first imports employees data from a CSV file into a Neo4j database using a Cypher query, and then displays the information on the console.

Adding and linking components

Procedure

1. Create a Job and add the following components to the Job by typing theirs names in the design workspace or dropping them from the Palette:
   - a **tNeo4jConnection** component, to open a connection to a Neo4j database,
   - a **tFileInputDelimited** component, to read the source data from a CSV file,
   - a **tNeo4jRow** component, to write the employees data to the Neo4j database with a Cypher query,
   - a **tNeo4jIntput** component, to read the employees data from the Neo4j database,
   - a **tLogRow** component, to display the data on the Run console, and
   - a **tNeo4jClose** component, to close the Neo4j database connection opened by the **tNeo4jConnection** component.
2. Link the **tNeo4jConnection** component to the **tFileInputDelimited** component using a **Trigger > On Subjob Ok** connection.
3. Link the **tFileInputDelimited** component to the **tNeo4jRow** component using a **Row > Main** connection.
4. Link the **tFileInputDelimited** component to the **tNeo4jIntput** component using a **Trigger > On Subjob Ok** connection.
5. Link the **tNeo4jIntput** component to the **tLogRow** component using a **Row > Main** connection.
6. Link the **tNeo4jIntput** component to the **tNeo4jClose** component using a **Trigger > On Subjob Ok** connection.
7. Label the components to better identify their roles in the Job.
Configuring the components

Configuring a Neo4j database connection

Procedure

1. Double-click the tNeo4jConnection component to open its Basic settings view on the Component tab.

2. From the DB Version list, select Neo4j 2.X.X.

3. Select the Use a remote server check box and specify the URL of the Neo4j server in the Server URL field, “http://localhost:7474/db/data” in this example.
In this example, you will use Neo4j in REST mode; to connect to a remote Neo4j server in embedded mode, clear the **Use a remote server** check box and specify the Neo4j data file directory in the **Database path** field.

### Configuring data import

**Procedure**

1. Double-click the **tFileInputDelimited** component to open its **Basic settings** view on the **Component** tab.

2. **Input employees_info(tFileInputDelimited_1)**

   ![Input employees_info(tFileInputDelimited_1)](image)

   - **Property Type**: Built-in
   - **File name/Stream**: "E:/Telend/Data/Input/employees_info.csv"
   - **Row Separator**: ";"  
   - **Field Separator**: ";"
   - **Header**: 1  
   - **Limit**: 
   - **Schema**: 
     - **Skip empty rows**: 
     - **Uncompress as zip file**: 
     - **Die on error**: 

3. In the **File name/Stream** field, specify the path to the CSV file that contains the employees data to read.

   The input CSV file used in this example is as follows:

   ```
   employeeID;employeeName;age;hireDate;salary;managerID
   1;Rutherford Roosevelt;38;06-10-2008;13336.58;m5
   2;Warren Adams;43;05-22-2008;11626.68;m6
   3;Andrew Roosevelt;55;04-01-2007;10052.95;m4
   4;Herbert Quincy;54;06-14-2007;10694.71;m6
   5;Woodrow Polk;33;08-14-2007;13751.50;m4
   6;Theodore Johnson;47;01-26-2008;12426.87;m6
   7;Benjamin Adams;32;02-25-2008;10438.65;m4
   8;Woodrow Harrison;51;10-11-2008;11188.27;m5
   9;George Truman;40;04-28-2008;14254.49;m5
   10;Harry Jackson;38;04-01-2008;12798.78;m6
   ```

4. **In the **Header** field, specify the number of rows to skip as header rows. In this example, the first row of the CSV file is the header row.**

4. **Click the [...] button next to **Edit schema** to open the [Schema] dialog box, and define the input schema based on the structure of the input file. In this example, the input schema is composed of six columns: employeeID (integer), employeeName (String), age (Integer), hireDate (Date), salary (Double), and managerID (String).**

   When done, click **OK** to close the [Schema] dialog box and propagate the schema to the next component.
5. Double-click the **tNeo4jRow** component to open its **Basic settings** view on the **Component** tab.

6. Select the **Use an existing connection** check box to reuse the Neo4j database connection opened by the **tNeo4jConnection** component, which is the only connection component used in this example.

7. In the **Query** field, type in the Cypher query to be executed by the component.
   In this example, type in the following query to create nodes with the label **Employees** and six properties, to hold the data from the input flow:
   - **ID**, which will take the value of the variable parameter **id**,
   - **Name**, which will take the value of the variable parameter **name**,
• **Age**, which will take the value of the variable parameter *age*,
• **HireDate**, which will take the value of the variable parameter *hire_date*,
• **Salary**, which will take the value of the variable parameter *salary*, and
• **ManagerID**, which will take the value of the variable parameter *manager_id*.

```
"CREATE (n:Employees{ID:{id}, Name:{name}, Age:{age}, HireDate:{hire_date}, Salary:{salary}, ManagerID:{manager_id}})"
```

8. In the **Parameters** table, type in the variable parameters in the **Parameter** field in accordance with your Cypher query, and map each of them with an input schema column by selecting it from the **Parameter value** list field.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Parameter value</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;id&quot;</td>
<td>employeeID</td>
</tr>
<tr>
<td>&quot;name&quot;</td>
<td>employeeName</td>
</tr>
<tr>
<td>&quot;age&quot;</td>
<td>age</td>
</tr>
<tr>
<td>&quot;hire_date&quot;</td>
<td>hireDate</td>
</tr>
<tr>
<td>&quot;salary&quot;</td>
<td>salary</td>
</tr>
<tr>
<td>&quot;manager_id&quot;</td>
<td>managerID</td>
</tr>
</tbody>
</table>

**Configuring data retrieving and display**

**Procedure**

1. Double-click the **tNeo4jInput** component to open its **Basic settings** view.

2. Select the **Use an existing connection** check box to reuse the connection opened the **tNeo4jConnection** component.
3. Click the [...] button next to **Edit schema** and define the schema corresponding to the node properties you want to retrieve and display.
When done, click **OK** to close the [Schema] dialog box and propagate the schema to the next component.

![Schema of Read_nodes_Employees](image)

The defined schema columns automatically appear in the **Mapping** table.

4. In the **Query** field, type in the Cypher query to match the data to read from the Neo4j database. In this example, use the following Cypher query to retrieve all the properties of all the nodes with the label **Employees**.

   "MATCH (n:Employees) RETURN *;"

5. Fill the **Return parameter** field for each schema column with a return parameter in double quotes to map the node properties in the Neo4j database with the schema columns.

6. Double-click the **tLogRow** component to open its **Basic settings** view, and select the **Table (print values in cells of a table)** option to display the retrieved information in a table.

**Executing the Job**

**Procedure**

1. Press **Ctrl+S** to save the Job.
2. Press **F6** or click **Run** on the **Run** tab to run the Job.
The employees data in the CSV file is written to the Neo4j database and displayed on the console.

### Scenario 3: Importing data from a CSV file to Neo4j and creating relationships using a single Cypher query

This scenario applies only to a Talend solution with Big Data.

This scenario describes a Job that imports family information from a CSV file into a remote Neo4j database and create relationships between persons and families using a single Cypher query through a tNeo4jRow component.

Below is content of the CSV file to import data from in this example:

```
Name;Gender;Age;Family
Jenny;Female;24;the Johnsons
Jack;Male;26;the Johnsons
Richard;Male;35;the Blacks
Anne;Female;36;the Whites
Helen;Female;28;the Blacks
Tom;Male;38;the Whites
```

As `MERGE` is used with `LOAD CSV` in this example, to ensure the Cypher query is executed in an efficient way, another tNeo4jRow component is used to create an index on the property to merge.

### Adding and linking components

**Procedure**

1. Create a Job and add two tNeo4jRow components to the Job by typing the component name in the design workspace or dropping them from the Palette.
2. Link the components using a Trigger > On Sub Job Ok connection.
3. Label the components to better identify their roles in the Job.
Configuring the components

Creating an index

Procedure

1. Double-click the first tNeo4jRow component to open its Basic settings view on the Component tab.

2. From the DB Version list, select Neo4J 2.X.X.

3. Select the Remote server check box and specify the URL of the Neo4j server in the Server URL field, "http://localhost:7474/db/data" in this example.

4. In the Query field, type in the following query to create an index on the property you are going to merge, which is the name property of the Family nodes in this example:

   "CREATE INDEX ON :Family(name)"

Importing data and creating relationships

Procedure

1. Double-click the second tNeo4jRow component to open its Basic settings view on the Component tab.
2. From the **DB Version** list, select **Neo4J 2.X.X**.

3. Select the **Remote server** check box and specify the URL of the Neo4j server in the **Server URL** field, "http://localhost:7474/db/data" in this example.

4. In the **Query** field, type in the following Cypher query to import family data from the CSV file, create relevant **Person** and **Family** nodes, and create relationships between persons and families:

```
"LOAD CSV WITH HEADERS FROM 'file:E:/Talend/Data/Input/families.csv' AS csvLine 
FIELDTERMINATOR ';' 
MERGE (family:Family { name: csvLine.Family }) 
CREATE (person:Person { name: csvLine.Name, gender: csvLine.Gender, age: toInt(csvLine.Age)}) 
CREATE (person)-[:From]->(family)"
```

**Executing the Job and checking the result**

**Procedure**

1. Press **Ctrl+S** to save the Job, and press **F6** or click **Run** on the **Run** tab to run the Job.

2. In the address bar of your Web browser, enter the URL of the Neo4j database browser, http://localhost:7474/ in this example, and enter the following Cypher query in the command line to view the **Person** and **Family** nodes linked via the relationship **From**:

```
MATCH (a:Person)-[:`From`]->(b:Family) RETURN a,b;
```

As shown in the graphic view, nodes labeled **Family** and **Person** have been created and the nodes of persons from the same families are linked with the relevant **Family** nodes via the relationship **From**.
tNetezzaBulkExec

Offers gains in performance while carrying out the Insert operations to a Netezza database.

**tNetezzaBulkExec Standard properties**

These properties are used to configure tNetezzaBulkExec running in the Standard Job framework.

The Standard tNetezzaBulkExec component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-in</strong>: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined.

**Note:**

When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see **Talend Studio User Guide**.
<table>
<thead>
<tr>
<th><strong>Host</strong></th>
<th>Database server IP address</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database.</td>
</tr>
<tr>
<td><strong>Username</strong> and <strong>Password</strong></td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Table</strong></td>
<td>Name of the table to be written. Note that only one table can be written at a time and that the table must exist for the insert operation to succeed.</td>
</tr>
<tr>
<td><strong>Schema</strong> and <strong>Edit Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Built-In: You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide. Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available: • View schema: choose this option to view the schema only. • Change to built-in property: choose this option to change the schema to Built-in for local changes. • Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the [Repository Content] window.</td>
</tr>
<tr>
<td><strong>File Name</strong></td>
<td>Name of the file to be loaded. This file should be located on the same machine where the Studio is installed or where the Job using tNetezzaBulkExec is deployed.</td>
</tr>
</tbody>
</table>

**Advanced settings**

<p>| <strong>Field Separator</strong> | Character, string or regular expression to separate fields. |</p>
<table>
<thead>
<tr>
<th><strong>Escape character</strong></th>
<th>Character of the row to be escaped.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Date format / Date delimiter</strong></td>
<td>Use Date format to distinguish the way years, months and days are represented in a string. Use Date delimiter to specify the separator between date values.</td>
</tr>
<tr>
<td><strong>Time format / Time delimiter</strong></td>
<td>Use Time format to distinguish the time is represented in a string. Use Time delimiter to specify the separator between time values.</td>
</tr>
<tr>
<td><strong>Encoding</strong></td>
<td>Select the encoding from the list or select Custom and define it manually. This field is compulsory for DB data handling.</td>
</tr>
<tr>
<td><strong>Max Errors</strong></td>
<td>Enter the maximum error limit that will not stop the process.</td>
</tr>
<tr>
<td><strong>Skip Rows</strong></td>
<td>Enter the number of rows to be skipped.</td>
</tr>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Global Variables</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Global Variables</strong></td>
</tr>
<tr>
<td><strong>NB_LINE</strong>: the number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td>To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td>For further information about variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Usage</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Usage rule</strong></td>
</tr>
<tr>
<td><strong>Dynamic settings</strong></td>
</tr>
</tbody>
</table>
when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>Limitation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
</tbody>
</table>

**Related scenarios**

For use cases in relation with **tNetezzaBulkExec**, see the following scenarios:

- *Scenario: Inserting transformed data in MySQL database* on page 2537.
- *Scenario: Inserting data in bulk in MySQL database* on page 2544.
- *Scenario: Truncating and inserting file data into an Oracle database* on page 2752.
tNetezzaClose

Closes the transaction committed in the connected Netezza database.

tNetezzaClose Standard properties

These properties are used to configure tNetezzaClose running in the Standard Job framework.
The Standard tNetezzaClose component belongs to the Databases family.
The component in this framework is generally available.

Note:
This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.
For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tNetezzaConnection component in the list if more than one connection are planned for the current Job.</td>
</tr>
</tbody>
</table>

Advanced settings

| tStat Catcher Statistics  | Select this check box to collect log data at the component level. |

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is to be used along with Netezza components, especially with tNetezzaConnection and tNetezzaCommit.</th>
</tr>
</thead>
</table>
| Dynamic settings           | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.
Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.
For examples on using dynamic parameters, see Scenario: Reading data from databases through context- |
Based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenarios

No scenario is available for the Standard version of this component yet.
tNetezzaCommit

Validates the data processed through the Job into the connected Netezza database.

Using a unique connection, tNetezzaCommit commits in one go a global transaction instead of doing that on every row or every batch and thus provides gain in performance.

**tNetezzaCommit Standard properties**

These properties are used to configure tNetezzaCommit running in the Standard Job framework.

The Standard tNetezzaCommit component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the <strong>tNetezzaConnection</strong> component in the list if more than one connection are planned for the current Job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Warning:**

*If you want to use a Row > Main connection to link tNetezzaCommit to your Job, your data will be committed row by row. In this case, do not select the Close connection check box or your connection will be closed before the end of your first row commit.*

### Advanced settings

<table>
<thead>
<tr>
<th>tStat Catcher Statistics</th>
<th>Select this check box to collect log data at the component level.</th>
</tr>
</thead>
</table>

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is more commonly used with other tNetezza* components, especially with the tNetezzaConnection and tNetezzaRollback components.</th>
</tr>
</thead>
</table>
Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenario

For tNetezzaCommit related scenario, see Scenario: Inserting data in mother/daughter tables on page 2476.
tNetezzaConnection

Opens a connection to a Netezza database to be reused in the subsequent subjob or subjobs.

**tNetezzaConnection Standard properties**

These properties are used to configure tNetezzaConnection running in the Standard Job framework.
The Standard tNetezzaConnection component belongs to the Databases and the ELT families.
The component in this framework is generally available.

**Note:**
This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Host</td>
<td>Database server IP address</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Additional JDBC Parameters</td>
<td>Specify additional connection properties for the DB connection you are creating.</td>
</tr>
<tr>
<td>Use or register a shared DB Connection</td>
<td>Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the Shared DB Connection Name field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child.</td>
</tr>
</tbody>
</table>
This option is incompatible with the **Use dynamic job** and **Use an independent process to run subjob** options of the `tRunJob` component. Using a shared connection together with a `tRunJob` component with either of these two options enabled will cause your Job to fail.

### Advanced settings

| **Auto Commit** | Select this check box to commit any changes to the database automatically upon the transaction. With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component. Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component. |
| **tStatCatcher Statistics** | Select this check box to gather the job processing metadata at a Job level as well as at each component level. |

### Usage

| **Usage rule** | This component is more commonly used with other `tNetezza*` components, especially with the `tNetezzaCommit` and `tNetezzaRollback` components. |
| **Limitation** | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |

### Related scenarios

For a `tNetezzaConnection` related scenario, see [Scenario: Inserting data in mother/daughter tables](#) on page 2476.
tNetezzaInput

Reads a database and extracts fields from a Netezza database based on a query.

tNetezzaInput executes a DB query with a strictly defined order which must correspond to the schema definition. Then it passes on the field list to the next component via a Main row link.

tNetezzaInput Standard properties

These properties are used to configure tNetezzaInput running in the Standard Job framework.
The Standard tNetezzaInput component belongs to the Databases family.
The component in this framework is generally available.

Note:
This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.
For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
</tbody>
</table>

  **Built-in**: No property data stored centrally.

  **Repository**: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.

Click this icon to open a database connection wizard and store the database connection parameters you set in the component Basic settings view.
For more information about setting up and storing database connection parameters, see Talend Studio User Guide.

Use an existing connection

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

Note:
When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component.
which creates that very database connection.

2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>

</table>

<table>
<thead>
<tr>
<th>Dynamic settings</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.</td>
<td></td>
</tr>
</tbody>
</table>

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defin
ed, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see **Scenario: Reading data from databases through context-based dynamic connections** on page 2497 and **Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters** on page 489. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

<table>
<thead>
<tr>

<tr>
<td>Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the <strong>Install</strong> button on the <strong>Component</strong> tab view. You can also find out and add all missing JARs easily on the <strong>Modules</strong> tab in the <strong>Integration</strong> perspective of your studio. You can find more details about how to install external modules in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
</tbody>
</table>

**Related scenarios**

Related scenarios for **tNetezzaInput** are:

- **Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters** on page 489.
tNetezzaNzLoad

Inserts data into a Netezza database table using Netezza's nzload utility.

tNetezzaNzLoad bulk loads data into a Netezza table either from an existing data file, an input flow, or directly from a data flow in streaming mode through a named-pipe.

**tNetezzaNzLoad Standard properties**

These properties are used to configure tNetezzaNzLoad running in the Standard Job framework.
The Standard tNetezzaNzLoad component belongs to the Databases family.
The component in this framework is generally available.

<td>Specify a name for the named-pipe to be used. Ensure that the name entered is valid.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| Use existing control file | Select this check box to provide a control file to be used with the nzload utility instead of specifying all the options explicitly in the component. When this check box is selected, **Data file** and the other nzload related options no longer apply. Please refer to Netezza's nzload manual for details on creating a control file. |

### Note:

The global variable `NB_LINE` is not supported when any control file is being used.

| Control file | Enter the path to the control file to be used, between double quotation marks, or click `[...]` and browse to the control file. This option is passed on to the nzload utility via the `-cf` argument. |

| Field separator | Character, string or regular expression used to separate fields. |

### Warning:

This is nzload's delim argument. If you do not use the **Wrap quotes around fields** option, you must make sure that the delimiter is not included in the data that's inserted to the database. The default value is `\t` or TAB. To improve performance, use the default value.

| Wrap quotes around fields | This option is only applied to columns of String, Byte, Byte[], Char, and Object types. Select either: |

#### None:

do not wrap column values in quotation marks.

#### Single quote:

wrap column values in single quotation marks.

#### Double quote:

wrap column values in double quotation marks.

### Warning:

If using the **Single quote** or **Double quote** option, it is necessary to use `\` as the **Escape char**.

| Advanced options | Set the nzload arguments in the corresponding table. Click `[+]` as many times as required to add arguments to the table. Click the **Parameter** field and choose among the arguments from the list. Then click the corresponding **Value** field and enter a value between quotation marks. |

For details about the available parameters, see **Parameters** on page 2691.
### Encoding
Select the encoding type from the list.

### Specify nzload path
Select this check box to specify the full path to the nzload executable. You must check this option if the nzload path is not specified in the PATH environment variable.

### Full path to nzload executable
Full path to the nzload executable on the machine in use. It is advisable to specify the nzload path in the PATH environment variable instead of selecting this option.

### tStatCatcher Statistics
Select this check box to collect log data at the component level.

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_LINE: the number of rows processed. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>

<th>Usage rule</th>
<th>This component is mainly used when non particular transformation is required on the data to be loaded on to the database.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>This component can be used as a standalone or an output component.</td>
</tr>
</tbody>
</table>

### Parameters
The following table lists the parameters you can use in the Advanced options table in the Advanced settings tab.

<p>| -If | Name of the log file to generate. The logs will be appended if the log file already exists. If the parameter is not specified, the default name for the log file is <code>&lt;table_name&gt;.&lt;db_name&gt;.nzlog</code>. And it’s generated under the current working directory where the job is running. |</p>
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>-bf</strong></td>
<td>Name of the bad file to generate. The bad file contains all the records that could not be loaded due to an internal Netezza error. The records will be appended if the bad file already exists. If the parameter is not specified, the default name for the bad file is <code>&lt;table_name&gt;.&lt;db_name&gt;.nzbad</code>. And it’s generated under the current working directory where the job is running.</td>
</tr>
<tr>
<td><strong>-outputDir</strong></td>
<td>Directory path to where the log and the bad file are generated. If the parameter is not specified the files are generated under the current directory where the job is currently running.</td>
</tr>
<tr>
<td><strong>-logFileSize</strong></td>
<td>Maximum size for the log file. The value is in MB. The default value is 2000 or 2GB. To save hard disk space, specify a smaller amount if your job runs often.</td>
</tr>
<tr>
<td><strong>-compress</strong></td>
<td>Specify this option if the data file is compressed. Valid values are &quot;TRUE&quot; or &quot;FALSE&quot;. Default value if &quot;FALSE&quot;. This option is only valid if this component is used by itself and not connected to another component via an input flow.</td>
</tr>
<tr>
<td><strong>-skipRows &lt;n&gt;</strong></td>
<td>Number of rows to skip from the beginning of the data file. Set the value to ‘1’ if you like to skip the header row from the data file. The default value is ‘0’. This option should only be used if this component is used by itself and not connected to another component via an input flow.</td>
</tr>
<tr>
<td><strong>-maxRows &lt;n&gt;</strong></td>
<td>Maximum number of rows to load from the data file. This option should only be used if this component is used by itself and not connected to another component via an input flow.</td>
</tr>
<tr>
<td><strong>-maxErrors</strong></td>
<td>Maximum number of error records to allow before terminating the load process. The default value is ‘1’.</td>
</tr>
<tr>
<td><strong>-ignoreZero</strong></td>
<td>Binary zero bytes in the input data will generate errors. Set this option to ‘NO’ to generate error or to ‘YES’ to ignore zero bytes. The default value is ‘NO’.</td>
</tr>
<tr>
<td><strong>-requireQuotes</strong></td>
<td>This option requires all the values to be wrapped in quotes. The default value is &quot;FALSE&quot;. This option currently does not work with input flow. Use this option only in standalone mode with an existing file.</td>
</tr>
<tr>
<td><strong>-nullValue &lt;token&gt;</strong></td>
<td>Specify the token to indicate a null value in the data file. The default value is ‘NULL’. To improve slightly performance you can set this value to an empty field by specifying the value as single quotes: &quot;&quot;.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>fillRecord</td>
<td>Treat missing trailing input fields as null. You do not need to specify a value for this option in the value field of the table. This option is not turned on by default, therefore input fields must match exactly all the columns of the table by default. Trailing input fields must be nullable in the database.</td>
</tr>
<tr>
<td>ctrlChar</td>
<td>Accept control chars in char/varchar fields (must escape NUL, CR and LF). You do not need to specify a value for this option in the value field of the table. This option is turned off by default.</td>
</tr>
<tr>
<td>ctnString</td>
<td>Accept un-escaped CR in char/varchar fields (LF becomes only end of row). You do not need to specify a value for this option in the value field of the table. This option is turned off by default.</td>
</tr>
<tr>
<td>truncString</td>
<td>Truncate any string value that exceeds its declared char/varchar storage. You do not need to specify a value for this option in the value field of the table. This option is turned off by default.</td>
</tr>
<tr>
<td>dateStyle</td>
<td>Specify the date format in which the input data is written in. Valid values are: “YMD”, “Y2MD”, “DMY”, “DMY2”, “MDY”, “MDY2”, “MONDY”, “MONDY2”. The default value is “YMD”. The date format of the column in the component’s schema must match the value specified here. For example if you want to load a DATE column, specify the date format in the component schema as ’yyyy-MM-dd” and the -dateStyle option as ’YMD’. For more description on loading date and time fields, see Loading DATE, TIME and TIMESTAMP columns on page 2694.</td>
</tr>
<tr>
<td>dateDelim</td>
<td>Delimiter character between date parts. The default value is ”-“ for all date styles except for “MONDY[2]” which is ” ” (empty space). The date format of the column in the component’s schema must match the value specified here.</td>
</tr>
<tr>
<td>y2Base</td>
<td>First year expressible using two digit year (Y2) dateStyle.</td>
</tr>
<tr>
<td>timeStyle</td>
<td>Specify the time format in which the input data is written in. Valid values are: ”24HOUR” and ”12HOUR”. The default value is ”24HOUR”. For slightly better performance you should keep the default value. The time format of the column in the component’s schema must match the value specified here. For example if you want to load a TIME column, specify the date format in the component schema as ”HH:mm:ss” and the -timeStyle option as ”24HOUR”. For more description on loading date and time fields, see Loading DATE, TIME and TIMESTAMP columns on page 2694.</td>
</tr>
</tbody>
</table>
-timeDelim

Delimiter character between time parts. The default value is ".".

**Note:**
The time format of the column in the component’s schema must match the value specified here.

-timeRoundNanos

Allow but round non-zero digits with smaller than microsecond resolution.

-boolStyle

Specify the format in which Boolean data is written in the data. The valid values are: "1_0", "T_F", "Y_N", "TRUE_FALSE", "YES". The default value is "1_0". For slightly better performance keep the default value.

-allowRelay

Allow load to continue after one or more SPU reset or failed over. The default behaviour is not allowed.

-allowRelay <n>

Specify number of allowable continuation of a load. Default value is "1".

### Loading DATE, TIME and TIMESTAMP columns

When this component is used with an input flow, the date format specified inside the component’s schema must match the value specified for -dateStyle, -dateDelim, -timeStyle, and -timeDelim options.

<table>
<thead>
<tr>

<td>':'</td>
</tr>
</tbody>
</table>

### Related scenario

For a related use case, see Scenario: Inserting data in bulk in MySQL database on page 2544.
tNetezzaOutput

 Writes, updates, makes changes or suppresses entries in a Netezza database.

 tNetezzaOutput executes the action defined on the table and/or on the data contained in the table, based on the flow incoming from the preceding component in the designed Job.

 tNetezzaOutput Standard properties

 These properties are used to configure tNetezzaOutput running in the Standard Job framework.

 The component in this framework is generally available.

 Note:

 This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

 For more information about dynamic database connectors, see Dynamic database components on page 598.

 Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

 ![Icon](image)

 Click this icon to open a database connection wizard and store the database connection parameters you set in the component Basic settings view.

 For more information about setting up and storing database connection parameters, see Talend Studio User Guide.

 Use an existing connection |

 Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

 Note:

 When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

 1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component.
which creates that very database connection.

2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>Host</th>
<th>Database server IP address</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>

<tr>
<td>Action on data</td>
<td>On the data of the table defined, you can perform:</td>
</tr>
<tr>
<td></td>
<td>Insert: Add new entries to the table. If duplicates are found, job stops.</td>
</tr>
<tr>
<td></td>
<td>Update: Make changes to existing entries</td>
</tr>
<tr>
<td></td>
<td>Insert or update: Insert a new record. If the record with the given reference already exists, an update would be made.</td>
</tr>
<tr>
<td></td>
<td>Update or insert: Update the record with the given reference. If the record does not exist, a new record would be inserted.</td>
</tr>
<tr>
<td></td>
<td>Delete: Remove entries corresponding to the input flow.</td>
</tr>
<tr>
<td></td>
<td>Warning: It is necessary to specify at least one column as a primary key on which the Update and Delete operations are based. You can do that by clicking...</td>
</tr>
</tbody>
</table>
**Edit Schema** and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the **Advanced settings** view where you can simultaneously define primary keys for the Update and Delete operations. To do that: Select the **Use field options** check box and then in the **Key in update column**, select the check boxes next to the column names you want to use as a base for the Update operation. Do the same in the **Key in delete column** for the Delete operation.

### Schema and Edit schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

**Built-In:** You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.

**Repository:** You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema:** choose this option to view the schema only.
- **Change to built-in property:** choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection:** choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.

### Die on error

This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a **Row > Rejects** link.
## Advanced settings

</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
</tbody>
</table>

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in a Netezza database. It also allows you to create a reject flow using a Row &gt; Rejects link to filter data in error. For an example of tMySqlOutput in use, see Scenario: Retrieving data in error with a Reject link on page 2529.</td>
</tr>
</tbody>
</table>

| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. |
|-----------------| The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. |
For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

**Limitation**

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

**Related scenarios**

For **tNetezzaOutput** related topics, see:

- Scenario: Inserting a column and altering data using tMysqlOutput on page 2521.
tNetezzaRollback

Cancels the transaction committed in the connected Netezza database to avoid committing part of a transaction involuntarily.

### tNetezzaRollback Standard properties

These properties are used to configure tNetezzaRollback running in the Standard Job framework.

The Standard tNetezzaRollback component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

#### Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td>Component list</td>
<td>Select the <strong>tNetezzaConnection</strong> component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

#### Advanced settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tStat Catcher Statistics</td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

#### Usage

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Usage rule</td>
<td>This component is more commonly used with other tNetezza* components, especially with the <strong>tNetezzaConnection</strong> and <strong>tNetezzaCommit</strong> components.</td>
</tr>
<tr>
<td>Dynamic settings</td>
<td>Click the [+] button to add a row in the table and fill the <strong>Code</strong> field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.</td>
</tr>
</tbody>
</table>
Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see **Scenario: Reading data from databases through context-based dynamic connections** on page 2497 and **Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters** on page 489. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

### Related scenarios

For **tNetezzaRollback** related scenario, see **Scenario: Rollback from inserting data in mother/daughter tables** on page 2480.
tNetezzaRow

Executes the SQL query stated onto the specified Netezza database.

Depending on the nature of the query and the database, tNetezzaRow acts on the actual DB structure or on the data (although without handling data). The SQLBuilder tool helps you write easily your SQL statements.

tNetezzaRow is the specific component for this database query. It implements a flow in the job design although it does not provide output.

tNetezzaRow Standard properties

These properties are used to configure tNetezzaRow running in the Standard Job framework.

The Standard tNetezzaRow component belongs to the Databases family.

The component in this framework is generally available.

Note:

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in:</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository:</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

Note:

When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th><strong>Host</strong></th>
<th>Database server IP address</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Schema and Edit Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td><strong>Built-In</strong>: You create and store the schema locally for this component only. Related topic: see <em>Talend Studio User Guide</em>.</td>
<td></td>
</tr>
<tr>
<td><strong>Repository</strong>: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see <em>Talend Studio User Guide</em>.</td>
<td></td>
</tr>
</tbody>
</table>

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.

<p>| <strong>Table Name</strong> | Enter the name of the table to be processed. |
| <strong>Query type</strong> | Either <strong>Built-in</strong> or <strong>Repository</strong>. |
| <strong>Built-in</strong>: Fill in manually the query statement or build it graphically using SQLBuilder |</p>
<table>
<thead>
<tr>
<th>Repository:</th>
<th>Select the relevant query stored in the Repository. The Query field gets accordingly filled in.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Query</strong></td>
<td>Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.</td>
</tr>
<tr>
<td><strong>Die on error</strong></td>
<td>This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a Row &gt; Rejects link.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| **Additional JDBC parameters** | Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the Use an existing connection check box in the Basic settings. |
| **Propagate QUERY’s recordset** | Select this check box to insert the result of the query into a COLUMN of the current flow. Select this column from the use column list. |
| | **Note:** |
| | This option allows the component to have a different schema from that of the preceding component. Moreover, the column that holds the QUERY’s recordset should be set to the type of Object and this component is usually followed by tParseRecordSet. |
| **Use PreparedStatement** | Select this check box if you want to query the database using a PreparedStatement. In the Set PreparedStatement Parameter table, define the parameters represented by “?” in the SQL instruction of the Query field in the Basic Settings tab. |
| | **Parameter Index:** Enter the parameter position in the SQL instruction. |
| | **Parameter Type:** Enter the parameter type. |
| | **Parameter Value:** Enter the parameter value. |
| | **Note:** |
| | This option is very useful if you need to execute the same query several times. Performance levels are increased |
| **Commit every** | Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions. |
| **tStat Catcher Statistics** | Select this check box to collect log data at the component level. |
### Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>QUERY</td>
<td>the query statement being processed. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td>NB_EFFECTED</td>
<td>the number of effected rows. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>ERROR_MESSAGE</td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>This component offers the flexibility of the DB query and covers all possible SQL queries.</td>
<td></td>
</tr>
</tbody>
</table>

### Dynamic settings

<table>
<thead>
<tr>
<th>Dynamic settings</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Click the [+ ] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.</td>
<td></td>
</tr>
</tbody>
</table>

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

### Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided.

You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find...
Related scenarios

For related scenarios, see:

- Scenario: Combining two flows for selective output on page 2558
- Scenario: Removing and regenerating a MySQL table index on page 2552
tNetezzaSCD

Reflects and tracks changes in a dedicated Netezza SCD table.

tNetezzaSCD addresses Slowly Changing Dimension needs, reading regularly a source of data and logging the changes into a dedicated SCD table.

**tNetezzaSCD Standard properties**

These properties are used to configure tNetezzaSCD running in the Standard Job framework.

The Standard tNetezzaSCD component belongs to the Business Intelligence and the Databases families.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>

<td><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

| Usage rule | This component is used as an Output component. It requires an Input component and Row main link as input. |

| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |

| Limitation | This component does not support using SCD type 0 together with other SCD types. |

Related scenario

For related scenarios, see tMysqlSCD on page 2563.
tNetsuiteConnection

Creates a connection to the NetSuite SOAP server so that other NetSuite components in the Job can reuse the connection.

**tNetsuiteConnection Standard properties**

These properties are used to configure tNetsuiteConnection running in the Standard Job framework.

The Standard tNetsuiteConnection component belongs to the Business family.

The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Endpoint</strong></td>
<td>Enter the WebService URL required to connect to the NetSuite server.</td>
</tr>
<tr>
<td><strong>API version</strong></td>
<td>Select the API version corresponding to the version of NetSuite you are using.</td>
</tr>
<tr>
<td><strong>E-mail and Password</strong></td>
<td>Enter your user credentials to access the NetSuite SOAP service. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Role</strong></td>
<td>Enter your NetSuite role ID.</td>
</tr>
<tr>
<td><strong>Account</strong></td>
<td>Enter your NetSuite web services account number (also called account ID).</td>
</tr>
<tr>
<td><strong>Application ID</strong></td>
<td>Enter the NetSuite application ID generated for your account. An application ID is required starting from NetSuite version 2015 and above. You can find your application ID or create a new one on NetSuite's Manage Integration page.</td>
</tr>
</tbody>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Enable customizations</strong></td>
<td>Select this check box to instruct the component to retrieve customizations - custom record types and custom fields. With this option enabled, custom record types will be retrieved and can be selected in the Record Type dialog box, and custom fields will be retrieved and included into the schema. This option is enabled by default. You can disable it if you don’t need custom record types or custom fields.</td>
</tr>
</tbody>
</table>

2712
With this option enabled in the tNetsuiteConnection component, all the other components using this connection will have this option enabled.

**tStatCatcher Statistics**
Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

---

### Global Variables

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it. For further information about variables, see *Talend Studio User Guide*. |

---

### Usage

| Usage rule | This component is more commonly used with other NetSuite components. |

---

### Related scenario

No scenario is available for this component yet.
tNetsuiteInput

Invokes the NetSuite SOAP service and retrieves data according to the conditions you specify.

**tNetsuiteInput Standard properties**

These properties are used to configure tNetsuiteInput running in the Standard Job framework.

The Standard tNetsuiteInput component belongs to the Business and the Cloud families.

The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>Connection Component</th>
<th>Select a tNetsuiteConnection component to reuse its connection details to set up the connection to the NetSuite server. With a tNetsuiteConnection selected, the settings related to connection setup will not be displayed.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Endpoint</td>
<td>Enter the WebService URL required to connect to the NetSuite server.</td>
</tr>
<tr>
<td>API version</td>
<td>Select the API version corresponding to the version of NetSuite you are using.</td>
</tr>
<tr>
<td>E-mail and Password</td>
<td>Enter your user credentials to access the NetSuite SOAP service. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Role</td>
<td>Enter your NetSuite role ID.</td>
</tr>
<tr>
<td>Account</td>
<td>Enter your NetSuite web services account number (also called account ID).</td>
</tr>
<tr>
<td>Application ID</td>
<td>Enter the NetSuite application ID generated for your account. An application ID is required starting from NetSuite version 2015 and above. You can find your application ID or create a new one on NetSuite’s Manage Integration page.</td>
</tr>
<tr>
<td>Record Type</td>
<td>Click the [...] button next to the field to open a dialog box, and then select a record type you want to retrieve or select the Use custom object check box and specify a custom record type in the Object Name field.</td>
</tr>
<tr>
<td>Schema and Edit schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
</tbody>
</table>
Built-In: You create and store the schema locally for this component only. Related topic: see *Talend Studio User Guide*.

Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see *Talend Studio User Guide*.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-In** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **[Repository Content]** window.

**Warning:**
The schema of this component is dynamically filled with columns corresponding to the NetSuite service fields, which vary depending on the **Record Type** selected. You can delete columns that are not relevant to your operation, but do not rename any schema columns or this may cause execution errors.

<table>

**Usage**

<table>
<thead>
<tr>
<th><strong>Usage rule</strong></th>
<th>This component is usually used as a start component in a <em>Talend</em> flow and it requires an output component.</th>
</tr>
</thead>
</table>

**Scenario: Handling data with NetSuite**

This scenario describes a Job that reads data from NetSuite, transforms the data and writes the transformed data to NetSuite, finally displays the transformed data on the console.
Adding the components

Create a new Job and add the following five components by typing their names in the design workspace or dropping them from the Palette:

- two tNetsuiteInput components: to read data that matches the specified search criteria from the NetSuite server.
- a tMap component: to transform the input data to the output structure.
- a tNetsuiteOutput component: to write the transformed data into the NetSuite server.
- a tLogRow component: to display the data received from the NetSuite server.

Configuring and linking the components

Reading, transforming, and writing data in NetSuite

Procedure

1. Double-click the first tNetsuiteInput to open its Basic settings view.
2. In the Endpoint, API version, E-mail, Password, Role, Account, and Application ID fields, enter the information required to access NetSuite.

3. Click the […] button next to the Record Type field, and from the dialog box that opens select Location to read the location type information from NetSuite.

   The schema corresponding to the location record type is automatically retrieved.

4. Define a search condition.
   a) Click the [+button below the Search conditions table to add one row.
   b) Click the cell of the Field column and select internalId from the drop-down list.
   c) Click the cell of the Operator column and select List - Any Of from the drop-down list.
   d) In the cell of the Value column, enter java.util.Arrays.asList("1") to retrieve only the record whose internalId is set to 1.

5. Connect the first tNetsuiteInput to tMap using a Row > Main connection.

6. Double-click tNetsuiteOutput to open its Basic settings view.
7. In the Endpoint, API version, E-mail, Password, Role, Account, and Application ID fields, enter the information required to access NetSuite.

8. In the Action list, select insert to insert the transformed data into NetSuite.

9. Click the [...] button next to the Record Type field, and in the dialog box that opens select Location to write the location type information into NetSuite.

10. Click the [...] button next to Edit schema to open the schema editor. You can see the schema has already been prefilled. Keep only the columns that are relevant to your operation and delete others. In this example, keep the column Name, Parent, IncludeChildren, IsInactive, TranPrefix, Logo, MakeInventoryAvailable, MakeInventoryAvailableStore, CustomFieldList, and ExternalId.

11. Connect tMap to tNetsuiteOutput using a Row > *New Output* (Main) connection. In the pop-up dialog box, enter the name of the output connection, out in this example. Then click Yes to let tMap get the schema of the target component tNetsuiteOutput.

12. Double-click tMap to open its Map Editor and configure data flow mappings.
a) In the **out** output table, set the value of the **Name** column by entering “**Paris**” in the corresponding **Expression** column field.

b) Drag and drop the **Parent** column in the **row1** input table onto the **Expression** column of the corresponding row in the **out** output table.

c) Do the same to drag and drop other columns **IncludeChildren**, **IsInactive**, **TranPrefix**, **Logo**, **MakeInventoryAvailable**, **MakeInventoryAvailableStore**, **CustomFieldList**, and **ExternalId** in the **row1** input table onto the **Expression** column of the corresponding row in the **out** output table.

**Retrieving the transformed data from NetSuite**

**Procedure**

1. Double-click the second **tNetsuitInput** to open its **Basic settings** view.
2. In the Endpoint, API version, E-mail, Password, Role, Account, and Application ID fields, enter the information required to access NetSuite.

3. Click the […] button next to the Record Type field, and from the dialog box that opens select Location to read the location type information from NetSuite.
   The schema corresponding to the location record type is automatically retrieved.

4. Define a search condition.
   a) Click the [+ ] button below the Search condition table to add one row.
   b) Click the cell of the Field column and select name from the drop-down list.
   c) Click the cell of the Operator column and select String - Contains from the drop-down list.
   d) In the cell of the Value column, enter Paris to retrieve only the record whose name contains Paris.

5. Double-click tLogRow to open its Basic settings view.

6. In the Mode area, select Vertical (each row is a key/value list) for better readability of the result.

7. Connect the second tNetsuiteInput to tLogRow using a Row > Main connection.

8. Connect the first tNetsuiteInput to the second tNetsuiteInput using a Trigger > OnSubjobOk connection.
Saving and executing the Job

Procedure

1. Press **Ctrl + S** to save the Job.
2. Press **F6** or click **Run** on the **Run** tab to run the Job.

As shown above, the data has been transformed and written into NetSuite, then the transformed data is retrieved from NetSuite and displayed on the console.
tNetsuiteOutput

Invokes the NetSuite SOAP service and inserts, updates, or removes data on the NetSuite SOAP server.

**tNetsuiteOutput Standard properties**

These properties are used to configure tNetsuiteOutput running in the Standard Job framework.

The Standard tNetsuiteOutput component belongs to the Business and the Cloud families.

The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>Connection Component</th>
<th>Select a tNetsuiteConnection component to reuse its connection details to set up the connection to the NetSuite server. With a tNetsuiteConnection selected, the settings related to connection setup will not be displayed.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Endpoint</td>
<td>Enter the WebService URL required to connect to the NetSuite server.</td>
</tr>
<tr>
<td>API version</td>
<td>Select the API version corresponding to the version of NetSuite you are using.</td>
</tr>
<tr>
<td>E-mail and Password</td>
<td>Enter your user credentials to access the NetSuite SOAP service. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Role</td>
<td>Enter your NetSuite role ID.</td>
</tr>
<tr>
<td>Account</td>
<td>Enter your NetSuite web services account number (also called account ID).</td>
</tr>
<tr>
<td>Application ID</td>
<td>Enter the NetSuite application ID generated for your account. An application ID is required starting from NetSuite version 2015 and above. You can find your application ID or create a new one on NetSuite’s Manage Integration page.</td>
</tr>
<tr>
<td>Record Type</td>
<td>Click the [...] button next to the field to open a dialog box, and then select a record type you want to retrieve or select the Use custom object check box and specify a custom record type in the Object Name field.</td>
</tr>
<tr>
<td>Schema and Edit schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
</tbody>
</table>
**Built-In:** You create and store the schema locally for this component only. Related topic: see *Talend Studio User Guide*.

**Repository:** You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see *Talend Studio User Guide*.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema:** choose this option to view the schema only.
- **Change to built-in property:** choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection:** choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.

Click **Sync columns** to retrieve the schema from the previous component connected in the Job.

**Warning:**

The schema of this component is prefilled with columns corresponding to the NetSuite service fields, which vary depending on the **Record Type** selected. You can delete columns that are not relevant to your operation, but do not rename any schema columns or this may cause execution errors.

<table>
<thead>
<tr>
<th>Action</th>
<th>Select an action to perform from the list.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Add</strong></td>
<td>Adds a new record to your data. If a duplicate is found and the <strong>Die on error</strong> check box is selected, the Job stops; if the <strong>Die on error</strong> check box is cleared, the duplicate is ignored and the Job continues.</td>
</tr>
<tr>
<td><strong>Update</strong></td>
<td>Makes changes to an existing record. If the record corresponding to the specified <strong>Internal ID</strong> does not exist, and the <strong>Die on error</strong> check box is selected, the Job stops. To use this option, the <strong>InternalId</strong> column must exist in the schema and set as Key.</td>
</tr>
</tbody>
</table>
### tNetsuiteOutput

- **Upsert**: Updates the record corresponding to the specified ID, or inserts a new record if it does not exist.
  
  To use this option, a column for record ID must exist in the schema and set as Key.

- **Delete**: Removes an existing record.
  
  If the record corresponding to the specified Internal ID does not exist and the **Die on error** check box is selected, the Job stops.

  To use this option, the **InternalId** column must exist in the schema and set as Key.

### Sync outgoing schema

After the component schema is updated, click this button propagate the schema to the outgoing flow(s), which can be a normal flow, a reject flow, or both, if the component has any.

### Advanced settings

#### Enable customizations

Select this check box to instruct the component to retrieve customizations - custom record types and custom fields. With this option enabled, custom record types will be retrieved and can be selected in the **Record Type** dialog box, and custom fields will be retrieved and included into the schema.

This option is enabled by default. You can disable it if you don’t need custom record types or custom fields.

#### Use native Upsert operation

Select this check box to use the Upsert operation provided by NetSuite.

To use NetSuite’s Upsert operation, the **ExternalId** column must exist in the schema and set as Key.

This option is available when **Upsert** is selected from the **Action** list in **Basic settings**.

By default, for compatibility reasons, this option is disabled and the component performs the Add or Update action for an upsert depending on whether the record ID is specified.

#### Batch size

Specify the number of records to be processed in each batch.

Note that batching will be disabled if the output component has an outgoing flow.

#### tStatCatcher Statistics

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.
### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_LINE: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>CURRENT_INTERNALID: The internal ID of the record currently inserted or processed. This is a Flow variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td></td>
<td>For further information about variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

### Usage

| Usage rule | This component is usually used as an end component in a Talend flow and it requires an input component. |

### Related scenario

For a related scenario, see Scenario: Handling data with NetSuite on page 2716.
tNormalize

Normalizes the input flow following SQL standard to help improve data quality and thus eases the data update.

tNormalize Standard properties

These properties are used to configure tNormalize running in the Standard Job framework.

The Standard tNormalize component belongs to the Processing family.

The component in this framework is generally available.

Basic settings

<table>
<thead>
<tr>
<th>Schema and Edit Schema</th>
<th>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word “line” when naming the fields. Click <strong>Edit schema</strong> to make changes to the schema. If the current schema is of the <strong>Repository</strong> type, three options are available:</th>
</tr>
</thead>
<tbody>
<tr>
<td>• <strong>View schema</strong>: choose this option to view the schema only.</td>
<td></td>
</tr>
<tr>
<td>• <strong>Change to built-in property</strong>: choose this option to change the schema to <strong>Built-in</strong> for local changes.</td>
<td></td>
</tr>
<tr>
<td>• <strong>Update repository connection</strong>: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select <strong>No</strong> upon completion and choose this schema metadata again in the [<strong>Repository Content</strong>] window.</td>
<td></td>
</tr>
<tr>
<td>Built-In: You create and store the schema locally for this component only. Related topic: see <strong>Talend Studio User Guide</strong>.</td>
<td></td>
</tr>
<tr>
<td>Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see <strong>Talend Studio User Guide</strong>.</td>
<td></td>
</tr>
<tr>
<td>Column to normalize</td>
<td>Select the column from the input flow which the normalization is based on.</td>
</tr>
<tr>
<td>Item separator</td>
<td>Enter the separator which will delimit data in the input flow.</td>
</tr>
</tbody>
</table>

**Note:**
The item separator is based on regular expressions, so the character `.` (a special
Normalization character for regular expression) should be avoided or used carefully here.

### Advanced settings

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Get rid of duplicated rows from output</td>
<td>Select this check box to deduplicate rows in the data of the output flow.</td>
</tr>
<tr>
<td>Use CSV parameters</td>
<td>Select this check box to include CSV specific parameters such as escape mode and enclosure character.</td>
</tr>
<tr>
<td>Discard the trailing empty strings</td>
<td>Select this check box to discard the trailing empty strings.</td>
</tr>
<tr>
<td>Trim resulting values</td>
<td>Select this check box to trim leading and trailing whitespace from the resulting data.</td>
</tr>
</tbody>
</table>

**Note:**
When both Discard the trailing empty string and Trim resulting values check boxes are selected, the former works first.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tStatCatcher Statistics</td>
<td>Select this check box to gather the Job processing metadata at the Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

### Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERROR_MESSAGE</td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td>NB_LINE</td>
<td>the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

### Usage

<table>

<tr>
<td>Limitation</td>
<td>Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the</td>
</tr>
</tbody>
</table>
**Scenario: Normalizing data**

This simple scenario illustrates a Job that normalizes a list of tags for Web forum topics, and displays the result in a table on the Run console.

This list is not well organized and it contains trailing empty strings, leading and trailing whitespace, and repeated tags, as shown below.

```
ldap,
  db2, jdbc driver,
grid computing, talend architecture ,
content, environment,,
tmap,,
eclipse,
database, java, postgresql,
tmap,
database, java, sybase,
deployment,,
repository,
database, informix, java
```

**Setting up the Job**

**Procedure**

1. Drop the following components from the Palette to the design workspace: tFileInputDelimited, tNormalize, tLogRow.
2. Connect the components using Row > Main connections.

![Diagram of component connections]

**Configuring the components**

**Procedure**

1. Double-click the tFileInputDelimited component to open its Basic settings view.
2. In the **File name** field, specify the path to the input file to be normalized.

3. Click the [...] button next to **Edit schema** to open the [Schema] dialog box, and set up the input schema by adding one column named **Tags**. When done, click **OK** to validate your schema setup and close the dialog box, leaving the rest of the settings as they are.

4. Double-click the **tNormalize** component to open **Basic settings** view.

5. Check the schema, and if necessary, click **Sync columns** to get the schema synchronized with the input component.

6. Define the column the normalization operation is based on.

   In this use case, the input schema has only one column, **Tags**, so just accept the default setting.
7. In the **Advanced settings** view, select the **Get rid of duplicate rows from output**, **Discard the trailing empty strings**, and **Trim resulting values** check boxes.

8. In the **tLogRow** component, select the **Print values in the cells of table** radio button.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl+S** to save your Job.
2. Click **Run** on the Run tab or press **F6** to execute the Job.

The list is tidied up, with duplicate tags, leading and trailing whitespace and trailing empty strings removed, and the result is displayed in a table cell on the console.
tOleDbInput

Executes a DB query with a strictly defined order which must correspond to the schema definition and passes on the field list to the next component via a Main row link.

This component reads a database and extracts fields based on a query. It offers the flexibility benefit of the DB query and covers all possible SQL queries.

**tOleDbInput Standard properties**

These properties are used to configure tOleDbInput running in the Standard Job framework.

The Standard tOleDbInput component belongs to the Databases family.

The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Schema and Edit schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <em>line</em> when naming the fields.</td>
</tr>
<tr>
<td><strong>Built-In</strong>: You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.</td>
<td></td>
</tr>
<tr>
<td><strong>Repository</strong>: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.</td>
<td></td>
</tr>
<tr>
<td>Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:</td>
<td></td>
</tr>
<tr>
<td>• View schema: choose this option to view the schema only.</td>
<td></td>
</tr>
<tr>
<td>• Change to built-in property: choose this option to change the schema to Built-in for local changes.</td>
<td></td>
</tr>
<tr>
<td>• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the [Repository Content] window.</td>
<td></td>
</tr>
<tr>
<td>Table Name</td>
<td>Enter the name of the table to be processed.</td>
</tr>
<tr>
<td><strong>Query Type</strong></td>
<td>Select either <strong>Built-in</strong> or <strong>Repository</strong> query type from the drop-down list.</td>
</tr>
<tr>
<td>----------------</td>
<td>----------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>Built-in</strong></td>
<td>Fill in manually the query statement or build it graphically using SQLBuilder.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the relevant query stored in the Repository. The <strong>Query</strong> field gets accordingly filled in.</td>
</tr>
</tbody>
</table>

**Guess Query**

Click the button to generate the query which corresponds to the defined table schema in the **Query** field.

**Guess schema**

Click the button to retrieve the schema from the table.

**Query**

Specify the database query paying particularly attention to properly sequence the fields in order to match the schema definition.

### Advanced settings

<table>
<thead>
<tr>
<th><strong>Trim all the String/Char columns</strong></th>
<th>Select this check box to remove leading and trailing whitespace from all the String/Char columns.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Trim column</strong></td>
<td>Select the check box in <strong>Trim column</strong> to remove leading and trailing whitespace from the corresponding column. This field appears only when the <strong>Trim all the String/Char columns</strong> check box is cleared.</td>
</tr>
</tbody>
</table>

**tStatCatcher Statistics**

Select this check box to collect log data at the component level.

### Global Variables

<table>
<thead>
<tr>
<th><strong>Global Variables</strong></th>
<th><strong>NB_LINE</strong>: the number of rows processed. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>QUERY</strong>: the query statement being processed. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td></td>
<td><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*. |
Usage

| Usage rule | This component is used as a start component in a Job and it always needs an output link. |

Related scenario

For similar scenarios, see tMysqlInput on page 2488.
tOleDbOutput

Executes the action defined on the table and/or on the data contained in the table, based on the flow incoming from the preceding component in the Job.

This component writes, updates, makes changes or suppresses entries in a database.

**tOleDbOutput Standard properties**

These properties are used to configure tOleDbOutput running in the Standard Job framework.

The Standard tOleDbOutput component belongs to the Databases family.

The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Enter the connection string used to open the database. For details, please see <a href="http://msdn.microsoft.com/en-us/library/system.data.oledb.oledbconnection.connectionstring.aspx">http://msdn.microsoft.com/en-us/library/system.data.oledb.oledbconnection.connectionstring.aspx</a>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>Specify the name of the table to be written. Note that only one table can be written at a time.</td>
</tr>
<tr>
<td>Action on data</td>
<td>Select one of the following actions that you want to perform on the data from the drop-down list.</td>
</tr>
<tr>
<td></td>
<td>• Insert: insert data.</td>
</tr>
<tr>
<td></td>
<td>• Update: update data.</td>
</tr>
<tr>
<td></td>
<td>• Insert or update: insert a new record. If the record with the given reference already exists, an update would be made.</td>
</tr>
<tr>
<td></td>
<td>• Update or insert: update the record with the given reference. If the record does not exist, a new record would be inserted.</td>
</tr>
<tr>
<td></td>
<td>• Delete: delete data.</td>
</tr>
</tbody>
</table>

**Warning:**

It is necessary to specify at least one column as a primary key on which the Update or Delete operation is based. You can do that by clicking **Edit schema** and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the **Advanced settings** view where you can simultaneously define primary keys for the Update or Delete operation. To do that, select the **Use field options** check box and then in the **Key in update** or **Key in delete** column, select the check box(es) next to the column name(s) you want to use as a base for the Update or Delete operation.
<table>
<thead>
<tr>
<th><strong>Clear data in table</strong></th>
<th>Select this check box to delete data in the defined table before any operation.</th>
</tr>
</thead>

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th><strong>NB_LINE</strong>: the number of rows processed. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>NB_LINE_UPDATED</strong>: the number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td><strong>NB_LINE_INSERTED</strong>: the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td><strong>NB_LINE_DELETED</strong>: the number of rows deleted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td><strong>NB_LINE_REJECTED</strong>: the number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td><strong>QUERY</strong>: the query statement processed. This is an After variable and it returns a string.</td>
</tr>
<tr>
<td></td>
<td><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.
Usage

| Usage rule | This component is normally an end component of a Job and always needs an input link. |

Related scenario

For similar scenarios, see tMysqlOutput on page 2515.
tOleDbRow

Acts on the actual database structure or on the data depending on the nature of the query and the database.

tOleDbRow is the specific component for this database query. It executes the SQL query stated in the specified database.

**tOleDbRow Standard properties**

These properties are used to configure tOleDbRow running in the Standard Job framework.

The Standard tOleDbRow component belongs to the Databases family.

The component in this framework is generally available.

**Basic settings**

<table>
<thead>

</tr>
<tr>
<td><strong>Change to built-in property:</strong> choose this option to change the schema to <code>Built-in</code> for local changes.</td>
<td></td>
</tr>
<tr>
<td><strong>Update repository connection:</strong> choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the [Repository Content] window.</td>
<td></td>
</tr>
<tr>
<td><strong>Table Name</strong></td>
<td>Name of the table to be processed.</td>
</tr>
</tbody>
</table>
### Query type

<table>
<thead>
<tr>
<th>Query type</th>
<th>Either <strong>Built-in</strong> or <strong>Repository</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-in</strong>: Fill in manually the query statement or build it graphically using SQLBuilder</td>
<td></td>
</tr>
<tr>
<td><strong>Repository</strong>: Select the relevant query stored in the Repository. The Query field gets accordingly filled in.</td>
<td></td>
</tr>
</tbody>
</table>

### Guess Query

- Click the **Guess Query** button to generate the query which corresponds to your table schema in the **Query** field.

### Query

Enter your database query paying particularly attention to properly sequence the fields in order to match the schema definition.

### Die on error

- This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a **Row > Rejects** link.

### Advanced settings

#### Propagate QUERY's recordset

- Select this check box to insert the result of the query in a COLUMN of the current flow. Select this column from the **use column** list.

  - **Note:**
    - This option allows the component to have a different schema from that of the preceding component. Moreover, the column that holds the QUERY's recordset should be set to the type of **Object** and this component is usually followed by **tParseRecordSet**.

#### Use PreparedStatement

- Select this check box if you want to query the database using a PreparedStatement. In the **Set PreparedStatement Parameter** table, define the parameters.

  - **Parameter Index**: Enter the parameter position in the SQL instruction.
  - **Parameter Type**: Enter the parameter type.
  - **Parameter Value**: Enter the parameter value.

  - **Note:**
    - This option is very useful if you need to execute the same query several times. Performance levels are increased

#### tStatCatcher Statistics

- Select this check box to collect log data at the component level.

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>QUERY: the query statement being processed. This is a Flow variable and it returns a string.</th>
</tr>
</thead>
</table>
**tOleDbRow**

**ERROR MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

---

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component offers the flexibility of the database query and covers all possible SQL queries.</th>
</tr>
</thead>
</table>

**Dynamic settings**

Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see *Scenario: Reading data from databases through context-based dynamic connections on page 2497* and *Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489*. For more information on **Dynamic settings** and context variables, see *Talend Studio User Guide*.

---

**Related scenario**

For similar scenarios, see *tMysqlRow on page 2548*. 
**tOpenbravoERPInput**

Extracts data from OpenBravoERP database according to the conditions defined in specific columns. tOpenbravoERPInput connects to an OpenbravoERP database entity via the appropriate Web service.

**tOpenbravoERPInput Standard properties**

These properties are used to configure tOpenbravoERPInput running in the Standard Job framework. The Standard tOpenbravoERPInput component belongs to the Business family. The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th><strong>Openbravo REST WebService URL</strong></th>
<th>Enter the URL of the Web service that allows you to connect to the OpenbravoERP database.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Username and Password</strong></td>
<td>User authentication information. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Entity</strong></td>
<td>Select the appropriate entity from the drop-down list.</td>
</tr>
<tr>
<td><strong>Schema and Edit Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:</td>
</tr>
<tr>
<td></td>
<td>• View schema: choose this option to view the schema only.</td>
</tr>
<tr>
<td></td>
<td>• Change to built-in property: choose this option to change the schema to Built-in for local changes.</td>
</tr>
<tr>
<td></td>
<td>• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.</td>
</tr>
<tr>
<td></td>
<td>Click Sync columns to retrieve the schema from the previous component connected in the Job.</td>
</tr>
<tr>
<td><strong>WHERE Clause</strong></td>
<td>Enter your WHERE clause.</td>
</tr>
</tbody>
</table>
| Order by | Select this check bow to define how to order the results (the elements in the drop-down list depend on the entity selected)  
|**Sort:** Choose whether to organise the results in either **Ascending** or **Descending** order. |
| First result | Enter the row number you want to retrieve first. |
| Max result | Enter the maximum number of results you want to retrieve. |

**Advanced settings**

| Advanced separator (for numbers) | Select this check box to modify the separators to be used for the numbers. Either:  
|**Thousands separator**  
or  
|**Decimal separator** |
| tStatCatcher Statistics | Select this check box to collect the log data at a component level. |

**Global Variables**

| Global Variables | **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.  
| **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
For further information about variables, see **Talend Studio User Guide**. |

**Usage**

| Usage rule | This component is generally used as an input component. An output component is required. |
Related Scenario

For a scenario in which `tOpenbravoERPInput` might be used, see Scenario: Writing data in a Microsoft CRM database and putting conditions on columns to extract specified rows on page 2252.
tOpenbravoERPOutput

Writes data in an OpenbravoERP database.

tOpenbravoERPOutput writes an object in an OpenbravoERP database via the appropriate Web service.

**tOpenbravoERPOutput Standard properties**

These properties are used to configure tOpenbravoERPOutput running in the Standard Job framework. The Standard tOpenbravoERPOutput component belongs to the Business family.

The component in this framework is generally available.

**Basic settings**

| **Openbravo REST Webservice URL** | Enter the URL of the Web service that allows you to connect to the OpenbravoERP database. |
| **Username and Password** | User authentication information. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| **Action on data** | From the list, select the one of the following actions: Update/Create or Remove |
| **Use existing data file** | Select this check box if desired and then select the file by browsing your directory. |
| **Entity** | Select the appropriate entity from the drop-down list. |
| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available: • View schema: choose this option to view the schema only. • Change to built-in property: choose this option to change the schema to Built-in for local changes. • Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No. |
upon completion and choose this schema metadata again in the [Repository Content] window.
Click Sync columns to retrieve the schema from the previous component connected in the Job.

Advanced settings

**tStatCatcher Statistics**
Select this check box to collect the log data at a component level.

Global Variables

**Global Variables**

**NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.

**NB_LINE_UPDATED**: the number of rows updated. This is an After variable and it returns an integer.

**NB_LINE_CREATED**: the number of rows created. This is an After variable and it returns an integer.

**NB_LINE_REMOVED**: the number of rows removed. This is an After variable and it returns an integer.

**NB_LINE_UNAUTHORIZED**: the number of rows unauthorized. This is an After variable and it returns an integer.

**NB_LINE_FAILED**: the number of rows failed. This is an After variable and it returns an integer.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

**Usage rule**
This component is used as an output component. It requires an input component.

Related scenario

For a scenario in which tOpenbravoERPOutput may be used, see Scenario: Writing data in a Microsoft CRM database and putting conditions on columns to extract specified rows on page 2252.
tOracleBulkExec

Offers gains in performance during operations performed on data of an Oracle database.

tOracleBulkExec inserts, appends, replaces or truncate data in an Oracle database.

The tOracleOutputBulk and tOracleBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tOracleOutputBulkExec component, detailed in a separate section. The advantage of using two separate steps is that the data can be transformed before it is loaded in the database.

**tOracleBulkExec Standard properties**

These properties are used to configure tOracleBulkExec running in the Standard Job framework.

The Standard tOracleBulkExec component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-in</strong>: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

**Note:**

When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection. For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th>Connection type</th>

<td>When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.</td>
</tr>
</tbody>
</table>
You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

### Advanced settings

<table>
<thead>
<tr>
<th>Advanced separator (for number)</th>
<th>Select this check box to change the separator used for the numbers.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use existing control file</td>
<td>Select this check box if you use a control file (.ctl) and specify its path in the .ctl file name field.</td>
</tr>
</tbody>
</table>
| Record format                   | Define the record format:  
|                                 | **Default**: format parameters are set by default.  
|                                 | **Stream**: set Record terminator.  
|                                 | **Fixed**: set the Record length.  
|                                 | **Variable**: set the Field size of the record length. |
| Specify .ctl file’s INTO TABLE clause manually | Select this check box to manually fill in the INTO TABLE clause of the control file. |
| Fields terminated by            | Character, string or regular expression to separate fields:  
|                                 | **None**: no separator is used.  
|                                 | **Whitespace**: the separator used is a space.  
|                                 | **EOF (used for loading LOBs from lobfile)**: the separator used is an EOF character (End Of File).  
|                                 | **Other terminator**: Set another terminator in the Field terminator field. |
| Use fields enclosure            | Select this check box if you want to use enclosing characters for the text:  
|                                 | **Fields enclosure (left part)**: character delimiting the left of the field.  
|                                 | **Field enclosure (right part)**: character delimiting the right of the field. |
| Use schema’s Date Pattern to load Date field | Select this check box to use the date pattern of the schema in the date field. |
| Specify field condition         | Select this check box to define data loading condition. |
| Preserve blanks                 | Select this check box to preserve the blanks. |
| Trailing null columns           | Select this check box to load null columns. |
| Load options                    | Click + to add data loading options:  
|                                 | **Parameter**: select a loading parameter from the list.  
|                                 | **Value**: enter a value for the parameter selected. |
| NLS Language                    | In the list, select the language used for the data that are not used in Unicode. |
Set Parameter NLS_TERRITORY

Select this check box to modify the territory conventions used for day and weeks numbering. Your OS value is the default value used.

Encoding

Select the encoding from the list, or enter the encoding between double quotes if it does not exist in the list. This field is compulsory for database data handling.

Output

Select the type of output for the standard output of the Oracle database:

to console,
to global variable.

Convert columns and table names to uppercase

Select this check box to uppercase the names of the columns and the name of the table.

tStatCatcher Statistics

Select this check box to collect log data at the component level.

Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_LINE_DATA: the number of rows read. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>NB_LINE_BAD: the number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>NB_LINE_INSERTED: the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>RETURN_CODE: the return code indicating the result of processing. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td></td>
<td>For further information about variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

Usage

Usage rule

This dedicated component offers performance and flexibility of Oracle DB query handling.

Dynamic settings

Click the [*] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple
connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>Limitation</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>The database server/client must be installed on the same machine where the Studio is installed or where the Job using <strong>tOracleBulkExec</strong> is deployed, so that the component functions properly.</td>
<td></td>
</tr>
</tbody>
</table>

**Scenario: Truncating and inserting file data into an Oracle database**

This scenario describes how to truncate the content of an Oracle database and load the content of an input file. The related Job is composed of three components that respectively creates the content, output this content into a file to be loaded into the Oracle database after the database table has been truncated.

**Building the Job**

**Procedure**

1. Drop the following components: **tOracleInput**, **tFileOutputDelimited** and **tOracleBulkExec** from the **Palette** to the design workspace.
2. Connect the **tOracleInput** to the **tFileOutputDelimited** using a **Row > Main** link.
3. Connect the **tOracleInput** to the **tOracleBulkExec** using a **OnSubjobOk** trigger link.
Configuring the components

Procedure

1. Double-click the **tOracleInput** to open its **Basic settings** view.
2. Define the Oracle connection details. It is recommended to store the database connection details in the **Metadata** folder of the **Repository** tree view in order to retrieve them easily at any time in any Job.

![tOracleInput 1](image)

3. Define the schema, if it is not stored in the **Repository**. In this example, the schema contains four columns as follows: **ID_Contract, ID_Client, Contract_type** and **Contract_Value**.

4. Define the **tFileOutputDelimited** component parameters, including output **File Name**, **Row separator** and **Fields delimiter**.

5. Double-click on the **tOracleBulkExec** to define the database populating properties.
6. In the Property Type list, select Repository if you stored the database connection details under the Metadata node of the Repository or select Built-in to define them manually. In this scenario, use the Built-in mode.

7. Set the connection parameters in the following fields: Host, Port, Database, Schema, Username, and Password.

8. Fill in the name of the Table to be populated and the Action on data to be carried out. In this use case, select insert.

9. In the Schema list, select Built-in, and click the [...] button next to the Edit schema field to define the structure of the data to be passed to the next component.

10. Click the Advanced settings view to configure the advanced settings of the component.
11. Select the **Use an existing control file** check box if you want to use a control file (.ctl) storing the status of the physical structure of the database. Or, fill in the following fields manually: **Record format**, **Specify .ctl file’s INTO TABLE clause manually**, **Field terminated by**, **Use field enclosure**, **Use schema’s Date Pattern to load Date field**, **Specify field condition**, **Preserve blanks**, **Trailing null columns**, **Load options**, **NLS Language** and **Set Parameter NLS_TERRITORY** according to your database.

12. In the **Encoding** list, select the encoding, or enter the encoding between double quotes if it does not exist in the list.

13. In the **Output** list, select **to console** to output the standard output of the database in the console.

### Executing the Job

**Procedure**

1. Press **Ctrl+S** to save your Job.
2. Press **F6** to run the Job. The log is shown in the console of the **Run** view and the table is populated with the parameter file data.

**Results**

Related topic: see [Scenario: Inserting data in bulk in MySQL database](#) on page 2544.
tOracleClose

Closes the transaction committed in the connected Oracle database.

**tOracleClose Standard properties**

These properties are used to configure tOracleClose running in the Standard Job framework.

The Standard tOracleClose component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the connection component of interest if more than one connection is planned for the current Job.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is to be used along with Oracle components, especially with tOracleConnection and tOracleCommit. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: |
Related scenarios

No scenario is available for the Standard version of this component yet.
**tOracleCommit**

Validates the data processed through the Job into the connected Oracle database

Using a unique connection, this component commits in one go a global transaction instead of doing that on every row or every batch and thus provides gain in performance.

**tOracleCommit Standard properties**

These properties are used to configure tOracleCommit running in the Standard Job framework.

The Standard tOracleCommit component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see [Dynamic database components](#) on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the <strong>tOracleConnection</strong> component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task. <strong>Warning:</strong> If you want to use a <strong>Row &gt; Main</strong> connection to link <strong>tOracleCommit</strong> to your Job, your data will be committed row by row. In this case, do not select the <strong>Close connection</strong> check box or your connection will be closed before the end of your first row commit.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| **tStatCatcher Statistics** | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is more commonly used with other tOracle components, especially with the **tOracleConnection** and **tOracleRollback** components. |
### Dynamic settings

Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see [Scenario: Reading data from databases through context-based dynamic connections](#) on page 2497 and [Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters](#) on page 489. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

## Related scenario

For **tOracleCommit** related scenario, see [Scenario: Inserting data in mother/daughter tables](#) on page 2476
tOracleConnection

Opens a connection to the specified Oracle database for reuse in the subsequent subjob or subjobs.

**tOracleConnection Standard properties**

These properties are used to configure tOracleConnection running in the Standard Job framework. The Standard tOracleConnection component belongs to the Databases and the ELT families. The component in this framework is generally available.

*Note:* This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see *Dynamic database components* on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>

<tr>
<td><strong>Disable CBC protection</strong></td>
<td>Select this check box to disable the use of CBC (Cipher Block Chaining) in SSL authentication. This property is available only when the <strong>Use SSL</strong> check box is selected.</td>
</tr>
</tbody>
</table>
| **Additional JDBC parameters** | Specify additional connection properties for the DB connection you are creating.  

**Note:**  
You can set the encoding parameters through this field. |
| **Use or register a shared DB Connection** | Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the **Shared DB Connection Name** field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child.  
This option is incompatible with the **Use dynamic job** and **Use an independent process to run subjob** options of the **tRunJob** component. Using a shared connection together with a **tRunJob** component with either of these two options enabled will cause your Job to fail.  
This check box is not available when the **Specify a data source alias** check box is selected. |
| **Specify a data source alias** | Select this check box and specify the alias of a data source created on the **Talend Runtime** side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in **Talend Runtime**. For a related use case, see Scenario: Deploying your Job on Talend Runtime to retrieve data from a MySQL database on page 2503. |
| **Advanced settings** | **Auto Commit**  
Select this check box to commit any changes to the database automatically upon the transaction.  
With this check box selected, you cannot use the corresponding **commit** component to commit changes to the database; likewise, when using the corresponding **commit** component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding **commit** component.  
Note that the auto commit function commits each SQL statement as a single transaction immediately after the |
statement is executed while the commit component
does not commit only until all of the statements are
executed. For this reason, if you need more room to
manage your transactions in a Job, it is recommended to
use the commit component.

| tStatCatcher Statistics | Select this check box to gather the job processing
metadata at a Job level as well as at each component
level. |

Usage

| Usage rule | This component is more commonly used with other
tOracle\* components, especially with the tOracleCommit
and tOracleRollback components. |

Related scenario

For tOracleConnection related scenario, see tMysqlConnection on page 2475
tOracleInput

Reads an Oracle database and extracts fields based on a query.

tOracleInput executes a database query with a strictly defined order which must correspond to the schema definition. Then it passes on the field list to the next component via a Main row link.

**tOracleInput Standard properties**

These properties are used to configure tOracleInput running in the Standard Job framework.

The Standard tOracleInput component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>

<table>
<thead>
<tr>
<th>Schema and Edit Schema</th>
<th>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <strong>line</strong> when naming the fields. Click <strong>Edit schema</strong> to make changes to the schema. If the current schema is of the <strong>Repository</strong> type, three options are available:</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>View schema</strong></td>
<td>choose this option to view the schema only.</td>
</tr>
<tr>
<td><strong>Change to built-in property</strong></td>
<td>choose this option to change the schema to <strong>Built-in</strong> for local changes.</td>
</tr>
<tr>
<td><strong>Update repository connection</strong></td>
<td>choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select <strong>No</strong></td>
</tr>
</tbody>
</table>
upon completion and choose this schema metadata again in the [Repository Content] window.

**Built-In**: You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>Table name</th>
<th>Database table name.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Query type</strong> and <strong>Query</strong></td>
<td>Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.</td>
</tr>
<tr>
<td><strong>Specify a data source alias</strong></td>
<td>Select this check box and specify the alias of a data source created on the Talend Runtime side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in Talend Runtime. For a related use case, see Scenario: Deploying your Job on Talend Runtime to retrieve data from a MySQL database on page 2503. If you use the component’s own DB configuration, your data source connection will be closed at the end of the component. To prevent this from happening, use a shared DB connection with the data source alias specified. This check box is not available when the Use an existing connection check box is selected.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| **Additional JDBC parameters** | Specify additional connection properties for the database connection you are creating. The properties are separated by semicolon and each property is a key-value pair, for example, encryption=1;clientname=Talend. This field is not available if the Use an existing connection check box is selected. |
| **tStatCatcher Statistics** | Select this check box to collect log data at the component level. |
| **Use cursor** | Select this check box and in the Cursor size field displayed, specify the number of rows to fetch in one go from the database. The performance can be improved by tuning this fetch size to an appropriate value. |
| **Trim all the String/Char columns** | Select this check box to remove leading and trailing whitespace from all the String/Char columns. |
| **Trim column** | Remove leading and trailing whitespace from defined columns. |
## Global Variables

**NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.

**QUERY**: the query statement being processed. This is a Flow variable and it returns a string.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

---

## Usage

**Usage rule**

This component covers all possible SQL queries for Oracle databases.

**Dynamic settings**

Click the [*] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

**Limitation**

Due to license incompatibility, one or more JARs required to use this component are not provided.
Scenario 1: Using context parameters when reading a table from an Oracle database

In this scenario, we will read a table from an Oracle database using a context parameter to refer to the table name.

Dropping and linking the components

Procedure
1. Create a new Job and add the following components by typing their names in the design workspace or dropping them from the Palette: a tOracleInput component and a tLogRow component.
2. Connect tOracleInput to tLogRow using a Row > Main link.

Configuring the components

Procedure
1. Double-click tOracleInput to open its Basic Settings view in the Component tab.
2. Select a connection type from the **Connection Type** drop-down list. In this example, it is **Oracle SID**.

Select the version of the Oracle database to be used from the **DB Version** drop-down list. In this example, it is **Oracle 12-7**.

In the **Host** field, enter the Oracle database server’s IP address. In this example, it is **192.168.31.32**.

In the **Database** field, enter the database name. In this example, it is **TALEND**.

In the **Oracle schema** field, enter the Oracle schema name. In this example, it is **TALEND**.

In the **Username** and **Password** fields, enter the authentication details.

3. Click the [...] button next to **Edit schema** to open the schema editor.
4. Click the [+ ] button to add four columns: ID and AGE of the integer type, NAME and SEX of the string type.
   Click OK to close the schema editor and accept the propagation prompted by the pop-up dialog box.

5. Put the cursor in the Table Name field and press F5 for context parameter setting. The dialog box [New Context Parameter] pops up.

   ![New Context Parameter dialog box]

   For more information about context settings, see Talend Studio User Guide.

6. In the Name field, enter the context parameter name. In this example, it is TABLE.
   In the Default value field, enter the name of the Oracle database table to be queried. In this example, it is PERSON.

7. Click Finish to validate the setting.
   The context parameter context.TABLE automatically appears in the Table Name field.

8. In the Query Type list, select Built-In. Then, click Guess Query to get the query statement.

   "SELECT "+context.TABLE+"."ID", "+context.TABLE+"."NAME", "+context.TABLE+"."SEX", "+context.TABLE+"."AGE FROM "+context.TABLE"

9. Double-click tLogRow to open its Basic settings view in the Component tab.
In the **Mode** area, select **Table (print values in cells of a table)** for a better display of the results.

### Saving and executing the Job

**Procedure**

1. Press **Ctrl + S** to save the Job.
2. Press **F6** to run the Job.

```plaintext
[statistics] connecting to socket on port 3750
[statistics] connected
<p>| tLogRow_1 |
|------|------|------|</p>
<table>
<thead>
<tr>
<th>ID</th>
<th>NAME</th>
<th>SEX</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Ford</td>
<td>Male</td>
<td>25</td>
</tr>
<tr>
<td>2</td>
<td>Rose</td>
<td>Female</td>
<td>30</td>
</tr>
<tr>
<td>3</td>
<td>Sabrina</td>
<td>Female</td>
<td>28</td>
</tr>
<tr>
<td>4</td>
<td>Teddy</td>
<td>Male</td>
<td>32</td>
</tr>
<tr>
<td>5</td>
<td>Kate</td>
<td>Male</td>
<td>35</td>
</tr>
</tbody>
</table>

[statistics] disconnected
```

As shown above, the data in the Oracle database table *PERSON* is displayed on the console.

### Related scenarios

For related scenarios, see:

- **Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters** on page 489.
tOracleOutput

Writes, updates, makes changes or suppresses entries in an Oracle database.
tOracleOutput executes the action defined on the table and/or on the data contained in the table, based on the flow incoming from the preceding component in the Job.

tOracleOutput Standard properties

These properties are used to configure tOracleOutput running in the Standard Job framework.
The Standard tOracleOutput component belongs to the Databases family.
The component in this framework is generally available.

Note:
This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>![icon]</td>
<td>Click this icon to open a database connection wizard and store the database connection parameters you set in the component Basic settings view.</td>
</tr>
<tr>
<td></td>
<td>For more information about setting up and storing database connection parameters, see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

Note:
When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component.
which creates that very database connection.

2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th>Connection type</th>
<th>Drop-down list of available drivers:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Oracle OCI</strong>: Select this connection type to use Oracle Call Interface with a set of C-language software APIs that provide an interface to the Oracle database.</td>
</tr>
<tr>
<td></td>
<td><strong>Oracle Custom</strong>: Select this connection type to access a clustered database.</td>
</tr>
<tr>
<td></td>
<td><strong>Oracle Service Name</strong>: Select this connection type to use the TNS alias that you give when you connect to the remote database.</td>
</tr>
<tr>

</thead>
<tbody>
<tr>
<td>Host</td>
<td>Database server IP address.</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Table</td>
<td>Name of the table to be written. Note that only one table can be written at a time.</td>
</tr>
</tbody>
</table>

**Note:**

The Action on table list will not be available if you select the Enable parallel execution check box in the Advanced settings view.

On the table defined, you can perform one of the following operations:

- **Default**: No operation is carried out.
- **Drop and create table**: The table is removed and created again.
- **Create table**: The table does not exist and gets created.
- **Create table if not exists**: The table is created if it does not exist.
Drop table if exists and create: The table is removed if it already exists and created again.

Clear table: The table content is deleted.

Truncate table: The table content is deleted. You do not have the possibility to rollback the operation.

Truncate table with reuse storage: The table content is deleted. You do not have the possibility to rollback the operation. However, it is allowed to reuse the existing storage allocated to the table though the storage is considered empty.

Warning:
If you select the Use an existing connection check box and select an option other than Default from the Action on table list, a commit statement will be generated automatically before the data insert/update/delete operation.

Action on data
On the data of the table defined, you can perform:

Insert: Add new entries to the table. If duplicates are found, job stops.

Update: Make changes to existing entries

Insert or update: Insert a new record. If the record with the given reference already exists, an update would be made.

Update or insert: Update the record with the given reference. If the record does not exist, a new record would be inserted.

Delete: Remove entries corresponding to the input flow.

Warning:
It is necessary to specify at least one column as a primary key on which the Update and Delete operations are based. You can do that by clicking Edit Schema and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the Advanced settings view where you can simultaneously define primary keys for the Update and Delete operations. To do that: Select the Use field options check box and then in the Key in update column, select the check boxes next to the column names you want to use as a base for the Update operation. Do the same in the Key in delete column for the Delete operation.

Schema and Edit schema
A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either Built-in or stored remotely in the Repository.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- View schema: choose this option to view the schema only.
• **Change to built-in property:** choose this option to change the schema to **Built-in** for local changes.

• **Update repository connection:** choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.

<table>
<thead>
<tr>
<th>Built-In: You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide. When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually. You can find more details about how to verify default values in retrieved schema in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
</tbody>
</table>

**Die on error**

This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a **Row > Rejects** link.

**Specify a data source alias**

Select this check box and specify the alias of a data source created on the Talend Runtime side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in Talend Runtime. For a related use case, see Scenario: Deploying your Job on Talend Runtime to retrieve data from a MySQL database on page 2503.

If you use the component’s own DB configuration, your data source connection will be closed at the end of the component. To prevent this from happening, use a shared DB connection with the data source alias specified.

This check box is not available when the **Use an existing connection** check box is selected.

---

</tbody>
</table>
Support null in “SQL WHERE” statement

Select this check box to validate null in “SQL WHERE” statement.

## Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>( \text{NB_LINE} ): the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>( \text{NB_LINE_UPDATED} ): the number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>( \text{NB_LINE_INSERTED} ): the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>( \text{NB_LINE_DELETED} ): the number of rows deleted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>( \text{NB_LINE_REJECTED} ): the number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>( \text{QUERY} ): the query statement processed. This is an After variable and it returns a string.</td>
</tr>
</tbody>
</table>

To fill up a field or expression with a variable, press \( \text{Ctrl} + \text{Space} \) to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

## Usage

### Usage rule

This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible.

This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in an Oracle database. It also allows you to create a reject flow using a \( \text{Row > Rejects} \) link to filter data in error. For an example of \tMysqlOutput in use, see [Scenario: Retrieving data in error with a Reject link on page 2529](#).

### Dynamic settings

Click the [+] button to add a row in the table and fill the \( \text{Code} \) field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The \( \text{Dynamic settings} \) table is available only when the \( \text{Use an existing connection} \) check box is selected in the
### Basic settings

Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see **Scenario: Reading data from databases through context-based dynamic connections** on page 2497 and **Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters** on page 489. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

### Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

### Related scenarios

For **tOracleOutput** related topics, see:

- **Scenario: Inserting a column and altering data using tMysqlOutput** on page 2521.
tOracleOutputBulk

Writes a file with columns based on the defined delimiter and the Oracle standards.

The tOracleOutputBulk and tOracleBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tOracleOutputBulkExec component, detailed in a separate section. The advantage of using two separate steps is that the data can be transformed before it is loaded in the database.

tOracleOutputBulk Standard properties

These properties are used to configure tOracleOutputBulk running in the Standard Job framework.

The Standard tOracleOutputBulk component belongs to the Databases family.

The component in this framework is generally available.

Note:

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in:</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository:</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>File Name</td>
<td>Name of the file to be generated.</td>
</tr>
<tr>
<td>Warning:</td>
<td>This file is generated on the local machine or a shared folder on the LAN.</td>
</tr>
<tr>
<td>Append</td>
<td>Select this check box to add the new rows at the end of the file</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either Built-in or stored remotely in the Repository.</td>
</tr>
<tr>
<td>Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:</td>
<td></td>
</tr>
</tbody>
</table>
**Built-In**: You create and store the schema locally for this component only. Related topic: see *Talend Studio User Guide*.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see *Talend Studio User Guide*.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

### Advanced settings

</tbody>
</table>

Related scenarios

For use cases in relation with tOracleOutputBulk, see the following scenarios:

- Scenario: Inserting transformed data in MySQL database on page 2537.
- Scenario: Inserting data in bulk in MySQL database on page 2544.
- Scenario: Truncating and inserting file data into an Oracle database on page 2752.
tOracleOutputBulkExec

Executes the Insert action in the specified Oracle database.

As a dedicated component, it allows gains in performance during Insert operations to an Oracle database.

The tOracleOutputBulk and tOracleBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tOracleOutputBulkExec component.

tOracleOutputBulkExec Standard properties

These properties are used to configure tOracleOutputBulkExec running in the Standard Job framework.

The Standard tOracleOutputBulkExec component belongs to the Databases family.

The component in this framework is generally available.

Note:
This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>

</thead>
</table>

<table>
<thead>
<tr>
<th>Action on table</th>
<th>On the table defined, you can perform one of the following operations:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>None:</strong> No operations is carried out.</td>
</tr>
<tr>
<td></td>
<td><strong>Drop and create table:</strong> The table is removed and created again.</td>
</tr>
<tr>
<td></td>
<td><strong>Create table:</strong> The table does not exist and gets created.</td>
</tr>
</tbody>
</table>
### Create table if not exists:
The table is created if does not exist.

### Drop table if exists and create:
The table is removed if it already exists and created again.

### Clear table:
The table content is deleted.

### Truncate table:
The table content is deleted. You do not have the possibility to rollback the operation.

<table>
<thead>
<tr>
<th><strong>File Name</strong></th>
<th>Name of the file to be generated and loaded.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Warning:</strong></td>
<td>This file is generated on the machine specified by the URI in the <strong>Host</strong> field so it should be on the same machine as the database server.</td>
</tr>
<tr>
<td><strong>Create directory if not exists</strong></td>
<td>This check box is selected by default. It creates a directory to hold the output table if required.</td>
</tr>
<tr>
<td><strong>Append</strong></td>
<td>Select this check box to add the new rows at the end of the file.</td>
</tr>
</tbody>
</table>

**Action on data**

On the data of the table defined, you can perform:

- **Insert**: Insert data to an empty table. If the table already contains data, the Job stops and the existing data remains in the table.
- **Update**: Update the existing data. You have to set the key on the schema if this option is selected.
- **Append**: Append data to the table, whether the table is empty or not.
- **Replace**: if the table already contains data, delete all the existing data and insert the new data. If the table is empty, insert the new data.
- **Truncate**: If the table already contains data, truncate all the existing data and insert the new data. If the table is empty, insert the new data.

### Schema and Edit Schema

A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either **Built-in** or stored remotely in the **Repository**.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No**.
upon completion and choose this schema metadata again in the [Repository Content] window.

**Built-In**: You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

<table>

<td>Select this check box to modify the conventions used for date and time formats. The default value is that of the operating system.</td>
</tr>
<tr>
<td><strong>Encoding</strong></td>
<td>Select the encoding from the list or select <strong>Custom</strong> and define it manually. This field is compulsory for DB data handling.</td>
</tr>
<tr>
<td><strong>Oracle encoding type</strong></td>
<td>Select the Oracle-specific encoding type for the data to be processed. This encoding type allows <strong>tOracleOutputBulkExec</strong> to properly generate the Sybase Bulk command.</td>
</tr>
</tbody>
</table>
| **Output** | Select the type of output for the standard output of the Oracle database:  
  - to console,  
  - to global variable. |
| **Convert columns and table names to uppercase** | Select this check box to put columns and table names in upper case. |
| **Bulk file parameters** | Set the parameters **Buffer Size** and **StringBuilder Size** for a performance gain according to the memory size. |
| **tStatCatcher Statistics** | Select this check box to gather the job processing metadata at a job level as well as at each component level. |

### Usage

<table>
<thead>
<tr>
<th><strong>Usage rule</strong></th>
<th>This component is mainly used when no particular transformation is required on the data to be loaded onto the database.</th>
</tr>
</thead>
</table>
| **Dynamic settings** | Click the **[+]** button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.  

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.  

For examples on using dynamic parameters, see **Scenario: Reading data from databases through context-based dynamic connections** on page 2497 and **Scenario: |
Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

| Limitation | The database server/client must be installed on the same machine where the Studio is installed or where the Job using tOracleOutputBulkExec is deployed, so that the component functions properly. |

Related scenarios

For use cases in relation with tOracleOutputBulkExec, see the following scenarios:

- Scenario: Inserting transformed data in MySQL database on page 2537.
- Scenario: Inserting data in bulk in MySQL database on page 2544.
- Scenario: Truncating and inserting file data into an Oracle database on page 2752.
tOracleRollback

Cancels the transaction commit in the connected Oracle database to avoid committing part of a transaction involuntarily.

**tOracleRollback Standard properties**

These properties are used to configure tOracleRollback running in the Standard Job framework. The Standard tOracleRollback component belongs to the Databases family. The component in this framework is generally available.

**Note:**
This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th><strong>Database</strong></th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Component list</strong></td>
<td>Select the tOracleConnection component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td><strong>Close Connection</strong></td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

### Advanced settings

| **tStatCatcher Statistics** | Select this check box to collect log data at the component level. |

### Usage

| **Usage rule** | This component is more commonly used with other tOracle* components, especially with the tOracleConnection and tOracleCommit components. |
| **Dynamic settings** | Click the [+ ] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. |
Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

## Related scenario

For **tOracleRollback** related scenario, see **tMysqlRollback** on page 2546
tOracleRow

Executes the stated SQL query on the specified Oracle database.

Depending on the nature of the query and the database, tOracleRow acts on the actual DB structure or on the data (although without handling data). The SQLBuilder tool helps you write easily your SQL statements.

tOracleRow is the specific component for this database query. It executes the SQL query stated onto the specified database. The row suffix means the component implements a flow in the job design although it doesn’t provide output.

**tOracleRow Standard properties**

These properties are used to configure tOracleRow running in the Standard Job framework.

The Standard tOracleRow component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in</strong>: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td><strong>Repository</strong>: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Note:</strong></td>
<td>When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:</td>
</tr>
<tr>
<td>1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.</td>
<td></td>
</tr>
</tbody>
</table>
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide.*

| Connection type | Drop-down list of available drivers:  
|----------------|---------------------------------|
| Oracle OCI     | Select this connection type to use Oracle Call Interface with a set of C-language software APIs that provide an interface to the Oracle database.  
| Oracle Service Name | Select this connection type to use the TNS alias that you give when you connect to the remote database.  
| Oracle SID      | Select this connection type to uniquely identify a particular database on a system.  
| Oracle Custom   | Select this connection type to access a clustered database.  

| DB Version | Select the Oracle version in use.  

| Host | Database server IP address.  

| Port | Listening port number of DB server.  

| Database | Name of the database.  

| Username and Password | DB user authentication data.  

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.  

| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.  

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  

- **View schema**: choose this option to view the schema only.  
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.  
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the [Repository Content] window.

<tr>
<th><strong>Use NB_LINE_</strong></th>
<th>This option allows you feed the variable with the number of rows inserted/updated/deleted to the next component or subjob. This field only applies if the query entered in Query field is a INSERT, UPDATE or DELETE query.</th>
</tr>
</thead>
<tbody>
<tr>
<td>• <strong>NONE:</strong> does not feed the variable.</td>
<td></td>
</tr>
<tr>
<td>• <strong>INSERTED:</strong> feeds the variable with the number of rows inserted.</td>
<td></td>
</tr>
<tr>
<td>• <strong>UPDATED:</strong> feeds the variable with the number of rows updated.</td>
<td></td>
</tr>
<tr>
<td>• <strong>DELETED:</strong> feeds the variable with the number of rows deleted.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Specify a data source alias</strong></th>
<th>Select this check box and specify the alias of a data source created on the Talend Runtime side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in Talend Runtime. For a related use case, see Scenario: Deploying your Job on Talend Runtime to retrieve data from a MySQL database on page 2503.</th>
</tr>
</thead>
<tbody>
<tr>
<td>If you use the component’s own DB configuration, your data source connection will be closed at the end of the component. To prevent this from happening, use a shared DB connection with the data source alias specified.</td>
<td></td>
</tr>
<tr>
<td>This check box is not available when the Use an existing connection check box is selected.</td>
<td></td>
</tr>
</tbody>
</table>

| **Die on error** | This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a Row > Rejects link. |
### Advanced settings

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Propagate QUERY’s recordset</td>
<td>Select this check box to insert the result of the query into a COLUMN of the current flow. Select this column from the use column list. Note: This option allows the component to have a different schema from that of the preceding component. Moreover, the column that holds the QUERY’s recordset should be set to the type of Object and this component is usually followed by tParseRecordSet.</td>
</tr>
<tr>
<td>Use PreparedStatement</td>
<td>Select this check box if you want to query the database using a PreparedStatement. In the Set PreparedStatement Parameter table, define the parameters represented by “?” in the SQL instruction of the Query field in the Basic Settings tab. Parameter Index: Enter the parameter position in the SQL instruction. Parameter Type: Enter the parameter type. Parameter Value: Enter the parameter value. Note: This option is very useful if you need to execute the same query several times. Performance levels are increased. You can also use PreparedStatement to avoid SQL injection. For a detailed scenario of utilizing this feature, see Scenario: Using PreparedStatement objects to query data on page 2553.</td>
</tr>
<tr>
<td>Commit every</td>
<td>Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions.</td>
</tr>
<tr>
<td>tStatCatcher Statistics</td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

### Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>QUERY</td>
<td>the query statement being processed. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td>NB_LINE_UPDATED</td>
<td>the number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>NB_LINE_INSERTED</td>
<td>the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>NB_LINE_DELETED</td>
<td>the number of rows deleted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>ERROR_MESSAGE</td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions...</td>
</tr>
</tbody>
</table>
only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component offers the flexibility of the DB query and covers all possible SQL queries.</th>
</tr>
</thead>
</table>

**Dynamic settings**

Click the [*] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see **Scenario: Reading data from databases through context-based dynamic connections** on page 2497 and **Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters** on page 489. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

### Related scenarios

For related topics, see:

- **Scenario: Combining two flows for selective output** on page 2558
- **Procedure** on page 625.
- **Scenario: Removing and regenerating a MySQL table index** on page 2552.
- **Scenario: Using PreparedStatement objects to query data** on page 2553.
tOracleSCD

Reflects and tracks changes in a dedicated Oracle SCD table.
tOracleSCD addresses Slowly Changing Dimension needs, reading regularly a source of data and logging the changes into a dedicated SCD table.

**tOracleSCD Standard properties**

These properties are used to configure tOracleSCD running in the Standard Job framework.
The Standard tOracleSCD component belongs to the Business Intelligence and the Databases families.
The component in this framework is generally available.

**Note:**
This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.
For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the Repository file where properties are stored. The following fields are pre-filled in using fetched data.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong></td>
</tr>
<tr>
<td></td>
<td>When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:</td>
</tr>
<tr>
<td></td>
<td>1. In the parent level, register the database connection to be shared in the <strong>Basic settings</strong> view of the connection component which creates that very database connection.</td>
</tr>
<tr>
<td></td>
<td>2. In the child level, use a dedicated connection component to read that registered database connection.</td>
</tr>
</tbody>
</table>
For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th><strong>Connection type</strong></th>
<th>Drop-down list of available drivers:</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Oracle OCI</strong></td>
<td>Select this connection type to use Oracle Call Interface with a set of C-language software APIs that provide an interface to the Oracle database.</td>
</tr>
<tr>
<td><strong>Oracle Service Name</strong></td>
<td>Select this connection type to use the TNS alias that you give when you connect to the remote database.</td>
</tr>
<tr>
<td><strong>Oracle SID</strong></td>
<td>Select this connection type to uniquely identify a particular database on a system.</td>
</tr>
<tr>
<td><strong>Oracle Custom</strong></td>
<td>Select this connection type to access a clustered database.</td>
</tr>
</tbody>
</table>

| **DB Version** | Select the Oracle version you are using. |
| **Host**       | Database server IP address. |
| **Port**       | Listening port number of DB server. |
| **Database**   | Name of the database. |
| **Schema**     | Name of the DB schema. |

| **Username and Password** | DB user authentication data. |
|                          | To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |

| **Table** | Name of the table to be written. Note that only one table can be written at a time. |

| **Action on table** | Select to perform one of the following operations on the table defined: |
|                    | - None: No action is carried out on the table. |
|                    | - Create table: A new table is created. |
|                    | - Create table if not exists: A table is created if it does not exist. |

| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. |
|                           | Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available: |
|                           |   • View schema: choose this option to view the schema only. |
|                           |   • Change to built-in property: choose this option to change the schema to Built-in for local changes. |
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the [Repository Content] window.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Built-in</td>
<td>The schema is created and stored locally for this component only. Related topic: see <a href="#">Talend Studio User Guide</a>.</td>
</tr>
<tr>
<td>Repository</td>
<td>The schema already exists and is stored in the Repository, hence can be reused. Related topic: see <a href="#">Talend Studio User Guide</a>.</td>
</tr>
</tbody>
</table>

**SCD Editor**

The SCD editor helps to build and configure the data flow for slowly changing dimension outputs. For more information, see [SCD management methodology](#) on page 2566.

**Use memory saving Mode**

Select this check box to maximize system performance.

**Source keys include Null**

Select this check box to allow the source key columns to have Null values.

**Warning:**

Special attention should be paid to the uniqueness of the source key(s) values when this option is selected.

**Die on error**

This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

### Advanced settings

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>

</tbody>
</table>
Related scenario

For related scenarios, see tMysqlSCD on page 2563.
tOracleSCDELT

Reflects and tracks changes in a dedicated Oracle SCD table through SQL queries.

*tOracleSCDELT* addresses Slowly Changing Dimension needs through SQL queries (server-side processing mode), and logs the changes into a dedicated Oracle SCD table.

**tOracleSCDELT Standard properties**

These properties are used to configure *tOracleSCDELT* running in the Standard Job framework.

The Standard *tOracleSCDELT* component belongs to the Business Intelligence and the Databases families.

The component in this framework is generally available.

*Note:*

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-in</strong>: No property data stored centrally. Enter properties manually.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: Select the repository file where Properties are stored. The fields that come after are pre-filled in using the fetched data.</td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined.

*Note:*

When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.

2. In the child level, use a dedicated connection component to read that registered database connection.
For an example about how to share a database connection across Job levels, see *Talend Studio User Guide.*

| **Connection type** | Drop-down list of available drivers:  
|---------------------|---|  
| **Oracle OCI**      | Select this connection type to use Oracle Call Interface with a set of C-language software APIs that provide an interface to the Oracle database.  
| **Oracle Service Name** | Select this connection type to use the TNS alias that you give when you connect to the remote database.  
| **Oracle SID**       | Select this connection type to uniquely identify a particular database on a system.  
| **Oracle Custom**    | Select this connection type to access a clustered database.  

| **DB Version** | Select the Oracle version you are using.  
| **Host** | The IP address of the database server.  
| **Port** | Listening port number of database server.  
| **Database** | Name of the database  
| **Username and Password** | User authentication data for a dedicated database.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.  

| **Source table** | Name of the input DB2 SCD table.  
| **Table** | Name of the table to be written. Note that only one table can be written at a time  
| **Action on table** | Select to perform one of the following operations on the table defined:  
| **None** | No action carried out on the table.  
| **Drop and create table** | The table is removed and created again  
| **Create table** | A new table gets created.  
| **Create table if not exists** | A table gets created if it does not exist.  
| **Clear table** | The table content is deleted. You have the possibility to rollback the operation.  
| **Truncate table** | The table content is deleted. You do not have the possibility to rollback the operation.  

| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.  

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **[Repository Content]** window.

| **Built-in** | The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide. |
| **Repository** | The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide. |

### Surrogate Key

Select the surrogate key column from the list.

### Creation

Select the method to be used for the surrogate key generation.

For more information regarding the creation methods, see SCD management methodology on page 2566.

### Source Keys

Select one or more columns to be used as keys, to ensure the unicity of incoming data.

### Source fields value include Null

Select this check box to allow the source columns to have Null values.

**Note:**

The source columns here refer to the fields defined in the **SCD type 1 fields** and **SCD type 2 fields** tables.

### Use SCD Type 1 fields

Use type 1 if tracking changes is not necessary. SCD Type 1 should be used for typos corrections for example. Select the columns of the schema that will be checked for changes.

### Use SCD Type 2 fields

Use type 2 if changes need to be tracked down. SCD Type 2 should be used to trace updates for example. Select the columns of the schema that will be checked for changes.

**Start date:** Adds a column to your SCD schema to hold the start date value. You can select one of the input schema columns as Start Date in the SCD table.

**End Date:** Adds a column to your SCD schema to hold the end date value for the record. When the record is currently active, the End Date column shows a null value,
or you can select Fixed Year value and fill it in with a fictive year to avoid having a null value in the End Date field.

**Log Active Status**: Adds a column to your SCD schema to hold the true or false status value. This column helps to easily spot the active record.

**Log versions**: Adds a column to your SCD schema to hold the version number of the record.

### Advanced settings

<table>
<thead>
<tr>
<th><strong>Additional JDBC parameters</strong></th>
<th>Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the <strong>Use an existing connection</strong> check box in the Basic settings.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Debug mode</strong></td>
<td>Select this check box to display each step during processing entries in a database.</td>
</tr>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

### Global Variables

<table>
<thead>
<tr>
<th><strong>Global Variables</strong></th>
<th><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press <strong>Ctrl + Space</strong> to access the variable list and choose the variable to use from it. For further information about variables, see <strong>Talend Studio User Guide</strong>.</th>
</tr>
</thead>
</table>

### Usage

<table>
<thead>
<tr>
<th><strong>Usage rule</strong></th>
<th>This component is used as an output component. It requires an input component and Row main link as input.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Dynamic settings</strong></td>
<td>Click the [*] button to add a row in the table and fill the <strong>Code</strong> field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.</td>
</tr>
</tbody>
</table>
The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see **Scenario: Reading data from databases through context-based dynamic connections** on page 2497 and **Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters** on page 489. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

---

**Related Scenario**

For related topics, see **tOracleSCD** on page 2795 and **tMysqlSCD** on page 2563.
**tOracleSP**

Calls an Oracle database stored procedure.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see [Dynamic database components](#) on page 598.

**tOracleSP Standard properties**

These properties are used to configure tOracleSP running in the Standard Job framework.

The component in this framework is generally available.

**Note:**

When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.

2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see [Talend Studio User Guide](#).

<th>Name of the schema.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th><strong>Username and Password</strong></th>
<th>DB user authentication data.</th>
</tr>
</thead>
</table>

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

<table>
<thead>
<tr>
<th><strong>Schema and Edit Schema</strong></th>
<th>A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either <strong>Built-in</strong> or stored remotely in the <strong>Repository</strong>.</th>
</tr>
</thead>
</table>

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No upon completion** and choose this schema metadata again in the **[Repository Content]** window.

<table>
<thead>
<tr>
<th><strong>Built-In</strong></th>
<th>You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.</th>
</tr>
</thead>
</table>
**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th>SP Name</th>
<th>Type in the exact name of the Stored Procedure (or Function)</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Is Function / Return result in</strong></td>
<td>Select this check box, if the stored procedure is a function and one value only is to be returned. Select on the list the schema column, the value to be returned is based on.</td>
</tr>
<tr>
<td><strong>Parameters</strong></td>
<td>Click the Plus button and select the various <strong>Schema Columns</strong> that will be required by the procedures. Note that the SP schema can hold more columns than there are parameters used in the procedure.</td>
</tr>
</tbody>
</table>

Select the **Type** of parameter:

- **IN**: Input parameter.
- **OUT**: Output parameter/return value.
- **IN OUT**: Input parameter is to be returned as value, likely after modification through the procedure (function).
- **RECORDSET**: Input parameters is to be returned as a set of values, rather than single value.

**Note:**

Check **Scenario: Inserting data in mother/daughter tables** on page 2476 if you want to analyze a set of records from a database table or DB query and return single records.

The Custom Type is used when a Schema Column you want to use is user-defined. Two Custom Type columns are available in the Parameters table. In the first Custom Type column:

- Select the check box in the Custom Type column when the corresponding Schema Column you want to use is of user-defined type.
- If all listed Schema Columns in the Parameters table are of custom type, you can select the check box before Custom Type once for them all.

Select a database type from the DB Type list to map the source database type to the target database type:

- **Auto-Mapping**: Map the source database type to the target database type automatically (default)
- **CLOB**: Character large object.
- **BLOB**: Binary large object.
- **DECIMAL**: Decimal numeric object.
- **NUMERIC**: Character 0 to 9.
- **XMLTYPE**: XML schema type.
Warning:
When mapping a column selected from the Return result in list box or set to the IN or OUT type of parameter to XMLTYPE, make sure that the column is of type String in the schema.

In the second Custom Type column, you can precise what the custom type is. The type may be:
- STRUCT: used for one element.
- ARRAY: used for a collection of elements.

In the Custom name column, specify the name of the custom type that you have given to this type.

Warning:
When an OUT parameter uses the custom type, make sure that its corresponding Schema Column has chosen the Object type in the schema table.

Specify a data source alias
Select this check box and specify the alias of a data source created on the Talend Runtime side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in Talend Runtime. For a related use case, see Scenario: Deploying your Job on Talend Runtime to retrieve data from a MySQL database on page 2503.

Advanced settings

**Additional JDBC parameters**
Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the Use an existing connection check box in the Basic settings.

**NLS Language**
In the list, select the language used for the data that are not used in Unicode.

**NLS Territory**
Select the conventions used for date and time formats. The default value is that of the operating system.

**tStatCatcher Statistics**
Select this check box to gather the job processing metadata at a Job level as well as at each component level.

Usage

**Usage rule**
This component is used as intermediary component. It can be used as start component but only input parameters are thus allowed.

**Dynamic settings**
Click the [+ ] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple
connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

| Limitation | The Stored Procedures syntax should match the Database syntax. When the parameters set in this component are of Custom Type, the tJava family components should be placed before the component in order for users to define values for the custom-type parameters, or after the component so as to read and output the Out-type custom parameters. |

**Scenario: Checking number format using a stored procedure**

The following job aims at connecting to an Oracle Database containing Social Security Numbers and their holders' name, calling a stored procedure that checks the SSN format of against a standard ###-###-#### format. Then the verification output results, 1 for valid format and 0 for wrong format get displayed onto the execution console.

- Drag and drop the following components from the Palette: tOracleConnection, tOracleInput, tOracleSP and tLogRow.
- Link the tOracleConnection to the tOracleInput using a Then Run connection as no data is handled here.
• And connect the other components using a **Row Main** link as rows are to be passed on as parameter to the SP component and to the console.

• In the **tOracleConnection**, define the details of connection to the relevant Database. You will then be able to reuse this information in all other DB-related components.

• Then select the **tOracleInput** and define its properties.

  ![tOracleInput_1](image)

  - Select the **Use an existing connection** check box and select the **tOracleConnection** component in the list in order to reuse the connection details that you already set.

  - Select **Repository** as **Property type** as the Oracle schema is defined in the DB Oracle connection entry of the Repository. If you haven’t recorded the Oracle DB details in the **Repository**, then fill in the Schema name manually.

  - Then select **Repository** as **Schema**, and retrieve the relevant schema corresponding to your Oracle DB table.

  ![Table](image)

  - In this example, the SSN table has a four-column schema that includes **ID**, **NAME**, **CITY** and **SSNUMBER**.

  - In the **Query** field, type in the following **Select query** or select it in the list, if you stored it in the Repository.

    ```sql
    select ID, NAME, CITY, SSNUMBER from SSN
    ```

  - Then select the **tOracleSP** and define its **Basic settings**.
Like for the **tOracleInput** component, select **Repository** in the **Property type** field and select the **Use an existing connection** check box, then select the relevant entries in the respective list.

The schema used for the **tOracleSP** slightly differs from the input schema. Indeed, an extra column (**SSN_Valid**) is added to the Input schema. This column will hold the format validity status (1 or 0) produced by the procedure.

In the **SP Name** field, type in the exact name of the stored procedure (or function) as called in the Database. In this use case, the stored procedure name is **is_ssn**.

The basic function used in this particular example is as follows:

```sql
CREATE OR REPLACE FUNCTION is_ssn(string_in VARCHAR2)
RETURN PLS_INTEGER
IS
  -- validating ###-##-#### format
BEGIN
  IF TRANSLATE(string_in, '0123456789A', 'AAAAAAAAAAB') = 'AAA-AA-AAAA' THEN
    RETURN 1;
  END IF;
  RETURN 0;
END is_ssn;
/
```

As a return value is expected in this use case, the procedure acts as a function, so select the **Is function** check box.

The only return value expected is based on the **ssn_valid** column, hence select the relevant list entry.

In the **Parameters** area, define the input and output parameters used in the procedure. In this use case, only the **SSNNumber** column from the schema is used in the procedure.
Click the plus sign to add a line to the table and select the relevant column (SSNumber) and type (IN).

Then select the tLogRow component and click Sync Column to make sure the schema is passed on from the preceding tOracleSP component.

Select the Print values in cells of a table check box to facilitate the output reading.

Then save your job and press F6 to run it.

On the console, you can read the output results. All input schema columns are displayed even though they are not used as parameters in the stored procedure.

The final column shows the expected return value, whether the SS Number checked is valid or not.

Note:
Check Scenario: Inserting data in mother/daughter tables on page 2476 if you want to analyze a set of records from a database table or DB query and return single records.

Related scenarios

For related scenarios, see:

- Scenario: Retrieving personal information using a stored procedure on page 2452.
- Scenario: Using tMysqlSP to find a State Label using a stored procedure on page 2583.
- Executing a stored procedure using tMDMSP on page 2190.
tOracleTableList

Lists the names of specified Oracle tables using a SELECT statement based on a WHERE clause. tOracleTableList iterates on a set of tables through a defined Oracle connection.

**tOracleTableList Standard properties**

These properties are used to configure tOracleTableList running in the Standard Job framework. The Standard tOracleTableList component belongs to the Databases family. The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tOracleConnection component in the list if more than one connection is planned for the current Job.</td>
</tr>
<tr>
<td>Where clause for table name selection</td>
<td>Enter the WHERE clause that will be used to identify the tables to iterate on.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>CURRENT_TABLE: the name of the table currently iterated upon. This is a Flow variable and it returns a string.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>NB_TABLE: the number of tables iterated upon so far. This is a Flow variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is to be used along with other Oracle components, especially with <strong>tOracleConnection</strong>.</th>
</tr>
</thead>
</table>
| Dynamic settings | Click the `[+]` button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see *Scenario: Reading data from databases through context-based dynamic connections* on page 2497 and *Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters* on page 489. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide. |

Related scenarios

For a **tOracleTableList** related scenario, see *Scenario: Iterating on DB tables and deleting their content using a user-defined SQL template* on page 2588.
tPaloCheckElements

Checks whether elements are present in an incoming data flow existing in a given cube. This component can be used along with tPaloOutputMulti. It checks if the elements from the input stream exist in the given cube, before writing them. It can also define a default value to be used for nonexistent elements.

tPaloCheckElements Standard properties

These properties are used to configure tPaloCheckElements running in the Standard Job framework. The Standard tPaloCheckElements component belongs to the Business Intelligence family. The component in this framework is generally available.

Basic settings

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host Name</td>
<td>Enter the host name or the IP address of the host server.</td>
</tr>
<tr>
<td>Server Port</td>
<td>Type in the listening port number of the Palo server.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>Enter the Palo user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Database</td>
<td>Type in the name of the database in which the data is to be written.</td>
</tr>
<tr>
<td>Cube</td>
<td>Type in the name of the cube in which the data should be written.</td>
</tr>
<tr>
<td>On element error</td>
<td>Select what should happen if an element does not exist: - Reject row: the corresponding row is rejected and placed in the reject flow. - Use default: the defined Default value is used. - Stop: the entire process is interrupted.</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
</tbody>
</table>
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.

<table>
<thead>
<tr>
<th><strong>Built-in</strong>: The schema is created and stored locally for this component only. Related topic: see <strong>Talend Studio User Guide</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Repository</strong>: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see <strong>Talend Studio User Guide</strong>.</td>
</tr>
</tbody>
</table>

Define the elements to be checked in the table provided.
- **Column**: shows the column(s) from the input schema. It is completed automatically once a schema is retrieved or created.
- **Element type**: select the element type for the input column. Only one column can be defined as **Measure**.
- **Default**: type in the default value to be used if you have selected the **Use default** option in the **On element error** field.

**Advanced settings**

| **tStat Catcher Statistics** | Select this check box to collect log data on the component level. |

**Global Variables**

| **Global Variables** | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it. |

For further information regarding connections, see 
*Talend Studio User Guide*.

**Limitation**

- This component only works on **Normal** Palo cubes.

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

**Related scenario**

For a related scenario, see **Scenario 2: Rejecting inflow data when the elements to be written do not exist in a given cube** on page 2865.
tPaloClose

Closes an active connection to a Palo Server.
This component is used to disconnect a connection to a Palo server to release occupied resources.

tPaloClose Standard properties

These properties are used to configure tPaloClose running in the Standard Job framework.
The Standard tPaloClose component belongs to the Business Intelligence family.
The component in this framework is generally available.

Basic settings

| Component List | Select a tPaloConnection component from the drop-down list if more than one connection is planned for the current Job. |

Advanced settings

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | This component is more commonly used with other Palo components, especially tPaloConnection. |

| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, |
especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

### Related scenarios

No scenario is available for the Standard version of this component yet.
tPaloConnection

Opens a connection to a Palo Server and allows other components involved in a process to share the connection for the duration of the process.

**tPaloConnection Standard properties**

These properties are used to configure tPaloConnection running in the Standard Job framework.

The Standard tPaloConnection component belongs to the Business Intelligence family.

The component in this framework is generally available.

### Related scenario

For related scenarios, see *Scenario: Creating a dimension with elements* on page 2841.
tPaloCube

Performs operations on a given Palo cube.
This component creates, deletes or clears Palo cubes from existing dimensions in a Palo database.

tPaloCube Standard properties

These properties are used to configure tPaloCube running in the Standard Job framework.
The Standard tPaloCube component belongs to the Business Intelligence family.
The component in this framework is generally available.

Basic settings

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host Name</td>
<td>Enter the host name or the IP address of the host server.</td>
</tr>
<tr>
<td>Server Port</td>
<td>Type in the listening port number of the Palo server.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>Enter the Palo user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Database</td>
<td>Type in the name of the database in which the operation is to take place.</td>
</tr>
<tr>
<td>Cube</td>
<td>Type in the name of the cube where the operation is to take place.</td>
</tr>
<tr>
<td>Cube type</td>
<td>From the drop-down list, select the type of cube on which the operation is to be carried out:</td>
</tr>
<tr>
<td></td>
<td>- Normal: this is the normal and default type of cube.</td>
</tr>
<tr>
<td></td>
<td>- Attribute: an Attribute cube is created with a normal cube.</td>
</tr>
<tr>
<td></td>
<td>- User Info: User Info cubes can be created/modified with this component.</td>
</tr>
<tr>
<td>Action on cube</td>
<td>Select the operation you want to carry out on the cube defined:</td>
</tr>
<tr>
<td></td>
<td>- Create cube: the cube does not exist and will be created.</td>
</tr>
<tr>
<td></td>
<td>- Create cube if not exists: the cube is created if it does not exist.</td>
</tr>
</tbody>
</table>
- **Delete cube if exists and create**: the cube is deleted if it already exists and a new one will be created.
- **Delete cube**: the cube is deleted from the database.
- **Clear cube**: the data is cleared from the cube.

### Dimension list
Add rows and enter the name of existing database dimension's to be used in the cube. The order of the dimensions in the list determines the order of the dimensions created.

### Advanced settings

<table>
<thead>
<tr>
<th>tStat Catcher Statistics</th>
<th>Select this check box to collect log data at the component level.</th>
</tr>
</thead>
</table>

### Global Variables

| Global Variables | CUBENAME: the name of the cube. This is an After variable and it returns a string.  
ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.  
For further information about variables, see [Talend Studio User Guide](#). |

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>Can be used as a standalone component for dynamic cube creation with a defined dimension list.</th>
</tr>
</thead>
</table>

### Connections

Outgoing links (from this component to another):

**Trigger**: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error.

Incoming links (from one component to this one):

**Row**: Iterate

**Trigger**: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error.

For further information regarding connections, see [Talend Studio User Guide](#).
**Limitation**

The cube creation process does not create dimensions from scratch, so the dimensions to be used in the cube must be created beforehand.

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

---

**Scenario: Creating a cube in an existing database**

The Job in this scenario creates a new two dimensional cube in the Palo demo database *Biker*.

To replicate this scenario, proceed as follows:

**Configuring the tPaloCube component**

**Procedure**

1. Drop **tPaloCube** from the **Palette** onto the design workspace.
2. Double-click **tPaloCube** to open its **Component** view.
3. In the **Host name** field, type in the host name or the IP address of the host server, *localhost* for this example.

4. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is **7777**.

5. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are *admin*.

6. In the **Database** field, type in the database name in which you want to create the cube, *Biker* in this example.

7. In the **Cube** field, type in the name you want to use for the cube to be created, for example, *bikerTalend*.

8. In the **Cube type** field, select the **Normal** type from the drop-down list for the cube to be created, meaning this cube will be normal and default.

9. In the **Action on cube** field, select the action to be performed. In this scenario, select **Create cube**.

10. Under the **Dimension list** table, click the plus button twice to add two rows into the table.

11. In the **Dimension list** table, type in the name for each newly added row to replace the default row name. In this scenario, type *Months* for the first row and *Products* for the second. These two dimensions exist already in the Biker database where the new cube will be created.

**Job execution**

Press **F6** to run the Job.

A new cube has been created in the *Biker* database and the two dimensions are added into this cube.
tPaloCubeList

Retrieves a list of cube details from the given Palo database.

This component lists cube names, cube types, number of assigned dimensions, the number of filled cells from the given database.

Discovering the read-only output schema of tPaloCubeList

The below table presents information related to the read-only schema of the tPaloCubeList component.

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cube_id</td>
<td>int</td>
<td>Internal id of the cube.</td>
</tr>
<tr>
<td>Cube_name</td>
<td>string</td>
<td>Name of the cube.</td>
</tr>
<tr>
<td>Cube_dimensions</td>
<td>int</td>
<td>Number of dimensions inside the cube.</td>
</tr>
<tr>
<td>Cube_cells</td>
<td>long</td>
<td>Number of calculated cells inside the cube.</td>
</tr>
<tr>
<td>Cube_filled_cells</td>
<td>long</td>
<td>Number of filled cells inside the cube.</td>
</tr>
<tr>
<td>Cube_status</td>
<td>int</td>
<td>Status of the cube. It may be:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- 0: unloaded</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- 1: loaded</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- 2: changed</td>

</tr>
</tbody>
</table>

The Standard tPaloCubeList component belongs to the Business Intelligence family.

The component in this framework is generally available.

**Basic settings**

| Use an existing connection | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. |
Note that when a Job contains the parent Job and the child Job, **Component List** presents only the connection components in the same Job level.

| **Host Name** | Enter the host name or the IP address of the host server. |
| **Server Port** | Type in the listening port number of the Palo server. |
| **Username and Password** | Enter the Palo user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| **Database** | Type in the name of the database whose cube details you want to retrieve. |

### Advanced settings

| **tStat Catcher Statistics** | Select this check box to collect log data at the component level. |

### Global Variables

| **Global Variables** | **NB_CUBES**: the number of cubes. This is an After variable and it returns an integer.  
**CUBEID**: the ID of the cube. This is a Flow variable and it returns an integer.  
**CUBENAME**: the name of the cube. This is a Flow variable and it returns a string.  
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
For further information about variables, see **Talend Studio User Guide**. |

### Usage

| **Usage rule** | This component can be used as a start component. It requires an output component. |
| **Connections** | Outgoing links (from this component to another):  
**Row**: Main, Iterate; |
### Scenario: Retrieving detailed cube information from a given database

The Job in this scenario retrieves detailed information of the cubes pertaining to the demo Palo database, Biker.

To replicate this scenario, proceed as follows:

**Setting up the Job**

**Procedure**

1. Drop tPaloCubeList and tLogRow from the component Palette onto the design workspace.
2. Right-click tPaloCubeList to open the contextual menu.
3. From this menu, select Row > Main to link the two components.

**Configuring the tPaloCube component**

**Procedure**

1. Double-click the tPaloCube component to open its Component view.
2. In the **Host name** field, type in the host name or the IP address of the host server, *localhost* for this example.

3. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is **7777**.

4. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are *admin*.

5. In the **Database** field, type in the database name in which you want to create the cube, *Biker* in this example.

**Job execution**

Press **F6** to run the Job.

The cube details are retrieved from the *Biker* database and are listed in the console of the **Run** view.

```
[statistics] connected

```

For further information about how to interpret the cube details listed in the console, see Discovering the read-only output schema of tPaloCubeList on page 2827.
tPaloDatabase

Manages the databases inside a Palo server.

The tPaloDatabase creates, drops or recreates databases in a given Palo server.

tPaloDatabase Standard properties

These properties are used to configure tPaloDatabase running in the Standard Job framework.

The Standard tPaloDatabase component belongs to the Business Intelligence family.

The component in this framework is generally available.

Basic settings

| Use an existing connection | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. 
Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Host Name</td>
<td>Enter the host name or the IP address of the host server.</td>
</tr>
<tr>
<td>Server Port</td>
<td>Type in the listening port number of the Palo server.</td>
</tr>
</tbody>
</table>
| Username and Password     | Enter the Palo user authentication data. 
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| Database                  | Type in the name of the database on which the given operation should take place. |
| Action on database        | Select the operation you want to perform on the database of interest: 
- Create database: the database does not exist and will be created. 
- Create database if not exists: the database is created when it does not exist. 
- Delete database if exists and create: the database is deleted if exist and a new one is then created. 
- Delete database: the database is removed from the server |

Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |
Global Variables

**DATABASENAME**: the name of the database. This is an After variable and it returns a string.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](https://help.talend.com).

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component can be used in standalone for database management in a Palo server.</th>
</tr>
</thead>
</table>

Connections

<table>
<thead>

</tr>
</tbody>
</table>

For further information regarding connections, see [Talend Studio User Guide](https://help.talend.com).

Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

Scenario: Creating a database

The Job in this scenario creates a new database on a given Palo server.
To replicate this scenario, proceed as follows:

**Procedure**

1. Drop tPaloDatabase from the component Palette onto the design workspace.
2. Double-click the tPaloDatabase component to open its Component view.
3. In the **Host name** field, type in the host name or the IP address of the host server, *localhost* for this example.
4. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is *7777*.
5. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are *admin*.
6. In the **Database** field, type in the database name in which you want to create the cube, *talenddatabase* in this example.
7. In the **Action on database** field, select the action to be performed. In this scenario, select *Create database* as the database to be created does not exist.
8. Press F6 to run the Job.

**Results**

A new database is created on the given Palo server.
tPaloDatabaseList

Lists database names, database types, number of cubes, number of dimensions, database status and database id from a given Palo server.

The tPaloDatabaseList retrieves a list of database details from the given Palo server.

Discovering the read-only output schema of tPaloDatabaseList

The below table presents information related to the read-only output schema of the tPaloDatabaseList component.

<table>
<thead>
<tr>
<th>Database</th>
<th>Type</th>
<th>Description</th>
</tr>

| Username and Password | Enter the Palo user authentication data.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Global Variables**

| Global Variables | **NB_DATABASES**: the number of databases. This is an After variable and it returns an integer.  
**DATABASEID**: the ID of the database. This is a Flow variable and it returns a long.  
**DATABASENAME**: the name of the database. This is a Flow variable and it returns a string.  
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.  
For further information about variables, see Talend Studio User Guide. |

**Usage**

| Usage rule | This component can be used as a start component. It requires an output component. |

| Connections | Outgoing links (from this component to another):  
**Row**: Main; Iterate  
**Trigger**: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error.  
Incoming links (from one component to this one):  
**Row**: Iterate |
Scenario: Retrieving detailed database information from a given Palo server

The Job in this scenario retrieves details of all of the databases from a given Palo server.

To replicate this scenario, proceed as follows:

**Setting up the Job**

*Procedure*

1. Drop `tPaloDatabaseList` and `tLogRow` from the component Palette onto the design workspace.
2. Right-click `tPaloDatabaseList` to open the contextual menu.
3. From this menu, select `Row > Main` to link the two components.

**Configuring the tPaloDatabaseList component**

*Procedure*

1. Double-click the `tPaloDatabaseList` component to open its Component view.
2. In the Host name field, type in the host name or the IP address of the host server, localhost for this example.

3. In the Server Port field, type in the listening port number of the Palo server. In this scenario, it is 7777.

4. In the Username field and the Password field, type in the authentication information. In this example, both of them are admin.

**Job execution**

Press F6 to run the Job.

Details of all of the databases in the Palo server are retrieved and listed in the console of the Run view.

```
0|System|7|6|1|1
1|Demo|23|23|1|0
6|Biker|27|28|1|0
9|tx_g|17|17|1|0
25|DBHSE24|13|12|1|0
31|elmCreate|13|12|1|0
32|tPaloOutputMulit|15|15|1|0
```

For further information about the output schema, see Discovering the read-only output schema of tPaloDatabaseList on page 2834.
tPaloDimension

Manages Palo dimensions, even elements inside a database.
The tPaloDimension creates, drops or recreates dimensions with or without dimension elements inside a Palo database.

tPaloDimension Standard properties

These properties are used to configure tPaloDimension running in the Standard Job framework.
The Standard tPaloDimension component belongs to the Business Intelligence family.
The component in this framework is generally available.

Basic settings

| Use an existing connection | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level. |
| Host Name | Enter the host name or the IP address of the host server. |
| Server Port | Type in the listening port number of the Palo server. |
| Username and Password | Enter the Palo user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| Database | Type in the name of the database in which the dimensions are managed. |
| Dimension | Type in the name of the dimension on which the given operation should take place. |
| Action on dimension | Select the operation you want to perform on the dimension of interest:  
- None: no action is taken on this dimension.  
- Create dimension: the dimension does not exist and will be created.  
- Create dimension if not exists: this dimension is created only when it does not exist.  
- Delete dimension if exists and create: this dimension is deleted if exist and then a new one will be created.  
- Delete dimension: this dimension is removed from the database. |
**Create dimension elements**

Select this check box to activate the dimension management fields and create dimension elements along with the creation of this dimension.

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Global Variables**

| Global Variables | **DIMENSIONNAME**: the name of the dimension. This is an After variable and it returns a string.  
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
For further information about variables, see *Talend Studio User Guide*. |

**Usage**

| Usage rule | This component can be used in standalone or as end component of a process. |

| **Note:**  
The below fields are available only when the **Create dimension elements** check box is selected | **Dimension type**  
| **Note:**  
Available only when the action on dimension is **None**. |

| Commit size |
| Schema and Edit Schema |

| **Consolidation type** - **None**  
| **Note:**  
With this option, you activate the corresponding parameter fields to be completed. |
Consolidation type - Normal

**Note:**
With this option, you activate the corresponding parameter fields to be completed.

---

Consolidation type - Self-referenced

**Note:**
With this option, you activate the corresponding parameter fields to be completed.

---

Element’s type

Creation mode

---

**Connections**

Outgoing links (from this component to another):

- **Trigger**: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error.

Incoming links (from one component to this one):

- **Trigger**: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error.

For further information regarding connections, see *Talend Studio User Guide*.

---

**Limitation**

Deletion of dimension elements is only possible with the consolidation type **None**. Only consolidation type **Self-Referenced** allows the placing of an factor on this consolidation.

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find...
Scenario: Creating a dimension with elements

The Job in this scenario creates a date dimension with simple element hierarchy composed of three levels: Year, Month, Date.

To replicate this scenario, proceed as follows:

Setting up the Job

Procedure

1. Drop tPaloConnection, tRowGenerator, tMap, tPaloDimension from the component Palette onto the design workspace.
2. Right-click tPaloConnection to open the contextual menu and select Trigger > On Subjob Ok to link it to tRowGenerator.
3. Right-click tRowGenerator to open the contextual menu and select Row > Main to link it to tMap.
4. Right-click tMap to open the contextual menu and select Row > New output to link to tPaloDimension, then name it as out1 in the dialog box that pops up.

Setting up the DB connection

Procedure

1. Double-click the tPaloConnection component to open its Component view.
2. In the **Host name** field, type in the host name or the IP address of the host server, `localhost` for this example.

3. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is `7777`.

4. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are `admin`.

**Configuring the input component**

**Procedure**

1. Double-click `tRowGenerator` to open its editor.

![Table]

2. On the upper part of the editor, click the plus button to add one column and rename it as `random_date` in the **Column** column.

3. In the newly added row, select `Date` in the **Type** column and `getRandomDate` in the **Functions** column.

4. In the **Function parameters** view on the lower part of this editor, type in the new minimum date and maximum date values in the **Value** column. In this example, the minimum is `2010-01-01`, the maximum is `2010-12-31`.

5. Click **OK** to validate your modifications and close the editor.

6. On the dialog box that pops up, click **OK** to propagate your changes.

**Configuration in the tMap editor**

**Procedure**

1. Double-click `tMap` to open its editor.
2. On the Schema editor view on the lower part of the tMap editor, under the out1 table, click the plus button to add three rows.

3. In the Column column of the out1 table, type in the new names for the three newly added rows. They are Year, Month, and Date. These rows are then added automatically into the out1 table on the upper part of the tMap editor.

4. In the out1 table on the upper part of the tMap editor, click the Expression column in the Year row to locate the cursor.

5. Press Ctrl+space to open the drop-down variable list.

6. Double-click TalendDate.formatDate to select it from the list. The expression to get the date displays in the Year row under the Expression column. The expression is TalendDate.formatDate("yyyy-MM-dd HH:mm:ss",myDate).

7. Replace the default expression with TalendDate.formatDate("yyyy",row1.random_date).

8. Do the same for the Month row and the Date row to add this default expression and to replace it with TalendDate.formatDate("MM",row1.random_date) for the Month row and with TalendDate.formatDate("dd-MM-yyyy", row1.random_date) for the Date row.

9. Click OK to validate this modification and accept the propagation by clicking OK in the dialog box that pops up.

Configuring the tPaloDimension component

Procedure

1. On the workspace, double-click tPaloDimension to open its Component view.
2. Select the **Use an existing connection** check box. Then **tPaloConnection_1** displays automatically in the **Connection configuration** field.

3. In the **Database** field, type in the database in which the new dimension is created, **talendDatabase** for this scenario.

4. In the **Dimension** field, type in the name you want to use for the dimension to be created, for example, **Date**.

5. In the **Action on dimension** field, select the action to be performed. In this scenario, select **Create dimension if not exist**.

6. Select the **Create dimension elements** check box.

7. In the **Consolidation Type** area, select the **Normal** check box.

8. Under the element hierarchy table in the **Consolidation Type** area, click the plus button to add three rows into the table.

9. In the **Input column** column of the element hierarchy table, select **Year** from the drop-down list for the first row, **Month** for the second and **Date** for the third. This determinates levels of elements from different columns of the input schema.

**Job execution**

Press F6 to run the Job.

A new dimension is then created in your Palo database **talendDatabase**.
tPaloDimensionList

Retrieves a list of dimension details from the given Palo database.

tPaloDimensionList lists dimension names, dimension types, number of dimension elements, maximum dimension indent, maximum dimension depth, maximum dimension level, dimension id from a given Palo server.

Discovering the read-only output schema of tPaloDimensionList

The below table presents information related to the read-only output schema of the tPaloDimensionList component.

<table>
<thead>
<tr>
<th>Database</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dimension_id</td>
<td>long</td>
<td>Internal ID of the dimension.</td>
</tr>
<tr>
<td>Dimension_name</td>
<td>string</td>
<td>Name of the dimension.</td>
</tr>
<tr>
<td>Dimension_attribute_cube</td>
<td>string</td>
<td>Name of the cube of attributes.</td>

</table>

tPaloDimensionList Standard properties

These properties are used to configure tPaloDimensionList running in the Standard Job framework.
The Standard tPaloDimensionList component belongs to the Business Intelligence family.
The component in this framework is generally available.

Basic settings

| Use an existing connection | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. |
Note that when a Job contains the parent Job and the child Job, **Component List** presents only the connection components in the same Job level.

| **Host Name** | Enter the host name or the IP address of the host server. |
| **Server Port** | Type in the listening port number of the Palo server. |
| **Username and Password** | Enter the Palo user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings. |
| **Database** | The name of the database where the dimensions of interest reside. |
| **Retrieve cube dimensions** | Select this check box to retrieve dimension information from an existing cube. |
| **Cube** | Type in the name of the cube from which dimension information is retrieved. **Note:** Available when you select the **Retrieve cube dimensions** check box. |
| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word **line** when naming the fields. Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
  - **View schema**: choose this option to view the schema only.  
  - **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
  - **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.  
  
  **Built-in**: The schema is created and stored locally for this component only. Related topic: see **Talend Studio User Guide**.  
  
  **Repository**: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see **Talend Studio User Guide**. |
## Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

## Global Variables

### Global Variables

<table>
<thead>
<tr>
<th>DIMENSIONNAME</th>
<th>the name of the dimension. This is a Flow variable and it returns a string.</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERROR_MESSAGE</td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

## Usage

### Usage rule

This component can be used in standalone or as start component of a process.

### Connections

Outgoing links (from this component to another):

- **Row**: Main; Iterate.
- **Trigger**: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error.

Incoming links (from one component to this one):

- **Row**: Iterate
- **Trigger**: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error.

For further information regarding connections, see *Talend Studio User Guide*.

### Limitation

The output schema is fixed and read-only.

Due to license incompatibility, one or more JARs required to use this component are not provided.

You can install the missing JARs for this particular component by clicking the **Install** button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).
**Scenario: Retrieving detailed dimension information from a given database**

The Job in this scenario retrieves details of all of the dimensions from a given database.

To replicate this scenario, proceed as follows:

**Setting up the Job**

**Procedure**

1. Drop tPaloDimensionList and tLogRow from the component Palette onto the design workspace.
2. Right-click tPaloDimensionList to open the contextual menu.
3. From this menu, select Row > Main to link the two components.

**Configuring the tPaloDimensionList component**

**Procedure**

1. Double-click the tPaloDimensionList component to open its Component view.

2. In the **Host name** field, type in the host name or the IP address of the host server, *localhost* for this example.
3. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is *7777*.
4. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are *admin*.
5. In the **Database** field, type in the database name where the dimensions of interest reside, *Biker* in this example.
Job execution

Press **F6** to run the Job.

Details of all the dimensions in the *Biker* database are retrieved and listed in the console of the **Run** view.

For further information about the output schema, see Discovering the read-only output schema of **tPaloDimensionList** on page 2846.
tPaloInputMulti

Retrieves the stored or calculated values in combination with the element records out of a cube.
The tPaloInputMulti retrieves data (elements as well as values) from a Palo cube.

tPaloInputMulti Standard properties

These properties are used to configure tPaloInputMulti running in the Standard Job framework.
The Standard tPaloInputMulti component belongs to the Business Intelligence family.
The component in this framework is generally available.

Basic settings

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level.</td>

<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
</tbody>
</table>
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.

**Built-in**: The schema is created and stored locally for this component only. Related topic: see *Talend Studio User Guide*.

**Repository**: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see *Talend Studio User Guide*.

**Cube Query**  
Complete this table with the query you want to use to retrieve data. The columns to be filled are:

- **Column**: the schema columns are added automatically to this column once defined in the schema editor. The schema columns are used to store the retrieved dimension elements.

- **Dimensions**: type in each of the dimension names of the cube from which you want to retrieve dimension elements.

  **Warning:**  
  *The dimension order listed in this column must be consistent with the order given in the cube that stores these dimensions.*

- **Elements**: type in the dimension elements from which data is retrieved. If several elements are needed from one single dimension, separate them with a comma.

**Advanced settings**

**tStat Catcher Statistics**  
Select this check box to collect log data at the component level.

**Global Variables**

**Global Variables**  
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions...
only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component requires an output component.</th>
</tr>
</thead>
</table>

#### Connections

Outgoing links (from this component to another):

- **Row**: Main
- **Trigger**: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error.

Incoming links (from one component to this one):

- **Row**: Iterate
- **Trigger**: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error.

For further information regarding connections, see *Talend Studio User Guide*.

### Limitation

According to the architecture of OLAP-Systems only one single value (text or numeric) could be retrieved from the cube. The **MEASURE** column and the **TEXT** column are fixed and read-only.

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

### Scenario: Retrieving dimension elements from a given cube

The Job in this scenario retrieves several dimension elements from a demo Palo cube *Sales*.
To replicate this scenario, proceed as follows:

**Setting up the Job**

**Procedure**

1. Drop `tPaloInputMulti` and `tLogRow` from the component Palette onto the design workspace.
2. Right-click `tPaloInputMulti` to open its contextual menu.
3. In the menu, select Row > Main to connect `tPaloInputMulti` to `tLogRow` with a row link.

**Setting up the DB connection**

**Procedure**

1. Double-click the `tPaloInputMulti` component to open its Component view.

   ![Component view](image)

   - **Host name** field: Type in the host name or the IP address of the host server, localhost for this example.
   - **Server Port** field: Type in the listening port number of the Palo server. In this scenario, it is 7777.
   - **Username** field and the **Password** field: Type in the authentication information. In this example, both of them are admin.

**Configuring the Cube Query**

**Procedure**

1. In the **Database** field, type in the database name in which the cube to be used is stored.
2. In the **Cube** field, type in the cube name in which the dimensions of interests are stored. In this scenario, it is one of the demo cubes *Sales*.

3. In the **Cube type** field, select the **Normal** type from the drop-down list for the cube to be created, meaning this cube will be normal and default.

4. Next to the **Edit schema** field, click the three-dot button to open the schema editor.

5. In the schema editor, click the plus button to add the rows of the schema to be edited. In this example, add rows corresponding to all of the dimensions stored in the *Sales* cube: **Products, Regions, Months, Years, Datatypes, Measures**. Type in them in the order given in this cube.

6. Click **OK** to validate this editing and accept the propagation of this change to the next component. Then these columns are added automatically into the **Column** column of the **Cube query** table in the **Component** view. If the order is not consistent with the one in the *Sales* cube, adapt it using the up and down arrows under the schema table.

7. In the **Dimensions** column of the **Cube query** table, type in each of the dimension names stored in the *Sales* cube regarding to each row in the **Column** column. In the *Sales* cube, the dimension names are: **Products, Regions, Months, Years, Datatypes, Measures**.

8. In the **Elements** columns of the **Cube query** table, type in the dimension elements you want to retrieve regarding to the dimensions they belong to. In this example, the elements to be retrieved are **All Products, Germany and Austria** (Belonging to the same dimension **Regions**, these two elements are entered in the same row and separated with a comma), **Jan, 2009, Actual, Turnover**.

**Job execution**

**Procedure**

1. Click **tLogRow** to open its **Component** view.
2. In the **Mode** area, select the **Table (print values in cells of a table)** check box to display the execution result in a table.

3. Press **F6** to run the Job.

**Results**

The dimension elements and the corresponding Measure values display in the **Run** console.

```

| Schema and Edit Schema   | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
  - View schema: choose this option to view the schema only.  
  - Change to built-in property: choose this option to change the schema to Built-in for local changes. |
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.

| Built-in | The schema is created and stored locally for this component only. Related topic: see [Talend Studio User Guide](#). |
| Repository | The schema already exists and is stored in the Repository, hence can be reused. Related topic: see [Talend Studio User Guide](#). |

**Column as Measure**
Select the column from the input stream which holds the Measure or Text values.

**Create element if not exist**
Select this check box to create the element being processed if it does not exist originally.

**Save cube at process end**
Select this check box to save the cube you have written the data in at the end of this process.

### Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

### Global variables

| Global variables | **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.  
 **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
 A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
 To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
 For further information about variables, see [Talend Studio User Guide](#). |

### Related scenario

For related topic, see *Scenario 1: Writing data into a given cube* on page 2862.
tPaloOutputMulti

Takes the input stream and writes it to a given Palo cube.

The tPaloOutputMulti writes data (elements as well as values) into a Palo cube.

tPaloOutputMulti Standard properties

These properties are used to configure tPaloOutputMulti running in the Standard Job framework. The Standard tPaloOutputMulti component belongs to the Business Intelligence family. The component in this framework is generally available.

Basic settings

| Use an existing connection | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level. |
| Host Name | Enter the host name or the IP address of the host server. |
| Server Port | Type in the listening port number of the Palo server. |
| Username and Password | Enter the Palo user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| Database | Type in the name of the database where the cube of interest resides. |
| Cube | Type in the name of the cube in which the incoming data is written. |
| Cube type | Select the cube type from the drop-down list for the cube of concern. This type may be: Normal, Attribut, System, User Info |
| Commit size | Type in the row count of each batch to be written into the cube. |
| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. |
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **[Repository Content]** window.

| **Built-in**: The schema is created and stored locally for this component only. Related topic: see **Talend Studio User Guide**. |
| **Repository**: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see **Talend Studio User Guide**. |

**Measure value**
Select the column from the input stream which holds the Measure or Text values.

**Splash mode**
Select the splash mode used to write data into a consolidated element. The mode may be:

- **Add**: it writes values to the underlying elements.
- **Default**: it uses the default splash mode.
- **Set**: it simply sets or replaces the current value and make the distribution based on the other values.
- **Disable**: it applies no splashing.

For further information about the Palo splash modes, see Palo’s user guide.

**Add values**
Select this check box to add new values to the current values for a sum. Otherwise these new values will overwrite the current ones.

**Use eventprocessor**
Select this check box to call the supervision server.

**Die on error**
This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

**Advanced settings**

| **tStat Catcher Statistics** | Select this check box to collect log data at the component level. |
### Global Variables

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](https://help.talend.com). |

### Usage

| Usage rule | This component requires an input component. |

| Connections | Outgoing links (from this component to another):

**Row**: Main

**Trigger**: Run if; On Component Ok; On Component Error.

Incoming links (from one component to this one):

**Row**: Main; Reject

For further information regarding connections, see [Talend Studio User Guide](https://help.talend.com). |

| Limitation | Numeric measures are only be accepted as Double or String type. When the string type is used, write the value to be processed between quotation marks.

Due to license incompatibility, one or more JARs required to use this component are not provided.

You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |

### Scenario 1: Writing data into a given cube

The Job in this scenario writes new values in the **Sales** cube given as demo in the **Demo** database installed with Palo.
To replicate this scenario, proceed as follows:

**Setting up the Job**

**Procedure**

1. Drop `tFixedFlowInput` and `tPaloOutputMulti` from the component Palette onto the design workspace.
2. Right-click `tFixedFlowInput` to open its contextual menu.
3. In this menu, select **Row > Main** to connect this component to `tPaloOutputMulti`.

**Configuring the input component**

**Procedure**

1. Double-click the `tFixedFlowInput` component to open its **Component** view.

![Component view](image)

- **Basic settings**
- **Advanced settings**
- **Dynamic settings**
- **View**
- **Documentation**

2. Click the three-dot button to open the schema editor.

![Schema editor](image)
3. In the schema editor, click the plus button to add 7 rows and rename them respectively as Products, Regions, Months, Years, Datatypes, Measures and Values. The order of these rows must be consistent with that of the corresponding dimensions in the Sales cube and the type of the Value column where the measure value resides is set to double/Double.

4. Click OK to validate the editing and accept the propagation prompted by the dialog box that pops up. Then the schema column labels display automatically in the Value table under the Use single table check box, in the Mode area.

5. In the Value table, type in values for each row in the Value column. In this example, these values are: Desktop L, Germany, Jan, 2009, Actual, Turnover, 1234.56.

**Configuring the output component**

**Procedure**

1. Double-click tPaloOutputMulti to open its Component view.
2. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is 7777.

3. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are `admin`.

4. In the **Database** field, type in the database name in which you want to create the cube, *Demo* in this example.

5. In the **Cube** field, type in the name of the cube you want to write data in, for example, *Sales*.

6. In the **Cube type** field, select the **Normal** type from the drop-down list for the cube to be created, meaning this cube will be normal and default.

7. In the **Measure Value** field, select the Measure element. In this scenario, select *Value*.

**Job execution**

Press **F6** to run the Job.

The inflow data has been written into the *Sales* cube.

---

**Scenario 2: Rejecting inflow data when the elements to be written do not exist in a given cube**

The Job in this scenario tries to write data into the *Sales* cube but as the elements of interest do not exist in this cube, the inflow data is rejected.

---

To replicate this scenario, proceed as follows:
Setting up the Job

Procedure

1. Drop **tFixedFlowInput**, **tPaloCheckElements**, **tPaloOutputMulti** and **tLogRow** from the component Palette onto the design workspace.
2. Right-click **tFixedFlowInput** to open its contextual menu.
3. In this menu, select **Row > Main** to connect this component to **tPaloCheckElements**.
4. Do the same to connect **tPaloOutputMulti** using **row** link.
5. Right-click **tPaloCheckElements** to open its contextual menu.
6. In this menu, select **Row > Reject** to connect this component to **tLogRow**.

Configuring the input component

Procedure

1. Double-click the **tFixedFlowInput** component to open its Component view.
2. Click the three-dot button to open the schema editor.

2. Click the three-dot button to open the schema editor.
3. In the schema editor, click the plus button to add 7 rows and rename them respectively as Products, Regions, Months, Years, Datatypes, Measures and Values. The order of these rows must be consistent with that of the corresponding dimensions in the Sales cube and the type of the Value column where the measure value resides is set to double/Double.

4. Click OK to validate the editing and accept the propagation prompted by the dialog box that pops up. Then the schema column labels display automatically in the Value table under the Use single table check box, in the Mode area.

5. In the Value table, type in values for each row in the Value column. In this example, these values are: Smart Products, Germany, Jan, 2009, Actual, Turnover, 1234.56. The Smart Products element does not exist in the Sales cube.

**Configuring the tPaloCheckElements component**

**Procedure**

1. Double-click tPaloCheckElements to open its Component view.
2. In the **Host name** field, type in *localhost*.

3. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is **7777**.

4. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are *admin*.

5. In the **Database** field, type in the database name in which you want to create the cube, *Demo* in this example.

6. In the **Cube** field, type in the name of the cube you want to write data in, for example, *Sales*.

7. In the **On Element error** field, select **Reject row** from the drop-down list.

8. In the element table at the bottom of the **Basic settings** view, click the **Element type** column in the **Value** row and select **Measure** from the drop down list.

### Configuring the output component

**Procedure**

1. Double-click **tPaloOutputMulti** to open its **Component** view.
2. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is 7777.

3. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are `admin`.

4. In the **Database** field, type in the database name in which you want to create the cube, `Demo` in this example.

5. In the **Cube** field, type in the name of the cube you want to write data in, for example, `Sales`.

6. In the **Cube type** field, select the **Normal** type from the drop-down list for the cube to be created, meaning this cube will be normal and default.

7. In the **Measure Value** field, select the Measure element. In this scenario, select `Value`.

### Job execution

Press **F6** to run the Job.

The data to be written is rejected and displayed in the console of the Run view. You can read that the error message is **Smart Products**.

```
[statistics] connecting to socket on port 3407

tPaloRule

Manages rules in a given cube.

The tPaloRule creates or modifies rules in a given cube.

**tPaloRule Standard properties**

These properties are used to configure tPaloRule running in the Standard Job framework.

The Standard tPaloRule component belongs to the Business Intelligence family.

The component in this framework is generally available.

**Basic settings**

| Use an existing connection | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.
Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level. |
| Host Name | Enter the host name or the IP address of the host server. |
| Server Port | Type in the listening port number of the Palo server. |
| Username and Password | Enter the Palo user authentication data.
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| Database | Type in the name of the database where the dimensions applying the rules of interest reside. |
| Cube | Type in the name of the cube whose dimension information is retrieved. |
| Cube rules | Complete this table to perform various actions on specific rules.
**Definition:** type in the rule to be applied.**
**External Id:** type in the user-defined external ID.**
**Comment:** type in comment for this rule.**
**Activated:** select this check box to activate this rule.**
**Action:** select the action to be performed from the drop-down list.
- **Create:** create this rule.
- **Delete:** delete this rule. |
**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Global Variables**

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. |
| | A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. |
| | To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it. |
| | For further information about variables, see **Talend Studio User Guide**. |

**Usage**

| Usage rule | This component can be used in standalone for rule creation, deletion or update. |

**Connections**

| Outgoing links (from this component to another): |
| **Trigger**: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error. |

| Incoming links (from one component to this one): |
| **Row**: Iterate |
| **Trigger**: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error. |

For further information regarding connections, see **Talend Studio User Guide**.

**Limitation**

| Update or deletion of a rule is available only when this rule has been created with external ID. |
| Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in **Talend Help Center** (https://help.talend.com). |
Scenario: Creating a rule in a given cube

The Job in this scenario creates a rule applied on dimensions of a given cube.

To replicate this scenario, proceed as follows:

**Setting up the DB connection**

**Procedure**

1. Drop **tPaloRule** from the component **Palette** onto the design workspace.
2. Double-click the **tPaloRule** component to open its **Component** view.
3. In the **Host name** field, type in the host name or the IP address of the host server, *localhost* for this example.
4. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is 7777.
5. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are *admin*.
6. In the **Database** field, type in the database name in which the dimensions applying the created rules reside, *Biker* in this example.
7. In the **Cube** field, type in the name of the cube which the dimensions applying the created rules belong to, for example, *Orders*.

### Setting the Cube rules

#### Procedure

1. Under the **Cube rules** table, click the plus button to add a new row.
2. In the **Cube rules** table, type in `['2009'] = 123` in the **Definition** column, `OrderRule1` in the **External Id** column and *Palo Demo Rules* in the **Comment** column.
3. In the **Activated** column, select the check box.
4. In the **Action** column, select **Create** from the drop-down list.

#### Job execution

Press **F6** to run the Job.

The new rule has been created and the value of every `2009` element is **123**.
tPaloRuleList

Lists all rules, formulas, comments, activation status, external IDs from a given cube. The tPaloRuleList retrieves a list of rule details from the given Palo database.

Discovering the read-only output schema of tPaloRuleList

The following table presents information related to the read-only output schema of the tPaloRuleList component.

<table>
<thead>
<tr>
<th>Database</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rule_identifier</td>
<td>long</td>
<td>The internal identifier/id for this rule.</td>
</tr>
<tr>
<td>rule_definition</td>
<td>string</td>
<td>The formula of this rule. For further information about this formula, see the Palo user guide.</td>
</tr>
<tr>
<td>ruleExtern_id</td>
<td>string</td>
<td>The user-defined external id.</td>
</tr>
<tr>
<td>ruleComment</td>
<td>string</td>
<td>The user-edited comment on this rule.</td>
</tr>
<tr>
<td>ruleActivated</td>
<td>boolean</td>
<td>Indicates if this rule had been activated or not.</td>
</tr>
</tbody>
</table>

tPaloRuleList Standard properties

These properties are used to configure tPaloRuleList running in the Standard Job framework. The Standard tPaloRuleList component belongs to the Business Intelligence family. The component in this framework is generally available.

Basic settings

- **Use an existing connection**: Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.
  Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level.

- **Host Name**: Enter the host name or the IP address of the host server.

- **Server Port**: Type in the listening port number of the Palo server.

- **Username** and **Password**: Enter the Palo user authentication data.
  To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.
### Database
The name of the database where the cube of interest resides.

### Cube
Type in the name of the cube in which you want to retrieve the rule information.

### Schema and Edit Schema
A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.

#### Built-in
The schema is created and stored locally for this component only. Related topic: see *Talend Studio User Guide*.

#### Repository
The schema already exists and is stored in the Repository, hence can be reused. Related topic: see *Talend Studio User Guide*.

### Advanced settings

<table>
<thead>
<tr>
<th>tStat Catcher Statistics</th>
<th>Select this check box to collect log data at the component level.</th>
</tr>
</thead>
</table>

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_RULES: the number of rules. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>EXTERNAL_RULEID: the external ID of the rule. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
</tbody>
</table>
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide.*

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component can be used in standalone or as start component of a process.</th>
</tr>
</thead>
</table>

### Connections

Outgoing links (from this component to another):

- **Row:** Main; Iterate.
- **Trigger:** Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error.

Incoming links (from one component to this one):

- **Row:** Iterate
- **Trigger:** Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error.

For further information regarding connections, see *Talend Studio User Guide.*

### Limitation

The output schema is fixed and read-only.

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

### Scenario: Retrieving detailed rule information from a given cube

The Job in this scenario retrieves rule details applied on the dimensions of a given cube.

To replicate this scenario, proceed as follows:

1. Drop **tPaloRuleList** and **tLogRow** from the component **Palette** onto the design workspace.
2. Right-click tPaloRuleList to open the contextual menu.
3. From this menu, select Row > Main to link the two components.

**Configuring the tPaloRuleList component**

**Procedure**

1. Double-click the tPaloRuleList component to open its Component view.

![Component view](image)

2. In the Host name field, type in the host name or the IP address of the host server, *localhost* for this example.
3. In the Server Port field, type in the listening port number of the Palo server. In this scenario, it is 7777.
4. In the Username and Password fields, type in the authentication information. In this example, both of them are *admin*.
5. In the Database field, type in the database name where the dimensions applying the rules of interest reside, *Biker* in this example.
6. In the Cube field, type in the name of the cube which the rules of interest belong to.

**Job execution**

Press **F6** to run the Job.

Details of all of the rules in the *Orders* cube are retrieved and listed in the console of the Run view.
For further information about the output schema, see Discovering the read-only output schema of tPaloRuleList on page 2874.
tParAccelBulkExec

Improves performance when loading data in ParAccel database.

The tParAccelOutputBulk and tParAccelBulkExec are generally used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tParAccelOutputBulkExec component, detailed in a different section. The advantage of using two separate steps is that the data can be transformed before it is loaded in the database.

The tParAccelBulkExec performs an Insert action on the data.

tParAccelBulkExec Standard properties

These properties are used to configure tParAccelBulkExec running in the Standard Job framework.

The Standard tParAccelBulkExec component belongs to the Databases family.

The component in this framework is generally available.

Note:

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
<td></td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td>Note:</td>
<td>When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:</td>
</tr>
<tr>
<td>1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.</td>
<td></td>
</tr>
</tbody>
</table>
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th><strong>Host</strong></th>
<th>Database server IP address.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of the DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Database name.</td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>Exact name of the schema.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td><strong>Table</strong></td>
<td>Name of the table to be written. Note that only one table can be written at a time</td>
</tr>
<tr>
<td><strong>Action on table</strong></td>
<td>On the table defined, you can perform one of the following operations: <strong>None</strong>: No operation is carried out. <strong>Drop and create table</strong>: The table is removed and created again. <strong>Create table</strong>: The table does not exist and gets created. <strong>Create table if not exists</strong>: The table is created if it does not exist. <strong>Drop table if exists and create</strong>: The table is removed if already exists and created again. <strong>Clear table</strong>: The table content is deleted.</td>
</tr>
<tr>
<td><strong>Schema and Edit Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <strong>line</strong> when naming the fields. <strong>Built-In</strong>: You create and store the schema locally for this component only. Related topic: see <em>Talend Studio User Guide</em>. <strong>Repository</strong>: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see <em>Talend Studio User Guide</em>. When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.</td>
</tr>
</tbody>
</table>
You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the [Repository Content] window.

### Advanced settings

| Copy mode | Select the copy mode you want to use from either:
| Basic: Standard mode, without optimisation.  
Parallel: Allows you to use several internal ParAccel APIs in order to optimise loading speed. |
| Filename | Name of the file to be loaded.

⚠️ **Warning:**  
This file is located on the machine specified by the URI in the **Host** field so it should be on the same machine as the database server.

| File Type | Select the file type from the list. |
| Field Layout | Select the field layout from the list. |
| Field separator | Character, string or regular expression to separate fields. |
| Explicit IDs | The ID is already present in the file to be loaded or will be set by the database. |
| Remove Quotes | Select this check box to remove quotation marks from the file to be loaded. |
| Max. Errors | Type in the maximum number of errors before your Job stops. |
| Date Format | Type in the date format to be used. |
| Time/Timestamp Format | Enter the date and hour format to be used. |
| Additional COPY Options | Enter the specific, customized ParAccel option that you want to use. |
| Log file | Browse to or enter the access path to the log file in your directory. |
| Logging level | Select the information type you want to record in your log file. |
| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component covers all possible SQL database queries. It allows you to carry out actions on a table or on the data of a table in a ParAccel database. It enables you to create a reject flow, with a Row > Reject link filtering the data in error. For a usage example, see Scenario: Retrieving data in error with a Reject link on page 2529. |
| Dynamic settings | Click the [+ ] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.  

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.  

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |

| Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |
Related scenarios

For related scenarios, see:

- Scenario: Inserting transformed data in MySQL database on page 2537 of tMysqlOutputBulk.
- Scenario: Inserting data in bulk in MySQL database on page 2544 of tMysqlOutputBulkExec.
- Scenario: Truncating and inserting file data into an Oracle database on page 2752 of tOracleBulkExec.
tParAccelClose

Closes a transaction.
The tParAccelClose closes the transaction committed in the connected DB.

**tParAccelClose Standard properties**

These properties are used to configure tParAccelClose running in the Standard Job framework.
The Standard tParAccelClose component belongs to the Databases family.
The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the <strong>tParAccelConnection</strong> component in the list if more than one connection are planned for the current Job.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is to be used along with ParAccel components, especially with **tParAccelConnection** and **tParAccelCommit**. |

| Dynamic settings | Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable. |
For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenarios

No scenario is available for the Standard version of this component yet.
tParAccelCommit

Commits in one go a global transaction, using a unique connection, instead of doing that on every row or every batch and thus provides gain in performance.

The tParAccelCommit validates the data processed through the job into the connected DB.

**tParAccelCommit Standard properties**

These properties are used to configure tParAccelCommit running in the Standard Job framework.

The Standard tParAccelCommit component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the <strong>tParAccelConnection</strong> component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task. <strong>Warning:</strong> If you want to use a <strong>Row &gt; Main</strong> connection to link <strong>tParAccelCommit</strong> to your Job, your data will be committed row by row. In this case, do not select the <strong>Close connection</strong> check box or your connection will be closed before the end of your first row commit.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is more commonly used with other tParAccel* components, especially with |
Dynamic settings

Click the [+ ] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

### Related scenario

For tParAccelCommit related scenario, see Scenario: Inserting data in mother/daughter tables on page 2476
tParAccelConnection

Opens a connection to the specified database that can then be reused in the subsequent subjob or subjobs.

The tParAccelConnection opens a connection to the database for a current transaction.

**tParAccelConnection Standard properties**

These properties are used to configure tParAccelConnection running in the Standard Job framework.

The Standard tParAccelConnection component belongs to the Databases and the ELT families.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td><strong>Property type</strong></td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in</strong></td>
<td>No property data stored centrally.</td>

</tr>
</tbody>
</table>
several database connection components from different Job levels that can be either parent or child.

This option is incompatible with the Use dynamic job and Use an independent process to run subjob options of the tRunJob component. Using a shared connection together with a tRunJob component with either of these two options enabled will cause your Job to fail.

Advanced settings

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Auto Commit</td>
<td>Select this check box to commit any changes to the database automatically upon the transaction. With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component. Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component.</td>
</tr>
<tr>

If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the <a href="#">Repository Content</a> window.</td>
</tr>
<tr>
<td>Table name</td>
<td>Name of the table to be read.</td>
</tr>
</tbody>
</table>
Query type and Query

Enter your DB query paying particularly attention to sequence the fields properly in order to match the schema definition.

Guess Query

Click the **Guess Query** button to generate the query which corresponds to your table schema in the Query field.

Guess schema

Click the **Guess schema** button to retrieve the table schema.

Advanced settings

Use cursor

When selected, helps to decide the row set to work with at a time and thus optimize performance.

Trim all the String/Char columns

Select this check box to remove leading and trailing whitespace from all the String/Char columns.

Trim column

Remove leading and trailing whitespace from defined columns.

tStat Catcher Statistics

Select this check box to collect log data at the component level.

Global Variables

Global Variables

**NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.

**QUERY**: the query statement being processed. This is a Flow variable and it returns a string.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

Usage

Usage rule

This component covers all possible SQL queries for ParAccel databases.

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular
component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

**Dynamic settings**

Click the **[+]** button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

**Related scenarios**

For related scenarios, see:
**tParAccelOutput**

Executes the action defined on the table and/or on the data of a table, according to the input flow from the previous component.

The tParAccelOutput writes, updates, modifies or deletes the data in a database.

**tParAccelOutput Standard properties**

These properties are used to configure tParAccelOutput running in the Standard Job framework.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

<td><strong>Database</strong></td>
<td>Database name.</td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>Exact name of the schema.</td>
</tr>
<tr>
<td><strong>Username</strong> and <strong>Password</strong></td>
<td>DB user authentication data.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Table</strong></td>
<td>Name of the table to be written. Note that only one table can be written at a time</td>
</tr>
<tr>
<td><strong>Action on table</strong></td>
<td>On the table defined, you can perform one of the following operations:</td>
</tr>
<tr>
<td></td>
<td><strong>None</strong>: No operation is carried out.</td>
</tr>
<tr>
<td></td>
<td><strong>Drop and create table</strong>: The table is removed and created again.</td>
</tr>
<tr>
<td></td>
<td><strong>Create table</strong>: The table does not exist and gets created.</td>
</tr>
<tr>
<td></td>
<td><strong>Create table if not exists</strong>: The table is created if it does not exist.</td>
</tr>
<tr>
<td></td>
<td><strong>Drop table if exists and create</strong>: The table is removed if already exists and created again.</td>
</tr>
<tr>
<td></td>
<td><strong>Clear table</strong>: The table content is deleted.</td>
</tr>
<tr>
<td><strong>Action on data</strong></td>
<td>On the data of the table defined, you can perform:</td>
</tr>
<tr>
<td></td>
<td><strong>Insert</strong>: Add new entries to the table. If duplicates are found, job stops.</td>
</tr>
<tr>
<td></td>
<td><strong>Update</strong>: Make changes to existing entries</td>
</tr>
<tr>
<td></td>
<td><strong>Insert or update</strong>: Insert a new record. If the record with the given reference already exists, an update would be made.</td>
</tr>
<tr>
<td></td>
<td><strong>Update or insert</strong>: Update the record with the given reference. If the record does not exist, a new record would be inserted.</td>
</tr>
<tr>
<td></td>
<td><strong>Delete</strong>: Remove entries corresponding to the input flow.</td>
</tr>
</tbody>
</table>

⚠️ **Warning:**
It is necessary to specify at least one column as a primary key on which the **Update** and **Delete** operations are based. You can do that by clicking **Edit Schema** and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the **Advanced settings** view where you can simultaneously define primary keys for the **Update** and **Delete** operations. To do that: Select the **Use field options** check box and then in the **Key in update column**, select the check boxes next to the column names you want to use as a base for the **Update** operation. Do the same in the **Key in delete column** for the **Delete** operation.

<tr>
<td></td>
<td><strong>NB_LINE_INSERTED:</strong> the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td><strong>NB_LINE_DELETED:</strong> the number of rows deleted. This is an After variable and it returns an integer.</td>
</tr>
</tbody>
</table>
**Usage**

| Usage rule | This component covers all possible SQL database queries. It allows you to carry out actions on a table or on the data of a table in a ParAccel database. It enables you to create a reject flow, with a Row > Rejects link filtering the data in error. For a usage example, see Scenario: Retrieving data in error with a Reject link on page 2529. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.  

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.  

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide. |
| Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the |
Related scenarios

For a related scenario, see:

- Scenario: Inserting a column and altering data using tMysqlOutput on page 2521.
tParAccelOutputBulk

Prepares the file to be used as parameter in the INSERT query to feed the ParAccel database.

The tParAccelOutputBulk and tParAccelBulkExec are generally used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tParAccelOutputBulkExec component, detailed in a different section. The advantage of using two separate steps is that the data can be transformed before it is loaded in the database.

The tParAccelOutputBulk writes a file with columns based on the defined delimiter and the ParAccel standards.

**tParAccelOutputBulk Standard properties**

These properties are used to configure tParAccelOutputBulk running in the Standard Job framework.

The Standard tParAccelOutputBulk component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td>Built-in: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
<td></td>
</tr>
<tr>
<td>File Name</td>
<td>Name of the file to be generated.</td>
</tr>
<tr>
<td><strong>Warning:</strong> This file is generated on the local machine or a shared folder on the LAN.</td>
<td></td>
</tr>
<tr>
<td>Append</td>
<td>Select this check box to add the new rows at the end of the file</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <strong>line</strong> when naming the fields.</td>
</tr>
</tbody>
</table>
**Built-In**: You create and store the schema locally for this component only. Related topic: see *Talend Studio User Guide*.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see *Talend Studio User Guide*.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-In** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.

### Advanced settings

<table>
<thead>
<tr>
<th><strong>Row separator</strong></th>
<th>String (ex: <code>\n</code> on Unix) to distinguish rows.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Field separator</strong></td>
<td>Character, string or regular expression to separate fields.</td>
</tr>
<tr>
<td><strong>Include header</strong></td>
<td>Select this check box to include the column header.</td>
</tr>
<tr>
<td><strong>Encoding</strong></td>
<td>Select the encoding type from the list or select Custom and define it manually. This field is compulsory for DB data handling.</td>
</tr>
<tr>
<td><strong>tStat Catcher Statistics</strong></td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

### Global Variables

<table>
<thead>
<tr>
<th><strong>Global Variables</strong></th>
<th><strong>NB_LINE</strong>: the number of rows processed. This is an After variable and it returns an integer. <strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions</th>
</tr>
</thead>
</table>
only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

### Related scenarios

For use cases in relation with **tParAccelOutputBulk**, see the following scenarios:

- **Scenario: Inserting transformed data in MySQL database** on page 2537.
- **Scenario: Inserting data in bulk in MySQL database** on page 2544.
- **Scenario: Truncating and inserting file data into an Oracle database** on page 2752.
tParAccelOutputBulkExec

Improves performance when loading data in ParAccel database.

The tParAccelOutputBulk and tParAccelBulkExec are generally used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in tParAccelOutputBulkExec.

The tParAccelOutputBulkExec performs an Insert action on the data.

**tParAccelOutputBulkExec Standard properties**

These properties are used to configure tParAccelOutputBulkExec running in the Standard Job framework.

The Standard tParAccelOutputBulkExec component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

</tbody>
</table>

**Usage**

| Usage rule     | This component covers all possible SQL database queries. It allows you to carry out actions on a table or |

2905
on the data of a table in a ParAccel database. It enables you to create a reject flow, with a Row > Reject link filtering the data in error. For a usage example, see Scenario: Retrieving data in error with a Reject link on page 2529.

**Limitation**

The database server must be installed on the same machine where the Studio is installed or where the Job using tParAccelOutputBulkExec is deployed, so that the component functions properly.

**Related scenarios**

For related scenarios, see:

- Scenario: Inserting transformed data in MySQL database on page 2537 of tMysqlOutputBulk.
- Scenario: Inserting data in bulk in MySQL database on page 2544 of tMysqlOutputBulkExec.
- Scenario: Truncating and inserting file data into an Oracle database on page 2752 of tOracleBulkExec.
**tParAccelRollback**

Avoids to commit part of a transaction involuntarily. The tParAccelRollback cancels the transaction commit in the connected DB.

**tParAccelRollback Standard properties**

These properties are used to configure tParAccelRollback running in the Standard Job framework. The Standard tParAccelRollback component belongs to the Databases family. The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see [Dynamic database components](#) on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tParAccelConnection component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is more commonly used with other tParAccel* components, especially with the tParAccelConnection and tParAccelCommit components. |
| Dynamic settings | Click the [+]{param} button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. |
Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenario

For tParAccelRollback related scenario, see tMysqlRollback on page 2546.
tParAccelRow

Acts on the actual DB structure or on the data (although without handling data), depending on the nature of the query and the database. The SQLBuilder tool helps you write easily your SQL statements.

The tParAccelRow is the specific component for this database query. It executes the SQL query stated onto the specified database. The row suffix means the component implements a flow in the job design although it doesn’t provide output.

**tParAccelRow Standard properties**

These properties are used to configure tParAccelRow running in the Standard Job framework.

The Standard tParAccelRow component belongs to the Databases family.

The component in this framework is generally available.

Note:

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td><strong>Property type</strong></td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><strong>Use an existing connection</strong></td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

Note:

When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>

<td></td>
</tr>
<tr>
<td><strong>Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:</strong></td>
<td></td>
</tr>
<tr>
<td>• <strong>View schema</strong>: choose this option to view the schema only.</td>
<td></td>
</tr>
<tr>
<td>• <strong>Change to built-in property</strong>: choose this option to change the schema to Built-in for local changes.</td>
<td></td>
</tr>
<tr>
<td>• <strong>Update repository connection</strong>: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the [Repository Content] window.</td>
<td></td>
</tr>
<tr>
<td><strong>Table Name</strong></td>
<td>Name of the table to be read.</td>
</tr>
<tr>
<td><strong>Query type</strong></td>
<td>Either Built-in or Repository.</td>
</tr>
</tbody>
</table>
**Built-in**: Fill in manually the query statement or build it graphically using SQLBuilder.

**Repository**: Select the relevant query stored in the Repository. The **Query** field gets accordingly filled in.

**Guess Query**
- Click the **Guess Query** button to generate the query which corresponds to your table schema in the **Query** field.

**Query**
- Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.

**Die on error**
- This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a **Row > Rejects** link.

### Advanced settings

**Propagate QUERY’s recordset**
- Select this check box to insert the result of the query into a **COLUMN** of the current flow. Select this column from the **use column** list.

  **Note:**
  - This option allows the component to have a different schema from that of the preceding component. Moreover, the column that holds the QUERY’s recordset should be set to the type of **Object** and this component is usually followed by tParseRecordSet.

**Use PreparedStatement**
- Select this check box if you want to query the database using a PreparedStatement. In the **Set PreparedStatement Parameter** table, define the parameters represented by “?” in the SQL instruction of the **Query** field in the **Basic Settings** tab.

  **Parameter Index**: Enter the parameter position in the SQL instruction.

  **Parameter Type**: Enter the parameter type.

  **Parameter Value**: Enter the parameter value.

  **Note:**
  - This option is very useful if you need to execute the same query several times. Performance levels are increased.

**Commit every**
- Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions.

**tStat Catcher Statistics**
- Select this check box to collect log data at the component level.
### Global Variables

| Global Variables | QUERY: the query statement being processed. This is a Flow variable and it returns a string. ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

### Usage

| Usage rule | This component offers the flexibility benefit of the DB query and covers all possible SQL queries. |

| Dynamic settings | Click the [+ ] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |

### Limitation

| Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find |
Related scenarios

For a related scenario, see:

- **Scenario: Combining two flows for selective output** on page 2558
- **Procedure** on page 625.
- **Scenario: Removing and regenerating a MySQL table index** on page 2552.
**tParAccelSCD**

Addresses Slowly Changing Dimension needs, reading regularly a source of data and logging the changes into a dedicated SCD table

The tParAccelSCD reflects and tracks changes in a dedicated ParAccel SCD table.

**tParAccelSCD Standard properties**

These properties are used to configure tParAccelSCD running in the Standard Job framework.

The Standard tParAccelSCD component belongs to the Business Intelligence and the Databases families.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the Repository file where properties are stored. The following fields are pre-filled in using fetched data.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Use an existing connection</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

**Note:**

When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.

2. In the child level, use a dedicated connection component to read that registered database connection.
For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th><strong>Connection type</strong></th>
<th>Select the relevant driver on the list.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Host</strong></td>
<td>Database server IP address.</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database.</td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>Name of the DB schema.</td>
</tr>
</tbody>
</table>
| **Username and Password** | DB user authentication data.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| **Table**           | Name of the table to be written. Note that only one table can be written at a time. |

**Schema and Edit schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the [Repository Content] window.

**Built-in**: The schema is created and stored locally for this component only. Related topic: see *Talend Studio User Guide*.

**Repository**: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see *Talend Studio User Guide*.

**SCD Editor**

The SCD editor helps to build and configure the data flow for slowly changing dimension outputs.

For more information, see *SCD management methodology* on page 2566.
### Use memory saving Mode
Select this check box to maximize system performance.

### Source keys include Null
Select this check box to allow the source key columns to have Null values.

**Warning:**
Special attention should be paid to the uniqueness of the source key(s) values when this option is selected.

### Die on error
This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

### Advanced settings

#### End date time details
Specify the time value of the SCD end date time setting in the format of HH:mm:ss. The default value for this field is 12:00:00.
This field appears only when SCD Type 2 is used and Fixed year value is selected for creating the SCD end date.

#### Debug mode
Select this check box to display each step during processing entries in a database.

#### tStatCatcher Statistics
Select this check box to collect log data at the component level.

### Global Variables

#### Global Variables
<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE_UPDATED</strong></td>
<td>the number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_INSERTED</strong></td>
<td>the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_REJECTED</strong></td>
<td>the number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>ERROR_MESSAGE</strong></td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>
## Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is used as Output component. It requires an Input component and Row main link as input.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic settings</td>
<td>Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Limitation</td>
<td>This component does not support using SCD type 0 together with other SCD types.</td>
</tr>
</tbody>
</table>

## Related scenario

For related scenarios, see tMysqlSCD on page 2563.
**tParseRecordSet**

Parses a recordset rather than individual records from a table.

The tParseRecordSet parses a set of records from a database table or DB query and possibly returns single records.

**tParseRecordSet Standard properties**

These properties are used to configure tParseRecordSet running in the Standard Job framework.

The Standard tParseRecordSet component belongs to the Databases family.

The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>Prev. Comp. Column list</th>
<th>Set the column from the database that holds the recordset.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Schema</strong> and <strong>Edit Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <code>line</code> when naming the fields.</td>
</tr>
<tr>
<td><strong>Built-in</strong></td>
<td>The schema is created and stored locally for this component only. Related topic: see <em>Talend Studio User Guide</em>.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>The schema already exists and is stored in the Repository, hence can be reused. Related topic: see <em>Talend Studio User Guide</em>.</td>
</tr>
<tr>
<td>Click <strong>Edit schema</strong> to make changes to the schema. If the current schema is of the <strong>Repository</strong> type, three options are available:</td>
<td></td>
</tr>
<tr>
<td><strong>View schema</strong></td>
<td>choose this option to view the schema only.</td>
</tr>
<tr>
<td><strong>Change to built-in property</strong></td>
<td>choose this option to change the schema to <strong>Built-in</strong> for local changes.</td>
</tr>
<tr>
<td><strong>Update repository connection</strong></td>
<td>choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select <strong>No</strong> upon completion and choose this schema metadata again in the [Repository Content] window.</td>
</tr>
<tr>
<td><strong>Attribute table</strong></td>
<td>Set the position value of each column for single records from the recordset.</td>
</tr>
</tbody>
</table>
**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

**Global Variables**

| Global Variables | NB_LINE: the number of rows processed. This is an After variable and it returns an integer.  
ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.  
For further information about variables, see Talend Studio User Guide. |

**Usage**

| Usage rule | This component is used as intermediary component. It can be used as start component but only input parameters are thus allowed. |

| Limitation | This component is mainly designed for a use with the SP component Recordset feature. |

**Related Scenario**

For an example of tParseRecordSet in use, see Scenario: Using PreparedStatement objects to query data on page 2553.
**tPigAggregate**

Adds one or more additional columns to the output of the grouped data to create data to be used by Pig.

The tPigAggregate groups the original data by column and adds one or more additional columns to the output of preceding grouped data.

**tPigAggregate Standard properties**

These properties are used to configure tPigAggregate running in the Standard Job framework.

The Standard tPigAggregate component belongs to the Big Data and the Processing families.

The component in this framework is available when you are using one of the Talend solutions with Big Data.

**Basic settings**

| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click [Edit schema](#) to make changes to the schema. If the current schema is of the [Repository](#) type, three options are available:  
- **View schema**: choose this option to view the schema only.  
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content](#) window. |
| **Built-in**: The schema will be created and stored locally for this component only. Related topic: Talend Studio User Guide. | |
| **Repository**: The schema already exists and is stored in the Repository, hence can be reused in various projects and Job designs. Related topic: see Talend Studio User Guide. | |
| **Group by** | Click the plus button to add one or more columns to set tuples in the source data as group condition. |
| **Operations** | Click the plus button to add one or more columns to generate one or more additional output columns based on conditions: |
**Additional Output Column**: Select a column in the original data as output column.

**Function**: Functions for operation on input data.

**Input Column**: Select a column in the original data as input column.

### Advanced settings

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Increase parallelism</strong></td>
<td>Select this check box to set the number of reduce tasks for the MapReduce Jobs.</td>

</tr>
</tbody>
</table>

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is commonly used as intermediate step together with input component and output component.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Prerequisites</strong></td>
<td>The Hadoop distribution must be properly installed, so as to guarantee the interaction with <strong>Talend Studio</strong>. The following list presents MapR related information for example.</td>
</tr>
<tr>
<td></td>
<td>• Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under \MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native. For example, the library for Windows is \lib\native\MapRClient.dll in the MapR client jar file. For further information, see the following link from MapR: <a href="http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr">http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr</a>.</td>
</tr>
</tbody>
</table>
Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path.

• Set the -Djava.library.path argument, for example, in the Job Run VM arguments area of the Run/Debug view in the [Preferences] dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

| Limitation | Knowledge of Pig scripts is required. |

**Related scenario**

For a tPigAggregate related scenario, Aggregating values and sorting data on page 121 of tAggregateRow.
tPigCode

Extends the functionalities of a Talend Job through using Pig scripts.

The tPigCode enters personalized Pig code to integrate it in Talend program. You can execute this code only once.

**tPigCode Standard properties**

These properties are used to configure tPigCode running in the Standard Job framework.

The Standard tPigCode component belongs to the Big Data and the Processing families.

The component in this framework is available when you are using one of the Talend solutions with Big Data.

**Basic settings**

<table>
<thead>
<tr>
<th>Schema and Edit Schema</th>
<th>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• <strong>View schema</strong>: choose this option to view the schema only.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Change to built-in property</strong>: choose this option to change the schema to Built-in for local changes.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Update repository connection</strong>: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the [Repository Content] window.</td>
</tr>
<tr>
<td>Built-In</td>
<td>You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Repository</td>
<td>You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Scripts</td>
<td>Type in Pig scripts you want to execute depending on the task you need to perform. For further information about Pig functions syntax, see Apache's documentation about Pig UDF: <a href="http://pig.apache.org">http://pig.apache.org</a></td>
</tr>
</tbody>
</table>
Pig components output tuples and automatically set up an alias for each tuple. When you use a tuple in your Pig script, you have to enter the right alias.

The alias syntax is `Component_ID_rowID_Result`, for example, `tPigCode_1_row2_Result`.

**Advanced settings**

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
<th>Select this check box to gather the Job processing metadata at the Job level as well as at each component level.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable escape</td>
<td>Select this check box so that you can simply write plain Pig code in the <em>Scripts</em> field without need to bear in mind the escape characters, otherwise required for proper Java code generation.</td>
</tr>
</tbody>
</table>

**Global Variables**

| Global Variables | `ERROR_MESSAGE`: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the *Die on error* check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press `Ctrl + Space` to access the variable list and choose the variable to use from it. For further information about variables, see *Talend Studio User Guide*. |

**Usage**

| Usage rule | This component is commonly used as intermediate step together with input component and output component. A *tPigCode* component can execute only one Pig Latin statement, therefore, if you need to execute multiple statements, you have to use a corresponding number of *tPigCode* components to run them, one after another. If a particular .jar file is required to execute a statement, you need to register that library file via the *tPigLoad* component that starts the Pig process in question. |

**Prerequisites**

The Hadoop distribution must be properly installed, so as to guarantee the interaction with *Talend Studio*. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or...
libraries of a MapR client corresponding to each OS version can be found under `MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native`. For example, the library for Windows is `\lib\native\MapRClient.dll` in the MapR client jar file. For further information, see the following link from MapR: http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr.

Without adding the specified library or libraries, you may encounter the following error:

```
no MapRClient in java.library.path.
```

- Set the `-Djava.library.path` argument, for example, in the Job Run VM arguments area of the Run/Debug view in the [Preferences] dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

| Limitation | Knowledge of Pig scripts is required. |

**Scenario: Selecting a column of data from an input file and store it into a local file**

This scenario applies only to a Talend solution with Big Data.

This scenario describes a three-component Job that selects a column of data that matches filter condition defined in `tPigCode` and stores the result into a local file.

![Diagram](image)

**Setting up the Job**

**Procedure**

1. Drop the following components from the Palette to the design workspace: `tPigCode`, `tPigLoad`, `tPigStoreResult`.
2. Right-click `tPigLoad` to connect it to `tPigCode` using a Row > Pig Combine connection.
3. Right-click `tPigCode` to connect it to `tPigStoreResult` using a Row > Pig Combine connection.
Loading the data

Procedure

1. Double-click tPigLoad to open its Basic settings view.

   ![tPigLoad component](image)

   - Property Type: Built-In
   - Schema: Built-In
   - Configuration: Local
   - Load function: PigStorage
   - Input file URI: /home/CustomerList
   - Field separator: ;
   - Compression: None
   - Force to compress output data: Off

2. Click the three-dot button next to Edit schema to add columns for tPigLoad.

   ![Column settings](image)

   - Click the plus button to add Name, Country and Age and click OK to save the setting.

3. Click the plus button to add Name, Country and Age and click OK to save the setting.

4. Select Local from the Mode area.

5. Fill in the Input filename field with the full path to the input file.
   
   In this scenario, the input file is CustomerList which contains rows of names, country names and age.

6. Select PigStorage from the Load function list.

7. Leave rest of the settings as they are.

Configuring the tPigCode component

Procedure

1. Double-click tPigCode component to open its Basic settings view.

   ![tPigCode component](image)
2. Click **Sync columns** to retrieve the schema structure from the preceding component.
3. Fill in the **Script Code** field with following expression:

   ```
   tPigCode_1_row2_RESULT = foreach tPigLoad_1_row1_RESULT generate $0 as name;
   ```

   This filter expression selects column *Name* from *CustomerList*.

**Saving the result data to a local file**

**Procedure**

1. Double-click **tPigStoreResult** to open its **Basic settings** view.

   2. Click **Sync columns** to retrieve the schema structure from the preceding component.
   3. Fill in the **Result file** field with the full path to the result file.
      
      In this scenario, the result is saved in *Result* file.
   4. Select **Remove result directory if exists**.
   5. Select **PigStorage** from the **Store function** list.
   6. Leave rest of the settings as they are.

**Executing the Job**

Save your Job and press **F6** to run it.
The *Result* file is generated containing the selected column of data.

### Global Variables

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

### Usage

| Usage rule | This component is commonly used as intermediate step together with input component and output component. |
Prerequisites

The Hadoop distribution must be properly installed, so as to guarantee the interaction with Talend Studio. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native. For example, the library for Windows is \lib\native\MapRClient.dll in the MapR client jar file. For further information, see the following link from MapR: http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr.

Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path.

- Set the -Djava.library.path argument, for example, in the Job Run VM arguments area of the Run/Debug view in the [Preferences] dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

Limitation

Knowledge of Pig scripts is required.

Scenario: aggregating data from two relations using COGROUP

This scenario applies only to a Talend solution with Big Data.

In this scenario, a four-component Job is designed to aggregate two relations on top of a given Hadoop cluster.
The two relations used in this scenario consist of the following sample data:

1. Alice, turtle, 17
   Alice, goldfish, 17
   Alice, cat, 17
   Bob, dog, 18
   Bob, cat, 18
   John, dog, 19
   Mary, goldfish, 16
   Bill, dog, 20

   This relation is composed of three columns that read owner, pet and age (of the owners).

2. Cindy, Alice
   Mark, Alice
   Paul, Bob
   Paul, Jane
   John, Mary
   William, Bill

   This relation provides a list of students' names alongside their friends, of which some are pet owners displayed in the first relation. Therefore, the schema of this relation contains two columns: student and friend.

Before replicating this scenario, you need to write the sample data into the HDFS system of the Hadoop cluster to be used. To do this, you can use tHDFSOutput. For further information about this component, see tHDFSOutput on page 1538.

The data used in this scenario is inspired by the examples that Pig's documentation uses to explain the GROUP and the GOGROUP operators. For related information, please see Apache's documentation for Pig.

**Linking the components**

**Procedure**

1. In the **Integration** perspective of the Studio, create an empty Job from the **Job Designs** node in the **Repository** tree view.
   For further information about how to create a Job, see **Talend Studio User Guide**.
2. In the workspace, enter the name of the component to be used and select this component from the list that appears. In this scenario, the components are two **tPigLoad** components, a
**tPigCoGroup** component and a **tPigStoreResult** component. One of the two **tPigLoad** components is used as the main loading component to connect to the Hadoop cluster to be used.

3. Connect the main **tPigLoad** component to **tPigCoGroup** using the Row > Main link.
4. Do the same to connect the second **tPigLoad** component to **tPigCoGroup**. The Lookup label appears over this link.
5. Repeat the operation to connect **tPigCoGroup** to **tPigStoreResult**.

### Reading data into the Pig flow

**Reading the owner-pet sample data**

#### Procedure

1. Double-click the main **tPigLoad** component to open its Component view.

   ![Diagram of tPigLoad component](image)

<table>
<thead>
<tr>
<th>Basic settings</th>
<th>Advanced settings</th>
<th>Dynamic settings</th>
<th>View</th>
<th>Documentation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property Type: Built-In</td>
<td>Schema: Built-In</td>
<td>Configuration: Local</td>
<td>Distribution: HortonWorks</td>
<td>Load function: PigStorage</td>
</tr>
<tr>
<td>Configuration: Local</td>
<td>Distribution: HortonWorks</td>
<td>Version: Hortonworks Data Platform V2.1.0 (Baikal)</td>
<td>Load function: PigStorage</td>
<td></td>
</tr>
<tr>
<td>NameNode URL: &quot;hdfs//tal-qa113.talend.land8020/&quot;</td>
<td>Resource Manager: &quot;tal-qa114.talend.land8050&quot;</td>
<td>JobHistory Address: &quot;tal-qa114.talend.land8030&quot;</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Use DataNode Hostname</td>
<td>Use Kerberos Authentication</td>
<td>User Name: &quot;hdfs&quot;</td>

<td>Die on SubJob Error</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

2. Click the [...] button next to **Edit schema** to open the schema editor and click the [+ ] button three times to add three rows.
3. In the Column column, rename the new rows to **owner**, **pet** and **age**, respectively, and in the Type column of the **age** row, select **Integer**.
4. Click **OK** to validate these changes and accept the propagation prompted by the pop-up dialog box.
5. In the Mode area, select **Map/Reduce** to use the remote Hadoop cluster to be used.
6. In the Distribution and the Version lists, select the Hadoop distribution you are using. In this example, *HortonWorks Data Platform V2.1.0 (Baikal)* is selected.
7. In the Load function list, select **PigStorage**. Then, the corresponding parameters to be set appear.
8. In the **NameNode URI** and the **Resource manager** fields, enter the locations of those services, respectively. If you are using WebHDFS, the location should be `webhdfs://masternode:portnumber`; if this WebHDFS is secured with SSL, the scheme should be `swebhdfs` and you need to use a `tLibraryLoad` in the Job to load the library required by the secured WebHDFS.

9. Select the **Set Resourcemanager scheduler address** check box and enter the URI of this service in the field that is displayed. This allows you to use the Scheduler service defined in the Hadoop cluster to be used. If this service is not defined in your cluster, you can ignore this step.

10. In the **User name** field, enter the name of the user having the appropriate right to write data in the cluster. In this example, it is `hdfs`.

11. In the **Input file URI** field, enter the path pointing to the relation you need to read data from. As explained previously, the relation to be read here is the one containing the owner and pet sample data.

12. In the **Field separator** field, enter the separator of the data to be read. In this example, it is `;`.

### Loading the student-friend sample data

**Procedure**

1. Double-click the second **tPigLoad** component to open its **Component** view.

   ![Component view of tPigLoad](image)

   - **Basic settings**
     - **Property Type**: Built-In
     - **Schema**: Built-In
   - **Advanced settings**
     - **Configuration**: Local
     - **Distribution**: HortonWorks
     - **Version**: Hortonworks Data Platform V2.1.0(Baikal)
     - **Load function**: PigStorage
   - **Dynamic settings**
     - **Use S3 endpoint**: False
     - **Input file URI**: `/user/ychen/pigco/friends.csv`
   - **Field separator**: `;`
   - **Compression**: False
   - **Force to compress the output data**: False
   - **Die on subjob error**: False

2. Click the `[...]` button next to **Edit schema** to open the schema editor.

3. Click the `[+]` button twice to add two rows and in the **Column** column, rename them to `student` and `friend`, respectively.

---

2934
4. Click OK to validate these changes and accept the propagation prompted by the pop-up dialog box.

5. In the Mode area, select Map/Reduce.
   This component reuses the Hadoop connection you have configured in that main tPigLoad component. Therefore, the Distribution and the Version fields have been automatically filled with the values from that main loading component.

6. In the Load function field, select the PigStorage function to read the source data.

7. In the Input file URI field, enter the directory where the source data is stored. As explained previously, this data is from the second relation containing the student and friend sample data.

Aggregating the relations

Procedure

1. Double-click tPigCoGroup to open its Component view.

2. Click the [...] button next to Edit schema to open the schema editor.
3. Click the [+] button five times to add five rows and in the **Column** column, rename them to *owner_friend*, *age*, *pet_number*, *pet* and *student*, respectively.

4. In the **Type** column of the *age* row, select **Integer**.

5. Click **OK** to validate these changes and accept the propagation prompted by the pop-up dialog box.

6. In the **Group by** table, click the [+] button once to add one row.

7. Then you need to set the grouping condition in this **Group by** table to aggregate the two input relations. In each column representing the input relation, click the newly added row and select the column you need to use to compose the grouping condition. In this scenario, the *owner* column from the owner-pet relation and the *friend* column from the student-friend relation are selected because they have common records. Based on these columns, the two relations are aggregated into bags.

   The bags regarding the record *Alice* might read as follow:

   ```
   Alice,\{(Alice,turtle,17),(Alice,goldfish,17),(Alice,cat,17)\},\{(Cindy,Alice),(Mark,Alice)\}
   ```

8. In the **Output mapping** table, the output schema you defined previously has been automatically fed into the **Column** column. You need to complete this table to define how the grouped bags are aggregated into the schema of the output relation. The following list provides more details about how this aggregation is configured for this scenario:

   **Column** | **Description**
   --- | ---
   **owner_friend** | Receive the literal records incoming from the columns that are used as the grouping condition.
   
   For this reason, select the **EMPTY** function from the **Function** drop-down list so that the incoming records stay as is. Then select *row1* from the **Source schema** list and *owner* from the **Expression** list to read the records from the corresponding input column; you can as well select *row2* and *friend*, the records to be received are the same because the *owner* column and the *friend* column are joined when they are used as grouping condition.
   
   Note that the label *row1* is the ID of the input link and thus may be different in your scenario.

   **age** | Receive the age data.
   
   As shown in the example bags in the previous step, the age of an owner repetitively appears in one of the bags after the grouping. You can select the **AVG** function from the **Function** list to make the average of the repetitive values such that this age appears only once in the final result. Then select *row1* from the **Source schema** list and *age* from the **Expression** list.
<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pet_number</td>
<td>Receive how many pets an owner has.</td>
</tr>
<tr>
<td></td>
<td>Select the <strong>COUNT</strong> function from the <strong>Function</strong> list to perform this</td>
</tr>
<tr>
<td></td>
<td>calculation. Then select <strong>row1</strong> from the <strong>Source schema</strong> list and <strong>pet</strong></td>
</tr>
<tr>
<td></td>
<td>from the <strong>Expression</strong> list.</td>
</tr>
</tbody>
</table>

**pet and student**

Receive the grouped records from the input **pet** and **student** columns, respectively.

Select **EMPTY** for both of them and from the **Source schema** list of each, select the corresponding input schema and from the **Expression** list, the corresponding column.

**Writing the aggregated data**

**Procedure**

1. Double-click **tPigStoreResult** to open its **Component** view.

2. If this component does not have the same schema of the preceding component, a warning icon appears. In this case, click the **Sync columns** button to retrieve the schema from the preceding one and once done, the warning icon disappears.

3. In the **Result folder URI** field, enter the path in HDFS pointing to the location you want to write the result in.

4. Select the **Remove result directory if exists** check box.

5. From the **Store function** list, select **PigStorage**.

6. In the **Field separator** field, enter the separator you want to use. In this scenario, enter a comma (,).

**Executing the Job**

Then you can press **F6** to run this Job.

Once done, check the result from the HDFS system you are using.
You can read, for example, that the pet owner *Alice* is 17 years old, has 3 pets, a cat, a goldfish and a turtle and two of her friends are Mark and Cindy.
tPigCross

Uses CROSS operator to compute the Cartesian product.
The tPigCross computes the cross data of two or more relations.

tPigCross Standard properties

These properties are used to configure tPigCross running in the Standard Job framework.
The Standard tPigCross component belongs to the Big Data and the Processing families.
The component in this framework is available when you are using one of the Talend solutions with Big Data.

Basic settings

| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
| • View schema: choose this option to view the schema only.  
| • Change to built-in property: choose this option to change the schema to Built-in for local changes.  
| • Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the [Repository Content] window. |
| Built-in: The schema will be created and stored locally for this component only. Related topic: see Talend Studio User Guide. |
| Repository: The schema already exists and is stored in the Repository, hence can be reused in various projects and Job designs. Related topic: see Talend Studio User Guide. |
| Cross filename | Fill in the path of the file to be computed. |
| Field separator | Enter character, string or regular expression to separate fields for the transferred data. |
## Advanced settings

<table>
<thead>
<tr>
<th>Use partitioner</th>
<th>Select this check box to specify the Hadoop Partitioner that controls the partitioning of the keys of the intermediate map-outputs. For further information about the usage of Hadoop Partitioner, see: <a href="http://hadoop.apache.org/docs/r2.2.0/api/org/apache/hadoop/mapred/Partitioner.html">http://hadoop.apache.org/docs/r2.2.0/api/org/apache/hadoop/mapred/Partitioner.html</a></th>
</tr>
</thead>
<tbody>
<tr>
<td>Increase parallelism</td>
<td>Select this check box to set the number of reduce tasks for the MapReduce Jobs</td>
</tr>
<tr>
<td>tStatCatcher Statistics</td>
<td>Select this check box to gather the Job processing metadata at the Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

## Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press <strong>Ctrl + Space</strong> to access the variable list and choose the variable to use from it. For further information about variables, see <a href="#">Talend Studio User Guide</a>.</th>
</tr>
</thead>
</table>

## Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is commonly used as intermediate step together with input component and output component.</th>
</tr>
</thead>
</table>
| Prerequisites | The Hadoop distribution must be properly installed, so as to guarantee the interaction with **Talend Studio**. The following list presents MapR related information for example.  

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under `MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native`. For example, the library for Windows is `\lib\native\MapRClient.dll` in the MapR client jar file. For further information, see the following link from MapR: [http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr](http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr). |
Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path.

- Set the `-Djava.library.path` argument, for example, in the Job Run VM arguments area of the Run/Debug view in the [Preferences] dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

| Limitation                  | Knowledge of Pig scripts is required. |

**Related scenarios**

No scenario is available for the Standard version of this component yet.
tPigDistinct

Removes duplicate tuples in a relation.

**tPigDistinct Standard properties**

These properties are used to configure tPigDistinct running in the Standard Job framework.

The Standard tPigDistinct component belongs to the Big Data and the Processing families.

The component in this framework is available when you are using one of the Talend solutions with Big Data.

**Basic settings**

Schema and Edit Schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the [Repository Content] window.

**Built-in**: The schema will be created and stored locally for this component only. Related topic: see Talend Studio User Guide.

**Repository**: The schema already exists and is stored in the Repository, hence can be reused in various projects and Job designs. Related topic: see Talend Studio User Guide.

**Advanced settings**

Increase parallelism

Select this check box to set the number of reduce tasks for the MapReduce Jobs

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.
### Global Variables

| **Global Variables** | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

### Usage

| **Usage rule** | **This component is commonly used as intermediate step together with input component and output component.** **Warning:** This component will not maintain the original order in the input file. |

### Prerequisites

| **Prerequisites** | **The Hadoop distribution must be properly installed, so as to guarantee the interaction with Talend Studio. The following list presents MapR related information for example.** **•** Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native. For example, the library for Windows is \lib\native\MapRClient.dll in the MapR client jar file. For further information, see the following link from MapR: http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr. Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path. **•** Set the -Djava.library.path argument, for example, in the Job Run VM arguments area of the Run/Debug view in the [Preferences] dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR. |
For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

| Limitation          | Knowledge of Pig scripts is required. |

**Related scenario**

For more information regarding the **tPigDistinct** component in use, see Scenario: Filtering rows of data based on a condition and saving the result to a local file on page 2950 of **tPigFilterRow**.
**tPigFilterColumns**

Selects data or filters out data from a relation based on defined filter conditions.

The tPigFilterColumns selects one or more columns from a relation based on defined condition.

**tPigFilterColumns Standard properties**

These properties are used to configure tPigFilterColumns running in the Standard Job framework.

The Standard tPigFilterColumns component belongs to the Big Data and the Processing families.

The component in this framework is available when you are using one of the Talend solutions with Big Data.

### Usage

| Usage rule | This component is commonly used as intermediate step together with input component and output component. |

### Prerequisites

| Prerequisites | The Hadoop distribution must be properly installed, so as to guarantee the interaction with *Talend Studio*. The following list presents MapR related information for example. |

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under `MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native`. For example, the library for Windows is `\lib\native\MapRClient.dll` in the MapR client jar file. For further information, see the following link from MapR: [http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr](http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr). Without adding the specified library or libraries, you may encounter the following error: `no MapRClient in java.library.path`. |

- Set the `-Djava.library.path` argument, for example, in the **Job Run VM arguments** area of the **Run/Debug** view in the **[Preferences]** dialog box in the **Window** menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the **Data viewer** to view locally in the Studio the data stored in MapR. |

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using. |

### Limitation

| Limitation | Knowledge of Pig script is required. |
Related Scenario

For a \texttt{tPigFilterColumns} related scenario, see Scenario: Joining two files based on an exact match and saving the result to a local file on page 2957 of \texttt{tPigJoin}. 
tPigFilterRow

Applies filtering conditions on one or more specified columns, in a Pig process, in order to split or filter data from a relation.

The tPigFilterRow filters or splits the input flow in a Pig process based on conditions set on given column(s).

**tPigFilterRow Standard properties**

These properties are used to configure tPigFilterRow running in the Standard Job framework.

The Standard tPigFilterRow component belongs to the Big Data and the Processing families.

The component in this framework is available when you are using one of the Talend solutions with Big Data.

**Basic settings**

| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:
| | - View schema: choose this option to view the schema only.
| | - Change to built-in property: choose this option to change the schema to Built-in for local changes.
| | - Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the [Repository Content] window.
| Built-In: You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.
| Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.
| Filter configuration | Click the Add button beneath the Filter configuration table to set one or more filter conditions.
| | Note that when the column to be used by a condition is of the string type, the text to be entered in the Value column must be surrounded by both single and double quotation marks (for example, "California"), because the
double quotation marks are required by Talend's code generator and the single quotation marks required by Pig's grammar.

**Note:**
This table disappears if you select **Use advanced filter**.

<table>
<thead>
<tr>
<th>Use advanced filter</th>
<th>Select this check box to define advanced filter condition by entering customized filter expression in the Filter field.</th>
</tr>
</thead>
</table>

### Advanced settings

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
<th>Select this check box to gather the Job processing metadata at the Job level as well as at each component level.</th>
</tr>
</thead>
</table>

### Global Variables

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
For further information about variables, see Talend Studio User Guide. |
|---------------------|------------------------------------------------------------------------------------------------------------------|

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is commonly used as an intermediate step in a Pig process.</th>
</tr>
</thead>
</table>

### Prerequisites

The Hadoop distribution must be properly installed, so as to guarantee the interaction with Talend Studio. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR's documentation, the library or libraries of a MapR client corresponding to each OS version can be found under `MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native`. For example, the library for Windows is `\lib\native\MapRClient.dll` in the MapR client jar file. For further information, see the following link from MapR: [http://www.mapr.com/](http://www.mapr.com/)
Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path.

- Set the `-Djava.library.path` argument, for example, in the Job Run VM arguments area of the Run/Debug view in the [Preferences] dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

| Limitation               | Knowledge of Pig scripts is required. |

**Scenario: Filtering rows of data based on a condition and saving the result to a local file**

This scenario applies only to a Talend solution with Big Data.

This scenario describes a four-component Job that filters a list of customers to find out customers from a particular country, and saves the result list to a local file. Before the input data is filtered, duplicate entries are first removed from the list.

The input file contains three columns: Name, Country, and Age, and it has some duplicate entries, as shown below:

<table>
<thead>
<tr>
<th>Name</th>
<th>Country</th>
<th>Age</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mario</td>
<td>PuertoRico</td>
<td>49</td>
</tr>
<tr>
<td>Mike</td>
<td>USA</td>
<td>22</td>
</tr>
<tr>
<td>Ricky</td>
<td>PuertoRico</td>
<td>37</td>
</tr>
<tr>
<td>Silvia</td>
<td>Spain</td>
<td>20</td>
</tr>
<tr>
<td>Billy</td>
<td>Canada</td>
<td>21</td>
</tr>
<tr>
<td>Ricky</td>
<td>PuertoRico</td>
<td>37</td>
</tr>
<tr>
<td>Romeo</td>
<td>UK</td>
<td>19</td>
</tr>
<tr>
<td>Natasha</td>
<td>Russia</td>
<td>25</td>

**Dropping and linking components**

**Procedure**

1. Drop the following components from the Palette to the design workspace: **tPigLoad**, **tPigDistinct**, **tPigFilterRow**, and **tPigStoreResult**.
2. Right-click **tPigLoad**, select Row > Pig Combine from the contextual menu, and click **tPigDistinct** to link these two components.
3. Repeat this operation to link **tPigDistinct** to **tPigFilterRow**, and **tPigFilterRow** to **tPigStoreResult** using Row > Pig Combine connections to form a Pig process.
Configuring the components

Loading the input data and removing duplicates

Procedure

1. Double-click **tPigLoad** to open its **Basic settings** view.

2. Click the [...] button next to **Edit schema** to open the [Schema] dialog box.
3. Click the \([+]\) button to add three columns according to the data structure of the input file: \textit{Name} (string), \textit{Country} (string) and \textit{Age} (integer), and then click \textbf{OK} to save the setting and close the dialog box.

4. Click \textbf{Local} in the \textit{Mode} area.

5. Fill in the \textit{Input file URI} field with the full path to the input file.

6. Select \textbf{PigStorage} from the \textit{Load function} list, and leave rest of the settings as they are.

7. Double-click \textbf{tPigDistinct} to open its \textbf{Basic settings} view, and click \textbf{Sync columns} to make sure that the input schema structure is correctly propagated from the preceding component.

   This component will remove any duplicates from the data flow.

### Configuring the filter

**Procedure**

1. Double-click \textbf{tPigFilterRow} to open its \textbf{Basic settings} view.

2. Click \textbf{Sync columns} to make sure that the input schema structure is correctly propagated from the preceding component.

3. Select \textbf{Use advanced filter} and fill in the \textbf{Filter} field with filter expression:

   \[
   "\text{Country matches 'PuertoRico'}"
   \]

   This filter expression selects rows of data that contains "PuertoRico" in the \textit{Country} column.
Configuring the file output

Procedure

1. Double-click tPigStoreResult to open its Basic settings view.

![tPigStoreResult Settings](image)

2. Click Sync columns to make sure that the input schema structure is correctly propagated from the preceding component.

3. Fill in the Result file field with the full path to the result file.

4. If the target file already exists, select the Remove result directory if exists check box.

5. Select PigStorage from the Store function list, and leave rest of the settings as they are.

Saving and executing the Job

Procedure

1. Press Ctrl+S to save your Job.

2. Press F6 or click the Run button on the Run tab to run the Job.

The result file contains the information of customers from the specified country.

![Result File](image)
tPigJoin

Performs inner joins and outer joins of two files based on join keys to create data that will be used by Pig.
The tPigJoin performs join of two files based on join keys.

tPigJoin Standard properties

These properties are used to configure tPigJoin running in the Standard Job framework.
The Standard tPigJoin component belongs to the Big Data and the Processing families.
The component in this framework is available when you are using one of the Talend solutions with Big Data.

</table>
**Schema and Edit schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Note:**

To make this component work, two schemas must be set: the schema of the main flow and the schema of the lookup flow. In the output part of the main schema, the columns of the main input file must be manually concatenated with those of the lookup file.

| **Built-in**: The schema will be created and stored locally for this component only. Related topic: see [Talend Studio User Guide](#). |
| **Repository**: The schema already exists and is stored in the Repository, hence can be reused in various projects and Job designs. Related topic: see [Talend Studio User Guide](#). |

**Filename**

Fill in the path of the **Lookup file**.

**Field Separator**

Enter character, string or regular expression to separate fields for the transferred data.

**Join key**

Click the plus button to add lines to set the **Join key** for **Input file** and **Lookup file**.

**Join mode**

Select a join mode from the list:

- **inner-join**: Select this mode to perform an inner join of two or more relations based on Join keys.
- **left-outer-join**: Select this mode to perform a left outer join of two or more relations based on Join keys.
- **right-outer-join**: Select this mode to perform a right outer join of two or more relations based on Join keys.
- **full-outer-join**: Select this mode to combine the effect of applying both left and right outer joins.
For further information about inner join and outer join, see:
http://en.wikipedia.org/wiki/Join_%28SQL%29

**Advanced settings**

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optimize the join</td>
<td>Select this check box to optimize the performance of joins using <strong>REPLICATED</strong>, <strong>SKEWED</strong>, or <strong>MERGE</strong> joins. For further information about optimized joins, see: <a href="http://pig.apache.org/docs/r0.8.1/piglatin_ref1.html#Specialized+Joins">http://pig.apache.org/docs/r0.8.1/piglatin_ref1.html#Specialized+Joins</a></td>
</tr>
<tr>
<td>Use partitioner</td>
<td>Select this check box to specify the Hadoop Partitioner that controls the partitioning of the keys of the intermediate map-outputs. For further information about the usage of Hadoop Partitioner, see: <a href="http://hadoop.apache.org/docs/r2.2.0/api/org/apache/hadoop/mapred/Partitioner.html">http://hadoop.apache.org/docs/r2.2.0/api/org/apache/hadoop/mapred/Partitioner.html</a></td>
</tr>
<tr>
<td>Increase parallelism</td>
<td>Select this check box to set the number of reduce tasks for the <strong>MapReduce</strong> Jobs</td>
</tr>
<tr>
<td>tStatCatcher Statistics</td>
<td>Select this check box to gather the Job processing metadata at the Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

**Global Variables**

**Global Variables**

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

**Usage**

**Usage rule**

This component is commonly used as intermediate step together with input component and output component.

**Prerequisites**

The Hadoop distribution must be properly installed, so as to guarantee the interaction with *Talend Studio*. The following list presents MapR related information for example.
**Scenario: Joining two files based on an exact match and saving the result to a local file**

This scenario applies only to a Talend solution with Big Data.

This scenario describes a four-component Job that combines data of an input file and a reference file that matches a given join key, removes unwanted columns, and then saves the final result to a local file.

The main input file contains the information about people’s IDs, first names, last names, group IDs, and salaries, as shown below:

```
1;Woodrow;Johnson;3;1013.39
2;Millard;Monroe;2;8077.59
3;Calvin;Eisenhower;3;6866.88
4;Lyndon;Wilson;3;5726.28
5;Ronald;Garfield;2;4158.58
6;Rutherford;Buchanan;3;2897.00
7;Calvin;Coolidge;1;6650.66
8;Ulysses;Roosevelt;2;7854.78
9;Grover;Tyler;1;5226.88
10;Bill;Tyler;2;8964.66
```

The reference file contains only the information of group IDs and group names:

```
1;group_A
```
Dropping and linking the components

Procedure

1. Drop the following components from the Palette to the design workspace: tPigLoad, tPigJoin, tPigFilterColumns, and tPigStoreResult.
2. Connect these components in a series using Row > Pig Combine connections.

Configuring the components

Loading the main input file

Procedure

1. Double-click tPigLoad to open its Basic settings view.
2. Click the [...] button next to Edit schema to open the [Schema] dialog box.
3. Click the [+] button to add columns, name them and define the column types according to the structure of the input file. In this example, the input schema has five columns: id (integer), firstName (string), lastName (string), groupid (integer), and salary (double). Then click OK to validate the setting and close the dialog box.

4. Click Local in the Mode area.

5. Select PigStorage from the Load function list.

6. Fill in the Input file URI field with the full path to the input file, and leave the rest of the setting as they are.

**Loading the reference file and setting up an inner join**

**Procedure**

1. Double-click tPigJoin to open its Basic settings view.
2. Click the [...] for the main schema to open the [Schema] dialog box.

3. Check that input schema is correctly retrieved from the preceding component. If needed, click the [...] button to copy all the columns of the input schema to the output schema.

4. Click the [+] button under the output panel to add new columns according to the data structure of the reference file, groupId_ref (integer) and groupName (string) in this example. Then click OK to close the dialog box.

5. Click the [...] for the schema lookup flow to open the [Schema] dialog box.
6. Click the [+] button under the output panel to add two columns: \textit{groupId\_ref} (integer) and \textit{groupName} (string), and then click \textbf{OK} to close the dialog box.

7. In the \textbf{Filename} field, specify the full path to the reference file.

8. Click the [+] button under the \textbf{Join key} table to add a new line, and select \textit{groupId} and \textit{groupId\_ref} respectively from the \textbf{Input} and \textbf{Lookup} lists to match data from the main input flow with data from the lookup flow based on the group ID.

9. From the \textbf{Join Mode} list, select \textbf{inner-join}.

**Defining the final output schema and the output file**

**Procedure**

1. Double-click \textbf{tPigFilterColumns} to open its \textbf{Basic settings} view.

2. Click the [...] button next to \textbf{Edit schema} to open the [Schema] dialog box.
3. From the input schema, select the columns you want to include in your result file by clicking them one after another while pressing the Shift key, and click the [->] button to copy them to the output schema. Then, click OK to validate the schema setting and close the dialog box. In this example, we want the result file to include all the information except the group IDs.

4. Double-click tPigStoreResult to open its Basic settings view.

5. Click Sync columns to retrieve the schema structure from the preceding component.

6. Fill in the Result file field with the full path to the result file, and select the Remove result file directory if exists check box.

7. Select PigStorage from the Store function list, and leave rest of the settings as they are.

Saving and executing the Job

Procedure

1. Press Ctrl+S to save your Job.

2. Press F6 or click Run on the Run tab to run the Job.

   The result file includes all the information related to people of group A and group B, except their group IDs.
<p>| | | | |</p>
<table>

</tbody>
</table>
**tPigLoad**

Loads original input data to an output stream in just one single transaction, once the data has been validated.

The tPigLoad sets up a connection to the data source for a current transaction.

**tPigLoad Standard properties**

These properties are used to configure tPigLoad running in the Standard Job framework.

The Standard tPigLoad component belongs to the Big Data and the Processing families.

The component in this framework is available when you are using one of the Talend solutions with Big Data.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-In or Repository.</th>

<td>For further information about the Hadoop Cluster node, see the Getting Started Guide.</td>
</tr>
</tbody>
</table>

**Schema and Edit Schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.
<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-In</strong></td>
<td>You create and store the schema locally for this component only. Related topic: see <em>Talend Studio User Guide</em>.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see <em>Talend Studio User Guide</em>.</td>
</tr>
<tr>
<td><strong>Local</strong></td>
<td>Click this radio button to run Pig scripts in Local mode. In this mode, all files are installed and run from your local host and file system.</td>
</tr>
</tbody>
</table>
| **Tez** | Click this radio button to run the Pig Job on the Tez framework. This Tez mode is available only when you are using one of the following distributions:  
- Hortonworks: V2.2 +.  
- Custom: this option allows you connect to a distribution supporting Tez but not officially supported by Talend.  
Before using Tez, ensure that the Hadoop cluster you are using supports Tez. You will need to configure the access to the relevant Tez libraries via the Advanced settings view of this component.  
For further information about Pig on Tez, see Apache’s related documentation in https://cwiki.apache.org/confluence/display/PIG/Pig+on+Tez. |
| **Map/Reduce** | Click this radio button to run Pig scripts in Map/Reduce mode. Once selecting this mode, you need to complete the fields in the Configuration area that appears:  
- **Distribution** and **Version**: Select the cluster you are using from the drop-down list. The options in the list vary depending on the component you are using. Among these options, the following ones requires specific configuration:  
  - If available in this **Distribution** drop-down list, the Microsoft HD Insight option allows you use a Microsoft HD Insight cluster. For this purpose, you need to configure the connections to the HD Insight cluster and the Windows Azure Storage service of that cluster in the areas that are displayed. For detailed explanation about these parameters, search for configuring the connection manually on Talend Help Center (https://help.talend.com).  
  - If you select Amazon EMR, you can find more details about how to configure an Amazon EMR cluster in Talend Help Center (https://help.talend.com). |
• The **Custom** option allows you to connect to a cluster different from any of the distributions given in this list, that is to say, to connect to a cluster not officially supported by **Talend**.

1. Select **Import from existing version** to import an officially supported distribution as base and then add other required jar files which the base distribution does not provide.

2. Select **Import from zip** to import the configuration zip for the custom distribution to be used. This zip file should contain the libraries of the different Hadoop elements and the index file of these libraries.

In **Talend Exchange**, members of **Talend** community have shared some ready-for-use configuration zip files which you can download from this [Hadoop configuration list](#) and directly use them in your connection accordingly. However, because of the ongoing evolution of the different Hadoop-related projects, you might not be able to find the configuration zip corresponding to your distribution from this list; then it is recommended to use the **Import from existing version** option to take an existing distribution as base to add the jars required by your distribution.

Note that custom versions are not officially supported by **Talend**. **Talend** and its community provide you with the opportunity to connect to custom versions from the Studio but cannot guarantee that the configuration of whichever version you choose will be easy, due to the wide range of different Hadoop distributions and versions that are available. As such, you should only attempt to set up such a connection if you have sufficient Hadoop experience to handle any issues on your own.

**Note:**

In this dialog box, the active check box must be kept selected so as to import the jar files pertinent to the connection to be created between the custom distribution and this component.

For a step-by-step example about how to connect to a custom distribution and share this connection, see [Connecting to a custom Hadoop distribution](#) on page 1589.

• **Use Kerberos authentication:**

  If you are accessing the Hadoop cluster running with Kerberos security, select this check box, then, enter the Kerberos principal name for the NameNode in the field displayed. This enables you to use your user name to authenticate against the credentials stored in Kerberos.
• If this cluster is a MapR cluster of the version 5.0.0 or later, you can set the MapR ticket authentication configuration in addition or as an alternative by following the explanation in Connecting to a security-enabled MapR on page 1652.

Keep in mind that this configuration generates a new MapR security ticket for the username defined in the Job in each execution. If you need to reuse an existing ticket issued for the same username, leave both the **Force MapR ticket authentication** check box and the **Use Kerberos authentication** check box clear, and then MapR should be able to automatically find that ticket on the fly.

In addition, since this component performs Map/Reduce computations, you also need to authenticate the related services such as the Job history server and the Resource manager or Jobtracker depending on your distribution in the corresponding field. These principals can be found in the configuration files of your distribution. For example, in a CDH4 distribution, the Resource manager principal is set in the `yarn-site.xml` file and the Job history principal in the `mapred-site.xml` file.

This check box is available depending on the Hadoop distribution you are connecting to.

The HBase related principals are required by the **HBaseStorage** function only.

• **Use a keytab to authenticate:**

  Select the **Use a keytab to authenticate** check box to log into a Kerberos-enabled system using a given keytab file. A keytab file contains pairs of Kerberos principals and encrypted keys. You need to enter the principal to be used in the **Principal** field and the access path to the keytab file itself in the **Keytab** field. This keytab file must be stored in the machine in which your Job actually runs, for example, on a Talend Jobserver.

  Note that the user that executes a keytab-enabled Job is not necessarily the one a principal designates but must have the right to read the keytab file being used. For example, the user name you are using to execute a Job is `user1` and the principal to be used is `guest`; in this situation, ensure that `user1` has the right to read the keytab file to be used.

• **NameNode URI:**

  Type in the location of the NameNode corresponding to the Map/Reduce version to be used. If you are using WebHDFS, the location should be webhdfs://masternode:portnumber; if this WebHDFS is secured with SSL, the scheme should be swebhdfs and you need to use a `tLibraryLoad` in the Job to load the library required by the secured WebHDFS.
• **JobTracker host:**

  Type in the location of the ResourceManager corresponding to the Map/Reduce version to be used.

  In JobHistory, you can easily find the execution status of your Pig Job because the name of the Job is automatically created by concatenating the name of the project that contains the Job, the name and version of the Job itself and the label of the first `tPigLoad` component used in it. The naming convention of a Pig Job in JobHistory is `ProjectName_JobNameVersion_FirstComponentName`.

  Then you can continue to set the following parameters depending on the configuration of the Hadoop cluster to be used (if you leave the check box of a parameter clear, then at runtime, the configuration about this parameter in the Hadoop cluster to be used will be ignored):

  1. Select the **Set resourcemanager scheduler address** check box and enter the Scheduler address in the field that appears.

  2. Select the **Set jobhistory address** check box and enter the location of the JobHistory server of the Hadoop cluster to be used. This allows the metrics information of the current Job to be stored in that JobHistory server.

  3. Select the **Set staging directory** check box and enter this directory defined in your Hadoop cluster for temporary files created by running programs. Typically, this directory can be found under the `yarn.app.mapreduce.am.staging-dir` property in the configuration files such as `yarn-site.xml` or `mapred-site.xml` of your distribution.

  4. Allocate proper memory volumes to the **Map** and the **Reduce** computations and the **ApplicationMaster** of YARN by selecting the **Set memory** check box in the Advanced settings view.

  5. Select the **Set Hadoop user** check box and enter the user name under which you want to execute the Job. Since a file or a directory in Hadoop has its specific owner with appropriate read or write rights, this field allows you to execute the Job directly under the user name that has the appropriate rights to access the file or directory to be processed.

  6. Select the **Use datanode hostname** check box to allow the Job to access datanodes via their hostnames. This actually sets the `dfs.client.use.datanode.hostname` property to `true`. When connecting to a S3N filesystem, you must select this check box.

For further information about these parameters, see the documentation or contact the administrator of the Hadoop cluster to be used.
**User name:**

Enter the user name under which you want to execute the Job. Since a file or a directory in Hadoop has its specific owner with appropriate read or write rights, this field allows you to execute the Job directly under the user name that has the appropriate rights to access the file or directory to be processed. Note that this field is available depending on the distribution you are using.

**WebHCat configuration**

Enter the address and the authentication information of the Microsoft HD Insight cluster to be used. For example, the address could be `your_hdinsight_cluster_name.azurehdinsight.net` and the authentication information is your Azure account name: `ychen`. The Studio uses this service to submit the Job to the HD Insight cluster.

In the **Job result folder** field, enter the location in which you want to store the execution result of a Job in the Azure Storage to be used.

**HDInsight configuration**

Enter the authentication information of the HD Insight cluster to be used.

**Windows Azure Storage configuration**

Enter the address and the authentication information of the Azure Storage account to be used. In this configuration, you do not define where to read or write your business data but define where to deploy your Job only. Therefore always use the Azure Blob Storage system for this configuration.

In the **Container** field, enter the name of the container to be used.

In the **Deployment Blob** field, enter the location in which you want to store the current Job and its dependent libraries in this Azure Storage account.

**Inspect the classpath for configurations**

Select this check box to allow the component to check the configuration files in the directory you have set with the `$HADOOP_CONF_DIR` variable and directly read parameters from these files in this directory. This feature allows you to easily change the Hadoop configuration for the component to switch between different environments, for example, from a test environment to a production environment.

In this situation, the fields or options used to configure Hadoop connection and/or Kerberos security are hidden.

If you want to use certain parameters such as the Kerberos parameters but these parameters are not included in these Hadoop configuration files, you need to create a file called `talend-site.xml` and put this file into the same directory defined with `$HADOOP_CONF_DIR`. This `talend-site.xml` file should read as follows:

```xml
<!-- Put site-specific property overrides in this file. -->
<configuration>
    <property>
```

2969

```xml
```
<name>talend.kerberos.authentication</name>
  <value>kinit</value>
  <description> Set the Kerberos authentication method to use. Valid values are: kinit or keytab. </description>
</property>

<property>
  <name>talend.kerberos.keytab.principal</name>
  <value>user@BIGDATA.COM</value>
  <description> Set the keytab's principal name. </description>
</property>

<property>
  <name>talend.kerberos.keytab.path</name>
  <value>/kdc/user.keytab</value>
  <description> Set the keytab's path. </description>
</property>

<property>
  <name>talend.encryption</name>
  <value>none</value>
  <description> Set the encryption method to use. Valid values are: none or ssl. </description>
</property>

<property>
  <name>talend.ssl.trustStore.path</name>
  <value>ssl</value>
  <description> Set SSL trust store path. </description>
</property>

<property>
  <name>talend.ssl.trustStore.password</name>
  <value>ssl</value>
  <description> Set SSL trust store password. </description>
</property>

The parameters read from these configuration files override the default ones used by the Studio. When a parameter does not exist in these configuration files, the default one is used.

<table>
<thead>
<tr>
<th><strong>Load function</strong></th>
<th>Select a load function for data to be loaded:</th>
</tr>
</thead>
<tbody>
<tr>
<td>• <strong>PigStorage</strong>: Loads data in UTF-8 format.</td>
<td></td>
</tr>
<tr>
<td>• <strong>BinStorage</strong>: Loads data in machine-readable format.</td>
<td></td>
</tr>
</tbody>
</table>
- **TextLoader**: Loads unstructured data in UTF-8 format.

- **HCatLoader**: Loads data from HCataLog managed tables using Pig scripts.
  
  This function is available only when you have selected HortonWorks as the Hadoop distribution to be used from the Distribution and the Version fields displayed in the Map/Reduce mode. For further information about HCatLoader, see [http://hive.apache.org/javadocs/hcat-r0.5.0/api/org/apache/hcatalog/pig/HCatLoader.html](http://hive.apache.org/javadocs/hcat-r0.5.0/api/org/apache/hcatalog/pig/HCatLoader.html).

- **HBaseStorage**: Loads data from HBase. Then you need to complete the HBase configuration in the HBase configuration area displayed.

- **SequenceFileLoader**: Loads data of the SequenceFile formats. Then you need to complete the configuration of the file to be loaded in the Sequence Loader Configuration area that appears. This function is for the Map/Reduce mode only.

- **RCFilePigStorage**: Loads data of the RCFile format. This function is for the Map/Reduce mode only.

- **AvroStorage**: Loads Avro files. For further information about AvroStorage, see Apache’s documentation on [https://cwiki.apache.org/confluence/display/PIG/AvroStorage](https://cwiki.apache.org/confluence/display/PIG/AvroStorage). This function is for the Map/Reduce mode only.

- **ParquetLoader**: Loads Parquet file. This function is for the Map/Reduce mode only.

- **Custom**: Loads data using any user-defined load function. To do this, you need to register, in the Advanced settings tab view, the jar file containing the function to be used, and then, in the field displayed next to this Load function field, specify that function.

  For example, after registering a jar file called piggybank.jar, you can enter `org.apache.pig.piggybank.storage.XMLLoader('attr') as (xml:chararray)` to use the custom function, XMLLoader contained in that jar file. For further information about this piggybank.jar file, see [https://cwiki.apache.org/confluence/display/PIG/PiggyBank](https://cwiki.apache.org/confluence/display/PIG/PiggyBank).

  Note that when the file format to be used is PARQUET, you might be prompted to find the specific Parquet jar file and install it into the Studio.

- When the connection mode to Hive is **Embedded**, the Job is run in your local machine and calls this jar installed in the Studio.

- When the connection mode to Hive is **Standalone**, the Job is run in the server hosting Hive and this jar file is sent to the HDFS system of the cluster you are connecting to. Therefore, ensure that you have properly defined the NameNode URI in the corresponding field of the Basic settings view.
This jar file can be downloaded from Apache's site. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

| Input file URI | Fill in this field with the full local path to the input file.  
| Note: This field is not available when you select HCatLoader from the Load function list or when you are using an S3 endpoint. |

| Use S3 endpoint | Select this check box to read data from a given Amazon S3 bucket folder.  
| Once this Use S3 endpoint check box is selected, you need to enter the following parameters in the fields that appear:  
| • S3 bucket name and folder: enter the bucket name and its folder from which you need to read data. You need to separate the bucket name and the folder name using a slash (/).  
| • Access key and Secret key: enter the authentication information required to connect to the Amazon S3 bucket to be used.  
| To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.  
| Note that the format of the S3 file is S3N (S3 Native Filesystem). |

| HCataLog Configuration | Fill the following fields to configure HCataLog managed tables on HDFS (Hadoop distributed file system):  
| Distribution and Version:  
| Select the cluster you are using from the drop-down list. The options in the list vary depending on the component you are using. Among these options, the following ones require specific configuration:  
| • If available in this Distribution drop-down list, the Microsoft HD Insight option allows you to use a Microsoft HD Insight cluster. For this purpose, you need to configure the connections to the HD Insight cluster and the Windows Azure Storage service of that cluster in the areas that are displayed. For detailed explanation about these parameters, search for configuring the connection manually on Talend Help Center (https://help.talend.com).  
| • If you select Amazon EMR, you can find more details about how to configure an Amazon EMR cluster in Talend Help Center (https://help.talend.com).  
| • The Custom option allows you to connect to a cluster different from any of the distributions given in this list, that is to say, to connect to a cluster not officially supported by Talend. |
| **HCat metastore**: Enter the location of the HCatalog’s metastore, which is actually Hive’s metastore, a system catalog. For further information about Hive and HCatalog, see [http://hive.apache.org/](http://hive.apache.org/). |
| **Database**: The database in which tables are placed. |
| **Table**: The table in which data is stored. |
| **Partition filter**: Fill this field with the partition keys to list partitions by filter. |

Note: **HCataLog Configuration area** is enabled only when you select **HCatLoader** from the **Load function** list. For further information about the usage of HCatalog, see [https://cwiki.apache.org/confluence/display/Hive/HCatalog](https://cwiki.apache.org/confluence/display/Hive/HCatalog). For further information about the usage of **Partition filter**, see [https://cwiki.apache.org/confluence/display/HCATALOG/Design+Document+-+Java+APIs+for+HCatalog+DDL+Commands](https://cwiki.apache.org/confluence/display/HCATALOG/Design+Document+-+Java+APIs+for+HCatalog+DDL+Commands).

| **Field separator** | Enter character, string or regular expression to separate fields for the transferred data. |
| **Note:** | This field is enabled only when you select **PigStorage** from the **Load function** list. |

| **Compression** | Select the **Force to compress the output data** check box to compress the data when the data is outputted by **tPigStoreResult** at the end of a Pig process. |

Hadoop provides different compression formats that help reduce the space needed for storing files and speed up data transfer. When you need to write and compress data using the Pig program, by default you have to add a compression format as a suffix to the path pointing to the folder in which you want to write data, for example, `/user/ychen/out.bz2`. However, if you select this check box, the output data will be compressed even if you do not add any compression format to that path, such as `/user/ychen/out`. |

**Note:** The output path is set in the **Basic settings** view of **tPigStoreResult**. |

<p>| <strong>HBase configuration</strong> | This area is available to the HBaseStorage function. The parameters to be set are: |
| <strong>Zookeeper quorum</strong>: | Type in the name or the URL of the Zookeeper service you use to coordinate the transaction between your Studio and your database. Note that when you configure the Zookeeper, you might need to explicitly set the Zookeeper.znode.parent property to define the path to the root znode that contains all the znodes created and used by your database; then select the <strong>Set Zookeeper znode parent</strong> check box to define this property. |</p>
<table>
<thead>
<tr>
<th><strong>Zookeeper client port:</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type in the number of the client listening port of the Zookeeper service you are using.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Table name:</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Enter the name of the HBase table you need to load data from.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Load key:</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Select this check box to load the row key as the first column of the result schema. In this situation, you must have created this column in the schema.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Mapping:</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Complete this table to map the columns of the table to be used with the schema columns you have defined for the data flow to be processed.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Sequence Loader configuration</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>This area is available only to the <strong>SequenceFileLoader</strong> function. Since a SequenceFile record consists of binary key/value pairs, the parameters to be set are:</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Key column:</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Select the Key column of a key/value record.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Value column</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Select the Value column of a key/value record.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Die on subjob error</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>This check box is cleared by default, meaning to skip the row on subjob error and to complete the process for error-free rows.</td>
</tr>
</tbody>
</table>

### Advanced settings

<table>
<thead>
<tr>
<th><strong>Tez lib</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Select how the Tez libraries are accessed:</td>
</tr>
</tbody>
</table>

- **Auto install:** at runtime, the Job uploads and deploys the Tez libraries provided by the Studio into the directory you specified in the **Install folder in HDFS** field, for example, `/tmp/usr/tez`. |
  
  If you have set the `tez.lib.uris` property in the properties table, this directory overrides the value of that property at runtime. But the other properties set in the properties table are still effective. |

- **Use exist:** the Job accesses the Tez libraries already deployed in the Hadoop cluster to be used. You need to enter the path pointing to those libraries in the **Lib path (folder or file)** field. |

- **Lib jar:** this table appears when you have selected **Auto install** from the **Tez lib** list and the distribution you are using is **Custom**. In this table, you need to add the Tez libraries to be uploaded. |

<table>
<thead>
<tr>
<th><strong>Hadoop Properties</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Talend Studio uses a default configuration for its engine to perform operations in a Hadoop distribution. If you need to use a custom configuration in a specific situation, complete this table with the property or</td>
</tr>
</tbody>
</table>
Then at runtime, the customized property or properties will override those default ones.

- Note that if you are using the centrally stored metadata from the **Repository**, this table automatically inherits the properties defined in that metadata and becomes uneditable unless you change the **Property type** from **Repository** to **Built-in**.

For further information about the properties required by Hadoop and its related systems such as HDFS and Hive, see the documentation of the Hadoop distribution you are using or see Apache’s Hadoop documentation on [http://hadoop.apache.org/docs](http://hadoop.apache.org/docs) and then select the version of the documentation you want. For demonstration purposes, the links to some properties are listed below:

- Typically, the HDFS-related properties can be found in the `hdfs-default.xml` file of your distribution, such as [http://hadoop.apache.org/docs/r2.6.0/hadoop-project-dist/hadoop-hdfs/hdfs-default.xml](http://hadoop.apache.org/docs/r2.6.0/hadoop-project-dist/hadoop-hdfs/hdfs-default.xml).

- Apache also provides a page to list the Hive-related properties: [https://cwiki.apache.org/confluence/display/Hive/Configuration+Properties](https://cwiki.apache.org/confluence/display/Hive/Configuration+Properties).

### Register jar
Click the `[+]` button to add rows to the table and from these rows, browse to the jar files to be added. For example, in order to register a jar file called `piggybank.jar`, click the `[+]` button once to add one row, then click this row to display the `[...]` browse button, and click this button to browse to the `piggybank.jar` file following the [Select Module] wizard.

### Define functions
Use this table to define UDFs (User-Defined Functions), especially those requiring alias such as Apache DataFu Pig functions, to be executed when loading data.

Click the `[+]` button to add as many rows as you need and specify an alias and a UDF in the relevant fields for each row.

If your Job includes a **tPigMap** component, once you have defined UDFs for this component in the **tPigMap**, this table is automatically filled. Likewise, once you have defined UDFs in this table, the **Define functions** table in the **tPigMap** component’s Map Editor is automatically filled.

For information on how to define UDFs when mapping Pig flows, see the section on mapping Big Data flows of the *Talend Open Studio for Big Data Getting Started Guide*.

For more information on Apache DataFu Pig, see [http://datafu.incubator.apache.org/](http://datafu.incubator.apache.org/).

### Pig properties
*Talend Studio* uses a default configuration for its Pig engine to perform operations. If you need to use a custom configuration in a specific situation, complete this table with the property or properties to be
customized. Then at runtime, the customized property or properties will override those default ones.

For example, the `default_parallel` key used in Pig could be set as 20.

### HBaseStorage configuration

Add and set more HBaseStorage loader options in this table. The options are:

- **gt**: the minimum key value;
- **lt**: the maximum key value;
- **gte**: the minimum key value (included);
- **lte**: the maximum key value (included);
- **limit**: maximum number of rows to retrieve per region;
- **caching**: number of rows to cache;
- **caster**: the converter to use for reading values out of HBase. For example, HBaseBinaryConverter.

### Define the jars to register for HCatalog

This check box appears when you are using `tHCatLoader`, while you can leave it clear as the Studio registers the required jar files automatically. In case any jar file is missing, you can select this check box to display the `Register jar for HCatalog` table and set the correct path to that missing jar.

### Path separator in server

Leave the default value of the `Path separator in server` as it is, unless you have changed the separator used by your Hadoop distribution's host machine for its PATH variable or in other words, that separator is not a colon (:). In that situation, you must change this value to the one you are using in that host.

### Mapred job map memory mb and Mapred job reduce memory mb

You can tune the map and reduce computations by selecting the `Set memory` check box to set proper memory allocations for the computations to be performed by the Hadoop system.

In that situation, you need to enter the values you need in the `Mapred job map memory mb` and the `Mapred job reduce memory mb` fields, respectively. By default, the values are both 1000 which are normally appropriate for running the computations.

The memory parameters to be set are **Map (in Mb)**, **Reduce (inMb)** and **ApplicationMaster (in Mb)**. These fields allow you to dynamically allocate memory to the map and the reduce computations and the ApplicationMaster of YARN.

### tStatCatcher Statistics

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an **After**
variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

| Usage rule | This component is always used to start a Pig process and needs **tPigStoreResult** at the end to output its data. In the **Map/Reduce** mode, you need only configure the Hadoop connection for the first **tPigLoad** component of a Pig process (a subjob), and any other **tPigLoad** component used in this process reuses automatically that connection created by that first **tPigLoad** component. |

### Prerequisites

<table>
<thead>
<tr>
<th>Prerequisites</th>
<th>The Hadoop distribution must be properly installed, so as to guarantee the interaction with <em>Talend Studio</em>. The following list presents MapR related information for example.</th>
</tr>
</thead>
</table>
| • Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under `MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native`. For example, the library for Windows is `\lib\native\MapRClient.dll` in the MapR client jar file. For further information, see the following link from MapR: [http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr](http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr).

Without adding the specified library or libraries, you may encounter the following error: `no MapRClient in java.library.path`. |
| • Set the `-Djava.library.path` argument, for example, in the **Job Run VM arguments** area of the **Run/Debug** view in the **[Preferences]** dialog box in the **Window** menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the **Data viewer** to view locally in the Studio the data stored in MapR. |

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using. |
Limitation

Knowledge of Pig scripts is required. If you select HCatLoader as the load function, knowledge of HCatalog DDL (HCatalog Data Definition Language, a subset of Hive Data Definition Language) is required. For further information about HCatalog DDL, see https://cwiki.apache.org/confluence/display/Hive/HCatalog.

Scenario: Loading an HBase table

This scenario applies only to a Talend solution with Big Data.

This scenario uses **tPigLoad** and **tPigStoreResult** to read data from HBase and to write them to HDFS.

```
thbasestorage
```

The HBase table to be used has three columns: **id**, **name** and **age**, among which **id** and **age** belong to the column family, **family1** and **name** to the column family, **family2**.

The data stored in that HBase table are as follows:

```
1;Albert;23
2;Alexandre;24
3;Alfred-Hubert;22
4;Andre;40
5;Didier;28
6;Anthony;35
7;Artus;32
8;Catherine;34
9;Charles;21
10;Christophe;36
11;Christian;67
12;Danniel;54
13;Elisabeth;58
14;Emile;32
15;Gregory;30
```

To replicate this scenario, perform the following operations:

**Linking the components**

**Procedure**

1. In the **Integration** perspective of **Talend Studio**, create an empty Job, named **hbase_storage** for example, from the **Job Designs** node in the **Repository** tree view.
   
   For further information about how to create a Job, see the **Talend Studio User Guide**.

2. Drop **tPigLoad** and **tPigStoreResult** onto the workspace.

3. Connect them using the **Row > Pig combine** link.
Configuring tPigLoad

Procedure

1. Double-click **tPigLoad** to open its **Component** view.

2. Click the button next to **Edit schema** to open the schema editor.

3. Click the button four times to add four rows and rename them: *rowkey*, *id*, *name* and *age*. The *rowkey* column put at the top of the schema to store the HBase row key column, but in practice, if you do not need to load the row key column, you can create only the other three columns in your schema.
4. Click OK to validate these changes and accept the propagation prompted by the pop-up dialog box.
5. In the Mode area, select Map/Reduce, as we are using a remote Hadoop distribution.
6. In the Distribution and the Version fields, select the Hadoop distribution you are using. In this example, we are using HortonWorks Data Platform V1.
7. In the Load function field, select HBaseStorage. Then, the corresponding parameters to set appear.
8. In the NameNode URI and the Resource Manager fields, enter the locations of those services, respectively. If you are using WebHDFS, the location should be webhdfs://masternode:portnumber; if this WebHDFS is secured with SSL, the scheme should be swebhdfs and you need to use a tLibraryLoad in the Job to load the library required by the secured WebHDFS.
9. In the Zookeeper quorum and the Zookeeper client port fields, enter the location information of the Zookeeper service to be used.
10. If the Zookeeper znode parent location has been defined in the Hadoop cluster you are connecting to, you need to select the Set zookeeper znode parent check box and enter the value of this property in the field that is displayed.
11. In the Table name field, enter the name of the table from which tPigLoad reads the data.
12. Select the Load key check box if you need to load the HBase row key column. In this example, we select it.
13. In the Mapping table, four rows have been added automatically. In the Column family:qualifier column, enter the HBase columns you need to map with the schema columns you defined. In this scenario, we put family1:id for the id column, family2:name for the name column and family1:age for the age column.

Configuring tPigStoreResult

Procedure
1. Double-click tPigStoreResult to open its Component view.
2. In the **Result file** field, enter the directory where you need to store the result. As **tPigStoreResult** reuses automatically the connection created by **tPigLoad**, the path in this scenario is the directory in the machine hosting the Hadoop distribution to be used.

3. Select **Remove result directory if exists**.

4. In the **Store function** field, select **PigStorage** to store the result in the UTF-8 format.

### Executing the Job

Then you can press **F6** run this Job.

Once done, you can verify the result in the HDFS system used.

If you need to obtain more details about the Job, it is recommended to use the web console of the Jobtracker provided by the Hadoop distribution you are using.

In JobHistory, you can easily find the execution status of your Pig Job because the name of the Job is automatically created by concatenating the name of the project that contains the Job, the name and version of the Job itself and the label of the first **tPigLoad** component used in it. The naming convention of a Pig Job in JobHistory is `ProjectName_JobNameVersion_FirstComponentName`. 
tPigMap

Transforms and routes data from single or multiple sources to single or multiple destinations.

The tPigMap transforms and routes the data in a Pig process. It provides a graphic interface that enables sophisticated configuration of multiple data flows.

Optional map settings

On the input side:

<table>
<thead>
<tr>
<th>Lookup properties</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Join Model</td>
<td>Inner Join;</td>
</tr>
<tr>
<td></td>
<td>Left Outer Join;</td>
</tr>
<tr>
<td></td>
<td>Right Outer Join;</td>
</tr>
<tr>
<td></td>
<td>Full Outer Join.</td>
</tr>
<tr>
<td></td>
<td>The default join option is <strong>Left Outer Join</strong> when you do not activate this option settings panel by displaying it. These options perform the join of two or more flows based on common field values. When more than one lookup tables need joining, the main input flow starts the joining from the first lookup flow, then uses the result to join the second and so on in the same manner until the last lookup flow is joined.</td>
</tr>
<tr>
<td>Join Optimization</td>
<td>None;</td>
</tr>
<tr>
<td></td>
<td>Replicated;</td>
</tr>
<tr>
<td></td>
<td>Skewed;</td>
</tr>
<tr>
<td></td>
<td>Merge.</td>
</tr>
<tr>
<td></td>
<td>The default join option is <strong>None</strong> when you do not activate this option settings panel by displaying it. These options are used to perform more efficient join operations. For example, if you are using the parallelism of multiple reduce tasks, the <strong>Skewed</strong> join can be used to counteract the load imbalance problem if the data to be processed is sufficiently skewed. Each of these options is subject to the constraints explained in Apache’s documentation about Pig Latin.</td>
</tr>
<tr>
<td>Custom Partitioner</td>
<td>Enter the Hadoop partitioner you need to use to control the partitioning of the keys of the intermediate map-outputs. For example, enter, in double quotation marks, org.apache.pig.test.utils.SimpleCustomPartitioner to use the partitioner SimpleCustomPartitioner. For further information about the code of this SimpleCustomPartitioner, see Apache’s documentation about Pig Latin. The jar file of this partitioner must have been registered in the Register jar table in the Advanced settings view of the tPigLoad component linked with the tPigMap component to be used.</td>
</tr>
</tbody>
</table>
### Lookup properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Increase Parallelism</td>
<td>Enter the number of reduce tasks. For further information about the parallel features, see Apache’s documentation about Pig Latin.</td>
</tr>
</tbody>
</table>

On the output side:

### Output properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Catch Output Reject</td>
<td>True; False. This option, once activated, allows you to catch the records rejected by a filter you can define in the appropriate area.</td>
</tr>
<tr>
<td>Catch Lookup Inner Join Reject</td>
<td>True; False. This option, once activated, allows you to catch the records rejected by the inner join operation performed on the input flows.</td>
</tr>
</tbody>
</table>

### tPigMap Standard properties

These properties are used to configure tPigMap running in the Standard Job framework.

The Standard tPigMap component belongs to the Big Data and the Processing families.

The component in this framework is available when you are using one of the Talend solutions with Big Data.

#### Basic settings

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
</table>
| Mapping links display as | **Auto**: the default setting is curves links  
**Curves**: the mapping display as curves  
**Lines**: the mapping displays as straight lines. This last option allows to slightly enhance performance. |
| Map editor | It allows you to define the tPigMap routing and transformation properties. |

#### Advanced settings

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tStatCatcher Statistics</td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

#### Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERROR_MESSAGE</td>
<td>The error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions</td>
</tr>
</tbody>
</table>
only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>Possible uses are from a simple reorganization of fields to the most complex Jobs of data multiplexing or demultiplexing transformation, concatenation, inversion, filtering/splitting and more, in a Pig process.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limitation</td>
<td>The use of <strong>tPigMap</strong> supposes minimum Java and Pig Latin knowledge in order to fully exploit its functionalities. This component is a junction step, and for this reason cannot be a start nor end component in the Job.</td>
</tr>
</tbody>
</table>

### Scenario: Joining data about road conditions in a Pig process

This scenario applies only to a Talend solution with Big Data.

The Job in this scenario uses two **tPigLoad** components to read data about the traffic conditions and the related events on given roads from a given Hadoop distribution, joins and filters the data using **tPigMap**, and writes the results into that Hadoop distribution using two **tPigStoreResult**.
The Hadoop distribution to be used is keeping the data about traffic situation such as normal or jam and the data about the traffic-related events such as road work, rain and even no event. In this example, the data to be used reads as follows:

1. The traffic situation data stored in the directory `/user/ychen/tpigmap/date&traffic`:

   2013-01-11 00:27:53;Bayshore Freeway;jam
   2013-02-28 07:01:18;Carpinteria Avenue;jam
   2013-01-26 11:27:59;Bayshore Freeway:normal
   2013-03-07 20:48:51;South Highway;jam
   2013-02-07 07:40:10;Lindbergh Blvd;normal
   2013-01-22 17:13:55;Pacific Hwy S;normal
   2013-03-17 23:12:26;Carpinteria Avenue;normal
   2013-01-15 08:06:53;San Diego Freeway;jam
   2013-03-19 15:18:28;Monroe Street;jam
   2013-01-20 05:53:12;Newbury Road;normal

2. The event data stored in the directory `/user/ychen/tpigmap/date&event`:

   2013-01-11 00:27:53;Bayshore Freeway;road work
   2013-02-28 07:01:18;Carpinteria Avenue;rain
   2013-01-26 11:27:59;Bayshore Freeway;road work
   2013-03-07 20:48:51;South Highway;no event
   2013-02-07 07:40:10;Lindbergh Blvd;second-hand market
   2013-01-22 17:13:55;Pacific Hwy S;no event
   2013-03-17 23:12:26;Carpinteria Avenue;no event
   2013-01-15 08:06:53;San Diego Freeway;second-hand market
   2013-03-19 15:18:28;Monroe Street;road work
   2013-01-20 05:53:12;Newbury Road;no event

For any given moment shown in the timestamps in the data, one row is logged to reflect the traffic situation and another row to reflect the traffic-related event. You need to join the data into one table in order to easily detect how the events on a given road are impacting the traffic.

**Note:**

The data used in this example is a sample with limited size.
To replicate this scenario, ensure that the Studio to be used has the appropriate right to read and write data in that Hadoop distribution and then proceed as follows:

**Linking the components**

**Procedure**

1. In the **Integration** perspective of **Talend Studio**, create an empty Job, named **pigweather** for example, from the **Job Designs** node in the **Repository** tree view.
   For further information about how to create a Job, see the **Talend Studio User Guide**.

2. Drop two **tPigLoad** components, **tPigMap** and two **tPigStoreResult** onto the workspace.
   The components can be labelled if needed be. In this scenario, we label the two **tPigLoad** components as **traffic** and **event**, respectively, which load accordingly the traffic data and the related event data. Then we label the two **tPigStoreResult** components as **normal** and **jam**, respectively, which write accordingly the results to the Hadoop distribution to be used. For further information about how to label a component, see the **Talend Studio User Guide**.

3. Right-click the **tPigLoad** component labeled **traffic** to connect it to **tPigMap** using the **Row > Pig combine** link from the contextual menu.

4. Repeat this operation to link the **tPigLoad** component labeled **event** to **tPigMap**, too. As this is the second link created, it becomes automatically the lookup link.

5. Use the **Row > Pig combine** link again to connect **tPigMap** to each of the two **tPigStoreResult** components.
   You need to name these links in the dialog box popped up once you select the link type from the contextual menu. In this scenario, we name the link to **tPigStoreResult** labeled **normal** as **out** and the link to **tPigStoreResult** labeled **jam** as **reject**.

**Configuring tPigLoad**

*Loading the traffic data*

**Procedure**

1. Double-click the **tPigLoad** labeled **traffic** to open its **Component** view.
2. Click the button next to **Edit schema** to open the schema editor.

3. Click the button three times to add three rows and in the **Column** column, rename them as **date**, **street** and **traffic**, respectively.

4. Click **OK** to validate these changes.

5. In the **Mode** area, select the **Map/Reduce** option, as we need the Studio to connect to a remote Hadoop distribution.

6. In the **Distribution** list and the **Version** field, select the Hadoop distribution to be used. In this example, it is **Hortonworks Data Platform V1.0.0**.
7. In the **Load function** list, select the **PigStorage** function to read the source data, as the data is a structured file in human-readable UTF-8 format.

8. In the **NameNode URI** and the **Resource Manager** fields, enter the locations of the master node and the Resource Manager of the Hadoop distribution to be used, respectively. If you are using WebHDFS, the location should be webhdfs://masternode:portnumber; if this WebHDFS is secured with SSL, the scheme should be swebhdfs and you need to use a tLibraryLoad in the Job to load the library required by the secured WebHDFS.

9. In the **Input file URI** field, enter the directory where the data about the traffic situation is stored. As explained earlier, the directory in this example is `/user/ychen/tpigmap/date&traffic`.

10. In the **Field separator** field, enter `;` depending on the separator used by the source data.

**Loading the event data**

**Procedure**

1. Double-click the **tPigLoad** labeled **event** to open its **Component** view.

   ![Component view](image)

2. Click the ![button](image) button next to **Edit schema** to open the schema editor.

3. Click the ![button](image) button three times to add three rows and in the **Column** column, rename them as **date**, **street** and **event**, respectively.
4. Click OK to validate these changes.
5. In the Mode area, select Map/Reduce.
   As you have configured the connection to the given Hadoop distribution in that first tPigLoad
   component, traffic, this event component reuses that connection and therefore, the corresponding
   options in the Distribution and the Version lists have been automatically selected.
6. In the Load function field, select the PigStorage function to read the source data.
7. In the Input file URI field, enter the directory where the event data is stored. As explained earlier,
   the directory in this example is "/user/ychen/tpigmap/date&event".

Configuring tPigMap

1. Double-click tPigMap to open its Map Editor view.

Creating the output schema

Procedure

1. On the input side (left side) of the Map Editor, each of the two tables represents one of the input fl
ow, the upper one for the main flow and the lower one for the lookup flow.
   On the output side (right side), the two tables represent the output flows that you named as out1
   and reject earlier.
   From the main flow table, drop its three columns onto each of the output flow table.
2. From the lookup flow, drop the event column onto each of the output flow table.
   Then from the Schema editor view, you can see the schemas of the both sides have been
   completed and as well, click each table to display its schema in this view.

Setting the mapping conditions

Procedure

1. On the lookup flow table, click the button to open the setting panel in this table.
2. In the **Join Model** row, select **Left Outer Join** to ensure that every record of the main flow is included in this join.

3. On the **out1** output flow table, click the **button** to display the editing field for the filter expression.

4. Enter `'normal'== row1.traffic`
   This allows **tPigMap** to output only the traffic records reading *normal* in the **out1** flow.

5. On the **reject** output flow table, click the **button** to open the setting panel.

6. In the **Catch Output Reject** row, select **true** to output the traffic records reading *jam* in the **reject** flow.

7. Click **Apply**, then click **OK** to validate these changes and accept the propagation prompted by the pop-up dialog box.

### Configuring tPigStoreResult

**Procedure**

1. Double-click the **tPigStoreResult** labeled **normal** to open its **Component** view.

   ![Component view](image)

   2. In the **Result file** field, enter the directory you need to write the result in. In this scenario, it is `/user/ychen/tpigmap/traffic_normal`, which receives the records reading *normal*.

   3. Select **Remove result directory if exists** check box.

   4. In the **Store function** list, select **PigStorage** to write the records in human-readable UTF-8 format.

   5. In the **Field separator** field, enter `;`

   6. Repeat the same operations to configure the **tPigStoreResult** labeled **jam**, but set the directory, in the **Result file** field, as `/user/ychen/tpigmap/traffic_jam`.

**Results**

**Note:**

If either of the components does not retrieve its schema from **tPigMap**, a warning icon appears. In this case, click the **Sync columns** button to retrieve the schema from the preceding one and once done, the warning icon disappears.

### Executing the Job

Then you can press **F6** to run this Job.

Once done, verify the results in the Hadoop distribution used.
From the traffic_jam records, you can analyze what event is often going on in the meantime of a traffic jam and from the traffic_normal records, how the smooth traffic situation is maintained.

If you need to obtain more details about the Job, it is recommended to use the web console of the Jobtracker provided by the Hadoop distribution you are using.

In JobHistory, you can easily find the execution status of your Pig Job because the name of the Job is automatically created by concatenating the name of the project that contains the Job, the name and version of the Job itself and the label of the first tPigLoad component used in it. The naming convention of a Pig Job in JobHistory is ProjectName_JobNameVersion_FirstComponentName.
**tPigReplicate**

Performs different operations on the same schema.

The tPigReplicate, used after an input Pig component, duplicates the incoming schema into as many identical output flows as needed.

**tPigReplicate Standard properties**

These properties are used to configure tPigReplicate running in the Standard Job framework.

The Standard tPigReplicate component belongs to the Big Data and the Processing families.

The component in this framework is available when you are using one of the **Talend** solutions with Big Data.

**Basic settings**

| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word *line* when naming the fields. Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
  • **View schema**: choose this option to view the schema only.  
  • **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
  • **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.  
  Click **Sync columns** to retrieve the schema from the previous component connected in the Job. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-In</strong>: You create and store the schema locally for this component only. Related topic: see <strong>Talend Studio User Guide</strong>.</td>
<td></td>
</tr>
<tr>
<td><strong>Repository</strong>: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see <strong>Talend Studio User Guide</strong>.</td>
<td></td>
</tr>
</tbody>
</table>
### Advanced settings

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
<th>Select this check box to gather the Job processing metadata at the Job level as well as at each component level.</th>
</tr>
</thead>
</table>

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide.</th>
</tr>
</thead>
</table>

### Usage

**Usage rule**

This component is not startable (green background); it requires tPigLoad as the input component and expects other Pig components to handle its output flow(s).

**Prerequisites**

The Hadoop distribution must be properly installed, so as to guarantee the interaction with Talend Studio. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR's documentation, the library or libraries of a MapR client corresponding to each OS version can be found under MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native. For example, the library for Windows is \lib\native\MapRClient.dll in the MapR client jar file. For further information, see the following link from MapR: http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr.

Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path.

- Set the -Djava.library.path argument, for example, in the Job Run VM arguments area of the Run/Debug view in the [Preferences] dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to
make full use of the Data viewer to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

| Connections                        | Outgoing links (from this component to another):
|                                  | **Row**: Pig combine. This link joins all data processes designed in the Job and executes them simultaneously.
|                                  | Incoming links (from one component to this one):
|                                  | **Row**: Pig combine.
|                                  | For further information regarding connections, see Talend Studio User Guide.

**Scenario: Replicating a flow and sorting two identical flows respectively**

This scenario applies only to a Talend solution with Big Data. The Job in this scenario uses Pig components to handle names and states loaded from a given HDFS system. It reads and replicates the input flow, then sorts the two identical flows based on name and state respectively, and writes the results back into that HDFS.

Before starting to replicate this Job, ensure that you have the appropriate right to read and write data in the Hadoop distribution to be used and that Pig is properly installed in that distribution.

**Linking the components**

**Procedure**

1. In the Integration perspective of Talend Studio, create an empty Job, named Replicate for example, from the Job Designs node in the Repository tree view.

   For further information about how to create a Job, see the Talend Studio User Guide.

2. Drop tPigLoad, tPigReplicate, two tPigSort and two tPigStoreResult onto the workspace.
The **tPigLoad** component reads data from the given HDFS system. The sample data used in this scenario reads as follows:

Andrew Kennedy;Mississippi  
Benjamin Carter;Louisiana  
Benjamin Monroe;West Virginia  
Bill Harrison;Tennessee  
Calvin Grant;Virginia  
Chester Harrison;Rhode Island  
Chester Hoover;Kansas  
Chester Kennedy;Maryland  
Chester Polk;Indiana  
Dwight Nixon;Nevada  
Dwight Roosevelt;Mississippi  
Franklin Grant;Nebraska

The location of the data in this scenario is `/user/ychen/raw/Name&State.csv`.

3. Connect them using the **Row > Pig combine** links.

### Configuring tPigLoad

**Procedure**

1. Double-click **tPigLoad** to open its **Component** view.

![Component view](image)

2. Click the button next to **Edit schema** to open the schema editor.
3. Click the button twice to add two rows and name them Name and State, respectively.

4. Click OK to validate these changes and accept the propagation prompted by the pop-up dialog box.

5. In the Mode area, select Map/Reduce because the Hadoop to be used in this scenario is installed in a remote machine. Once selecting it, the parameters to be set appear.

6. In the Distribution and the Version lists, select the Hadoop distribution to be used.

7. In the Load function list, select PigStorage.

8. In the NameNode URI field and the Resource Manager field, enter the locations of the NameNode and the Resource Manager to be used for Map/Reduce, respectively. If you are using WebHDFS, the location should be webhdfs://masternode:portnumber; if this WebHDFS is secured with SSL, the scheme should be swebhdfs and you need to use a tLibraryLoad in the Job to load the library required by the secured WebHDFS.

9. In the Input file URI field, enter the location of the data to be read from HDFS. In this example, the location is /user/ychen/raw/NameState.csv.

10. In the Field separator field, enter the semicolon ;.

**Configuring tPigReplicate**

**Procedure**

1. Double-click tPigReplicate to open its Component view.

2. Click the button next to Edit schema to open the schema editor to verify whether its schema is identical with that of its preceding component.
Note:
If this component does not have the same schema of the preceding component, a warning icon appears. In this case, click the **Sync columns** button to retrieve the schema from the preceding one and once done, the warning icon disappears.

**Configuring tPigSort**

**About this task**

Two **tPigSort** components are used to sort the two identical output flows: one based on the *Name* column and the other on the *State* column.

**Procedure**

1. Double-click the first **tPigSort** component to open its **Component** view to define the sorting by name.

2. In the **Sort key** table, add one row by clicking the **+** button under this table.

3. In the **Column** column, select *Name* from the drop-down list and select **ASC** in the **Order** column.

4. Double-click the other **tPigSort** to open its **Component** view to define the sorting by state.
5. In the Sort key table, add one row, then select Name from the drop-down list in the Column column and select ASC in the Order column.

Configuring tPigStoreResult

About this task

Two tPigStoreResult components are used to write each of the sorted data into HDFS.

Procedure

1. Double-click either the first tPigStoreResult component to open its Component view to write the data sorted by name.

2. In the Result file field, enter the directory where the data will be written. This directory will be created if it does not exist. In this scenario, we put /user/ychen/sort/tPigreplicate/byName.csv.

3. Select Remove result directory if exists.

4. In the Store function list, select PigStorage.

5. In the Field separator field, enter the semicolon ;

6. Do the same for the other tPigStoreResult component but set another directory for the data sorted by state. In this scenario, it is /user/ychen/sort/tPigreplicate/byState.csv.
Executing the Job

About this task

Then you can run this Job.

Procedure

Press F6 to run this Job.

Results

Once done, browse to the locations where the results were written in HDFS.

The following image presents the results sorted by name:

File: /user/ychen/sort/tPigreplicate/byName.csv/part-r-00000

The following image presents the results sorted by state:
If you need to obtain more details about the Job, it is recommended to use the web console of the Jobtracker provided by the Hadoop distribution you are using.

In JobHistory, you can easily find the execution status of your Pig Job because the name of the Job is automatically created by concatenating the name of the project that contains the Job, the name and version of the Job itself and the label of the first PigLoad component used in it. The naming convention of a Pig Job in JobHistory is $\text{ProjectName\_JobNameVersion\_FirstComponentName}$. 
tPigSort

Sorts relation based on one or more defined sort keys.

**tPigSort Standard properties**

These properties are used to configure tPigSort running in the Standard Job framework.

The Standard tPigSort component belongs to the Big Data and the Processing families.

The component in this framework is available when you are using one of the Talend solutions with Big Data.

**Basic settings**

| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.
Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:
- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the [Repository Content] window.

| **Built-in**: The schema will be created and stored locally for this component only. Related topic: see Talend Studio User Guide.

| **Repository**: The schema already exists and is stored in the Repository, hence can be reused in various projects and Job designs. Related topic: see Talend Studio User Guide.

| **Sort key** | Click the Add button beneath the Sort key table to add one or more lines to specify column and sorting order for each sort key.

**Advanced settings**

| **Increase parallelism** | Select this check box to set the number of reduce tasks for the MapReduce Jobs |
### tStatCatcher Statistics

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

### Global Variables

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  

For further information about variables, see *Talend Studio User Guide*. |

### Usage

| Usage rule | This component is commonly used as intermediate step together with input component and output component. |

### Prerequisites

| Prerequisites | The Hadoop distribution must be properly installed, so as to guarantee the interaction with *Talend Studio*. The following list presents MapR related information for example.  

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under `MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native`. For example, the library for Windows is `\lib\native\MapRClient.dll` in the MapR client jar file. For further information, see the following link from MapR: [http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr](http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr).  

Without adding the specified library or libraries, you may encounter the following error: `no MapRClient in java.library.path`.  

- Set the `-Djava.library.path` argument, for example, in the **Job Run VM arguments** area of the **Run/Debug** view in the **[Preferences]** dialog box in the **Window** menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the **Data viewer** to view locally in the Studio the data stored in MapR. |
For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

**Limitation**

Knowledge of Pig scripts is required.

### Scenario: Sorting data in ascending order

This scenario applies only to a Talend solution with Big Data.

This scenario describes a three-component Job that sorts rows of data based on one or more sorting conditions and stores the result into a local file.

### Setting up the Job

**Procedure**

1. Drop the following components from the **Palette** to the design workspace: tPigSort, tPigLoad, tPigStoreResult.
2. Connect tPigLoad to tPigFilterRow using a **Row > Pig Combine** connection.
3. Connect tPigFilterRow to tPigStoreResult using a **Row > Pig Combine** connection.

### Loading the data

**Procedure**

1. Double-click **tPigLoad** to open its **Basic settings** view.
2. Click the [...] button next to Edit schema to add columns for tPigLoad.

<table>
<thead>
<tr>
<th>Column</th>
<th>Key</th>
<th>Type</th>
<th>N..</th>
<th>Date P..</th>
<th>Le..</th>
<th>Or..</th>
<th>Pr..</th>
<th>D..</th>
<th>C..</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>✓</td>
<td>String</td>
<td>✓</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Country</td>
<td></td>
<td>String</td>
<td>✓</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Age</td>
<td></td>
<td>Character</td>
<td>✓</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

3. Click the [+] button to add Name, Country and Age and click OK to save the setting.
4. Select Local from the Mode area.
5. Fill in the Input filename field with the full path to the input file.
   In this scenario, the input file is CustomerList that contains rows of names, country names and age.
6. Select PigStorage from the Load function list.
7. Leave rest of the settings as they are.

**Setting the sorting condition**

**Procedure**

1. Double-click tPigSort to open its Basic settings view.
2. Click **Sync columns** to retrieve the schema structure from the preceding component.

3. Click the [+ ] button beneath the **Sort key** table to add a new sort key. Select **Age** from the Column list and select **ASC** from the Order list.

   This sort key will sort the data in **CustomerList** in ascending order based on **Age**.

### Saving the data to a local file

**Procedure**

1. Double-click **tPigStoreResult** to open its **Basic settings** view.

2. Click **Sync columns** to retrieve the schema structure from the preceding component.

3. Select **Remove result directory if exists**.

4. Fill in the **Result file** field with the full path to the result file.

   In this scenario, the result of filter is saved in **Lucky_Customer** file.

5. Select **PigStorage** from the **Store function** list.

6. Leave rest of the settings as they are.

### Executing the Job

Save your Job and press **F6** to run it.
The *Lucky_Customer* file is generated containing the data in ascending order based on *Age*.
tPigStoreResult

Stores the result of your Pig Job into a defined data storage space.

tPigStoreResult Standard properties

These properties are used to configure tPigStoreResult running in the Standard Job framework.

The Standard tPigStoreResult component belongs to the Big Data and the Processing families.

The component in this framework is available when you are using one of the Talend solutions with Big Data.

Basic settings

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Repository or Built-in.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>The Repository option allows you to reuse the connection properties centrally stored under the Hadoop cluster node of the Repository tree. Once selecting it, the button appears, then you can click it to display the list of the stored properties and from that list, select the properties you need to use. Once done, the appropriate parameters are automatically set. Otherwise, if you select Built-in, you need to manually set each of the parameters.</td>
</tr>
</tbody>
</table>

Schema and Edit Schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the [Repository Content] window.

**Built-In**: You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various
**Use S3 endpoint**

Select this check box to write data into a given Amazon S3 bucket folder.

Once this **Use S3 endpoint** check box is selected, you need to enter the following parameters in the fields that appear:

- **S3 bucket name and folder**: enter the bucket name and its folder in which you need to write data. You need to separate the bucket name and the folder name using a slash (/).
- **Access key** and **Secret key**: enter the authentication information required to connect to the Amazon S3 bucket to be used.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

Note that the format of the S3 file is S3N (S3 Native Filesystem).

**Result folder URI**

Select the path to the result file in which data is stored.

**Remove result directory if exists**

Select this check box to remove an existing result directory.

*Note:*

This check box is disabled when you select **HCatStorer** from the **Store function** list.

**Store function**

Select a store function for data to be stored:

- **PigStorage**: Stores data in UTF-8 format.
- **BinStorage**: Stores data in machine-readable format.
- **PigDump**: Stores data as tuples in human-readable UTF-8 format.
- **HCatStorer**: Stores data in HCatalog managed tables using Pig scripts.
- **HBaseStorage**: Stores data in HBase. Then you need to complete the HBase configuration in the **HBase configuration** area displayed.
- **SequenceFileStorage**: Stores data of the SequenceFile formats. Then you need to complete the configuration of the file to be stored in the **Sequence Storage Configuration** area that appears.
- **RCFilePigStorage**: Stores data of the RCFile format.
- **AvroStorage**: Stores Avro files. For further information about AvroStorage, see Apache’s documentation on [https://cwiki.apache.org/confluence/display/PIG/AvroStorage](https://cwiki.apache.org/confluence/display/PIG/AvroStorage).
- **ParquetStorer**: Stores Parquet files. Then from the **Associate tPigLoad component** list, you need...
to select the **tPigLoad** component in which the connection to the MapReduce cluster to be used is defined.

Then from the **Compression** list that appears, select the compression mode you need to use to handle the Parquet file. The default mode is **Uncompressed**.

- **Custom**: Stores data using any user-defined store function. To do this, you need to register, in the **Advanced settings** tab view, the jar file containing the function to be used, and then, in the field displayed next to this **Store function** field, specify that function.

Note that when the file format to be used is **PARQUET**, you might be prompted to find the specific Parquet jar file and install it into the Studio.

- When the connection mode to Hive is **Embedded**, the Job is run in your local machine and calls this jar installed in the Studio.

- When the connection mode to Hive is **Standalone**, the Job is run in the server hosting Hive and this jar file is sent to the HDFS system of the cluster you are connecting to. Therefore, ensure that you have properly defined the NameNode URI in the corresponding field of the **Basic settings** view.

This jar file can be downloaded from Apache's site. You can find more details about how to install external modules in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

### HCatalog Configuration

Fill the following fields to configure HCatalog managed tables on HDFS (Hadoop distributed file system):

**Distribution and Version**:
Select the Hadoop distribution to which you have defined the connection in the **tPigLoad** component, used in the same Pig process of the active **tPigStoreResult**.

If that **tPigLoad** component connects to a custom Hadoop distribution, you must select **Custom** for this **tPigStoreResult** component, too. Then the **Custom jar** table appears, in which, you need to add only the jar files required by the selected **Store function**.

**HCat metastore**: Enter the location of the HCatalog’s metastore, which is actually Hive’s metastore.

**Database**: The database in which tables are placed.

**Table**: The table in which data is stored.

**Partition filter**: Fill this field with the partition keys to list partitions by filter.

**Note**: **HCataLog Configuration area** is enabled only when you select **HCatStorer** from the **Store function** list. For further information about the usage of HCatalog, see [https://cwiki.apache.org/confluence/display/Hive/HCatalog](https://cwiki.apache.org/confluence/display/Hive/HCatalog). For further information about the
**HBase configuration**

This area is available to the HBaseStorage function. The parameters to be set are:

**Distribution and Version:**
Select the Hadoop distribution to which you have defined the connection in the **tPigLoad** component, used in the same Pig process of the active **tPigStoreResult**.

If that **tPigLoad** component connects to a custom Hadoop distribution, you must select **Custom** for this **tPigStoreResult** component, too. Then the **Custom jar table** appears, in which you need to add only the jar files required by the selected **Store function**.

**Zookeeper quorum:**
Type in the name or the URL of the Zookeeper service you use to coordinate the transaction between your Studio and your database. Note that when you configure the Zookeeper, you might need to explicitly set the `zookeeper.znode.parent` property to define the path to the root znode that contains all the znodes created and used by your database; then select the **Set Zookeeper znode parent** check box to define this property.

**Zookeeper client port:**
Type in the number of the client listening port of the Zookeeper service you are using.

**Table name:**
Enter the name of the HBase table you need to store data in. The table must exist in the target HBase.

**Row key column:**
Select the column used as the row key column of the HBase table.

**Store row key column to Hbase column:**
Select this check box to make the row key column an HBase column belonging to a specific column family.

**Mapping:**
Complete this table to map the columns of the table to be used with the schema columns you have defined for the data flow to be processed.

The **Column** column of this table is automatically filled once you have defined the schema; in the **Family name** column, enter the column families you want to create or use to group the columns in the **Column** column. For further information about a column family, see Apache documentation at Column families.

**Field separator:**
Enter character, string or regular expression to separate fields for the transferred data.

**Note:**

This field is enabled only when you select PigStorage from the Store function list.

### Sequence Storage configuration
This area is available only to the SequenceFileStorage function. Since a SequenceFile record consists of binary key/value pairs, the parameters to be set are:

- **Key column**: Select the Key column of a key/value record.
- **Value column**: Select the Value column of a key/value record.

### Advanced settings

#### Register jar
Click the [+] button to add rows to the table and from these rows, browse to the jar files to be added. For example, in order to register a jar file called piggybank.jar, click the [+] button once to add one row, then click this row to display the [...] browse button, and click this button to browse to the piggybank.jar file following the [Select Module] wizard.

#### HBaseStorage configuration
Add and set more HBaseStorage storer options in this table. The options are:

- **loadKey**: enter true to store the row key as the first column of the result schema, otherwise, enter false;
- **gt**: the minimum key value;
- **lt**: the maximum key value;
- **gte**: the minimum key value (included);
- **lte**: the maximum key value (included);
- **limit**: maxum number of rows to retrieve per region;
- **caching**: number of rows to cache;
- **caster**: the converter to use for writing values to HBase. For example, Utf8StorageConverter.

#### Define the jars to register
This check box appears when you are using tHCatStorer, while by default, you can leave it clear as the Studio registers the required jar files automatically. In case any jar file is missing, you can select this check box to display the Register jar for HCatalog table and set the correct path to that missing jar.

#### tStatCatcher Statistics
Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions
only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
</tr>
</thead>
<tbody>
<tr>
<td>This component is always used to end a Pig process and needs <strong>tPigLoad</strong> at the beginning of that chain to provide data. This component reuses automatically the connection created by the <strong>tPigLoad</strong> component in that Pig process. Note that if you use <em>Hortonworks Data Platform V2.0.0</em>, the type of the operating system for running the distribution and a <em>Talend</em> Job must be the same, such as Windows or Linux. Otherwise, you have to use <em>Talend</em> Jobserver to execute the Job in the same type of operating system in which the <em>Hortonworks Data Platform V2.0.0</em> distribution you are using is run.</td>
</tr>
</tbody>
</table>

### Prerequisites

<table>
<thead>
<tr>
<th>Prerequisites</th>
</tr>
</thead>
<tbody>
<tr>
<td>The Hadoop distribution must be properly installed, so as to guarantee the interaction with <em>Talend Studio</em>. The following list presents MapR related information for example.</td>
</tr>
<tr>
<td>- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under <code>MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native</code>. For example, the library for Windows is <code>\lib\native\MapRClient.dll</code> in the MapR client jar file. For further information, see the following link from MapR: <a href="http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr">http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr</a>. Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path.</td>
</tr>
<tr>
<td>- Set the <code>-Djava.library.path</code> argument, for example, in the <strong>Job Run VM arguments</strong> area of the <strong>Run/Debug</strong> view in the <strong>[Preferences]</strong> dialog box in the <strong>Window</strong> menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the <strong>Data viewer</strong> to view locally in the Studio the data stored in MapR.</td>
</tr>
</tbody>
</table>
For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

| Limitation | Knowledge of Pig scripts is required. If you select **HCatStorer** as the store function, knowledge of HCatLog DDL (HCatLog Data Definition Language, a subset of Hive Data Definition Language) is required. For further information about HCatLog DDL, see [https://cwiki.apache.org/confluence/display/Hive/HCatalog](https://cwiki.apache.org/confluence/display/Hive/HCatalog). |

### Related Scenario

- Related scenario in which **tPigStoreResult** uses the **Local** mode, see *Scenario: Sorting data in ascending order* on page 3003 of **tPigSort**.
- Related scenario in which **tPigStoreResult** uses the **Map/Reduce** mode, see *Scenario: Loading an HBase table* on page 2978.
tPivotToColumnsDelimited

Fine-tunes the selection of data to output.

The tPivotToColumnsDelimited outputs data based on an aggregation operation carried out on a pivot column.

**tPivotToColumnsDelimited Standard properties**

These properties are used to configure tPivotToColumnsDelimited running in the Standard Job framework.

The Standard tPivotToColumnsDelimited component belongs to the File family.

The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Pivot column</strong></td>
<td>Select the column from the incoming flow that will be used as pivot for the aggregation operation.</td>
</tr>
<tr>
<td><strong>Aggregation column</strong></td>
<td>Select the column from the incoming flow that contains the data to be aggregated.</td>
</tr>
<tr>
<td><strong>Aggregation function</strong></td>
<td>Select the function to be used in case several values are available for the pivot column.</td>
</tr>
<tr>
<td><strong>Group by</strong></td>
<td>Define the aggregation sets, the values of which will be used for calculations.</td>
</tr>
<tr>
<td><strong>Input Column</strong></td>
<td>Match the input column label with your output columns, in case the output label of the aggregation set needs to be different.</td>
</tr>
<tr>
<td><strong>File Name</strong></td>
<td>Name or path to the file to be processed and/or the variable to be used. For further information about how to define and use a variable in a Job, see <em>Talend Studio User Guide</em>.</td>
</tr>
<tr>
<td><strong>Field separator</strong></td>
<td>Character, string or regular expression to separate fields of the output file.</td>
</tr>
<tr>
<td><strong>Row separator</strong></td>
<td>String (ex: <code>\n</code> on Unix) to distinguish rows in the output file.</td>
</tr>
</tbody>
</table>

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE</strong></td>
<td>the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_OUT</strong></td>
<td>the number of rows written to the file by the component. This is an After variable and it returns an integer.</td>
</tr>
</tbody>
</table>
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component requires an input flow.</th>
</tr>
</thead>
</table>

### Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

### Scenario: Using a pivot column to aggregate data

The following scenario describes a Job that aggregates data from a delimited input file, using a defined pivot column.

**Dropping and linking components**

**Procedure**

1. Drop the following component from the **Palette** to the design workspace: **tFileInputDelimited**, **tPivotToColumnsDelimited**.
2. Link the two components using a **Row > Main** connection.
Configuring the components

Set the input component

Procedure

1. Double-click the `tFileInputDelimited` component to open its Basic settings view.

   - Property Type: Built-In
   - File name/Stream: `D:/Input/pivot/n.csv`
   - Row Separator: ` carriage return`
   - Field Separator: `;`
   - CSV options:
     - Header: 1
     - Footer: 0
     - Limit: 0
   - Schema: Built-In

2. Browse to the input file to fill out the File Name field.
   - The file to use as input file is made of 3 columns, including: ID, Question and the corresponding Answer.

<table>
<thead>
<tr>
<th>Id</th>
<th>Question</th>
<th>Answer</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Name</td>
<td>Juan</td>
</tr>
<tr>
<td>2</td>
<td>Name</td>
<td>Jean</td>
</tr>
<tr>
<td>3</td>
<td>Name</td>
<td>John</td>
</tr>
<tr>
<td>1</td>
<td>Gender</td>
<td>M</td>
</tr>
<tr>
<td>2</td>
<td>Gender</td>
<td>F</td>
</tr>
<tr>
<td>3</td>
<td>Gender</td>
<td>M</td>
</tr>
<tr>
<td>1</td>
<td>Surgery</td>
<td>Yes</td>
</tr>
<tr>
<td>2</td>
<td>Surgery</td>
<td>No</td>
</tr>
<tr>
<td>3</td>
<td>Surgery</td>
<td>Yes</td>
</tr>
<tr>
<td>1</td>
<td>Age</td>
<td>45</td>
</tr>
<tr>
<td>2</td>
<td>Age</td>
<td>23</td>
</tr>
<tr>
<td>3</td>
<td>Age</td>
<td>42</td>
</tr>
<tr>
<td>1</td>
<td>Name</td>
<td>Mary</td>
</tr>
</tbody>
</table>

3. Define the Row and Field separators, in this example, respectively: carriage return and semi-colon.
4. As the file contains a header line, define it also.
5. Set the schema describing the three columns: ID, Questions, Answers.

Set the output component

Procedure

1. Double-click the `tPivotToColumnsDelimited` component to open its Basic settings view.
2. In the **Pivot column** field, select the pivot column from the input schema. This is often the column presenting most duplicates (pivot aggregation values).

3. In the **Aggregation column** field, select the column from the input schema that should get aggregated.

4. In the **Aggregation function** field, select the function to be used in case duplicates are found out.

5. In the **Group by** table, add an Input column, that will be used to group by the aggregation column.

6. In the **File Name** field, browse to the output file path. And on the **Row** and **Field separator** fields, set the separators for the aggregated output rows and data.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl+S** to save your Job.

2. Press **F6** or click **Run** on the Run tab to execute the Job.

<table>
<thead>
<tr>
<th>id</th>
<th>Name</th>
<th>Gender</th>
<th>Surgery</th>
<th>Age</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Mary</td>
<td>M</td>
<td>Yes</td>
<td>45</td>
</tr>
<tr>
<td>2</td>
<td>Jean</td>
<td>M</td>
<td>No</td>
<td>23</td>
</tr>
<tr>
<td>3</td>
<td>John</td>
<td>F</td>
<td>Yes</td>
<td>42</td>
</tr>
</tbody>
</table>

The output file shows the newly aggregated data.
tPOP

Fetches one or more email messages from a server using the POP3 or IMAP protocol.
tPOP uses the POP or IMAP protocol to connect to a specific email server. Then it fetches one or more
email messages and writes the recovered information in specified files. Parameters in the Advanced
settings view allows you to use filters on your selection.

**tPOP Standard properties**

These properties are used to configure tPOP running in the Standard Job framework.
The Standard tPOP component belongs to the Internet family.
The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>Host</th>
<th>IP address of the email server you want to connect to.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>Port number of the email server.</td>
</tr>
</tbody>
</table>
| Username and Password | User authentication data for the email server.  
Username: enter the username you use to access your email box.  
Password: enter the password you use to access your email box. |
| Output directory | Enter the path to the file in which you want to store the email messages you retrieve from the email server, or click the three-dot button next to the field to browse to the file. |
| Filename pattern | Define the syntax of the names of the files that will hold each of the email messages retrieved from the email server, or press Ctrl+Space to display the list of predefined patterns. |
| Retrieve all emails? | Select this check box to retrieve all email messages present on the specified server. |
| Number of emails to retrieve | Enter the number of email messages you want to retrieve.  
This field is available only when the Retrieve all emails? check box is cleared. |
| Newer email first | Select this check box to retrieve the most recent email messages according to the number specified in the Number of emails to retrieve field, and the email messages will be returned in chronological order.  
This check box is available only when the Retrieve all emails? check box, which is selected by default, is cleared. |
### Delete emails from server

Select this check box if you do not want to keep the retrieved email messages on the server.

**Note:**
For Gmail servers, this option does not work for the POP3 protocol. Select the IMAP protocol and ensure that the Gmail account is configured to use IMAP.

### Choose the protocol

From the list, select the protocol to be used to retrieve the email messages from the server. This protocol is the one used by the email server. If you choose the IMAP protocol, you will be able to select the folder from which you want to retrieve your emails.

### Use SSL

Select this check box if your email server uses this protocol for authentication and communication confidentiality.

**Note:**
This option is obligatory for users of Gmail.

### Advanced settings

#### tStatCatcher Statistics

Select this check box to gather the job processing metadata at a job level as well as at each component level.

#### Filter

Click the plus button to add as many lines as needed to filter email messages and retrieve only a specific selection:

- **Filter item**: select one of the following filter types from the list:
  - **From**: email messages are filtered according to the sender email address.
  - **To**: email messages are filtered according to the recipient email address.
  - **Subject**: email messages are filtered according to the message subject matter.
  - **Before date**: email messages are filtered by the sending or receiving date. All messages before the set date are retrieved.
  - **After date**: email messages are filtered by the sending or receiving date. All messages after the set date are retrieved.

- **Pattern**: press Ctrl+Space to display the list of available values. Select the value to use for each filter.

#### Filter condition relation

Select the type of logical relation you want to use to combine the specified filters:

- **and**: the conditions set by the filters are combined together, the research is more restrictive.
or: the conditions set by the filters are independent, the research is large.

Global Variables

Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERROR_MESSAGE</td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td>NB_EMAIL</td>
<td>the number of emails received. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>CURRENT_FILE</td>
<td>the current file name. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td>CURRENT_FILEPATH</td>
<td>the current file path. This is a Flow variable and it returns a string.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule

<table>

<td></td>
</tr>
</tbody>
</table>

Limitation

<table>
<thead>
<tr>
<th>Limitation</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>When the Use SSL check box or the imap protocol is selected, tPOP cannot work with IBM Java 6.</td>
<td></td>
</tr>
</tbody>
</table>

Scenario: Retrieving a selection of email messages from an email server

This scenario is a one-component Job that retrieves a predefined number of email messages from an email server.

- Drop the tPOP component from the Palette to the design workspace.
- Double click tPOP to display the Basic settings view and define the component properties.
- Enter the email server IP address and port number in the corresponding fields.
- Enter the username and password for your email account in the corresponding fields. In this example, the email server is called Free.
In the **Output directory** field, enter the path to the output directory manually, or click the three-dot button next to the field and browse to the output directory where the email messages retrieved from the email server are to be stored.

In the **Filename pattern** field, define the syntax you want to use to name the output files that will hold the messages retrieved from the email server, or press **Ctrl+Space** to display a list of predefined patterns. The syntax used in this example is the following: `TalendDate.getDate("yyyyMMdd-hhmmss") + "." + (counter_tPOP_1 + 1) + ".txt"`.

The output files will be stored as .txt files and are defined by date, time and arrival chronological order.

Clear the **Retrieve all emails?** field and in the **Number of emails to retrieve** field, enter the number of email messages you want to retrieve, 10 in this example.

Select the **Delete emails from server** check box to delete the email messages from the email server once they are retrieved and stored locally.

In the **Choose the protocol** field, select the protocol type you want to use. This depends on the protocol used by the email server. Certain email suppliers, like Gmail, use both protocols. In this example, the protocol used is **pop3**.

Save your Job and press **F6** to execute it.
The tPOP component retrieves the 10 recent messages from the specified email server. In the tPOP directory stored locally, a .txt file is created for each retrieved message. Each file holds the metadata of the email message headings (sender’s address, recipient’s address, subject matter) in addition to the message content.
**tPostgresPlusBulkExec**

Improves performance during Insert operations to a DB2 database.

The tPostgresPlusBulkExec executes the Insert action on the data provided.

The tPostgresplusOutputBulk and tPostgresplusBulkExec components are generally used together as part of a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tPostgresPlusOutputBulkExec component, detailed in a separate section. The advantage of using two separate components is that the data can be transformed before it is loaded in the database.

**tPostgresPlusBulkExec Standard properties**

These properties are used to configure tPostgresPlusBulkExec running in the Standard Job framework. The Standard tPostgresPlusBulkExec component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see [Dynamic database components on page 598](#).

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-in</strong>: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined.

**Note:**

When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>DB Version</th>
<th>List of database versions.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>Database server IP address</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database</td>
</tr>
<tr>
<td>Schema</td>
<td>Name of the DB schema.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Table</td>
<td>Name of the table to be written. Note that only one table can be written at a time</td>
</tr>
<tr>
<td>Action on table</td>
<td>On the table defined, you can perform one of the following operations: None: No operation is carried out. Drop and create table: The table is removed and created again. Create table: The table does not exist and gets created. Create table if not exists: The table is created if it does not exist. Drop table if exists and create: The table is removed if it already exists and created again. Clear table: The table content is deleted. Truncate table: The table content is deleted. You do not have the possibility to rollback the operation.</td>
</tr>
<tr>
<td>File Name</td>
<td>Name of the file to be loaded.</td>
</tr>
<tr>
<td>Warning</td>
<td>This file is located on the machine specified by the URI in the Host field so it should be on the same machine as the database server.</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:</td>
</tr>
</tbody>
</table>
- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the [Repository Content] window.

<table>
<thead>
<tr>
<th>Built-In</th>
<th>You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Repository</td>
<td>You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

### Advanced settings

### Related scenarios

No scenario is available for the Standard version of this component yet.
**tPostgresPlusCommit**

Commits in one go a global transaction, using a unique connection, instead of doing that on every row or every batch and thus improves performance.

The tPostgresPlusCommit validates the data processed through the Job into the connected DB.

**tPostgresPlusCommit Standard properties**

These properties are used to configure tPostgresPlusCommit running in the Standard Job framework.

The Standard tPostgresPlusCommit component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tPostgresPlusConnection component in the list if more than one connection are planned for the current Job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Warning:**

*If you want to use a Row > Main connection to link tPostgresPlusCommit to your Job, your data will be committed row by row. In this case, do not select the Close connection check box or your connection will be closed before the end of your first row commit.*

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is more commonly used with other tPostgresPlus" components, especially with the |
Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489.

For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenario

For tPostgresPlusCommit related scenario, see Scenario: Inserting data in mother/daughter tables on page 2476
tPostgresPlusConnection

Opens a connection to the specified database that can then be reused in the subsequent subjob or subjobs.

The tPostgresPlusConnection opens a connection to the database for a current transaction.

**tPostgresPlusConnection Standard properties**

These properties are used to configure tPostgresPlusConnection running in the Standard Job framework.

The Standard tPostgresPlusConnection component belongs to the Databases and the ELT families.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>DB Version</td>
<td>List of database versions.</td>
</tr>
<tr>
<td>Host</td>
<td>Database server IP address</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database</td>
</tr>
<tr>
<td>Schema</td>
<td>Exact name of the schema</td>
</tr>
<tr>
<td>Username and Password</td>
<td>Enter your DB authentication data.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td>Use or register a shared DB Connection</td>
<td>Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the <strong>Shared DB Connection Name</strong> field displayed, enter the name for the shared database</td>
</tr>
</tbody>
</table>
connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child.

This option is incompatible with the Use dynamic job and Use an independent process to run subjob options of the tRunJob component. Using a shared connection together with a tRunJob component with either of these two options enabled will cause your Job to fail.

Advanced settings

**Auto Commit**
Select this check box to commit any changes to the database automatically upon the transaction.

With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component.

Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component.

**tStatCatcher Statistics**
Select this check box to gather the job processing metadata at a Job level as well as at each component level.

Usage

**Usage rule**
This component is more commonly used with other tPostgresPlus* components, especially with the tPostgresPlusCommit and tPostgresPlusRollback components.

Related scenario

For tPostgresPlusConnection related scenario, see tMysqlConnection on page 2475.
tPostgresPlusInput

Executes a DB query with a strictly defined order which must correspond to the schema definition. Then it passes on the field list to the next component via a Main row link.

The tPostgresPlusInput reads a database and extracts fields based on a query.

**tPostgresPlusInput Standard properties**

These properties are used to configure tPostgresPlusInput running in the Standard Job framework.

The component tPostgresPlusInput belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td><strong>Built-in:</strong> No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td><strong>Repository:</strong> Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
<td></td>
</tr>
<tr>
<td>![Database icon]</td>
<td>Click this icon to open a database connection wizard and store the database connection parameters you set in the component Basic settings view.</td>
</tr>
<tr>
<td>![Database icon]</td>
<td>For more information about setting up and storing database connection parameters, see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td>![Database icon]</td>
<td>Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:</td>
</tr>
<tr>
<td>![Database icon]</td>
<td>1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component.</td>
</tr>
</tbody>
</table>
which creates that very database connection.

2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>DB Version</th>
<th>List of database versions.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>Database server IP address.</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database.</td>
</tr>
<tr>
<td>Schema</td>
<td>Exact name of the schema.</td>
</tr>
</tbody>
</table>

**Username and Password**

DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

**Schema and Edit Schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the [Repository Content] window.

**Built-in**: The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide.

**Repository**: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide.

**Table name**

Name of the table to be read.
### Query type and Query

Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.

### Advanced settings

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use cursor</td>
<td>When selected, helps to decide the row set to work with at a time and thus optimize performance.</td>
</tr>
<tr>
<td>Trim all the String/Char columns</td>
<td>Select this check box to remove leading and trailing whitespace from all the String/Char columns.</td>
</tr>
<tr>
<td>Trim column</td>
<td>Remove leading and trailing whitespace from defined columns.</td>
</tr>
<tr>
<td>tStat Catcher Statistics</td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NB_LINE</td>
<td>the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>QUERY</td>
<td>the query statement being processed. This is a Flow variable and it returns a string.</td>
</tr>
</tbody>
</table>

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component covers all possible SQL queries for Postgresql databases.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic settings</td>
<td>Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. Once a dynamic parameter is defin</td>
</tr>
</tbody>
</table>
ed, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenarios

For related scenarios, see:
tPostgresPlusOutput

Executes the action defined on the table and/or on the data contained in the table, based on the flow incoming from the preceding component in the job.

The tPostgresPlusOutput writes, updates, makes changes or suppresses entries in a database.

tPostgresPlusOutput Standard properties

These properties are used to configure tPostgresPlusOutput running in the Standard Job framework.

The Standard tPostgresPlusOutput component belongs to the Databases family.

The component in this framework is generally available.

Note:

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>

<tr>
<td></td>
<td>Drop table if exists and create: The table is removed if already exists and created again.</td>
</tr>
<tr>
<td></td>
<td>Clear table: The table content is deleted.</td>
</tr>
<tr>
<td></td>
<td>Truncate table: The table content is deleted. You don't have the possibility to rollback the operation.</td>
</tr>
<tr>
<td>Action on data</td>
<td>On the data of the table defined, you can perform:</td>
</tr>
<tr>
<td></td>
<td>Insert: Add new entries to the table. If duplicates are found, Job stops.</td>
</tr>
<tr>
<td></td>
<td>Update: Make changes to existing entries</td>
</tr>
<tr>
<td></td>
<td>Insert or update: Insert a new record. If the record with the given reference already exists, an update would be made.</td>
</tr>
</tbody>
</table>
|                  | Update or insert: Update the record with the given reference. If the record does not exist, a new record would be inserted.
Delete: Remove entries corresponding to the input flow.

Warning:

It is necessary to specify at least one column as a primary key on which the Update and Delete operations are based. You can do that by clicking Edit Schema and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the Advanced settings view where you can simultaneously define primary keys for the Update and Delete operations. To do that: Select the Use field options check box and then in the Key in update column, select the check boxes next to the column names you want to use as a base for the Update operation. Do the same in the Key in delete column for the Delete operation.

Schema and Edit Schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the [Repository Content] window.

Built-In: You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.

Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Die on error

This check box is selected by default. Clear the check box to skip the row on error and complete the process.
for error-free rows. If needed, you can retrieve the rows on error via a **Row > Rejects** link.

**Advanced settings**

| **Commit every** | Enter the number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and, above all, better performance at execution. |
| **Additional Columns** | This option is not offered if you create (with or without drop) the DB table. This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing. |

**Name:** Type in the name of the schema column to be altered or inserted as new column

**SQL expression:** Type in the SQL statement to be executed in order to alter or insert the relevant column data.

**Position:** Select **Before**, **Replace** or **After** following the action to be performed on the reference column.

**Reference column:** Type in a column of reference that the **tDBOutput** can use to place or replace the new or altered column.

**Use field options** | Select this check box to customize a request, especially when there is double action on data. |
| **Enable debug mode** | Select this check box to display each step during processing entries in a database. |
| **Support null in “SQL WHERE” statement** | Select this check box if you want to deal with the Null values contained in a DB table. |

**Note:**

Ensure that the Nullable check box is selected for the corresponding columns in the schema.

**Use Batch** | Select this check box to activate the batch mode for data processing. |

**Note:**

This check box is available only when you have selected the **Insert**, the **Update** or the **Delete** option in the **Action on data** field.

**Batch Size** | Specify the number of records to be processed in each batch. |

This field appears only when the **Use batch mode** check box is selected.
### tStat Catcher Statistics

Select this check box to collect log data at the component level.

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_LINE: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>NB_LINE_UPDATED: the number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>NB_LINE_INSERTED: the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>NB_LINE_DELETED: the number of rows deleted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>NB_LINE_REJECTED: the number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>QUERY: the query statement processed. This is an After variable and it returns a string.</td>
</tr>
</tbody>
</table>

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

### Usage

#### Usage rule

This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible.

This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in a PostgresPlus database. It also allows you to create a reject flow using a Row > Rejects link to filter data in error. For an example of tMySqlOutput in use, see Scenario: Retrieving data in error with a Reject link on page 2529.

#### Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defin
ed, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenarios

For tPostgresPlusOutput related topics, see:

- Scenario: Inserting a column and altering data using tMysqlOutput on page 2521.
tPostgresPlusOutputBulk

Prepares the file to be used as parameter in the INSERT query to feed the PostgresPlus database.

The tPostgresPlusOutputBulk writes a file with columns based on the defined delimiter and the PostgresPlus standards.

The tPostgresplusOutputBulk and tPostgresplusBulkExec components are generally used together as part of a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tPostgresPlusOutputBulkExec component, detailed in a separate section. The advantage of using two separate components is that the data can be transformed before it is loaded in the database.

**tPostgresPlusOutputBulk Standard properties**

These properties are used to configure tPostgresPlusOutputBulk running in the Standard Job framework.

The Standard tPostgresPlusOutputBulk component belongs to the Databases family.

The component in this framework is generally available.

ℹ️ **Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td><strong>Property type</strong></td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><strong>File Name</strong></td>
<td>Name of the file to be generated.</td>
</tr>
<tr>
<td><strong>Warning:</strong></td>
<td>This file is generated on the local machine or a shared folder on the LAN.</td>
</tr>
<tr>
<td><strong>Append</strong></td>
<td>Select this check box to add the new rows at the end of the file</td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <strong>line</strong> when naming the fields.</td>
</tr>
</tbody>
</table>
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.

<table>
<thead>
<tr>
<th>Built-In: You create and store the schema locally for this component only. Related topic: see <strong>Talend Studio User Guide.</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see <strong>Talend Studio User Guide.</strong></td>
</tr>
</tbody>
</table>

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

### Advanced settings

| **Row separator** | String (ex: `\n` on Unix) to distinguish rows. |
| **Field separator** | Character, string or regular expression to separate fields. |
| **Include header** | Select this check box to include the column header to the file. |
| **Encoding** | Select the encoding from the list or select **Custom** and define it manually. This field is compulsory for DB data handling. |
| **tStatCatcher Statistics** | Select this check box to collect log data at the component level. |

### Global Variables

| **Global Variables** | **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer. |
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is to be used along with tPostgresPlusBulkExec component. Used together they offer gains in performance while feeding a PostgresPlus database.</th>
</tr>
</thead>
</table>

### Related scenarios

For use cases in relation with **tPostgresPlusOutputBulk**, see the following scenarios:

- **Scenario: Inserting transformed data in MySQL database** on page 2537.
- **Scenario: Inserting data in bulk in MySQL database** on page 2544.
- **Scenario: Truncating and inserting file data into an Oracle database** on page 2752.
tPostgresPlusOutputBulkExec

Improves performance during Insert operations to a PostgresPlus database.

The tPostgresPlusOutputBulkExec executes the Insert action on the data provided.

The tPostgresplusOutputBulk and tPostgresplusBulkExec components are generally used together as part of a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tPostgresPlusOutputBulkExec component.

tPostgresPlusOutputBulkExec Standard properties

These properties are used to configure tPostgresPlusOutputBulkExec running in the Standard Job framework.

The Standard tPostgresPlusOutputBulkExec component belongs to the Databases family.

The component in this framework is generally available.

Note:

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

DB user authentication data.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

### Table

Name of the table to be written. Note that only one table can be written at a time and that the table must exist for the insert operation to succeed.

### Action on table

On the table defined, you can perform one of the following operations:

- **None**: No operation is carried out.
- **Drop and create a table**: The table is removed and created again.
- **Create a table**: The table does not exist and gets created.
- **Create a table if not exists**: The table is created if it does not exist.
- **Clear a table**: The table content is deleted.

### File Name

Name of the file to be generated and loaded.

**Warning:**

This file is generated on the machine specified by the URI in the **Host** field so it should be on the same machine as the database server.

### Schema and Edit Schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word **line** when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Built-In**: You create and store the schema locally for this component only. Related topic: see **Talend Studio User Guide**.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see **Talend Studio User Guide**.
When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually. You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

### Advanced settings

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is mainly used when no particular transformation is required on the data to be loaded onto the database.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Limitation</th>
<th>The database server must be installed on the same machine where the Studio is installed or where the Job using tPostgresPlusOutputBulkExec is deployed, so that the component functions properly.</th>
</tr>
</thead>
</table>

### Related scenarios

For use cases in relation with tPostgresPlusOutputBulkExec, see the following scenarios:

- Scenario: Inserting transformed data in MySQL database on page 2537.
- Scenario: Inserting data in bulk in MySQL database on page 2544.
- Scenario: Truncating and inserting file data into an Oracle database on page 2752.
tPostgresPlusRollback

Avoids to commit part of a transaction involuntarily.
The tPostgresPlusRollback cancels the transaction committed in the connected DB.

tPostgresPlusRollback Standard properties

These properties are used to configure tPostgresPlusRollback running in the Standard Job framework.
The Standard tPostgresPlusRollback component belongs to the Databases family.
The component in this framework is generally available.

Note:
This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.
For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tPostgresPlusConnection component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

Usage

| Usage rule | This component is more commonly used with other tPostgresPlus* components, especially with the tPostgresPlusConnection and tPostgresPlusCommit components. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. |
Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenarios

For tPostgresPlusRollback related scenario, see Scenario: Rollback from inserting data in mother/daughter tables on page 2480.
tPostgresPlusRow

Acts on the actual DB structure or on the data (although without handling data), depending on the nature of the query and the database. The SQLBuilder tool helps you write easily your SQL statements.

The tPostgresPlusRow is the specific component for the database query. It executes the SQL query stated onto the specified database. The row suffix means the component implements a flow in the job design although it doesn't provide output.

tPostgresPlusRow Standard properties

These properties are used to configure tPostgresPlusRow running in the Standard Job framework.

The Standard tPostgresPlusRow component belongs to the Databases family.

The component in this framework is generally available.

Note:

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
<td></td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

Note:

When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection. For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

| **DB Version** | List of database versions. |
| **Host** | Database server IP address |
| **Port** | Listening port number of DB server. |
| **Database** | Name of the database |
| **Schema** | Exact name of the schema. |
| **Username and Password** | DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings. |
| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word **line** when naming the fields. Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
  - **View schema**: choose this option to view the schema only.  
  - **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
  - **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window. |
| **Table name** | Name of the table to be read. |
| **Query type** | Either **Built-in** or **Repository**. |

**Built-in**: The schema is created and stored locally for this component only. Related topic: see *Talend Studio User Guide*. 

**Repository**: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see *Talend Studio User Guide*. 

---

3052
### Built-in
Fill in manually the query statement or build it graphically using SQLBuilder.

### Repository
Select the relevant query stored in the Repository. The Query field gets accordingly filled in.

#### Query
Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.

#### Die on error
This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a Row > Rejects link.

### Advanced settings

#### Propagate QUERY's recordset
Select this check box to insert the result of the query into a COLUMN of the current flow. Select this column from the use column list.

**Note:**
This option allows the component to have a different schema from that of the preceding component. Moreover, the column that holds the QUERY's recordset should be set to the type of Object and this component is usually followed by tParseRecordSet.

#### Use PreparedStatement
Select this check box if you want to query the database using a PreparedStatement. In the Set PreparedStatement Parameter table, define the parameters represented by “?” in the SQL instruction of the Query field in the Basic Settings tab.

- **Parameter Index:** Enter the parameter position in the SQL instruction.
- **Parameter Type:** Enter the parameter type.
- **Parameter Value:** Enter the parameter value.

**Note:**
This option is very useful if you need to execute the same query several times. Performance levels are increased.

#### Commit every
Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions.

#### tStat Catcher Statistics
Select this check box to collect log data at the component level.
Global Variables

| Global Variables | QUERY: the query statement processed. This is an After variable and it returns a string. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. |

Usage

| Usage rule | This component offers the flexibility of the DB query and covers all possible SQL queries. |

| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |

Related scenarios

For related topics, see:

- **Scenario: Combining two flows for selective output** on page 2558
- **Procedure** on page 625.
- **Scenario: Removing and regenerating a MySQL table index** on page 2552.
tPostgresPlusSCD

Addresses Slowly Changing Dimension needs, reading regularly a source of data and logging the changes into a dedicated SCD table.

The tPostgresPlusSCD reflects and tracks changes in a dedicated MSSQL SCD table.

**tPostgresPlusSCD Standard properties**

These properties are used to configure tPostgresPlusSCD running in the Standard Job framework.

The Standard tPostgresPlusSCD component belongs to the Business Intelligence and the Databases families.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

## Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is used as Output component. It requires an Input component and Row main link as input.</th>
</tr>
</thead>
</table>
| Dynamic settings | Click the \([+]\) button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.  

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.  

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489.  

For more information on **Dynamic settings** and context variables, see Talend Studio User Guide. |
| Limitation | This component does not support using SCD type 0 together with other SCD types. |

## Related scenario

For related topics, see **tMysqlSCD** on page 2563.
tPostgresPlusSCDELT

Addresses Slowly Changing Dimension needs through SQL queries (server-side processing mode), and logs the changes into a dedicated PostgresPlus SCD table.

The tPostgresPlusSCDELT reflects and tracks changes in a dedicated Oracle SCD table.

tPostgresPlusSCDELT Standard properties

These properties are used to configure tPostgresPlusSCDELT running in the Standard Job framework.

The Standard tPostgresPlusSCDELT component belongs to the Business Intelligence and the Databases families.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-in</strong>: No property data stored centrally. Enter properties manually.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: Select the repository file where Properties are stored. The fields that come after are pre-filled in using the fetched data.</td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined.

**Note:**

When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.

2. In the child level, use a dedicated connection component to read that registered database connection.
For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th><strong>DB Version</strong></th>
<th>List of database versions.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Host</strong></td>
<td>The IP address of the database server.</td>
</tr>
<tr>

<td>User authentication data for a dedicated database. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Source table</strong></td>
<td>Name of the input DB2 SCD table.</td>
</tr>
<tr>
<td><strong>Table</strong></td>
<td>Name of the table to be written. Note that only one table can be written at a time</td>
</tr>
</tbody>
</table>
| **Action on table** | Select to perform one of the following operations on the table defined:  
  **None**: No action carried out on the table.  
  **Drop and create table**: The table is removed and created again  
  **Create table**: A new table gets created.  
  **Create table if not exists**: A table gets created if it does not exist.  
  **Clear table**: The table content is deleted. You have the possibility to rollback the operation.  
  **Truncate table**: The table content is deleted. You don't have the possibility to rollback the operation. |
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
  • **View schema**: choose this option to view the schema only.  
  • **Change to built-in property**: choose this option to change the schema to Built-in for local changes.  
  • **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate |
the changes to the current Job, you can select No upon completion and choose this schema metadata again in the [Repository Content] window.

<table>
<thead>
<tr>
<th><strong>Built-in:</strong></th>
<th>The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Repository:</strong></td>
<td>The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

**Surrogate Key**  
Select the surrogate key column from the list.

**Creation**  
Select the method to be used for the surrogate key generation.

For more information regarding the creation methods, see SCD management methodology on page 2566.

**Source Keys**  
Select one or more columns to be used as keys, to ensure the unicity of incoming data.

**Use SCD Type 1 fields**  
Use type 1 if tracking changes is not necessary. SCD Type 1 should be used for typos corrections for example. Select the columns of the schema that will be checked for changes.

**Use SCD Type 2 fields**  
Use type 2 if changes need to be tracked down. SCD Type 2 should be used to trace updates for example. Select the columns of the schema that will be checked for changes.

- **Start date:** Adds a column to your SCD schema to hold the start date value. You can select one of the input schema columns as Start Date in the SCD table.

- **End Date:** Adds a column to your SCD schema to hold the end date value for the record. When the record is currently active, the End Date column shows a null value, or you can select Fixed Year value and fill it in with a fictive year to avoid having a null value in the End Date field.

- **Log Active Status:** Adds a column to your SCD schema to hold the true or false status value. This column helps to easily spot the active record.

- **Log versions:** Adds a column to your SCD schema to hold the version number of the record.

**Advanced settings**

<table>
<thead>
<tr>
<th><strong>Debug mode</strong></th>
<th>Select this check box to display each step during processing entries in a database.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>
Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | This component is used as an output component. It requires an input component and Row main link as input. |

Dynamic settings

| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489.

For more information on Dynamic settings and context variables, see Talend Studio User Guide. |

Related Scenario

For related topics, see tMysqlSCD on page 2563.
**tPostgresqlBulkExec**

Improves performance while carrying out the Insert operations to a Postgresql database.

The tPostgresqlBulkExec executes the Insert action on the data provided.

The tPostgresqlOutputBulk and tPostgresqlBulkExec components are used together to first output the file that will be then used as parameter to execute the SQL query stated. These two steps compose the tPostgresqlOutputBulkExec component, detailed in a separate section. The interest in having two separate elements lies in the fact that it allows transformations to be carried out before the data loading in the database.

**tPostgresqlBulkExec Standard properties**

These properties are used to configure tPostgresqlBulkExec running in the Standard Job framework.

The Standard tPostgresqlBulkExec component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

</table>
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see [Talend Studio User Guide](#).

<table>
<thead>
<tr>
<th>DB Version</th>
<th>List of database versions.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>Database server IP address</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database.</td>
</tr>
<tr>
<td>Schema</td>
<td>Name of the schema.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Table</td>
<td>Name of the table to be written. Note that only one table can be written at a time and that the table must exist for the insert operation to succeed.</td>
</tr>
</tbody>
</table>
| Action on table | On the table defined, you can perform one of the following operations:  
   - **None**: No operation is carried out.  
   - **Drop and create table**: The table is removed and created again.  
   - **Create table**: The table does not exist and gets created.  
   - **Create table if not exists**: The table is created if it does not exist.  
   - **Drop table if exists and create**: The table is removed if it already exists and created again.  
   - **Clear table**: The table content is deleted.  
   - **Truncate table**: The table content is deleted. You do not have the possibility to rollback the operation. |
| File Name  | Name of the file to be loaded.  
   - **Warning**:  
     This file is located on the machine specified by the URI in the Host field so it should be on the same machine as the database server. |
| Schema and Edit Schema | A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either **Built-in** or stored remotely in the **Repository** |
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.

**Built-In**: You create and store the schema locally for this component only. Related topic: see *Talend Studio User Guide*.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see *Talend Studio User Guide*.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

### Advanced settings

<table>
<thead>

</tr>
<tr>
<td>Text enclosure</td>
<td>Character used to enclose text.</td>
</tr>
</tbody>
</table>
Activate standard_conforming_string | Activate the variable.
---|---
Force not null for columns | Define the columns nullability. 
**Force not null**: Select the check box next to the column you want to define as not null.

**tStatCatcher Statistics** | Select this check box to collect log data at the component level.

### Usage

**Usage rule** | This component is to be used along with **tPostgresqlOut putBulk** component. Used together, they can offer gains in performance while feeding a Postgresql database.

**Dynamic settings** | Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see **Scenario: Reading data from databases through context-based dynamic connections** on page 2497 and **Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters** on page 489. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

### Related scenarios

For use cases in relation with **tPostgresqlBulkExec**, see the following scenarios:

- **Scenario: Inserting transformed data in MySQL database** on page 2537.
- **Scenario: Inserting data in bulk in MySQL database** on page 2544.
- **Scenario: Truncating and inserting file data into an Oracle database** on page 2752.
tPostgresqlClose

Closes the transaction committed in the connected Postgresql database.

### tPostgresqlClose Standard properties

These properties are used to configure tPostgresqlClose running in the Standard Job framework.

The Standard tPostgresqlClose component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

#### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the <strong>tPostgresqlConnection</strong> component in the list if more than one connection are planned for the current Job.</td>
</tr>
</tbody>
</table>

#### Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

#### Usage

| Usage rule | This component is to be used along with Postgresql components, especially with **tPostgresqlConnection** and **tPostgresqlCommit**. |
| Dynamic settings | Click the [+•] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see **Scenario: Reading data from databases through context-**
Related scenarios

No scenario is available for the Standard version of this component yet.
**tPostgresqlCommit**

Commits in one go a global transaction, using a unique connection, instead of doing that on every row or every batch and thus improves performance.

The tPostgresqlCommit validates the data processed through the Job into the connected DB.

**tPostgresqlCommit Standard properties**

These properties are used to configure tPostgresqlCommit running in the Standard Job framework.

The Standard tPostgresqlCommit component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tPostgresqlConnection component in the list if more than one connection are planned for the current Job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Warning:**

If you want to use a Row > Main connection to link tPostgresqlCommit to your Job, your data will be committed row by row. In this case, do not select the Close connection check box or your connection will be closed before the end of your first row commit.

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is more commonly used with other tPostgresql* components, especially with the |
tPostgresqlCommit and tPostgresqlRollback components.

### Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489.

For more information on Dynamic settings and context variables, see Talend Studio User Guide.

### Related scenario

For tPostgresqlCommit related scenario, see Scenario: Inserting data in mother/daughter tables on page 2476.
tPostgresqlConnection

Opens a connection to the specified database that can then be reused in the subsequent subjob or subjobs.

The tPostgresqlConnection opens a connection to the database for a current transaction.

**tPostgresqlConnection Standard properties**

These properties are used to configure tPostgresqlConnection running in the Standard Job framework.

The Standard tPostgresqlConnection component belongs to the Databases and the ELT families.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click <code>Apply</code>.</td>
</tr>
<tr>
<td><strong>Property type</strong></td>
<td>Either <em>Built-in</em> or <em>Repository</em></td>
</tr>
<tr>
<td><strong>Built-in</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><strong>DB Version</strong></td>
<td>List of database versions.</td>
</tr>
<tr>
<td><strong>Host</strong></td>
<td>Database server IP address</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of database server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database.</td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>Exact name of the schema.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>Database user authentication data.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Use or register a shared DB Connection</strong></td>
<td>Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the <strong>Shared DB Connection Name</strong> field displayed, enter the name for the shared database connection. This allows you to share one single database connection.</td>
</tr>
</tbody>
</table>
connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child.

This option is incompatible with the Use dynamic job and Use an independent process to run subjob options of the tRunJob component. Using a shared connection together with a tRunJob component with either of these two options enabled will cause your Job to fail.

This check box is not available when the Specify a data source alias check box is selected.

Specify a data source alias

Select this check box and specify the alias of a data source created on the Talend Runtime side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in Talend Runtime. For a related use case, see Scenario: Deploying your Job on Talend Runtime to retrieve data from a MySQL database on page 2503.

This check box is not visible when the Use or register a shared DB Connection check box is selected.

Data source alias

Enter the alias of the data source created on the Talend Runtime side.

This field is available only when the Specify a data source alias check box is selected.

Advanced settings

Auto Commit

Select this check box to commit any changes to the database automatically upon the transaction.

With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component.

Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component.

tStatCatcher Statistics

Select this check box to collect log data at the component level.

Usage

Usage rule

This component is more commonly used with other tPostgresql* components, especially with
Related scenario

For `tPostgresqlConnection` related scenario, see `tMysqlConnection` on page 2475
tPostgresqlInput

Executes a DB query with a strictly defined order which must correspond to the schema definition. Then it passes on the field list to the next component via a Main row link.

The tPostgresqlInput reads a database and extracts fields based on a query.

**tPostgresqlInput Standard properties**

These properties are used to configure tPostgresqlInput running in the Standard Job framework.

The Standard tPostgresqlInput component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see *Dynamic database components* on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in</strong>: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td><strong>Repository</strong>: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
<td></td>
</tr>
<tr>
<td>Click this icon to open a database connection wizard and store the database connection parameters you set in the component <strong>Basic settings</strong> view.</td>
<td></td>
</tr>
<tr>
<td>For more information about setting up and storing database connection parameters, see <em>Talend Studio User Guide</em>.</td>
<td></td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td><strong>Note:</strong></td>
<td></td>
</tr>
<tr>
<td>When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:</td>
<td></td>
</tr>
<tr>
<td>1. In the parent level, register the database connection to be shared in the <strong>Basic settings</strong> view of the connection component</td>
<td></td>
</tr>
</tbody>
</table>
which creates that very database connection.

2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

| DB Version | List of database versions. |
| Host | Database server IP address |
| Port | Listening port number of DB server. |
| Database | Name of the database |
| Schema | Exact name of the schema. |

**Username and Password**

DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

**Schema and Edit Schema**

A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either **Built-in** or stored remotely in the **Repository**. Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **[Repository Content]** window.

**Built-In**: You create and store the schema locally for this component only. Related topic: see *Talend Studio User Guide*.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see *Talend Studio User Guide*.

**Table name**

Name of the table to be read.
**Query type** and **Query**

Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.

**Specify a data source alias**

Select this check box and specify the alias of a data source created on the **Talend Runtime** side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in **Talend Runtime**. For a related use case, see Scenario: Deploying your Job on Talend Runtime to retrieve data from a MySQL database on page 2503.

This check box is not available when the **Use an existing connection** check box is selected.

**Data source alias**

Enter the alias of the data source created on the **Talend Runtime** side.

This field is available only when the **Specify a data source alias** check box is selected.

---

### Advanced settings

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Use cursor</strong></td>
<td>When selected, helps to decide the row set to work with at a time and thus optimize performance.</td>
</tr>
<tr>
<td><strong>Trim all the String/Char columns</strong></td>
<td>Select this check box to remove leading and trailing whitespace from all the String/Char columns.</td>
</tr>
<tr>
<td><strong>Trim column</strong></td>
<td>Remove leading and trailing whitespace from defined columns.</td>
</tr>
<tr>
<td><strong>tStat Catcher Statistics</strong></td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE</strong>: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.</td>
<td></td>
</tr>
<tr>
<td><strong>QUERY</strong>: the query statement being processed. This is a Flow variable and it returns a string.</td>
<td></td>
</tr>
<tr>
<td><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</td>
<td></td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.
Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component covers all possible SQL queries for Postgresql databases.</th>
</tr>
</thead>
</table>

**Dynamic settings**

Click the [+\(] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489.

For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

**Limitation**

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

**Related scenarios**

For related scenarios, see:

- Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489.
tPostgresqlOutput

Executes the action defined on the table and/or on the data contained in the table, based on the flow incoming from the preceding component in the job.

The tPostgresqlOutput writes, updates, makes changes or suppresses entries in a database.

tPostgresqlOutput Standard properties

These properties are used to configure tPostgresqlOutput running in the Standard Job framework.

The Standard tPostgresqlOutput component belongs to the Databases family.

The component in this framework is generally available.

Note:

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
<td></td>

<tr>
<td></td>
<td><strong>Truncate table</strong>: The table content is deleted. You don't have the possibility to rollback the operation.</td>
</tr>
<tr>
<td>Action on data</td>
<td>On the data of the table defined, you can perform:</td>
</tr>
<tr>
<td></td>
<td><strong>Insert</strong>: Add new entries to the table. If duplicates are found, job stops.</td>
</tr>
<tr>
<td></td>
<td><strong>Update</strong>: Make changes to existing entries</td>
</tr>
<tr>
<td></td>
<td><strong>Insert or update</strong>: Insert a new record. If the record with the given reference already exists, an update would be made.</td>
</tr>
<tr>
<td></td>
<td><strong>Update or insert</strong>: Update the record with the given reference. If the record does not exist, a new record would be inserted.</td>
</tr>
</tbody>
</table>
Delete: Remove entries corresponding to the input flow.

Warning:

It is necessary to specify at least one column as a primary key on which the Update and Delete operations are based. You can do that by clicking Edit Schema and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the Advanced settings view where you can simultaneously define primary keys for the Update and Delete operations. To do that: Select the Use field options check box and then in the Key in update column, select the check boxes next to the column names you want to use as a base for the Update operation. Do the same in the Key in delete column for the Delete operation.

Schema and Edit Schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

Built-In: You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.

Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Use spatial options

Note:
This check box is available when you selected the table creation related option from the Action on table list.

Select this check box to use the PostgreSQL database as a spatial database for geographic information system (GIS). When this check box is selected, two other check boxes are displayed:

- **Create Spatial index**: select this check box to create spatial index.
- **Create geometry columns reference**: select this check box to create geometry columns reference.

For more information about the PostgreSQL database, see [http://www.postgresql.org/about/](http://www.postgresql.org/about/).

### Specify a data source alias

Select this check box and specify the alias of a data source created on the **Talend Runtime** side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in **Talend Runtime**. For a related use case, see Scenario: Deploying your Job on Talend Runtime to retrieve data from a MySQL database on page 2503.

This check box is not available when the **Use an existing connection** check box is selected.

### Data source alias

Enter the alias of the data source created on the **Talend Runtime** side.

This field is available only when the Specify a data source alias check box is selected.

### Die on error

This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

### Advanced settings

#### Commit every

Enter the number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and, above all, better performance at execution.

#### Additional Columns

This option is not offered if you create (with or without drop) the DB table. This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing.

- **Name**: Type in the name of the schema column to be altered or inserted as new column
- **SQL expression**: Type in the SQL statement to be executed in order to alter or insert the relevant column data.
<table>
<thead>
<tr>
<th><strong>Position:</strong></th>
<th>Select <em>Before</em>, <em>Replace</em> or <em>After</em> following the action to be performed on the reference column.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Reference column:</strong></td>
<td>Type in a column of reference that the <em>tDBOutput</em> can use to place or replace the new or altered column.</td>
</tr>
</tbody>
</table>
| **Use save point** | Select this check box to use savepoints in the transaction. This check box will not be available if you select:  
  - the *Die on error* check box in the *Basic settings* view, or  
  - the *Use Batch Size* check box in the *Advanced settings* view.  
  This check box will not work if you:  
  - type in 0 in the *Commit every* field, or  
  - select the *Use an existing connection* check box in the *Basic settings* view while the *Auto Commit* mode is activated in the database connection component. |
| **Use field options** | Select this check box to customize a request, especially when there is double action on data. |
| **Enable debug mode** | Select this check box to display each step during processing entries in a database. |
| **Support null in “SQL WHERE” statement** | Select this check box if you want to deal with the Null values contained in a DB table.  
  **Note:** Ensure that the Nullable check box is selected for the corresponding columns in the schema. |
| **Use Batch** | Select this check box to activate the batch mode for data processing.  
  **Note:** This check box is available only when you have selected the *Insert*, the *Update* or the *Delete* option in the *Action on data* field. |
| **Batch Size** | Specify the number of records to be processed in each batch.  
  This field appears only when the *Use batch mode* check box is selected. |
| **tStat Catcher Statistics** | Select this check box to collect log data at the component level. |

**Global Variables**

| **Global Variables** | **NB_LINE:** the number of rows processed. This is an After variable and it returns an integer. |
**NB_LINE_UPDATED**: the number of rows updated. This is an After variable and it returns an integer.

**NB_LINE_INSERTED**: the number of rows inserted. This is an After variable and it returns an integer.

**NB_LINE_DELETED**: the number of rows deleted. This is an After variable and it returns an integer.

**NB_LINE_REJECTED**: the number of rows rejected. This is an After variable and it returns an integer.

**QUERY**: the query statement processed. This is an After variable and it returns a string.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see **Talend Studio User Guide**.

---

### Usage

#### Usage rule

This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible.

This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in a Postgresql database. It also allows you to create a reject flow using a Row > Reverts link to filter data in error. For an example of **tMySqlOutput** in use, see Scenario: Retrieving data in error with a Reject link on page 2529.

#### Dynamic settings

Click the [+ ] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-
| Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |

**Related scenarios**

For **tPostgresqlOutput** related topics, see:

- Scenario: Inserting a column and altering data using **tMysqlOutput** on page 2521.
tPostgresqlOutputBulk

Prepares the file to be used as parameters in the INSERT query to feed the Postgresql database.

The tPostgresqlOutputBulk writes a file with columns based on the defined delimiter and the Postgresql standards.

The tPostgresqlOutputBulk and tPostgresqlBulkExec components are generally used together as part of a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tPostgresqlOutputBulkExec component, detailed in a separate section. The advantage of having two separate steps is that it makes it possible to transform data before it is loaded in the database.

tPostgresqlOutputBulk Standard properties

These properties are used to configure tPostgresqlOutputBulk running in the Standard Job framework.

The Standard tPostgresqlOutputBulk component belongs to the Databases family.

The component in this framework is generally available.

Note:

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository</td>
</tr>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>File Name</td>
<td>Name of the file to be generated.</td>
</tr>
<tr>
<td></td>
<td>Warning: This file is generated on the local machine or a shared folder on the LAN.</td>
</tr>
<tr>
<td>Append</td>
<td>Select this check box to add the new rows at the end of the file.</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either Built-in or stored remotely in the Repository</td>
</tr>
</tbody>
</table>
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **[Repository Content]** window.

**Built-In**: You create and store the schema locally for this component only. Related topic: see **Talend Studio User Guide**.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see **Talend Studio User Guide**.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

### Advanced settings

<table>
<thead>
<tr>
<th><strong>Row separator</strong></th>
<th>String (ex: <code>\n</code>on Unix) to distinguish rows.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Field separator</strong></td>
<td>Character, string or regular expression to separate fields.</td>
</tr>
<tr>
<td><strong>Include header</strong></td>
<td>Select this check box to include the column header to the file.</td>
</tr>
<tr>
<td><strong>Encoding</strong></td>
<td>Select the encoding from the list or select <strong>Custom</strong> and define it manually. This field is compulsory for DB data handling.</td>
</tr>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

### Global Variables

**NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string.
variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

| Usage rule | This component is to be used along with **tPostgresqlBulkExec** component. Used together they offer gains in performance while feeding a Postgresql database. |

### Related scenarios

For use cases in relation with **tPostgresqlOutputBulk**, see the following scenarios:

- **Scenario: Inserting transformed data in MySQL database** on page 2537.
- **Scenario: Inserting data in bulk in MySQL database** on page 2544.
- **Scenario: Truncating and inserting file data into an Oracle database** on page 2752.
tPostgresqlOutputBulkExec

Improves performance during Insert operations to a Postgresql database.

The tPostgresqlOutputBulkExec executes the Insert action on the data provided.

The tPostgresqlOutputBulk and tPostgresqlBulkExec components are generally used together as part of a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tPostgresqlOutputBulkExec component.

**tPostgresqlOutputBulkExec Standard properties**

These properties are used to configure tPostgresqlOutputBulkExec running in the Standard Job framework.

The Standard tPostgresqlOutputBulkExec component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td><strong>Property type</strong></td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong></td>
</tr>
<tr>
<td></td>
<td><strong>Built-in</strong>: No property data stored centrally.</td>
</tr>
<tr>

<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Table</strong></td>
<td>Name of the table to be written. Note that only one table can be written at a time and that the table must exist for the insert operation to succeed.</td>
</tr>
</tbody>
</table>
| **Action on table** | On the table defined, you can perform one of the following operations:  
- **None**: No operation is carried out.  
- **Drop and create table**: The table is removed and created again.  
- **Create table**: The table does not exist and gets created.  
- **Create table if not exists**: The table is created if it does not exist.  
- **Drop table if exists and create**: The table is removed if already exists and created again.  
- **Clear a table**: The table content is deleted. |
| **File Name** | Name of the file to be generated and loaded.  
**Warning:**  
This file is generated on the machine specified by the URI in the **Host** field and it should be on the same machine as the database server. |
| **Schema and Edit Schema** | A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either **Built-in** or stored remotely in the **Repository**.  
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
- **View schema**: choose this option to view the schema only.  
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.  
**Built-In**: You create and store the schema locally for this component only. Related topic: see **Talend Studio User Guide**. |
Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

## Advanced settings

<table>
<thead>
<tr>
<th>Action on data</th>
<th>On the data of the table defined, you can perform:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bulk Insert</td>
<td>Add multiple entries to the table. If duplicates are found, job stops.</td>
</tr>
<tr>
<td>Bulk Update</td>
<td>Make simultaneous changes to multiple entries.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Copy the OID for each row</th>
<th>Retrieve the ID item for each row.</th>

</table>

<table>
<thead>
<tr>
<th>Activate standard_conforming_string</th>
<th>Activate the variable.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Force not null for columns</th>
<th>Define the columns nullability.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Force not null</td>
<td>Select the check box next to the column you want to define as not null.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
<th>Select this check box to collect log data at the component level.</th>
</tr>
</thead>
</table>
**Usage**

<table>
<thead>
<tr>
<th><strong>Usage rule</strong></th>
<th>This component is mainly used when no particular transformation is required on the data to be loaded onto the database.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Limitation</strong></td>
<td>The database server must be installed on the same machine where the Studio is installed or where the Job using \texttt{tPostgresqlOutputBulkExec} is deployed, so that the component functions properly.</td>
</tr>
</tbody>
</table>

**Related scenarios**

For use cases in relation with \texttt{tPostgresqlOutputBulkExec}, see the following scenarios:

- Scenario: Inserting transformed data in MySQL database on page 2537.
- Scenario: Inserting data in bulk in MySQL database on page 2544.
- Scenario: Truncating and inserting file data into an Oracle database on page 2752.
tPostgresqlRollback

Avoids to commit part of a transaction involuntarily.

The tPostgresqlRollback cancels the transaction commit in the connected DB.

**tPostgresqlRollback Standard properties**

These properties are used to configure tPostgresqlRollback running in the Standard Job framework. The Standard tPostgresqlRollback component belongs to the Databases family. The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tPostgresqlConnection component in the list if more than one connection are planned for the current Job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is more commonly used with other tPostgresql* components, especially with the tPostgresqlConnection and tPostgresqlCommit components. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. |
Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenario

For tPostgresqlRollback related scenario, see tMysqlRollback on page 2546
tPostgresqlRow

Acts on the actual DB structure or on the data (although without handling data), depending on the nature of the query and the database. The SQLBuilder tool helps you write easily your SQL statements.

The tPostgresqlRow is the specific component for the database query. It executes the SQL query stated onto the specified database. The row suffix means the component implements a flow in the job design although it doesn't provide output.

tPostgresqlRow Standard properties

These properties are used to configure tPostgresqlRow running in the Standard Job framework.

The Standard tPostgresqlRow component belongs to the Databases family.

The component in this framework is generally available.

Note:

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td></td>
<td>Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:</td>
</tr>
<tr>
<td></td>
<td>1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.</td>
</tr>
</tbody>
</table>
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

| **DB Version** | List of database versions. |
| **Host** | Database server IP address. |
| **Port** | Listening port number of DB server. |
| **Database** | Name of the database. |
| **Schema** | Name of the schema. |
| **Username and Password** | DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| **Schema and Edit Schema** | A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either **Built-in** or stored remotely in the **Repository**. Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window. |
| **Query type** | Either **Built-in** or **Repository**. |

**Built-In**: You create and store the schema locally for this component only. Related topic: see *Talend Studio User Guide*.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see *Talend Studio User Guide*.
### Repository
Select the relevant query stored in the Repository. The Query field gets accordingly filled in.

### Query
Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.

### Specify a data source alias
Select this check box and specify the alias of a data source created on the Talend Runtime side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in Talend Runtime. For a related use case, see Scenario: Deploying your Job on Talend Runtime to retrieve data from a MySQL database on page 2503.

This check box is not available when the **Use an existing connection** check box is selected.

### Data source alias
Enter the alias of the data source created on the Talend Runtime side.

This field is available only when the **Specify a data source alias** check box is selected.

### Die on error
This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a Row > Rejects link.

### Advanced settings

#### Propagate QUERY’s recordset
Select this check box to insert the result of the query into a COLUMN of the current flow. Select this column from the *use column* list.

**Note:**
This option allows the component to have a different schema from that of the preceding component. Moreover, the column that holds the QUERY’s recordset should be set to the type of Object and this component is usually followed by tParseRecordSet.

#### Use PreparedStatement
Select this check box if you want to query the database using a PreparedStatement. In the *Set PreparedStatement Parameter* table, define the parameters represented by ‘?’ in the SQL instruction of the Query field in the Basic Settings tab.

- **Parameter Index**: Enter the parameter position in the SQL instruction.
- **Parameter Type**: Enter the parameter type.
- **Parameter Value**: Enter the parameter value.

**Note:**
This option is very useful if you need to execute the same query several times. Performance levels are increased.

<table>
<thead>
<tr>
<th>Commit every</th>
<th>Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions.</th>
</tr>
</thead>
<tbody>
<tr>
<td>tStat Catcher Statistics</td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

**Global Variables**

| Global Variables | QUERY: the query statement being processed. This is a Flow variable and it returns a string. ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component offers the flexibility benefit of the DB query and covers all possible SQL queries.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic settings</td>
<td>Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using...</td>
</tr>
</tbody>
</table>
Related scenarios

For related topics, see:

- **Scenario: Combining two flows for selective output** on page 2558
- **Procedure** on page 625.
- **Scenario: Removing and regenerating a MySQL table index** on page 2552.
tPostgresqlSCD

Addresses Slowly Changing Dimension needs, reading regularly a source of data and logging the changes into a dedicated SCD table.

The tPostgresqlSCD reflects and tracks changes in a dedicated Postgresql SCD table.

**tPostgresqlSCD Standard properties**

These properties are used to configure tPostgresqlSCD running in the Standard Job framework.

The Standard tPostgresqlSCD component belongs to the Business Intelligence and the Databases families.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see [Dynamic database components](#) on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in</strong>: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td><strong>Repository</strong>: Select the Repository file where Properties are stored. The following fields are pre-filled in using fetched data.</td>
<td></td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined.

**Note:**

When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.

2. In the child level, use a dedicated connection component to read that registered database connection.
For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

</table>
### Use memory saving Mode
Select this check box to maximize system performance.

### Source keys include Null
Select this check box to allow the source key columns to have Null values.

**Warning:**
Special attention should be paid to the uniqueness of the source key(s) values when this option is selected.

### Die on error
This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

### Advanced settings

<table>

</tbody>
</table>

---

**NB_LINE_UPDATED**: the number of rows updated. This is an After variable and it returns an integer.

**NB_LINE_INSERTED**: the number of rows inserted. This is an After variable and it returns an integer.

**NB_LINE_REJECTED**: the number of rows rejected. This is an After variable and it returns an integer.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*. 
## Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is used as Output component. It requires an Input component and Row main link as input.</th>
</tr>
</thead>
</table>
| Dynamic settings | Click the [+]-button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.  

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.  

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |
| Limitation | This component does not support using SCD type 0 together with other SCD types. |

## Related scenario

For related topics, see tMysqlSCD on page 2563.
tPostgresqlSCDELT

Addresses Slowly Changing Dimension needs through SQL queries (server-side processing mode), and logs the changes into a dedicated DB2 SCD table.

The tPostgresqlSCDELT reflects and tracks changes in a dedicated Postgresql SCD table.

**tPostgresqlSCDELT Standard properties**

These properties are used to configure tPostgresqlSCDELT running in the Standard Job framework.

The Standard tPostgresqlSCDELT component belongs to the Business Intelligence and the Databases families.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-in</strong>: No property data stored centrally. Enter properties manually.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: Select the repository file where Properties are stored. The fields that come after are pre-filled in using the fetched data.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Note:</strong></td>
</tr>
<tr>
<td></td>
<td>When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:</td>
</tr>
<tr>
<td></td>
<td>1. In the parent level, register the database connection to be shared in the <strong>Basic settings</strong> view of the connection component which creates that very database connection.</td>
</tr>
<tr>
<td></td>
<td>2. In the child level, use a dedicated connection component to read that registered database connection.</td>
</tr>
</tbody>
</table>
For an example about how to share a database connection across Job levels, see [Talend Studio User Guide](#).

<table>
<thead>
<tr>
<th><strong>DB Version</strong></th>
<th>List of database versions.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Host</strong></td>
<td>The IP address of the database server.</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of database server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>User authentication data for a dedicated database. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Source table</strong></td>
<td>Name of the input DB2 SCD table.</td>
</tr>
<tr>
<td><strong>Table</strong></td>
<td>Name of the table to be written. Note that only one table can be written at a time</td>
</tr>
</tbody>
</table>
| **Action on table** | Select to perform one of the following operations on the table defined:  
  - **None**: No action carried out on the table.  
  - **Drop and create table**: The table is removed and created again  
  - **Create table**: A new table gets created.  
  - **Create table if not exists**: A table gets created if it does not exist.  
  - **Clear table**: The table content is deleted. You have the possibility to rollback the operation.  
  - **Truncate table**: The table content is deleted. You do not have the possibility to rollback the operation. |
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.  
  Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
  - **View schema**: choose this option to view the schema only.  
  - **Change to built-in property**: choose this option to change the schema to Built-in for local changes.  
  - **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No |
upon completion and choose this schema metadata again in the [Repository Content] window.

**Built-in**: The schema is created and stored locally for this component only. Related topic: see *Talend Studio User Guide*.

**Repository**: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see *Talend Studio User Guide*.

### Surrogate Key
Select the surrogate key column from the list.

### Creation
Select the method to be used for the surrogate key generation.

For more information regarding the creation methods, see *SCD management methodology* on page 2566.

### Source Keys
Select one or more columns to be used as keys, to ensure the unicity of incoming data.

### Use SCD Type 1 fields
Use type 1 if tracking changes is not necessary. SCD Type 1 should be used for typos corrections for example. Select the columns of the schema that will be checked for changes.

### Use SCD Type 2 fields
Use type 2 if changes need to be tracked down. SCD Type 2 should be used to trace updates for example. Select the columns of the schema that will be checked for changes.

- **Start date**: Adds a column to your SCD schema to hold the start date value. You can select one of the input schema columns as Start Date in the SCD table.

- **End Date**: Adds a column to your SCD schema to hold the end date value for the record. When the record is currently active, the End Date column shows a null value, or you can select *Fixed Year value* and fill it in with a fictive year to avoid having a null value in the End Date field.

- **Log Active Status**: Adds a column to your SCD schema to hold the true or false status value. This column helps to easily spot the active record.

- **Log versions**: Adds a column to your SCD schema to hold the version number of the record.

### Advanced settings

<table>
<thead>
<tr>
<th><strong>Debug mode</strong></th>
<th>Select this check box to display each step during processing entries in a database.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>tStat Catcher Statistics</strong></td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>
## Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#). |

## Usage

| Usage rule | This component is used as an output component. It requires an input component and Row main link as input. |

| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide. |

## Related Scenario

For related topics, see tMysqlSCD on page 2563.
tPostjob

Triggers a task required after the execution of a Job

BoxPostjob starts the execution of a postjob.

tPostjob Standard properties

These properties are used to configure tPostjob running in the Standard Job framework.
The Standard tPostjob component belongs to the Orchestration family.
The component in this framework is generally available.

Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by
the component when an error occurs. This is an After
variable and it returns a string. This variable functions
only if the Die on error check box is cleared, if the
component has this check box.

A Flow variable functions during the execution of
a component while an After variable functions after
the execution of the component.

To fill up a field or expression with a variable, press
Ctrl + Space to access the variable list and choose the
variable to use from it.

For further information about variables, see Talend
Studio User Guide. |

Usage

| Usage rule | tPostjob is a start component and can only be used with
an iterate connection to the next component. |

Connections

| Outgoing links (from this component to another):
| Trigger: On Component Ok. |

| Incoming links (from one component to this one):
| Trigger: Synchronize; Parallelize. |

For further information regarding connections, see
Talend Studio User Guide.

For more information about the tPostjob component, see Talend Studio User Guide.

- Scenario: Creating a bar chart from the input data on page 334
tPrejob

Triggers a task required for the execution of a Job

TPrejob starts the execution of a prejob.

**tPrejob Standard properties**

These properties are used to configure tPrejob running in the Standard Job framework.
The Standard tPrejob component belongs to the Orchestration family.
The component in this framework is generally available.

**Global Variables**

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it. For further information about variables, see *Talend Studio User Guide*. |

**Usage**

| Usage rule | tPrejob is a start component and can only be used with an iterate connection to the next component. |

| Connections | Outgoing links (from this component to another): **Trigger**: On Component Ok. 

**Incoming links (from one component to this one):**

**Trigger**: Synchronize; Parallelize.

For further information regarding connections, see *Talend Studio User Guide*. |

For more information about the **tPrejob** component, see *Talend Studio User Guide*. |
**Scenario: Handling files before and after the execution of a data Job**

In this scenario, a pre-job and a post-job are added to the Job describes in *Scenario 2: Finding duplicate files between two folders* on page 1101 to handle files before and after the execution of the main data Job.

As described in the above-mentioned scenario, when the main data Job is started, it creates a temporary text file to store the fetched filenames. If the specified temporary file already exists, it will be overwritten.

To prevent possible loss of data, the pre-job saves a backup copy of the specified file by renaming it, if it exists, before the main Job is executed.

After the execution of the main data Job, the post-job deletes the temporary file created by the data Job and restores the backup file, if any.

---

**Adding and linking components**

**Procedure**

1. With the main Job open on the design workspace, add a **tPrejob**, a **tPostjob**, a **tFileDelete**, and two **tFileCopy** components to the Job.
2. Link the **tPrejob** component to the first **tFileCopy** component using a **Trigger > On Component Ok** connection to build the pre-job.
3. Link the **tPostjob** component to the **tFileDelete** component using a **Trigger > On Component Ok** connection, and link the **tFileDelete** component to the other **tFileCopy** component to build the post-job.
4. Label the relevant components to better identify their roles.
Configuring the components

Configuring the pre-job

About this task
In the pre-job, the tPrejob component does not have any parameter or property to configure; it just triggers the tFileCopy component before the execution of the main data Job to rename the specified file, so all the required configurations are made in the tFileCopy component.

Procedure
1. Double-click the tFileCopy component to show its Basic settings view.

   ![Save backup (tFileCopy_1)](image)

   2. Fill the File Name field with the path and filename of the temporary text file to be renamed, D:/temp/tempdata.csv in this example.

   3. In the Destination directory field, specify or browse to destination directory. In this example, we will save the backup copy in the same directory, D:/temp/.

   4. Select the Rename check box, and specify the new filename in the Destination filename field, backup-tempdata.csv. Leave the other parameters as they are.

Configuring the post-job

About this task
In the post-job, the tPostjob component does not have any parameter or property to configure; it just triggers the tFileDelete component after the execution of the main data Job to delete the temporary file used to store the fetched filenames, which then triggers the tFileCopy component to name the backup file back to its original name.

Procedure
1. In the Basic settings view of the tFileDelete component, fill the File Name field with the path and filename of the temporary file to be deleted, D:/temp/tempdata.csv in this example, and leave the other parameters as they are.
2. Double-click the tFileCopy component to open its Basic settings view.

3. Fill the File Name field with the path and filename of the backup file, D:/temp/backup-tempdata.csv in this example.

4. In the Destination directory field, specify or browse to destination directory, D:/temp/ in this example.

5. Select the Rename check box, and specify the original name of the temporary file in the Destination filename field, tempdata.csv.

6. Select the Remove source file check box to remove the backup file after the renaming action. Leave the other parameters as they are.

**Expected execution result**

If the specified temporary file exists, its data will be saved in a backup copy before the main data Job is executed and restored thereafter.

If the temporary file does not exist, the two tFileCopy components will generate an error, but this does not prevent the main data Job from being executed.

For the execution result of the main data Job, see Scenario 2: Finding duplicate files between two folders on page 1101.

**Related scenario**

For another scenario that uses the tPrejob component, see Scenario: Creating a bar chart from the input data on page 334.
tPubSubOutput

Receives messages serialized into byte arrays by its preceding component and issues these messages into a given PubSub service.
**tRedshiftBulkExec**

Loads data into Amazon Redshift from Amazon S3, Amazon EMR cluster, Amazon DynamoDB, or remote hosts.

The `tRedshiftOutputBulk` and `tRedshiftBulkExec` components can be used together in a two step process to load data to Amazon Redshift from a delimited/CSV file on Amazon S3. In the first step, a delimited/CSV file is generated. In the second step, this file is used in the INSERT statement used to feed Amazon Redshift. These two steps are fused together in the `tRedshiftOutputBulkExec` component. The advantage of using two separate steps is that the data can be transformed before it is loaded to Amazon Redshift.

`tRedshiftBulkExec` loads data into an Amazon Redshift table from an Amazon DynamoDB table or from data files located in an Amazon S3 bucket, an Amazon EMR cluster, or a remote host that is accessed using an SSH connection.

**tRedshiftBulkExec Standard properties**

These properties are used to configure `tRedshiftBulkExec` running in the Standard Job framework.

The Standard `tRedshiftBulkExec` component belongs to the Cloud and the Databases families.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td><strong>Property Type</strong></td>
<td>Either <strong>Built-In</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Built-In</strong>: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Repository</strong>: Select the repository file where the properties are stored.</td>
</tr>
<tr>
<td><strong>Use an existing connection</strong></td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td><strong>Host</strong></td>
<td>Type in the IP address or hostname of the database server.</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Type in the listening port number of the database server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Type in the name of the database.</td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>Type in the name of the schema.</td>
</tr>
</tbody>
</table>
**Username and Password**  
Type in the database user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

**Additional JDBC Parameters**  
Specify additional JDBC properties for the connection you are creating. The properties are separated by ampersand & and each property is a key-value pair. For example, `ssl=true & sslfactory=com.amazon.redshift.ssl.N onValidatingFactory`, which means the connection will be created using SSL.

**Table Name**  
Specify the name of the table to be written. Note that only one table can be written at a time.

**Action on table**  
On the table defined, you can perform one of the following operations:

- **None**: No operation is carried out.
- **Drop and create table**: The table is removed and created again.
- **Create table**: The table does not exist and gets created.
- **Create table if not exists**: The table is created if it does not exist.
- **Drop table if exists and create**: The table is removed if it already exists and created again.
- **Clear table**: The table content is deleted. You have the possibility to rollback the operation.

**Schema and Edit schema**  
A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

- **Built-In**: You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the
Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.

| Data source type | Select the location of the source data to be loaded.  
|------------------|------------------------------------------------------|
| • **S3**: load data from a file in an Amazon S3 bucket.  
| • **EMR**: load data from an Amazon EMR cluster.  
| • **DynamoDB**: load data from an existing DynamoDB table.  
| • **Remote host**: load data from one or more remote hosts, such as Amazon Elastic Compute Cloud (Amazon EC2) instances or other computers.  
| For more information, see Data Sources. |

| Access Key | Specify the Access Key ID that uniquely identifies an AWS Account. For how to get your Access Key and Access Secret, visit Getting Your AWS Access Keys. |

| Secret Key | Specify the Secret Access Key, constituting the security credentials in combination with the access Key.  
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
<td></td>
</tr>
</tbody>
</table>

| Bucket | Specify the name of the Amazon S3 bucket in which the file is located.  
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>This field is available only when <strong>S3</strong> or <strong>Remote host</strong> is selected from the Data source type drop-down list.</td>
<td></td>
</tr>
</tbody>
</table>

| Key | Specify the object key for the file that contains the data to be loaded.  
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>This field is available only when <strong>S3</strong> is selected from the Data source type drop-down list.</td>
<td></td>
</tr>
</tbody>
</table>

| Cluster id | Specify the ID of the cluster that stores the data to be loaded.  
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>This field is available only when <strong>EMR</strong> is selected from the Data source type drop-down list.</td>
<td></td>
</tr>
</tbody>
</table>

| HDFS path | Specify the HDFS file path that references the data file.  
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>This field is available only when <strong>EMR</strong> is selected from the Data source type drop-down list.</td>
<td></td>
</tr>
</tbody>
</table>

| Table | Specify the name of the DynamoDB table that contains the data to be loaded.  
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>This field is available only when <strong>DynamoDB</strong> is selected from the Data source type drop-down list.</td>
<td></td>
</tr>
</tbody>
</table>

| Read ratio | Specify the percentage of the DynamoDB table’s provisioned throughput to use for the data load. |
### Advanced settings

<table>

Note that only a base64 encoded AES 128-bit or AES 256-bit envelope key is supported. For more information, see Loading Encrypted Data Files from Amazon S3. This check box is available when S3, EMR, or Remote host is selected from the Data source type drop-down list.</td>
</tr>
<tr>
<td><strong>Encoding</strong></td>
<td>Select the encoding type of the data to be loaded from the list. This list is available when S3, EMR, or Remote host is selected from the Data source type drop-down list.</td>
</tr>
<tr>
<td><strong>Date format</strong></td>
<td>Select one of the following items from the list to specify the date format in the source data: • <strong>NONE</strong>: No date format is specified. • <strong>PATTERN</strong>: Select this item and specify the date format in the field displayed. The default date format is YYYY-MM-DD. • <strong>AUTO</strong>: Select this item if you want Amazon Redshift to recognize and convert automatically the date format.</td>
</tr>
<tr>
<td><strong>Time format</strong></td>
<td>Select one of the following items from the list to specify the time format in the source data: • <strong>NONE</strong>: No time format is specified. • <strong>PATTERN</strong>: Select this item and specify the time format in the field displayed. The default time format is YYYY-MM-DD HH:MI:SS. • <strong>AUTO</strong>: Select this item if you want Amazon Redshift to recognize and convert automatically the time format. • <strong>EPOCHSECS</strong>: Select this item if the source data is represented as epoch time, the number of seconds since Jan 1, 1970 00:00:00 UTC.</td>
</tr>
</tbody>
</table>

Note that the column label in the string has no relation to the table column name and it can be either a text string or an integer. The order of the label/width pairs must match the order of the table columns exactly. This field is available only when Fixed width is selected from the File type list.
- **EPOCHMILLISECS**: Select this item if the source data is represented as epoch time, the number of milliseconds since Jan 1, 1970 00:00:00 UTC.

**Settings**

Click the [*] button below the table to specify more parameters for loading the data.

- **Parameter**: Click the cell and select a parameter from the drop-down list.
- **Value**: Set the value for the corresponding parameter. Note that you cannot set the value for a parameter (such as `IGNOREBLANKLINES`) that does not need a value.

For more information about the parameters, see [http://docs.aws.amazon.com/redshift/latest/dg/r_Copy.html](http://docs.aws.amazon.com/redshift/latest/dg/r_Copy.html).

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

**Global Variables**

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](http://docs.aws.amazon.com/redshift/latest/dg/r_Copy.html).

**Usage**

**Usage rule**

The `tRedshiftBulkExec` component supports loading data to Amazon Redshift from a delimited/CSV, JSON, or fixed-width file on Amazon S3, but the `tRedshiftOutputBulk` component now only supports generating and uploading a delimited/CSV file to Amazon S3. When you need to load data from a JSON or fixed-width file, you can use the `tFileOutputJSON` or `tFileOutputPositional` component together with the `tS3Put` component instead of using the `tRedshiftOutputBulk` component to generate and upload the file to Amazon S3.

**Dynamic settings**

Click the [*] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases,
especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see **Scenario: Reading data from databases through context-based dynamic connections** on page 2497 and **Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters** on page 489. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

---

**Scenario: loading/unloading data from/to Amazon S3**

This scenario describes a Job that generates a delimited file and uploads the file to S3, loads data from the file on S3 to Redshift and displays the data on the console, then unloads the data from Redshift to files on S3 per slice of the Redshift cluster, and finally lists and gets the unloaded files on S3.
Prerequisites:
The following context variables have been created and saved in the Repository tree view. For more information about context variables, see Talend Studio User Guide.

- **redshift_host**: the connection endpoint URL of the Redshift cluster.
- **redshift_port**: the listening port number of the database server.
- **redshift_database**: the name of the database.
- **redshift_username**: the username for the database authentication.
- **redshift_password**: the password for the database authentication.
- **redshift_schema**: the name of the schema.
- **s3_accesskey**: the access key for accessing Amazon S3.
- **s3_secretkey**: the secret key for accessing Amazon S3.
- **s3_bucket**: the name of the Amazon S3 bucket.
Adding and linking components

Procedure

1. Create a new Job and apply all context variables listed above to the new Job.

2. Add the following components by typing their names in the design workspace or dropping them from the Palette: a `tRowGenerator` component, a `tRedshiftOutputBulk` component, a `tRedshiftBulkExec` component, a `tRedshiftInput` component, a `tLogRow` component, a `tRedshiftUnload` component, a `tS3List` component, and a `tS3Get` component.

3. Link `tRowGenerator` to `tRedshiftOutputBulk` using a `Row > Main` connection.

4. Do the same to link `tRedshiftInput` to `tLogRow`.

5. Link `tS3List` to `tS3Get` using a `Row > Iterate` connection.

6. Link `tRowGenerator` to `tRedshiftBulkExec` using a `Trigger > On Subjob Ok` connection.

7. Do the same to link `tRedshiftBulkExec` to `tRedshiftInput`, link `tRedshiftInput` to `tRedshiftUnload`, link `tRedshiftUnload` to `tS3List`.

Configuring the components

Preparing a file and uploading the file to S3

Procedure

1. Double-click `tRowGenerator` to open its `RowGenerator Editor`.

<table>
<thead>
<tr>
<th></th>
<th>Name</th>
<th>Type</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>redshift_host</td>
<td>String</td>
<td>redshift-cluster.abc123.redshift.amazonaws.com</td>
</tr>
<tr>
<td>2</td>
<td>redshift_port</td>

<td>String</td>
<td>redshift-bucket-talend</td>
</tr>
</tbody>
</table>
2. Click the [+] button to add two columns: **ID** of Integer type and **Name** of String type.

3. Click the cell in the **Functions** column and select a function from the list for each column. In this example, select **Numeric.sequence** to generate sequence numbers for the **ID** column and select **TalendDataGenerator.getFirstName** to generate random first names for the **Name** column.

4. In the **Number of Rows for RowGenerator** field, enter the number of data rows to generate. In this example, it is 20.

5. Click **OK** to close the schema editor and accept the propagation prompted by the pop-up dialog box.

6. Double-click **tRedshiftOutputBulk** to open its **Basic settings** view on the **Component** tab.

7. In the **Data file path at local** field, specify the local path for the file to be generated. In this example, it is `E:/Redshift/redshift_bulk.txt`.

8. In the **Access Key** field, press **Ctrl + Space** and from the list select `context.s3_accesskey` to fill in this field.

   Do the same to fill the **Secret Key** field with `context.s3_accesskey` and the **Bucket** field with `context.s3_bucket`.

9. In the **Key** field, enter a new name for the file to be generated after being uploaded on Amazon S3. In this example, it is **person_load**.
Loading data from the file on S3 to Redshift

Procedure

1. Double-click tRedshiftBulkExec to open its Basic settings view on the Component tab.

2. In the Host field, press Ctrl + Space and from the list select context.redshift_host to fill in this field. Do the same to fill:
   - the Port field with context.redshift_port,
   - the Database field with context.redshift_database,
   - the Schema field with context.redshift_schema,
   - the Username field with context.redshift_username,
   - the Password field with context.redshift_password,
   - the Access Key field with context.s3_accesskey,
   - the Secret Key field with context.s3_secretkey, and
   - the Bucket field with context.s3_bucket.

3. In the Table Name field, enter the name of the table to be written. In this example, it is person.

4. From the Action on table list, select Drop table if exists and create.

5. In the Key field, enter the name of the file on Amazon S3 to be loaded. In this example, it is person_load.

6. Click the [...] button next to Edit schema and in the pop-up window define the schema by adding two columns: ID of Integer type and Name of String type.
Retrieving data from the table on Redshift

Procedure

1. Double-click tRedshiftInput to open its Basic settings view on the Component tab.

2. Fill the Host, Port, Database, Schema, Username, and Password fields with their corresponding context variables.

3. In the Table Name field, enter the name of the table to be read. In this example, it is person.

4. Click the [...] button next to Edit schema and in the pop-up window define the schema by adding two columns: ID of Integer type and Name of String type.

5. In the Query field, enter the following SQL statement based on which the data are retrieved.

   "SELECT * FROM " + context.redshift_schema + "person ORDER BY "ID""

6. Double-click tLogRow to open its Basic settings view on the Component tab.
7. In the Mode area, select Table (print values in cells of a table) for a better display of the result.

**Unloading data from Redshift to file(s) on S3**

**Procedure**

1. Double-click `tRedshiftUnload` to open its Basic settings view on the Component tab.

2. Fill the Host, Port, Database, Schema, Username, and Password fields with their corresponding context variables.

3. Fill the Access Key, Secret Key, and Bucket fields also with their corresponding context variables.

4. In the Table Name field, enter the name of the table from which the data will be read. In this example, it is `person`.

5. Click the [...] button next to Edit schema and in the pop-up window define the schema by adding two columns: ID of Integer type and Name of String type.

6. In the Query field, enter the following SQL statement based on which the result will be unloaded.

   ```sql
   "SELECT * FROM person"
   ```

7. In the Key prefix field, enter the name prefix for the unload files. In this example, it is `person_unload_`. 
Retrieving files unloaded to Amazon S3

Procedure

1. Double-click tS3List to open its Basic settings view on the Component tab.

   ![tS3List_1](image)

   - Connection
     - Use an existing connection
     - Access Key: `context.s3_accesskey`
     - Secret Key: `context.s3_secretkey`
     - Inherit credentials from AWS role
     - Assume Role
   - Region: `US Standard`
   - List all buckets objects
   - Bucket:
     - Bucket name: `context.s3_bucket`
     - Key prefix: "person_unload_"

2. Fill the Access Key and Secret Key fields with their corresponding context variables.
3. From the Region list, select the AWS region where the unload files are created. In this example, it is US Standard.
4. Clear the List all buckets objects check box, and click the [+ ] button under the table displayed to add one row.
   - Fill in the Bucket name column with the name of the bucket in which the unload files are created. In this example, it is the context variable `context.s3_bucket`.
   - Fill in the Key prefix column with the name prefix for the unload files. In this example, it is `person_unload_`.

5. Double-click tS3Get to open its Basic settings view on the Component tab.

   ![tS3Get_1](image)

   - Connection
     - Use an existing connection
     - Access Key: `context.s3_accesskey`
     - Secret Key: `context.s3_secretkey`
     - Inherit credentials from AWS role
     - Assume Role
   - Region: `US Standard`
   - Encrypt
   - Bucket: `context.s3_bucket`
   - Key: `"E\//Redshift/\" + ((String)globalMap.get("S3List\_1\_CURRENT\_KEY"))`
   - File: `"E\//Redshift/\" + ((String)globalMap.get("S3List\_1\_CURRENT\_KEY"))`

6. Fill the Access Key field and Secret Key field with their corresponding context variables.
7. From the Region list, select the AWS region where the unload files are created. In this example, it is US Standard.
8. In the **Bucket** field, enter the name of the bucket in which the unload files are created. In this example, it is the context variable `context.s3_bucket`.

   In the **Key** field, enter the name of the unload files by pressing **Ctrl + Space** and from the list selecting the global variable `((String)globalMap.get("tS3List_1_CURRENT_KEY"))`.

9. In the **File** field, enter the local path where the unload files are saved. In this example, it is `E:/Redshift/ + ((String)globalMap.get("tS3List_1_CURRENT_KEY"))`.

### Saving and executing the Job

**Procedure**

1. Press **Ctrl + S** to save the Job.

2. Execute the Job by pressing **F6** or clicking **Run** on the **Run** tab.

   ![Image of save and execute process](image.png)

   ```plaintext
   [statistics] connecting to socket on port 3726
   [statistics] connected
   tLogRow_1
   ID  Name
   1  Abraham
   2  Herbert
   3  Chester
   4  John
   5  Gerald
   6  Lyndon
   7  Warren
   8  Calvin
   9  Chester
   10  Herbert
   11  Ronald
   12  Herbert
   13  Martin
   14  James
   15  Franklin
   16  Herbert
   17  Richard
   18  Warren
   19  Jimmy
   20  George
   [statistics] disconnected
   ```
As shown above, the generated data is written into the local file `redshift_bulk.txt`, the file is uploaded on S3 with the new name `person_load`, and then the data is loaded from the file on S3 to the table `person` in Redshift and displayed on the console. After that, the data is unloaded from the table `person` in Redshift to two files `personUnload_0000_part_00` and `personUnload_0001_part_00` on S3 per slice of the Redshift cluster, and finally the unloaded files on S3 are listed and retrieved in the local folder.
tRedshiftClose

Closes the transaction committed in the connected DB.

This component is used together with tRedshiftConnection and tRedshiftCommit to ensure the integrity of the transaction performed into the database.

**tRedshiftClose Standard properties**

These properties are used to configure tRedshiftClose running in the Standard Job framework.

The Standard tRedshiftClose component belongs to the Cloud and the Databases families.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tRedshiftConnection component in the list if more than one connection are planned for the current Job.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is to be used along with Amazon Redshift components, especially with tRedshiftConnection and tRedshiftCommit.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic settings</td>
<td>Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.</td>
</tr>
</tbody>
</table>
For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

### Related scenario

For a related scenario, see Scenario: Handling data with Redshift on page 3139.
tRedshiftCommit

Provides gain in performance.

Using a unique connection, this component commits in one go a global transaction instead of doing that on every row or every batch.

tRedshiftCommit validates the data processed through the Job into the connected database.

**tRedshiftCommit Standard properties**

These properties are used to configure tRedshiftCommit running in the Standard Job framework.

The Standard tRedshiftCommit component belongs to the Cloud and the Databases families.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Component list</th>
<th>Select the tRedshiftConnection component in the list if more than one connection are planned for the current job.</th>

</tr>
</thead>
</table>

| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |

Related scenario

For a similar scenario, see Scenario: Inserting data in mother/daughter tables on page 2476.
tRedshiftConnection

Opens a connection to the specified database that can then be reused in the subsequent subjob or subjobs.

tRedshiftConnection opens a connection to the database for a current transaction.

**tRedshiftConnection Standard properties**

These properties are used to configure tRedshiftConnection running in the Standard Job framework. The Standard tRedshiftConnection component belongs to the Cloud and the Databases families. The component in this framework is generally available.

**Note:**
This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Host</td>
<td>Host name or IP address of DB server.</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database.</td>
</tr>
<tr>
<td>Schema</td>
<td>Name of the schema.</td>
</tr>
</tbody>
</table>
| Username and Password | DB user authentication data.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| Additional JDBC Parameters | Specify additional JDBC properties for the connection you are creating. The properties are separated by ampersand & and each property is a key-value pair. For example, ssl=true & ssifactory=com.amazon.redshift.ssl.NonValidatingFactory, which means the connection will be created using SSL. |
Use or register a shared DB Connection

Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the Shared DB Connection Name field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child.

This option is incompatible with the Use dynamic job and Use an independent process to run subjob options of the tRunJob component. Using a shared connection together with a tRunJob component with either of these two options enabled will cause your Job to fail.

Advanced settings

Auto Commit

Select this check box to commit any changes to the database automatically upon the transaction.

With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared.

By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component.

Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component.

tStatCatcher Statistics

Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

Usage

Usage rule

This component is more commonly used with other tRedshift* components, especially with the tRedshiftCommit and tRedshiftRollback components.

Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).
Related scenario

For a related scenario, see Scenario: Handling data with Redshift on page 3139.
tRedshiftInput

Reads data from a database and extracts fields based on a query so that you may apply changes to the extracted data.

tRedshiftInput executes a DB query with a strictly defined order which must correspond to the schema definition. Then it passes on the field list to the next component through a Main row link.

### tRedshiftInput Standard properties

These properties are used to configure tRedshiftInput running in the Standard Job framework.

The Standard tRedshiftInput component belongs to the Cloud and the Databases families.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

#### Basic settings

<table>
<thead>
<tr>
<th>Property type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

Click this icon to open a database connection wizard and store the database connection parameters you set in the component **Basic settings** view.

For more information about setting up and storing database connection parameters, see **Talend Studio User Guide**.

**Use an existing connection**

Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined.

**Note:**

When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic**
settings view of the connection component which creates that very database connection.

2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th>Host</th>
<th>Hostname or IP address of the database server.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>Listening port number of the database server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database.</td>
</tr>
<tr>
<td>Schema</td>
<td>Exact name of the schema.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>Database user authentication data. The properties are separated by ampersand &amp; and each property is a key-value pair. For example, <code>ssl=true &amp; ssifactory=com.amazon.redshift.ssl.NonValidatingFactory</code>, which means the connection will be created using SSL.</td>
</tr>
<tr>
<td>Additional JDBC Parameters</td>
<td>Specify additional JDBC properties for the connection you are creating. For example, <code>ssl=true &amp; ssifactory=com.amazon.redshift.ssl.NonValidatingFactory</code>, which means the connection will be created using SSL.</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <code>line</code> when naming the fields.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-In</strong>: You create and store the schema locally for this component only. Related topic: see <em>Talend Studio User Guide</em>.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see <em>Talend Studio User Guide</em>.</td>
</tr>
<tr>
<td></td>
<td>Click <strong>Edit schema</strong> to make changes to the schema. If the current schema is of the Repository type, three options are available:</td>
</tr>
<tr>
<td></td>
<td>• <strong>View schema</strong>: choose this option to view the schema only.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Change to built-in property</strong>: choose this option to change the schema to Built-in for local changes.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Update repository connection</strong>: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate</td>
</tr>
</tbody>
</table>
the changes to the current Job, you can select No upon completion and choose this schema metadata again in the [Repository Content] window.

<table>
<thead>
<tr>
<th>Table Name</th>
<th>Name of the table from which the data will be read.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Query Type and Query</strong></td>
<td>Enter your database query paying particularly attention to sequence the fields properly in order to match the schema definition.</td>
</tr>
<tr>
<td><strong>Guess Query</strong></td>
<td>Click the Guess Query button to generate the query which corresponds to your table schema in the Query field.</td>
</tr>
<tr>
<td><strong>Guess schema</strong></td>
<td>Click the Guess schema button to retrieve the table schema.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| Log file | Specify the path to the log file to be generated during the data retrieval process. Note that if the logging information needs to be saved and this component reuses the connection created by a tRedshiftConnection component, you must specify the property loglevel=1/2/3 in the Additional JDBC Parameters field of the tRedshiftConnection component. |
| Logging level | Select a logging level from the drop-down list to specify which kind of events will be logged in the log file. |
| Use cursor | Select this check box to help to decide the row set to work with at a time and thus optimize performance. |
| Trim all the String/Char columns | Select this check box to remove leading and trailing whitespace from all the String/Char columns. |
| Trim column | Remove leading and trailing whitespace from defined columns. |
| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

**Global Variables**

| Global Variables | **NB_LINE**: the number of rows processed. This is an After variable and it returns an integer. **QUERY**: the query statement being processed. This is a Flow variable and it returns a string. **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. |

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component covers all possible SQL queries for Amazon Redshift databases.</th>
</tr>
</thead>
</table>

**Dynamic settings**

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

**Limitation**

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

**Scenario: Handling data with Redshift**

This scenario describes a Job that writes the personal information into Redshift, then retrieves the information in Redshift and displays it on the console.
The scenario requires the following six components:

- **tRedshiftConnection**: opens a connection to Redshift.
- **tFixedFlowInput**: defines the personal information data structure, and sends the data to the next component.
- **tRedshiftOutput**: writes the data it receives from the preceding component into Redshift.
- **tRedshiftInput**: reads the data from Redshift.
- **tLogRow**: displays the data it receives from the preceding component on the console.
- **tRedshiftClose**: closes the connection to Redshift.

**Dropping and linking the components**

**Procedure**

1. Drop the six components listed previously from the **Palette** onto the design workspace.
2. Connect **tFixedFlowInput** to **tRedshiftOutput** using a **Row > Main** connection.
3. Connect **tRedshiftInput** to **tLogRow** also using a **Row > Main** connection.
4. Connect **tRedshiftConnection** to **tFixedFlowInput** using a **Trigger > OnSubjobOk** connection.
5. Connect **tFixedFlowInput** to **tRedshiftInput** and **tRedshiftInput** to **tRedshiftClose** also using a **Trigger > OnSubjobOk** connection.
Configuring the components

Opening a connection to Redshift

Procedure

1. Double-click \texttt{tRedshiftConnection} to open its \textit{Basic settings} view.

   \begin{center}
   \includegraphics[width=\textwidth]{tRedshiftConnection_1}
   \end{center}

   \begin{itemize}
   \item Select \textit{Built-In} from the \textit{Property Type} drop-down list.
   \item In the \texttt{Host}, \texttt{Port}, \texttt{Database}, \texttt{Schema}, \texttt{Username}, and \texttt{Password} fields, enter the information required for the connection to Redshift.
   \item In \textit{Advanced settings} view, select \textit{Auto Commit} check box to commit any changes to Redshift upon each transaction.
   \end{itemize}

Defining the input data

Procedure

1. Double-click \texttt{tFixedFlowInput} to open its \textit{Basic settings} view.

   \begin{center}
   \includegraphics[width=\textwidth]{tFixedFlowInput_1}
   \end{center}

   \begin{itemize}
   \item Click the [...] button next to \textit{Edit schema} to open the schema editor.
   \end{itemize}
In the schema editor, click the [+ ] button to add three columns: id of the integer type, name of the string type, and age of the integer type.

Click OK to validate the changes and accept the propagation prompted by the pop-up [Propagate] dialog box.

In the Mode area, select Use Inline Content (delimited file) and enter the following personal information in the Content field.

Writing the data into Redshift

Procedure

1. Double-click tRedshiftOutput to open its Basic settings view.

2. Select the Use an existing connection check box, and then select the connection you have already configured for tRedshiftConnection from the Component List drop-down list.

3. In the Table field, enter or browse to the table into which you want to write the data, redshiftexample in this scenario.

4. Select Drop table if exists and create from the Action on table drop-down list, and select Insert from the Action on data drop-down list.

5. Click Sync columns to retrieve the schema from the preceding component tFixedFlowInput.
Retrieving the data from Redshift

Procedure

1. Double-click **tRedshiftInput** to open its **Basic settings** view.

   ![tRedshiftInput Basic settings view](image)

2. Select the **Use an existing connection** check box, and then select the connection you have already configured for **tRedshiftConnection** from the **Component List** drop-down list.

3. Click the [...] button next to **Edit schema** to open the schema editor.

4. In the schema editor, click the [+ ] button to add three columns: **id** of the integer type, **name** of the string type, and **age** of the integer type. The data structure is same as the structure you have defined for **tFixedFlowInput**.

5. Click **OK** to validate the changes and accept the propagation prompted by the pop-up **[Propagate]** dialog box.

6. In the **Table Name** field, enter or browse to the table into which you write the data, **redshiftexample** in this scenario.

7. Click the **Guess Query** button to generate the query. The **Query** field will be filled with the automatically generated query.

Displaying the defined information

Procedure

1. Double-click **tLogRow** to open its **Basic settings** view.

   ![tLogRow Basic settings view](image)

2. In the **Mode** area, select **Table (print values in cells of a table)** for a better view of the results.
Closing the connection to Redshift

Procedure

1. Double-click **tRedshiftClose** to open its **Basic settings** view.

   ![tRedshiftClose](image)

2. From **Component List**, select the connection you have already configured for **tRedshiftConnection**.

Saving and executing the Job

Procedure

1. Press **Ctrl+S** to save the Job.
2. Press **F6** to execute the Job.

```
Starting job DOCTS151_tRedshift_S01 at 17:18 19/03/2014
[statistics] connecting to socket on port 3000
[statistics] connected
| tLogRow_1
<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
<th>age</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Arthur</td>
<td>16</td>
</tr>
<tr>
<td>2</td>
<td>Ford</td>
<td>18</td>
</tr>
<tr>
<td>3</td>
<td>Jackson</td>
<td>17</td>
</tr>
</tbody>
</table>
[statistics] disconnected
Job DOCTS151_tRedshift_S01 ended at 17:18 19/03/2014. [exit code=0]
```

The personal information is written to the specified target Redshift database, and then the data is retrieved from the database and displayed on the console.
tRedshiftOutput

 Writes, updates, modifies or deletes the data in a database.

 tRedshiftOutput executes the action defined on the table and/or on the data of a table, according to the input flow from the previous component.

**tRedshiftOutput Standard properties**

These properties are used to configure tRedshiftOutput running in the Standard Job framework.

The Standard tRedshiftOutput component belongs to the Cloud and the Databases families.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository .</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>![Database icon]</td>
<td>Click this icon to open a database connection wizard and store the database connection parameters you set in the component Basic settings view.</td>
</tr>
<tr>
<td></td>
<td>For more information about setting up and storing database connection parameters, see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td>![Database icon]</td>
<td>Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:</td>
</tr>
<tr>
<td></td>
<td>1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component</td>
</tr>
</tbody>
</table>
which creates that very database connection.

2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>Host</th>
<th>Hostname or IP address of the database server.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>Listening port number of the database server.</td>
</tr>
<tr>
<td>Database</td>
<td>Database name.</td>
</tr>
<tr>
<td>Schema</td>
<td>Exact name of the schema.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>Database user authentication data.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Additional JDBC Parameters</td>
<td>Specify additional JDBC properties for the connection you are creating. The properties are separated by ampersand &amp; and each property is a key-value pair. For example, ssl=true &amp; sslfactory=com.amazon.redshift.ssl.NonValidatingFactory, which means the connection will be created using SSL.</td>
</tr>
<tr>
<td>Table</td>
<td>Name of the table to which the data will be written. Note that only one table can be written at a time.</td>
</tr>
<tr>
<td>Action on table</td>
<td>On the table defined, you can perform one of the following operations:</td>
</tr>
<tr>
<td></td>
<td><strong>None</strong>: No operation is carried out.</td>
</tr>
<tr>
<td></td>
<td><strong>Drop and create a table</strong>: The table is removed and created again.</td>
</tr>
<tr>
<td></td>
<td><strong>Create a table</strong>: The table does not exist and gets created.</td>
</tr>
<tr>
<td></td>
<td><strong>Create a table if not exists</strong>: The table is created if it does not exist.</td>
</tr>
<tr>
<td></td>
<td><strong>Drop a table if exists and create</strong>: The table is removed if already exists and created again.</td>
</tr>
<tr>
<td></td>
<td><strong>Clear a table</strong>: The table content is deleted.</td>
</tr>
<tr>
<td>Action on data</td>
<td>On the data of the table defined, you can perform:</td>
</tr>
<tr>
<td></td>
<td><strong>Insert</strong>: Add new entries to the table. If duplicates are found, the operation will stop.</td>
</tr>
<tr>
<td></td>
<td><strong>Update</strong>: Make changes to existing entries.</td>
</tr>
<tr>
<td></td>
<td><strong>Insert or update</strong>: Insert a new record. If the record with the given reference already exists, an update would be made.</td>
</tr>
</tbody>
</table>
**Update or insert**: Update the record with the given reference. If the record does not exist, a new record would be inserted.

**Delete**: Remove entries corresponding to the input flow.

**Warning:**

*It is necessary to specify at least one column as a primary key on which the Update and Delete operations are based. You can do that by clicking Edit Schema and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the Advanced settings view where you can simultaneously define primary keys for the Update and Delete operations. To do that: Select the Use field options check box and then in the Key in update column select the check boxes next to the column names you want to use as a base for the Update operation. Do the same in the Key in delete column for the Delete operation.*

**Schema** and **Edit Schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

**Built-In**: You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Click **Edit schema** to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.
### Die on error

This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error through a Row > Rejects link.

### Advanced settings

#### Extend Insert

Select this check box to carry out a bulk insert of a defined set of lines instead of inserting lines one by one. The gain in system performance is considerable.

**Number of rows per insert:** enter the number of rows to be inserted per operation. Note that the higher the value specified, the lower performance levels shall be due to the increase in memory demands.

Amazon Redshift requires the number of rows per insert to be less than 32767. For this reason, if the number you enter exceeds this maximum limit, the Studio automatically resets this number below this limit.

**Note:**

This option is not compatible with the Reject link. You should therefore clear the check box if you are using a Row > Rejects link with this component.

#### Use Batch

Select this check box to activate the batch mode for data processing.

**Note:**

This check box is available only when you have selected the Update or the Delete option in the Action on data field.

#### Batch Size

Specify the number of records to be processed in each batch.

This field appears only when the Use batch mode check box is selected.

#### Commit every

Enter the number of rows to be completed before committing batches of rows together into the database. This option ensures transaction quality (but not rollback) and, above all, better performance at execution.

#### Additional Columns

This option is not offered if you create (with or without drop) the DB table. This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing.

**Name:** Type in the name of the schema column to be altered or inserted as new column.

**SQL expression:** Type in the SQL statement to be executed in order to alter or insert the relevant column data.
**Position:** Select *Before*, *Replace* or *After* following the action to be performed on the reference column.

**Reference column:** Type in a column of reference that the tDBOutput can use to place or replace the new or altered column.

**Use field options**
Select this check box to customize a request, especially when there is double action on data.

**tStat Catcher Statistics**
Select this check box to collect log data at the component level.

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_LINE: the number of rows processed. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>NB_LINE_UPDATED: the number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>NB_LINE_INSERTED: the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>NB_LINE_DELETED: the number of rows deleted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>NB_LINE_REJECTED: the number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press <em>Ctrl + Space</em> to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td></td>
<td>For further information about variables, see <em>Talend Studio User Guide</em>.</td>
</tr>
</tbody>
</table>

### Usage

**Usage rule**
This component covers all possible SQL database queries. It allows you to carry out actions on a table or on the data of a table in an Amazon Redshift database. It enables you to create a reject flow, with a *Row > Rejects* link filtering the data in error. For a usage example, see *Scenario: Retrieving data in error with a Reject link* on page 2529.

**Dynamic settings**
Click the [*+*] button to add a row in the table and fill the *Code* field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful.
when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see **Scenario: Reading data from databases through context-based dynamic connections** on page 2497 and **Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters** on page 489. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>Limitation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the <strong>Install</strong> button on the <strong>Component</strong> tab view. You can also find out and add all missing JARs easily on the <strong>Modules</strong> tab in the <strong>Integration</strong> perspective of your studio. You can find more details about how to install external modules in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
</tbody>
</table>

**Related scenarios**

For a related scenario, see **Scenario: Handling data with Redshift** on page 3139.
tRedshiftOutputBulk

Prepares a delimited/CSV file that can be used by tRedshiftBulkExec to feed Amazon Redshift.

The tRedshiftOutputBulk and tRedshiftBulkExec components can be used together in a two step process to load data to Amazon Redshift from a delimited/CSV file on Amazon S3. In the first step, a delimited/CSV file is generated. In the second step, this file is used in the INSERT statement used to feed Amazon Redshift. These two steps are fused together in the tRedshiftOutputBulkExec component. The advantage of using two separate steps is that the data can be transformed before it is loaded to Amazon Redshift.

This component receives data from the preceding component, generates a single delimited/CSV file and then uploads the file to Amazon S3.

tRedshiftOutputBulk Standard properties

These properties are used to configure tRedshiftOutputBulk running in the Standard Job framework.

The Standard tRedshiftOutputBulk component belongs to the Cloud and the Databases families.

The component in this framework is generally available.

Note:

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data file path at local</td>
<td>Specify the local path to the file to be generated. Note that the file is generated on the same machine where the Studio is installed or where the Job using this component is deployed.</td>
</tr>
<tr>
<td>Schema and Edit schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td>Built-In</td>
<td>You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Repository</td>
<td>You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.

**Compress the data file**

Select this check box and select a compression type from the list displayed to compress the data file.

This check box disappears when the **Append the local file** check box is selected.

**Encrypt**

Select this check box to generate and upload the data file to Amazon S3 using client-side encryption. In the **Encryption key** field displayed, enter the encryption key used to encrypt the file.

By default, this check box is cleared and the data file will be uploaded to Amazon S3 using server-side encryption.

For more information about the client-side and server-side encryption, see Protecting Data Using Encryption.

**Access Key**

Specify the Access Key ID that uniquely identifies an AWS Account. For how to get your Access Key and Access Secret, visit Getting Your AWS Access Keys.

**Secret Key**

Specify the Secret Access Key, constituting the security credentials in combination with the access Key.

To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

**Bucket**

Type in the name of the Amazon S3 bucket, namely the top level folder, to which the file is uploaded.

**Key**

Type in an object key to assign to the file uploaded to Amazon S3.

**Advanced settings**

- **Field Separator**: Enter the character used to separate fields.
- **Text enclosure**: Select the character in a pair of which the fields are enclosed.
Delete local file after putting it to s3
Select this check box to delete the local file after being uploaded to Amazon S3. By default, this check box is selected.

Create directory if not exists
Select this check box to create the directory specified in the Data file path at local field if it does not exist. By default, this check box is selected.

Encoding
Select an encoding type for the data in the file to be generated.

Config client
Select this check box to configure client parameters for Amazon S3. Click the [+] button below the table displayed to add as many rows as needed, each row for a client parameter, and set the following attributes for each parameter:
- Client Parameter: Click the cell and select a parameter from the drop-down list.
- Value: Enter the value for the corresponding client parameter.

TStatCatcher Statistics
Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

Global Variables

**Global Variables**

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE</strong>:</td>
<td>the number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>ERROR_MESSAGE</strong>:</td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>
Related scenario

For a related scenario, see Scenario: loading/unloading data from/to Amazon S3 on page 3119.
tRedshiftOutputBulkExec

Executes the Insert action on the data provided.

As a dedicated component, it allows gains in performance during Insert operations to Amazon Redshift.

The tRedshiftOutputBulk and tRedshiftBulkExec components can be used together in a two step process to load data to Amazon Redshift from a delimited/CSV file on Amazon S3. In the first step, a delimited/CSV file is generated. In the second step, this file is used in the INSERT statement used to feed Amazon Redshift. These two steps are fused together in the tRedshiftOutputBulkExec component. The advantage of using two separate steps is that the data can be transformed before it is loaded to Amazon Redshift.

This component receives data from the preceding component, generates a single delimited/CSV file and uploads the file to Amazon S3, finally it loads the data from Amazon S3 to Redshift.

tRedshiftOutputBulkExec Standard properties

These properties are used to configure tRedshiftOutputBulkExec running in the Standard Job framework.

The Standard tRedshiftOutputBulkExec component belongs to the Cloud and the Databases families.

The component in this framework is generally available.

Note:
This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property Type</td>
<td>Either Built-In or Repository.</td>
</tr>
<tr>
<td>Host</td>
<td>Type in the IP address or hostname of the database server.</td>
</tr>
<tr>
<td>Port</td>
<td>Type in the listening port number of the database server.</td>
</tr>
</tbody>
</table>

Built-In: No property data stored centrally.

Repository: Select the repository file in which the properties are stored. The database connection fields that follow are completed automatically using the data retrieved.

Use an existing connection

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.
| **Database** | Type in the name of the database. |
| **Schema** | Type in the name of the schema. |
| **Username and Password** | Type in the database user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| **Additional JDBC Parameters** | Specify additional JDBC properties for the connection you are creating. The properties are separated by ampersand & and each property is a key-value pair. For example, `ssl=true & sslfactory=com.amazon.redshift.ssl.NonValidatingFactory`, which means the connection will be created using SSL. |
| **Table Name** | Specify the name of the table to be written. Note that only one table can be written at a time. |
| **Action on table** | On the table defined, you can perform one of the following operations: <ul> • **None**: No operation is carried out. • **Drop and create table**: The table is removed and created again. • **Create table**: The table does not exist and gets created. • **Create table if not exists**: The table is created if it does not exist. • **Drop table if exists and create**: The table is removed if it already exists and created again. • **Clear table**: The table content is deleted. You have the possibility to rollback the operation. </ul> |
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. <ul> • **Built-In**: You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide. • **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide. </ul> Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available: <ul> • **View schema**: choose this option to view the schema only. </ul>
• **Change to built-in property**: choose this option to change the schema to Built-in for local changes.

• **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the [Repository Content] window.

<table>
<thead>
<tr>
<th><strong>Data file path at local</strong></th>
<th>Specify the local path to the file to be generated. Note that the file is generated on the same machine where the Studio is installed or where the Job using this component is deployed.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Append the local file</strong></td>
<td>Select this check box to append data to the specified local file if it already exists, instead of overwriting it.</td>
</tr>
<tr>
<td><strong>Create directory if not exists</strong></td>
<td>Select this check box to create the directory specified in the <strong>Data file path at local</strong> field if it does not exist. By default, this check box is selected.</td>
</tr>
<tr>
<td><strong>Access Key</strong></td>
<td>Specify the Access Key ID that uniquely identifies an AWS Account. For how to get your Access Key and Access Secret, visit <a href="#">Getting Your AWS Access Keys</a>.</td>
</tr>
<tr>
<td><strong>Secret Key</strong></td>
<td>Specify the Secret Access Key, constituting the security credentials in combination with the access Key. To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>

</tr>
</tbody>
</table>
### Config client

Select this check box to configure client parameters for Amazon S3. Click the [+] button below the table displayed to add as many rows as needed, each row for a client parameter, and set the following attributes for each parameter:

- **Client Parameter**: Click the cell and select a parameter from the drop-down list.
- **Value**: Enter the value for the corresponding client parameter.

### tStatCatcher Statistics

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

**Global Variables**

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

#### Usage rule

This component is mainly used when no particular transformation is required on the data to be loaded to Amazon Redshift.

#### Dynamic settings

Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see *Scenario: Reading data from databases through context-*
Related scenario

For a related scenario, see Scenario: loading/unloading data from/to Amazon S3 on page 3119.
tRedshiftRollback

Cancels the transaction commit in the Redshift database to avoid committing part of a transaction involuntarily.

**tRedshiftRollback Standard properties**

These properties are used to configure tRedshiftRollback running in the Standard Job framework.
The Standard tRedshiftRollback component belongs to the Cloud and the Databases families.
The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.
For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tRedshiftConnection component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

### Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

### Usage

| Usage rule | This component is more commonly used with other tRedshift* components, especially with the tRedshiftConnection and tRedshiftCommit components. |
| Dynamic settings | Click the [+button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. |
Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see **Scenario: Reading data from databases through context-based dynamic connections** on page 2497 and **Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters** on page 489. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

**Related scenario**

For a similar scenario, see **Scenario: Rollback from inserting data in mother/daughter tables** on page 2480.
tRedshiftRow

Acts on the actual DB structure or on the data (although without handling data), depending on the nature of the query and the database.

The SQLBuilder tool helps you write easily your SQL statements.

tRedshiftRow is the specific component for this database query. It executes the SQL query stated onto the specified database. The row suffix means the component implements a flow in the job design although it does not provide output.

**tRedshiftRow Standard properties**

These properties are used to configure tRedshiftRow running in the Standard Job framework.

The Standard tRedshiftRow component belongs to the Cloud and the Databases families.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
<td></td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td>Note:</td>
<td>When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:</td>
</tr>
<tr>
<td>1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.</td>
<td></td>
</tr>
</tbody>
</table>
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see [Talend Studio User Guide](#).

<table>
<thead>
<tr>

<td><strong>Note:</strong></td>
<td>This option is very useful if you need to execute the same query several times. Performance levels are increased.</td>
</tr>
</tbody>
</table>

| Commit every | Number of rows to be completed before committing batches of rows together into the database. This option |
ensures transaction quality (but not rollback) and above all better performance on executions.

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

### Global Variables

**Global Variables**

<table>
<thead>
<tr>
<th>QUERY</th>
<th>the query statement being processed. This is a Flow variable and it returns a string.</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERROR_MESSAGE</td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

### Usage

**Usage rule**

This component offers the flexibility benefit of the database query and covers all possible SQL queries.

**Dynamic settings**

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

**Limitation**

Due to license incompatibility, one or more JARs required to use this component are not provided.
Related scenarios

For similar scenarios, see:

- Scenario: Combining two flows for selective output on page 2558
- Procedure on page 625
- Scenario: Removing and regenerating a MySQL table index on page 2552
tRedshiftUnload

Unloads data on Amazon Redshift to files on Amazon S3.
This component runs a specified query in Amazon Redshift and then unloads the result of the query to
one or more files on Amazon S3.

**tRedshiftUnload Standard properties**

These properties are used to configure tRedshiftUnload running in the Standard Job framework.
The Standard tRedshiftUnload component belongs to the Cloud and the Databases families.
The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Either Built-In or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Built-In:</strong> No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository:</strong> Select the repository file in which the properties are stored. The database connection fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

**Host**

Type in the IP address or hostname of the database server.

**Port**

Type in the listening port number of the database server.

**Database**

Type in the name of the database.

**Schema**

Type in the name of the schema.

**Username and Password**

Type in the database user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

**Additional JDBC Parameters**

Specify additional JDBC properties for the connection you are creating. The properties are separated by ampersand & and each property is a key-value pair. For example, `ssl=true & ssifactory=com.amazon.redshift.ssl.NonValidatingFactory`, which means the connection will be created using SSL.

**Table Name**

Type in the name of the table from which the data will be read.
### Schema and Edit schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

**Built-In**: You create and store the schema locally for this component only. Related topic: see [Talend Studio User Guide](#).

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see [Talend Studio User Guide](#).

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.

### Query Type and Query

Enter the database query paying particularly attention to the proper sequence of the fields in order to match the schema definition.

### Guess Query

Click the button to generate the query which corresponds to the table schema in the **Query** field.

### Access Key

Specify the Access Key ID that uniquely identifies an AWS Account. For how to get your Access Key and Access Secret, visit [Getting Your AWS Access Keys](#).

### Secret Key

Specify the Secret Access Key, constituting the security credentials in combination with the access Key.

To enter the secret key, click the `[...]` button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

### Bucket

Type in the name of the Amazon S3 bucket, namely the top level folder, to which the data is unloaded.

### Key prefix

Type in the name prefix for the unload files on Amazon S3. By default, the unload files are written per slice of the Redshift cluster and the file names are written in the format `<object_path>/<name_prefix><slice-number>_part_<file-number>`.
### Advanced settings

| **File type** | Select the type of the unload files on Amazon S3 from the list:  
| | • Delimited file or CSV: a delimited/CSV file.  
| | • Fixed width: a fixed-width file. |

| **Fields terminated by** | Enter the character used to separate fields.  
| | This field appears only when Delimited file or CSV is selected from the File type list.  

| **Enclosed by** | Select the character in a pair of which the fields are enclosed.  
| | This list appears only when Delimited file or CSV is selected from the File type list.  

| **Fixed width mapping** | Enter a string that specifies a user-defined column label and column width between double quotation marks. The format of the string is:  
| | ColumnLabel1:ColumnWidth1,ColumnLabel2:ColumnWidth2,...  
| | Note that the column label in the string has no relation to the table column name and it can be either a text string or an integer. The order of the label/width pairs must match the order of the table columns exactly.  
| | This field appears only when Fixed width is selected from the File type list. |

| **Compressed by** | Select this check box and from the list displayed select the compression type of the files. |

| **Encrypt** | Select this check box to encrypt unload file(s) using Amazon S3 client-side encryption. In the Encryption key field displayed, enter the encryption key used to encrypt the unload file(s). Note that only a base64 encoded AES 128-bit or AES 256-bit envelope key is supported. For more information, see Unloading Encrypted Data Files. |

| **Specify null string** | Select this check box and from the list displayed select a string that represents a null value in unload files. |

| **Escape** | Select this check box to place an escape character (\) before every occurrence of the following characters for CHAR and VARCHAR columns in the delimited unload files: linefeed (\n), carriage return (\r), the delimiter character specified for the unloaded data, the escape character (\), a quote character (" or "). |

| **Overwrite s3 object if exist** | Select this check box to overwrite the existing Amazon S3 object files. |

| **Parallel** | Select this check box to write data in parallel to multiple unload files on Amazon S3 according to the number of slices in the Redshift cluster. |
tStatCatcher Statistics

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

Global Variables

Global Variables

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

Usage

**Usage rule**

This component covers all possible SQL queries for the Amazon Redshift database.

**Dynamic settings**

Click the [*] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see *Scenario: Reading data from databases through context-based dynamic connections* on page 2497 and *Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters* on page 489. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

Related Scenario

For a related scenario, see *Scenario: loading/unloading data from/to Amazon S3* on page 3119.
tReplace

Cleanses all files before further processing.
Carries out a Search & Replace operation in the input columns defined.

tReplace Standard properties

These properties are used to configure tReplace running in the Standard Job framework.
The Standard tReplace component belongs to the Processing family.
The component in this framework is generally available.

Basic settings

| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.
Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:
• View schema: choose this option to view the schema only.
• Change to built-in property: choose this option to change the schema to Built-in for local changes.
• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the [Repository Content] window.
Two read-only columns, Value and Match are added to the output schema automatically. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Built-In</td>
<td>You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Repository</td>
<td>You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>
| Simple Mode Search / Replace | Click the button to add as many conditions as needed. The conditions are performed one after the other for each row.
Input column: Select the column of the schema the search & replace is to be operated on.
Search: Type in the value to search in the input column. |
| **Replace with**: Type in the substitution value. |
| **Whole word**: Select this check box if the searched value is to be considered as whole. |
| **Case sensitive**: Select this check box to care about the case. |

Note that you cannot use regular expression in these columns.

### Use advanced mode

Select this check box when the operation you want to perform cannot be carried out through the simple mode. In the text field, type in the regular expression as required.

### Advanced settings

**tStatCatcher Statistics**

Select this check box to gather the job processing metadata at a job level as well as at each component level.

### Global Variables

**Global Variables**

- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.
- **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

**Usage rule**

This component is not startable as it requires an input flow. And it requires an output component.

### Scenario 1: Multiple replacements and column filtering

This following Job searches and replaces various typos and defects in a csv file then operates a column filtering before producing a new csv file with the final output.
• Drop the following components from the Palette onto the design workspace: tFileInputDelimited, tReplace, tFilterColumn and tFileOutputDelimited.

• Connect the components using Main Row connections via a right-click each component.

• Select the tFileInputDelimited component and set the input flow parameters.

  Property Type: Built-In
  File name: 'D:\Input\replace.csv'
  Row Separator: "\r"  Field Separator: ","  Header: 0  Footer: 0
  Schema: Built-In  Edit schema: ...
  Extract lines at random
  Encoding Type: ISO-8859-15

• The File is a simple csv file stored locally. The Row Separator is a carriage return and the Field Separator is a semi-colon. In the Header is the name of the column, and no Footer nor Limit are to be set.

• The file contains characters such as: *t, . or Nikson which we want to turn into Nixon, and streat, which we want to turn into Street.

<table>
<thead>
<tr>
<th>Street</th>
<th>FirstName</th>
<th>Name</th>
<th>Amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>street</td>
<td>John</td>
<td>Kennedy</td>
<td>98.30$</td>
</tr>
<tr>
<td>street</td>
<td>Richad</td>
<td>Nikson</td>

</tbody>
</table>

• The schema for this file is built in also and made of four columns of various types (string or int).

• Now select the tReplace component to set the search & replace parameters.
- The schema can be synchronized with the incoming flow.

- Select the **Simple mode** check box as the search parameters can be easily set without requiring the use of regexp.

- Click the plus sign to add some lines to the parameters table.

- On the first parameter line, select **Amount** as **InputColumn**. Type "." in the **Search** field, and "," in the **Replace** field.

- On the second parameter line, select **Street** as **InputColumn**. Type "street" in the **Search** field, and "Street" in the **Replace** field.

- On the third parameter line, select again **Amount** as **InputColumn**. Type "$" in the **Search** field, and "£" in the **Replace** field.

- On the fourth parameter line, select **Name** as **InputColumn**. Type "Nikson" in the **Search** field, and "Nixon" in the **Replace** field.

- On the fifth parameter line, select **Firstname** as **InputColumn**. Type "*t" in the **Search** field, and replace them with nothing between double quotes.

- The advanced mode isn’t used in this scenario.

- Select the next component in the Job, **tFilterColumn**.

- The **tFilterColumn** component holds a schema editor allowing to build the output schema based on the column names of the input schema. In this use case, add one new column named **empty_field**
and change the order of the input schema columns to obtain a schema as follows: empty field, Firstname, Name, Street, Amount.

- Click OK to validate.

- Set the tFileOutputDelimited properties manually.

- The schema is built-in for this scenario, and comes from the preceding component in the Job.

- Save the Job and press F6 to execute it.

<table>
<thead>
<tr>
<th>John</th>
<th>Kennedy</th>
<th>Street</th>
<th>98,30£</th>
</tr>
</thead>
<tbody>
<tr>
<td>Richad</td>

</tbody>
</table>

The first column is empty, the rest of the columns have been cleaned up from the parasitical characters, and Nikson was replaced with Nixon. The street column was moved and the decimal delimiter has been changed from a dot to a comma, along with the currency sign.
tReplaceList

Cleanses all files before further processing.
Carries out a Search and Replace operation in the input columns defined based on an external lookup.

tReplaceList Standard properties

These properties are used to configure tReplaceList running in the Standard Job framework.
The Standard tReplaceList component belongs to the Data Quality family.
The component in this framework is generally available.

Basic settings

<table>
<thead>
<tr>
<th>Schema and Edit schema</th>
<th>A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either Built-in or stored remotely in the Repository. Two read-only columns, Value and Match are added to the output schema automatically.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Warning:</strong> The data Type defined in the schemas must be consistent, ie., an integer can only be replaced by another integer using an integer as a look up field. Values of one type cannot be replaced by values of another type.</td>
</tr>
<tr>
<td>Built-in:</td>
<td>The schema will be created and stored locally for this component only. Related topic: see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Repository:</td>
<td>The schema already exists and is stored in the Repository, hence can be reused in various projects and job designs. Related topic: see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

Lookup search column

Select the column to be searched in the lookup schema.

Lookup replacement column

Select the column where the replacement values are stored.

Column options

Select the columns of the main flow where the replacement is to be carried out.

Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |
Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | tReplaceList is an intermediary component. It requires an input flow and an output component. |

Scenario: Replacement from a reference file

The following Job searches and replaces a list of states with their corresponding two-letter codes. The relevant codes are taken from a reference file placed as lookup flow in the Job.

Setting up the Job

Procedure

1. Drop the following components from the Palette onto the design workspace: two tFileInputDelimited components, a tReplaceList and a tLogRow.
2. Connect the two tFileInputDelimited components to the tReplaceList component using Row > Main connections. Note that the link between the reference input component (the second tFileInputDelimited) and the tReplaceList component appears as a lookup row.
3. Connect the tReplaceList component to the tLogRow component using a Row > Main connection.
Configuring the components

Procedure

1. Double-click the first tFileInputDelimited component to open its Basic settings view and set the parameters of the main input flow, including the path and name of the file to read and the number of header rows to skip.

![tFileInputDelimited_1](image)

In this example, the main input file provides a list of people names and US state names. The following shows an extract of the file content:

```
name;state
Andrew Kennedy;Mississippi
Benjamin Carter;Louisiana
Benjamin Monroe;West Virginia
Bill Harrison;Tennessee
Calvin Grant;Virginia
Chester Harrison;Rhode Island
Chester Hoover;Kansas
Chester Kennedy;Maryland
Chester Polk;Indiana
Dwight Nixon;Nevada
Dwight Roosevelt;Mississippi
Franklin Grant;Nebraska
```

2. Click the [...] button next to Edit schema to open the [Schema] dialog box and set the input schema.

According to the structure of the main input file, the input schema should contain two columns: `name` and `state`. 

When done, click OK to close the dialog box and propagate the changes to the next component.

3. Define the properties of the second tFileInputDelimited component similarly.

In this example, the reference input file provides a list of states and their two-letter codes. Accordingly, the reference input schema should have two columns: state and code.

4. Double-click the tReplaceList component to open its Basic settings view to set the operation to carry out.
5. From the **Lookup search column** list, select the column to be searched. In this use case, we want to carry out a search on the *state* column.

6. From the **Lookup replacement column** list, select the column containing the replacement values, *code* for the two-letter state codes in this example.

7. In the **Column options** table, select **Replace** check box for the *states* column, to replace the state names with their corresponding codes.

8. In the **tLogRow** component, select the **Table** check box for a better readability of the output.

### Executing the Job

#### Procedure

Save the Job and press **F6** to execute it.

The state names have been replaced with their respective two-letter codes.
tReplicate

Duplicates the incoming schema into two identical output flows.
This component performs different operations on the same schema.

tReplicate Standard properties

These properties are used to configure tReplicate running in the Standard Job framework.
The Standard tReplicate component belongs to the Orchestration family.
The component in this framework is generally available.

Basic settings

<table>
<thead>
<tr>
<th>Schema and Edit Schema</th>
<th>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:</th>
</tr>
</thead>
<tbody>
<tr>
<td>• View schema: choose this option to view the schema only.</td>
<td></td>
</tr>
<tr>
<td>• Change to built-in property: choose this option to change the schema to Built-in for local changes.</td>
<td></td>
</tr>
<tr>
<td>• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the [Repository Content] window. Click Sync columns to retrieve the schema from the previous component in the Job.</td>
<td></td>
</tr>
<tr>
<td>Built-In: You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.</td>
<td></td>
</tr>
<tr>
<td>Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.</td>
<td></td>
</tr>
</tbody>
</table>

Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions</th>
</tr>
</thead>
</table>
Replicate 3183 only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

---

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is not startable (green background), it requires an Input component and an output component.</th>
</tr>
</thead>
</table>

**Connections**

Outgoing links (from this component to another):
- **Row**: Main.
- **Trigger**: Run if; On Component Ok; On Component Error.

Incoming links (from one component to this one):
- **Row**: Main; Reject;

For further information regarding connections, see *Talend Studio User Guide*.

---

**Scenario: Replicating a flow and sorting two identical flows respectively**

The scenario describes a Job that reads an input flow which contains names and states from a CSV file, replicates the input flow, then sorts the two identical flows based on name and state respectively, and displays the sorted data on the console.
**Setting up the Job**

**Procedure**

1. Drop the following components from the **Palette** to the design workspace: one **tFileInputDelimited** component, one **tReplicate** component, two **tSortRow** components, and two **tLogRow** components.
2. Connect **tFileInputDelimited** to **tReplicate** using a **Row > Main** link.
3. Repeat the step above to connect **tReplicate** to two **tSortRow** components respectively and connect **tSortRow** to **tLogRow**.
4. Label the components to better identify their functions.

**Configuring the components**

**Procedure**

1. Double-click the **tFileInputDelimited** component to open its **Basic settings** view in the **Component** tab.

   ![Source(tFileInputDelimited_1)](image)

   2. Click the [...] button next to the **File name/Stream** field to browse to the file from which you want to read the input flow. In this example, the input file is *Names&States.csv*, which contains two columns: *name* and *state*.

   ```
   name;state
   Andrew Kennedy;Mississippi
   Benjamin Carter;Louisiana
   Benjamin Monroe;West Virginia
   Bill Harrison;Tennessee
   Calvin Grant;Virginia
   Chester Harrison;Rhode Island
   Chester Hoover;Kansas
   Chester Kennedy;Maryland
   Chester Polk;Indiana
   Dwight Nixon;Nevada
   Dwight Roosevelt;Mississippi
   Franklin Grant;Nebraska
   ```

   3. Fill in the **Header**, **Footer** and **Limit** fields according to your needs. In this example, type in 1 in the **Header** field to skip the first row of the input file.
4. Click **Edit schema** to define the data structure of the input flow.

![Schema of Source](image)

5. Double-click the first **tSortRow** component to open its **Basic settings** view.

![Sort by name(tSortRow_1)](image)

6. In the **Criteria** panel, click the [+](image) button to add one row and set the sorting parameters for the schema column to be processed. To sort the input data by name, select **name** under **Schema column**. Select **alpha** as the sorting type and **asc** as the sorting order.

For more information about those parameters, see **tSortRow Standard properties** on page 3577.

7. Double-click the second **tSortRow** component and repeat the step above to define the sorting parameters for the state column.

![Sort by state(tSortRow_2)](image)
8. In the Basic settings view of each tLogRow component, select Table in the Mode area for a better view of the Job execution result.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl+S** to save your Job.
2. Execute the Job by pressing **F6** or clicking **Run** on the Run tab.

The data sorted by name and state are both displayed on the console.
**tREST**

Serves as a REST Web service client.

The tREST component sends HTTP requests to a REpresentational State Transfer (REST) Web service provider and gets responses correspondingly.

**tREST Standard properties**

The Standard tREST component belongs to the Internet family.

**Note:**

To build Jobs that need to be deployed into the Talend Runtime, it is recommended to use the tRESTClient component which is best suited for the Talend Runtime.

For more information about the tRESTClient component, see tRESTClient on page 3191.

The component in this framework is generally available.

**Basic settings**

| **Schema and Edit Schema** | A schema is a row description, it defines the number of fields that will be processed and passed on to the next component. This component always uses a built-in, read-only schema that contains two columns:  
- **Body**: stores the result from the server end.  
- **ERROR_CODE**: stores the HTTP status code from the server end when an error occurs during the invocation process. The specific meanings of the errors codes are subject to definitions of your Web service provider. For reference information, visit en.wikipedia.org/wiki/List_of_HTTP_status_codes.  
Click Edit Schema to view the schema structure.  
**Warning:** Changing the schema type may result in loss of the schema structure and therefore failure of the component. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>URL</strong></td>
<td>Type in the URL address of the REST Web server to be invoked.</td>
</tr>
</tbody>
</table>
| **HTTP Method** | From this list, select an HTTP method that describes the desired action. The specific meanings of the HTTP methods are subject to definitions of your Web service provider. Listed below are the generally accepted HTTP method definitions:  
- **GET**: retrieves data from the server end based on the given parameters.  
- **POST**: creates and uploads data based on the given parameters. |
| **- PUT**: updates data based on the given parameters, or if the data does not exist, creates it.  
**- DELETE**: removes data based on the given parameters. |
| --- |
| **HTTP Headers**  
Type in the name-value pair(s) for HTTP headers to define the parameters of the requested HTTP operation.  
For the specific definitions of HTTP headers, consult your REST Web service provider. For reference information, visit en.wikipedia.org/wiki/List_of_HTTP_headers. |
| **HTTP Body**  
Type in the payload to be uploaded to the server end when the **POST** or **PUT** action is selected. |
| **Advanced settings** |
| **tStatCatcher Statistics**  
Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |
| **Global Variables** |
| **Global Variables**  
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
For further information about variables, see **Talend Studio User Guide**. |
| **Usage** |
| **Usage rule**  
Use this component as a REST Web service client to communicate with a REST Web service provider. It must be linked to an output component. |
| **Limitation**  
JRE 1.6 must be running for this component to work properly. |

**Scenario: Creating and retrieving data by invoking REST Web service**

This scenario describes a simple Job that invokes a REST Web service to create a new customer record on the server end and then retrieve the customer information. When executed, the Job displays relevant information on the **Run** console.
• Drop the following components from the Palette onto the design workspace: two tREST components and two tLogRow components, and label the two tREST components to best describe the actions to perform.

• Connect each tREST to one tLogRow using a Row > Main connection.

• Connect the first tREST to the second tREST using a Trigger > OnSubjobOK connection.

• Double click the first tREST component to open its Basic settings view.

  ![Create_customer(tREST_1)](image)

  - Fill the URL field with the URL of the Web service you are going to invoke. Note that the URL provided in this use case is for demonstration purposes only and is not a live address.
  - From the HTTP Method list, select POST to send an HTTP request for creating a new record.
  - Click the plus button to add a line in the HTTP Headers table, and type in the appropriate name-value key pair, which is subject to definition of your service provider, to indicate the media type of the payload to send to the server end. In this use case, type in Content-Type and application/xml. For reference information about Internet media types, visit www.w3.org/Protocols/rfc2616/rfc2616-sec3.html#sec3.7.
  - Fill the HTTP Body field with the payload to be uploaded to the server end. In this use case, type in <Customer><name>Steven</name></Customer> to create a record for a new customer named Steven.

  **Note:**
If you want to include double quotation marks in your payload, be sure to use a backslash escape character before each of the quotation marks. In this use case, for example, type in `<Customer><name>"Steven"</name></Customer>` if you want to enclose the name Steven in a pair of double quotation marks.

• Double click the second tREST component to open its Basic settings view.

• Fill the URL field with the same URL.

• From the HTTP Method list, select GET to send an HTTP request for retrieving the existing records.

• In the Basic settings view of each tLogRow, select the Print component unique name in front of each output row and Print schema column name in front of each value check boxes for better identification of the output flows.

• Save your Job and press F6 to launch it.

The console shows that the first tREST component sends an HTTP request to the server end to create a new customer named Steven, and the second tREST component successfully reads data from the server end, which includes the information of the new customer you just created.
tRESTClient

Interacts with RESTful Web service providers by sending HTTP and HTTPS requests using CXF (JAX-RS) getting the corresponding responses.

This component integrates well with Talend Runtime to get HTTPS support, with more QoS features to be supported in time.

**tRESTClient Standard properties**

These properties are used to configure tRESTClient running in the Standard Job framework.

The Standard tRESTClient component belongs to the ESB family.

The component in this framework is generally available.

**Basic settings**

| URL | Type in the URL address of the REST server to be invoked. When the Use Service Locator check box is selected, this field will not show and the URL of the REST server will be obtained from the Service Locator server automatically. |
| Relative Path | Enter the relative path of the REST server to be invoked. For example, if you want to access http://localhost:8888/services/Customers/list: If Use Service Locator is disabled: You can enter any of the first part of the address in the URL field, and the second part in the Relative Path field. For example, you can enter http://localhost:8888 in URL and /services/Customers/list in Relative Path. You can also enter the full path of the REST server in URL and leave Relative Path blank. If Use Service Locator is enabled: The URL part will be given by the Service Locator. In this case, you need to know the URL part, and specify the rest part in Relative Path. This depends on the service you request. For example, on tRESTRequest, you specify REST Endpoint as http://localhost:8888/services and enable Use Service Locator. Then, if you want to use this service, on tRESTClient side, you should specify /customers/list in Relative Path. |
| HTTP Method | From this list, select an HTTP method that describes the desired action. The specific meanings of the HTTP methods are subject to definitions of your Web service provider. Listed below are the generally accepted HTTP method definitions:  
- **GET**: retrieves data from the server end based on the given parameters.  
- **POST**: uploads data to the server end based on the given parameters. |
#### tRESTClient

| PUT: updates data based on the given parameters, or if the data does not exist, creates it. |
| PATCH: modifies data partially based on the given parameters. |
| DELETE: removes data based on the given parameters. |

### Content Type

Select **XML**, **JSON**, or **FORM** according to the media type of the content to be uploaded to the server end. This list appears only when you select the **POST**, **PUT**, or **PATCH** HTTP method.

### Accept Type

Select the media type the client end is prepared to accept for the response from the server end. Available options are **XML**, **JSON**, and **ANY**. When **ANY** is selected, the response message can be of any type and will be transformed into a string.

### Query parameters

Specify the URI query parameters in the form of name-value pairs. This option is mostly used with the GET method.

### Schema and Edit Schema

A schema is a row description, it defines the number of fields that will be processed and passed on to the next component. This component uses three built-in, read-only schemas. Click **Edit Schema** to view the schema structure.

**Warning:**

*Changing the schema type may result in loss of the schema structure and therefore failure of the component.*

### Input Schema

Schema for the input data. This schema contains two columns:
- **body**: stores the content of structured input data
- **string**: stores the input content when it is, or is handled as, a string.

### Response Schema

Schema for server response. This schema is passed onto the next component via a **Row > Response** link, and it contains three columns:
- **statusCode**: stores the HTTP status code from the server end.
- **body**: stores the content of a structured response from the server end.
- **string**: stores the response content from the server end when it is, or is handled as, a string.

### Error Schema

Schema for error information. This schema is passed onto the next component via a **Row > Error** link, and it contains two columns:
- **errorCode**: stores the HTTP status code from the server end when an error occurs during the invocation
process. The specific meanings of the errors codes are subject to definitions of your Web service provider. For reference information, visit en.wikipedia.org/wiki/List_of_HTTP_status_codes.

- **errorMessage**: stores the error message corresponding the error code.

<table>
<thead>
<tr>
<th>Use Service Locator</th>
<th>Select this check box to enable the Service Locator. It maintains the availability of the service to help meet demands and service level agreements (SLAs). Specify the Service namespace and the Service name in the corresponding fields.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Use Service Activity Monitor</th>
<th>Select this check box to enable the Service Activity Monitor. It captures events and stores this information to facilitate in-depth analysis of service activity and track-and-trace of messages throughout a business transaction. This can be used to analyze service response times, identify traffic patterns, perform root cause analysis and more.</th>
</tr>
</thead>
</table>

| Use Authentication | Select this check box if authentication is required on the REST server end. Select the authentication type from:

  - **Basic HTTP**: Fill the **Username** and **Password** fields with your credentials.
  - **HTTP Digest**: Fill the **Username** and **Password** fields with your credentials.
  - **SAML Token (ESB runtime only)**: Fill the **Username** and **Password** fields with your credentials.
  - **OAuth2 Bearer**: Fill the **Bearer Token** field with a base64-encoded credential string.

  To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings. |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| Use Business Correlation | Select this check box to create a correlation ID in this component.

  You can specify a correlation ID in the **Correlation Value** field. In this case the correlation ID will be passed on to the service it calls so that chained service calls will be grouped under this correlation ID. If you leave this field empty, this value will be generated automatically at runtime.

  When this option is enabled, **tRESTClient** will also extract the correlation ID from the response header and store it in the component variable for further use in the flow. |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

<p>| Die on error | This check box is selected to kill the Job when an error occurs. Clear the check box to skip the row on error and complete the process for error-free rows. |</p>
<table>
<thead>
<tr>
<th>Advanced settings</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Log messages</strong></td>
<td>Select this check box to log the message exchange between the service provider and the consumer.</td>
</tr>
<tr>
<td><strong>Enable WebClient Operation Reporting</strong></td>
<td>If this check box is selected, a CXF endpoint property will be set on the client side which may be used by some outgoing CXF metrics interceptors, to track requests to services using their URL's. The property set is <code>org.apache.cxf.resource.operation.name</code> and it contains service URL together with the HTTP method name, for example <code>GET:http://example.com:8080/service/</code>. If this check box is not selected, the property will not be set and some metrics will not be counted, which may increase the performance.</td>
</tr>
<tr>
<td><strong>Convert Response To DOM Document</strong></td>
<td>Select this check box to convert the response from the server to document type. Clear this check box if you want the response to be handled as a string.</td>
</tr>
<tr>
<td><strong>Convert Types To Strings</strong></td>
<td>This option appears when Content Type is JSON, or Accept Type is JSON or any. Select this check box to convert all values in JSON to string between quotation marks. For example, with this option enabled, the JSON data:</td>
</tr>
</tbody>
</table>
| | ```json
"root": {
  "test": 111
}
``` |
| | will be changed to: |
| | ```json
"root": {
  "test": "111"
}
``` |
| **Drop JSON Request Root** | This option appears when HTTP Method is POST, PUT or PATCH and Content Type is JSON. Select this check box to drop root JSON elements. |
| **Wrap JSON Response** | This option appears and is enabled by default when JSON is selected from the Accept Type list in the Basic settings view. With this check box selected, the response is wrapped with a root element. Clear this check box to remove the root element from the response. |
| **HTTP Headers** | Type in the name-value pair(s) for HTTP headers to define the parameters of the requested HTTP operation. For the specific definitions of HTTP headers, consult your REST Web service provider. For reference |
### Disable chunked encoding
This option appears when **HTTP Method** is **POST**, **PUT** or **PATCH**. Select this check box to disable encoding the payload as chunks.

### Service Locator Customer Properties
This option appears when **Use Service Locator** is enabled in the **Basic settings** tab. Click [+] to add as many properties as needed to the table. Enter the name and the value of each property in the **Property Name** field and the **Property Value** field respectively to identify the service.

### Service Activity Customer Properties
This option appears when **Use Service Activity Monitor** is enabled in the **Basic settings** tab. Click [+] to add as many properties as needed to the table. Enter the name and the value of each property in the **Property Name** field and the **Property Value** field respectively to identify the service.

### Connection timeout
Set the amount of time, in seconds, that the client will attempt to establish a connection before it times out. If set to 0, the client will continue to attempt to open a connection indefinitely. (default: 30)

This option only works in the Studio. To use it after the component is deployed in runtime, in the configuration file <TalendRuntimePath>/container/etc/org.apache.cxf.http.conduits-common.cfg, add `url = http://.*` to handle both HTTP and HTTPS requests, and specify the `client.ConnectionTimeout` parameter in milliseconds. If you need to use the **Receive timeout** option, specify the `client.ReceiveTimeout` in milliseconds too.

### Receive timeout
Set the amount of time, in seconds, that the client will wait for a response before it times out. If set to 0, the client will wait indefinitely. (default: 60) This option only works in the studio. For how to use it after the component is deployed in runtime or in Talend Administration Center, see the **Connection timeout** option.

### Use HTTP proxy
Select this check box if you are using a proxy server. Once selected, you need to provide the connection details: host, port, username and password.

### tStatCatcher Statistics
Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

| Global Variables | NB_LINE: the number of rows processed. This is an After variable and it returns an integer. |
**tRESTClient**

**HEADERS**: the HTTP response headers. This is a Flow variable and it returns a list of HTTP response header values.

**CORRELATION_ID**: the correlation ID by which chained service calls will be grouped. This is a Flow variable and it returns a string.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see **Talend Studio User Guide**.

**Usage**

**Usage rule**

This component is used as a RESTful Web service client to communicate with a RESTful service provider, with the ability to input a request to a service into a Job and return the Job result as a service response. Depending on the actions to perform, it usually works as a start or middle component in a Job or subjob.

**Dynamic settings**

Click the [+] button to add a row in the table and fill the **Code** field with a context variable to turn on or off the **Use Authentication** or **Use HTTP proxy** option dynamically at runtime. You can add two rows in the table to set both options.

Once a dynamic parameter is defined, the corresponding option becomes highlighted and unusable in the **Basic settings** view or **Advanced settings** view.

For examples on using dynamic parameters, see **Scenario: Reading data from databases through context-based dynamic connections** on page 2497 and **Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters** on page 489. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

**Connections**

**Outgoing links:**

- **Row**: Response; Error.

**Trigger**: On Subjob Ok; On Subjob Error; Run if; On Component Ok; On Component Error.

**Incoming links:**

- **Row**: Main; Reject.
Scenario 1: Getting user information by interacting with a RESTful service

This scenario describes a three-component Job that retrieves user information based on the user ID from a REST service via HTTP GET and displays the retrieved user information, as well as the message exchange between the client and the server, on the Run console.

Prerequisites:

If you are a Talend Open Studio for ESB user, create a Job as described in Scenario 2: Using URI Query parameters to explore the data of a database on page 3219, run the Job to expose a REST service, and enter the REST service URL in your Web browser, http://localhost:8088/users in this example. You should see information like the following:

```xml
- <users>
  - <user id="1">
    <first_name>Ronald</first_name>
    <last_name>Johnson</last_name>
  </user>
  - <user id="2">
    <first_name>Theodore</first_name>
    <last_name>Harding</last_name>
  </user>
  - <user id="3">
    <first_name>Bill</first_name>
    <last_name>Roosevelt</last_name>
  </user>
</users>
```

If you are not a Talend Open Studio for ESB user, then you need to get from your REST service provider the URL, the data structure, and the required parameters of the REST service you are going to call and make necessary modifications in the scenario configurations accordingly.

Setting up the Job

Procedure

1. Drop the following components from the Palette onto the design workspace:
   - tRESTClient, used to call the REST service and retrieve user information from the server end,
   - tXMLMap, used to adapt the tree structure of the REST service, and
- tLogRow, to display the retrieved user information on the Run console.

2. Connect the tRESTClient to the tXMLMap using a Row > Response connection.

3. Connect the tXMLMap to the tLogRow using a Row > Main connection, and give it a name, out in this example.

4. Label the components to best describe the actions to perform.

Configuring the components

Configuring the service call

Procedure

1. Double-click the tRESTClient component to open its Basic settings view.

2. Fill the URL field with the URL of the REST service you are going to invoke, "http://localhost:8088/users" in this example. Note that the URL provided in this use case is for demonstration purposes only and not a live address.

3. From the HTTP Method list, select GET to send an HTTP request for retrieving the existing records.
From the **Accept Type** list, select the type the client end is prepared to accept for the response from the server end, **XML**. Leave the rest of the settings as they are.

4. Click the [+] button beneath the **Query parameters** table to add two parameters, *from* and *to*, and set both parameters to 2, to get the information of the user with the ID of 2.

   Alternatively, you can query the information of the user with the ID of 2 by adding `?from=2&to=2` to the service URL.

5. In the **Advanced settings** view of the **tRESTClient** component, select the **Log messages** and the **Convert Response To DOM Document** check boxes to log the message exchange to the server and convert the response from the server to document type.

**Mapping the service structure and displaying the retrieved user information**

**Procedure**

1. Double-click the **tXMLMap** component to open the Map Editor.

2. If you selected **XML** in the **Accept Type** list of the **tRESTClient** component, define the input XML tree structure according to the service structure.
   a) In the input table, right-click the default *root* node of the *body* column, select **Rename** from the contextual menu, and rename it to *users*.

   b) Right-click the *users* node, select **Create Sub-Element** from the contextual menu, and create sub-element named *user*. Set *user* as the loop element because the XML structure of the Web service to be invoked is looped on this element.

   c) Right-click the *user* node, select **Create Attribute** from the contextual menu, and enter *id* in the **Create New Attribute** dialog box to create an attribute named *id* for the *user* node.

   d) Right-click the *user* node again, select **Create Sub-Element** from the contextual menu, and enter *first_name* in the **Create New Element** dialog box to create an sub-element named *first_name* for the *user* node.

   Repeat this operation to create another sub-element under the *user node*, *last_name*.

   e) Drop the *id*, *first_name* and *last_name* columns from the input table to the output table, and then click **OK** to validate the mapping and close the Map Editor.
If you selected JSON in the Accept Type list of the tRESTClient component, the response from the server end will be sent back in JSON format and converted to document type. In this example, the converted response structure looks like the following:

```xml
<root>
  <users>
    <user>
      <id>2</id>
      <first_name>Theodore</first_name>
      <last_name>Harding</last_name>
    </user>
  </users>
</root>
```

Note that the <root> element is removed if the Wrap JSON Response check box is cleared in the Advanced settings of the tRESTClient component.

Define the input XML tree structure accordingly and map it with the output data flow in a similar manner as described above.
3. Double-click the tLogRow component to open its **Basic settings** view.

4. Click the **Sync columns** button to make sure the component schema is synchronized with the output schema of the tXMLMap component.

5. In the **Mode** field, select the **Table** option to display the GET result in table cells.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl+S** to save your Job.
2. Press **F6** or click **Run** on the Run console to launch the Job.

   The console shows that the tRESTClient component successfully reads the user information from the server end corresponding to the specified user ID.
If you selected XML in the Accept Type list of the tRESTClient component, the execution result will be:

```
[statistics] connecting to socket on port 3496
[statistics] connected
May 26, 2014 5:30:17 PM
org.apache.cxf.interceptor.LoggingOutInterceptor

```

If you selected JSON in the Accept Type list of the tRESTClient component, the execution result will be:
Scenario 2: Updating user information by interacting with a RESTful service

This scenario describes a three-component Job that updates the information of a list of users to a remote database through a REST service using the HTTP POST method. When executed, the Job displays the client-server message exchange information on the Run console.

The user information to be updated to the server is stored in a CSV file, which looks like the following:

```
id;first_name;last_name
1;John;Smith
2;Martin;Reagan
3;James;White
```
Prerequisites:

If you are a *Talend Open Studio for ESB* user, create a Job as described in *Scenario 3: REST service accepting HTTP POST requests* on page 3227 and run the Job as a REST server to expose a REST service that accepts HTTP POST requests. Upon execution of the Job, the console displays the service implementation information, including the service endpoint URL, which is http://localhost:8045/users in this example. If you enter http://localhost:8045/users?_wadl in your Web browser, you should see the service definition information like the following:

```xml
<application>
  <grammars/>
  <resources base="http://localhost:8045/users">
    <resource path="/">
      <resource path="/post/(id)/{first_name}/" last_name" style="template" type="xs:string"/>
      <param name="id" style="template" type="xs:int"/>
      <param name="first_name" style="template" type="xs:string"/>
    </resource>
    <method name="POST">
      <response>
        <representation mediaType="application/xml"/>
        <representation mediaType="text/xml"/>
        <representation mediaType="application/json"/>
      </response>
    </method>
  </resources>
</application>
```

If you are not a *Talend Open Studio for ESB* user, then you need to get the service-related information from your REST service provider including the URL, the resource path, and the data structure, and make necessary modifications in the scenario configurations accordingly.

Setting up the Job

Procedure

1. Create a Job and add the following components by typing their names in the design workspace or drop them from the Palette:
• **tFileInputDelimited**, to read user information of a local file,
• **tXMLMap**, to adapt the input structure to the REST service structure, and
• **tRESTClient**, used to call the REST service to send data to the remote database.

2. Connect the **tFileInputDelimited** to the **tXMLMap** using a **Row > Main** connection.
3. Connect the **tXMLMap** to the **tRESTClient** using a **Row > Main** connection, and give the output flow a name, **request** in this example.
4. Label the components to best describe the actions to perform.

### Configuring the components

#### Configuring the input data and the structure mappings

**Procedure**

1. Double-click the **tFileInputDelimited** component to open its **Basic settings** view.

   ![Input(tFileInputDelimited_1)](image)

2. Specify the input file in the **File name** field, fill the **Header** field with 1 to skip the header row, and keep the rest parameters as they are.
3. Click the [...] button next to **Edit schema** to open the [Schema] dialog box, and edit the input schema as follows:
   - **id**, type Integer, 2 characters long, set as the key column
   - **first_name**, type String
   - **last_name**, type String
4. Double-click the **tXMLMap** component to open the Map Editor.

5. Rename the root node in the output table: right-click the node, select **Rename** from the contextual menu, and specify a new name in the pop-up dialog box, **user** in this example.

6. Select all the three columns in the input table and drop them onto the **user** node, and select the **Create as sub-element of target node** option from the pop-up dialog box to set these columns as sub-elements of the **user** node. When done, click **OK** to validate the mappings and close the Map Editor.
Configuring the service call

Procedure

1. Double-click the tRESTClient component to open its Basic settings view.

2. Fill the URL field with the URI location where the REST service is accessible, "http://localhost:8088/users" in this example.

3. In the Relative Path field, enter the resource path, "/post/" + row1.id + "/" + row1.first_name + "/" + row1.last_name in this example. This will send the data from the input row to the server end via the resource path.

4. From the HTTP Method list, select GET to send an HTTP request for retrieving the existing records. From the Accept Type list, select the type the client end is prepared to accept for the response from the server end, XML.

5. In the Advanced settings view of the tRESTClient component, select the Log messages check box to log the message exchange information with the server. Leave the rest of the settings as they are.

Running the Job and checking the result

Press Ctrl+S to save your Job, and press F6 to execute it.

The console displays the client-server exchange information:
The console of the server Job displays the exchange information and the database update result.
ID: 5
Encoding: ISO-8859-1

tRESTRequest

Receives GET/POST/PUT/PATCH/DELETE requests from the clients on the server end.

tRESTRequest accepts the HTTP and/or HTTPS requests from the clients and supports GET, POST, PUT, PATCH and DELETE HTTP methods.

Note:
To enable the HTTPS support, you have to generate a keystore and add some HTTPS security configuration properties in the org.ops4j.pax.web.cfg file of your Runtime container before deploying the service on it. For more information, see the Talend ESB Container Administration Guide.

tRESTRequest Standard properties

These properties are used to configure tRESTRequest running in the Standard Job framework.

The Standard tRESTRequest component belongs to the ESB family.

This component is relevant only when used with one of the Talend solutions with ESB, as it should be used with the Service Repository node and the Data Service creation related wizard(s).

Basic settings

<table>
<thead>
<tr>
<th>REST Endpoint</th>
<th>Fill this field with the URI location where REST-ful web service will be accessible for requests.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Note:</td>
</tr>
<tr>
<td></td>
<td>If you want your service to be available on both HTTP and HTTPS, fill the field with a relative path.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>REST API Mapping</th>
<th>Click the [+] button beneath the mapping table to add lines to specify HTTP request:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Output Flow: Click the [...] button to specify the name of an output flow and set the schema for that output flow in the dialog box afterwards.</td>
</tr>
<tr>
<td></td>
<td>The schema is not mandatory, so if you do not need to pass additional parameters to the tRESTRequest component, you can leave the schema empty. However, you will have to populate the schema if you have URI Path parameters set in the URI Pattern field or if you need to add optional request parameters such as URI Query, HTTP Header or Form parameters, to the URI specified in the REST Endpoint field.</td>
</tr>
<tr>
<td></td>
<td>Add a schema with the name body to get the request body of POST and PUT methods. It supports Document, String, and Byte[] types.</td>
</tr>
<tr>
<td></td>
<td>If you specify URI parameters in the output flow schema, you might need to define what type of parameter it is in the Comment field of the schema. By default, if you leave the Comment field empty, the</td>
</tr>
</tbody>
</table>
The parameter is considered as a Path parameter. Below is a list of supported Comment values:

- empty or path corresponds to the default @PathParam,
- query corresponds to @QueryParam,
- form corresponds to @FormParam,
- header corresponds to @HeaderParam.
- matrix corresponds to @MatrixParam.
- multipart corresponds to the CXF specific @Multipart, representing the request body. It can be used only with POST and PUT HTTP methods.

Note:
We recommend you to set the default values of your optional parameters (Header, Query, Form). To do so, fill in the Default columns of the schema.

HTTP Verb: Select a HTTP method (GET/POST/PUT/PATCH/DELETE/OPTIONS/HEAD) from the list.

URI pattern: Fill this field with REST-ful URIs that describe the resource.

Consumes: Select the format type of the consume content that the component will use from XML or JSON, XML, JSON, Form, Multipart and Any in the list when the HTTP method is POST, PUT or PATCH.

Produces: When the HTTP method is GET, POST, PUT, PATCH, or DELETE, select the format type of the produce content that the component will use from XML or JSON, XML, JSON, HTML and Any, or select <oneway> in the list to accept one way requests.

Streaming: Select this check box to stream the response data by chunks so that the large volumes of data can be processed efficiently.

Use Service Locator: Select this check box to enable the Service Locator. It maintains the availability of the service to help meet demands and service level agreements (SLAs). Specify the Service namespace and the Service name in the corresponding fields.

Use Service Activity Monitor: Select this check box to enable the Service Activity Monitor. It captures events and stores this information to facilitate in-depth analysis of service activity and track-and-trace of messages throughout a business transaction. This can be used to analyze service response times, identify traffic patterns, perform root cause analysis and more.

Use Authentication (ESB runtime only): Select this check box to enable the authentication option for the current service. This option works in runtime only. Select the authentication type from:
- **Basic HTTP**: The simplest technique for enforcing access controls to web resources using standard fields in the HTTP header.
- **SAML Token**: An XML-based, open-standard data format for exchanging authentication and authorization data between an identity provider and a service provider.

### Use Business Correlation

Select this check box to enable the correlation option so that chained service calls will be grouped under the same correlation ID. tRESTRequest will extract the correlation ID from the request header and store it in the component variable for further use in the flow.

If this option is not enabled on the client side, a correlation ID will be generated automatically in tRESTRequest.

### Advanced settings

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Log messages</strong></td>
<td>Select this check box to log the message exchange between the service provider and the consumer.</td>
</tr>
<tr>
<td><strong>Wrap JSON Request</strong></td>
<td>Select this check box to wrap the JSON request with a root element.</td>
</tr>
<tr>
<td><strong>Convert JSON values to String in response</strong></td>
<td>Select this check box to convert the JSON values to string format in the response.</td>
</tr>
<tr>
<td><strong>Service Locator Customer Properties</strong></td>
<td>This option appears when Use Service Locator is enabled in the Basic settings tab. Click [+] to add as many properties as needed to the table. Enter the name and the value of each property in the Property Name field and the Property Value field respectively to identify the service.</td>
</tr>
<tr>
<td><strong>Service Activity Customer Properties</strong></td>
<td>This option appears when Use Service Activity Monitor is enabled in the Basic settings tab. Click [+] to add as many properties as needed to the table. Enter the name and the value of each property in the Property Name field and the Property Value field respectively to identify the service.</td>
</tr>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to gather the Job processing metadata at a Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE</strong></td>
<td>the number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>URI</strong></td>
<td>the URI of the REST request. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td><strong>URI_BASE</strong></td>
<td>the base URI of the REST request. This is a Flow variable and it returns a string.</td>
</tr>
</tbody>
</table>
### Usage

#### Usage rule

This component covers the possibility that a **Talend** Job can be wrapped as a service, with the ability to input a request to a service into a Job and return the Job result as a service response.

The **tRESTRequest** component should be used with the **tRESTResponse** component to provide a Job result as a response, in case of a request-response communication style.

#### Limitation

Using context variables for dynamic endpoint or Service Locator namespace works in the Studio only. It is not supported in Runtime.

---

### Scenario 1: REST service accepting HTTP GET requests and sending responses

This scenario applies only to a Talend solution with ESB.

This scenario describes the process of accepting an HTTP request from the client, processing it and sending the response back.
Configuring the tRESTRequest component

Procedure

1. Drop the following components from the Palette onto the design workspace: a tRESTRequest, two tXMLMap and two tRESTResponse.

2. Double-click tRESTRequest in the design workspace to display its Basic settings view.

3. Fill the REST Endpoint field with the URI location where the REST-ful web service will be accessible for requests. For example, "http://192.168.0.235:8088/user".

   **Note:**
   If you want your service to be available on both HTTP and HTTPS, fill the field with a relative path. For example, if you type in "/test", your service will be available on both http://<DefaultHTTPEnpointAddress>/test and https://<DefaultHTTPSEnpointAddress>/test, provided that you have configured your Runtime container to support HTTPS. For more information, see the Talend ESB Container Administration Guide.

4. Click the [+] button to add one line in the REST API Mapping table.
5. Select the newly-added line and click the [...] button in the **Output Flow** column to add a schema for the output flow.

In this scenario, the output flow will be named as *GetOneUser*.

<table>
<thead>
<tr>
<th>Column</th>
<th>Key</th>
<th>Type</th>
<th>N.</th>
<th>Date Patter</th>
<th>Length</th>
<th>Prec.</th>
<th>De.</th>
<th>Co.</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td></td>
<td>String</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Then click the [+] button to add a new line *id* to the schema in the dialog box.

6. Click **OK** to save the schema.

7. Select **GET** from the list in the **HTTP Verb** column.

8. Fill the field in the **URI Pattern** column with "/{id}/".

9. In the same way, add another line in the **REST API Mapping** table and name this schema *GetUserNumber*. Add a line *string* of *String* type to the schema. Enter *query* in the **Comment** field to get the number parameter in the request.

Select **GET** from the list in the **HTTP Verb** column. Fill the field in the **URI Pattern** column with "/number".

**Configuring the first tXMLMap component**

**Procedure**

1. Connect **tRESTRequest** to a **tXMLMap** using the **Row > GetOneUser** connection.

2. Double-click **tXMLMap** in the design workspace to open the **Map Editor**.
3. Click the [+] button on the top right to add an output and name it as `ResponseUsers`.
4. Click the [+] button on the bottom right to add two columns for the output.
   - Name the first column as `body` and set the Type to Document.
   - Name the second column as `string` and set the Type to String.
5. Right-click on the node `root` and select Create Sub-Element to create a sub-element. Name the sub-element as `foo` in the popup dialog box.
6. Right-click on the `foo` node created in the previous step and select As loop element.
7. Select the `id` column of the `GetOneUser` table to the left and drop it onto the Expression field of the `foo` node of the `ResponseUsers` table to the right.
8. Click OK to save the settings.

**Configuring the second tXMLMap component**

**Procedure**
1. Connect `tRESTRequest` to the other `tXMLMap` using the Row > GetUserNumber connection.
2. Double-click the first `tXMLMap` in the design workspace to open the Map Editor.
3. Click the [+] button on the top right to add an output and name it as `ResponseUserNumber`.

4. Click the [+] button on the bottom right to add one column for the output. Name the first column as `body` and set the Type to Document.

5. Right-click on the node `root` and select Create Sub-Element to create a sub-element. Name the sub-element as `number` in the popup dialog box.

6. Right-click on the `number` node created in the previous step and select As loop element.

7. Select the `string` column of the `GetUserNumber` table to the left and drop it onto the Expression field of the `number` node of the `ResponseUserNumber` table to the right.

8. Click OK to save the settings.

**Configuring the tRESTResponse component**

**Procedure**

1. Connect `tXMLMap` to a `tRESTResponse` using Row > ResponseUsers connection. The schema defined in `tXMLMap` is retrieved in `tRESTResponse` automatically.
2. Select **OK(200)** from the **Return status code** list.
3. Leave the rest of the settings as they are.
4. Connect **tRESTRequest** to the other **tRESTResponse** using the **Row > GetUserNumber** connection.

### Saving and executing the Job

**Procedure**

1. Save the Job and press **F6** to execute it.

   ```
   [statistics] connecting to socket on port 3888
   [statistics] connected
   [INFO ]: org.apache.cxf.endpoint.ServerImpl - Setting the server's publish address to be http://localhost:8088/user
   [INFO ]: org.eclipse.jetty.server.AbstractConnector - Started
   SelectChannelConnector@localhost:8088
   ```

2. Go to your browser if you want to test the service.

   ![Firefox](http://localhost:8088/users/1)
   ![Firefox](http://localhost:8088/users/fuo)

   The HTTP request for a user id is accepted by the REST service and the HTTP response is sent back to the server.

3. Repeat this step and type in **http://localhost:8088/user/number?string=123** in the address bar. Press **Enter**.

   You can see that **123** is returned in the response.
Scenario 2: Using URI Query parameters to explore the data of a database

This scenario applies only to a Talend solution with ESB.

This scenario describes how to use URI query parameters in tRESTRequest to explore data of a database, and send the response via the tRESTResponse.

To do so, you can create two subjobs linked together by an OnSubjobOk connection; this way the two subjobs will be executed sequentially. For more information on Trigger connection, see the Talend Studio User Guide. The first subjob will create and populate the database and the second one will allow to explore the database through the REST service.

Creating the first subjob

About this task

To do this, proceed as follows:

Procedure

1. Drop the following components from the Palette onto the design workspace: tFixedFlowInput from the Misc family and tMysqlOutput from the Databases > Mysql family.
2. Link tFixedFlowInput to tMysqlOutput using a Row > Main connection.
3. Double-click **tFixedFlowInput** to display its **Basic settings** view:

![tFixedFlowInput settings](image)

4. Click the [...] button next to **Edit schema** to open the schema editor.

![Schema editor](image)

5. In the schema editor, click the [+] button three times to add three lines and set them as displayed in the above screenshot.

6. Click **Ok**.

7. Back to **tFixedFlowInput Basic settings** view, in the **Mode** area, select the **Use inline table** option.

8. Under the inline table, click the [+] button three times to add three rows in the table.

9. In the inline table, click the **id** field of the first row and type in 1.

10. Click the **firstname** field of the first row, press Ctrl+Space to display the autocompletion list and select the **TalendDataGenerator.getFirstName()** variable in the list.

11. Click the **lastname** field of the first row, press Ctrl+Space to display the autocompletion list and select the **TalendDataGenerator.getLastName()** variable in the list.

12. Do the same for the two following rows to obtain the settings displayed in the screenshot.
13. Double-click **tMysqlOutput** to display its **Basic settings** view:

![tMysqlOutput](image)

14. From the **Property Type** list, leave **Built-in** and fill in the **Host**, **Port**, **Database**, **Username** and **Password** fields manually. If you centralized your connection information to the database in the **Metadata > DB Connections** node of the **Repository**, you can select **Repository** from the list and the fields will be automatically filled in.

For more information about storing metadata, see *Talend Studio User Guide*.

15. In the **Table** field, type in the name of the table in which the data will be loaded, for example: **users**.

16. From the **Action on table** list, select **Drop table if exists and create**, select **Insert** from the **Action on data** list.

17. Click **Sync columns** to retrieve the schema coming from the previous component.

**Creating the second subjob**

The following components are used as displayed in the first screenshot:

- **tRESTRequest** and **tRESTResponse** from the **ESB > REST** family,
- **tFlowToIterate** from the **Orchestration** family,
- **tMysqlInput** from the **Databases > Mysql** family,
- **tXMLMap** from the **Processing** family.

**Configuring the tRESTRequest component**

**About this task**

To do this, proceed as follows:
Procedure

1. Double-click `tRESTRequest` in the design workspace to display its **Basic settings** view:

![tRESTRequest Basic settings](image)

2. Fill the **REST Endpoint** field with the URI location where the REST-ful web service will be accessible for requests. For example, "http://localhost:8088/users".

3. Click the `[+]` button to add one line in the **REST API Mapping** table.

4. Select the newly-added line and click the `[...]` button in the **Output Flow** column to add a schema for the output flow.

5. In the dialog box, name the output flow `getUsers`. A schema editor dialog box appears.

![Schema editor dialog box](image)

6. In the schema editor, click the `[+]` button twice to add two lines and set them as displayed in the above screenshot.

7. Click **OK**.

8. Back to `tRESTRequest Basic settings` view, select **GET** from the list in the **HTTP Verb** column.

9. Leave the **URI Pattern** column as is.

10. Use the corresponding link to connect to the following component: connect `tRESTRequest` to `tFlowToIterate` using **Row > getUsers** connection.
11. Leave the tFlowToIterate settings as is.
12. Connect tFlowToIterate to tMysqlInput using Row > Iterate connection.

**Configuring the tMysqlInput component**

**About this task**

To do this, proceed as follows:

**Procedure**

1. Double-click tMysqlInput to display its Basic settings view:

   ![tMysqlInput_1](image)

   1. From the **Property Type** list, leave **Built-in** and fill in the **Host**, **Port**, **Database**, **Username** and **Password** fields manually. If you centralized your connection information to the database in the Metadata > DB Connections node of the Repository, you can select **Repository** from the list and the fields will be automatically filled in.

      For more information about storing metadata, see Talend Studio User Guide.

   2. Leave the **Schema** list as **Built-in** and click the [...] button next to the **Edit schema** field.

   3. In the schema editor, define the schema exactly like the one of the tFixedFlowInput.

   4. Leave the **Query Type** list as **Built-in** and fill in the **Query** field with the following SQL query allowing to explore the database data with the URI query set in the tRESTRequest component:

      "select * from users where id >= " + globalMap.get("getUsers.from") + " and id <= " + globalMap.get("getUsers.to")

**Configuring the tXMLMap component**

**Procedure**

1. Right-click tMysqlInput, hold and drag to tXMLMap to connect the two components together.
2. Double-click **tXMLMap** in the design workspace to open the **Map Editor**.

3. Click the [+] button on the top right to add an output and name it as **ResponseUsers**.
4. Click the [+] button on the bottom right to add two columns for the output.
   - Name the first column as **body** and set the **Type** to **Document**.
   - Name the second column as **string** and set the **Type** to **String**.
5. Right-click on the **root** node, select **Rename** in the list and rename it **users**.
6. Right-click on the **users** node and select **Create Sub-Element** to create a sub-element. Name the sub-element **user** in the popup dialog box.
7. Right-click on the **user** node created in the previous step and select **As loop element**.
8. Select the **id** column of the **row2** table to the left and drop it onto the **user** node of the **ResponseUsers** table to the right.
9. In the [Selection] dialog box, select the **Create as attribute of target** node option and click **OK**.
10. Select the **firstname** and **lastname** columns of the **row2** table to the left and drop it onto the **user** node of the **ResponseUsers** table to the right.
11. In the [Selection] dialog box, select the **Create as sub-element of target node** option and click **OK**.

12. Click the wrench icon on the top of the **ResponseUsers** table to open the setting panel.

13. Set the **All in one** feature as **true**, this way all XML data is outputted in one single flow.

14. Click **OK** to save the settings.

**Configuring the tRESTResponse component**

**Procedure**

1. Connect **tXMLMap** to **tRESTResponse** using **Row > ResponseUsers** connection.

2. The schema defined in **tXMLMap** is retrieved in **tRESTResponse** automatically. Leave the other settings as they are.
Connecting the two subjobs

About this task

Now that the two subjobs are created, you can connect them together:

Procedure

1. Right-click the \texttt{tFixedFlowInput} component of the first subjob.
2. Select \texttt{Trigger > OnSubjobOk} on the list.
3. Click the \texttt{tRESTRequest} component of the second subjob.

Results

This way, when executing the job, the second subjob will be executed only if the first one’s execution succeeded.

Saving and executing the Job

Procedure

1. Save the Job and press \texttt{F6} to execute it.

```
[statistics] connecting to socket on port 4020
[statistics] connected
[INFO ]: org.apache.cxf.endpoint.ServerImpl - Setting the server's publish address to be http://localhost:8088/users
[INFO ]: org.eclipse.jetty.server.AbstractConnector - Started
SelectChannelConnector:localhost:8088
```

2. Go to your browser if you want to test the service.
   For example, use the URI query \texttt{?to=2} to retrieve the data of the two first users.
This XML file does not appear to have any style information associated with it. The document tree is shown below.

```xml
- <users>
  - <user id="1">
    <firstname>George</firstname>
    <lastname>Ford</lastname>
  </user>
  - <user id="2">
    <firstname>Rutherford</firstname>
    <lastname>Coolidge</lastname>
  </user>
- </users>
```

The HTTP request for a user id is accepted by the REST service and the HTTP response is sent back to the server.

For a use case that calls this REST service using Talend Open Studio for ESB components, see Scenario 1: Getting user information by interacting with a RESTful service on page 3197.

**Scenario 3: REST service accepting HTTP POST requests**

This scenario applies only to a Talend solution with ESB.

This scenario describes a Job composed of two subjobs: the first subjob exposes a REST service that accepts HTTP POST requests from REST clients, writes data to a database upon receiving an HTTP request, and displays the server-client exchange information on the Run console; the second subjob displays the results of database updates.
**Setting up the Job**

**Procedure**

1. Create a Job and add the following components to the Job by typing their names in the design workspace or dropping them from the Palette: a tRESTRequest, a tMysqlOutput, a tXMLMap, and a tRESTResponse.

2. Connect the tRESTRequest to the tMysqlOutput component using a Row > Main connection, and give the output flow a name, request in this example.

3. Connect the tMysqlOutput component to the tXMLMap component using a Row > Main connection.

4. Connect the tXMLMap component to the tRESTResponse component using a Row > Main connection, and give it a name, response in this example. Click OK in the pop-up dialog box to accept the schema propagation from the tRESTResponse component.

5. Add a tMysqlInput component and a tLogRow component to the Job by typing their names in the design workspace or dropping them from the Palette, and connect the tMysqlInput to the tLogRow using a Row > Main connection.

6. Connect the tMysqlOutput to the tMysqlInput using a Trigger > OnComponentOk connection to link the two subjobs.

**Configuring the components**

**Configuring REST request parameters**

**Procedure**

1. Double-click the tRESTRequest component to open its Basic settings view.

   ![tRESTRequest settings](image)

2. Fill the REST Endpoint field with the URI location where the REST service will be accessible for requests, "http://localhost:8045/users" in this example.

3. Click the output flow name, which is request in this example, in the Output Flow column of the REST API Mapping table to show the [...] button, and click the button to open the [Schema] dialog box. Then define the schema for the request flow as follows:
   - id, type Integer, 2 characters long, set as the key column
   - first_name, type String
   - last_name, type String
When done, click OK to validate the schema setting and close the dialog box.

4. Click the HTTP Verb column and select POST from the list.

5. In the URI Pattern column, enter the acceptable URI pattern of POST requests, "/post/{id}/{first_name}/{last_name}" in this example. Leave the rest parameters as they are.

6. Click the Advanced settings tab, and select the Log messages check box.

Configuring the database and the response parameters

Procedure

1. Double-click the tMysqlOutput component to open its Basic settings view.

2. Leave the Property Type as Built-in and fill in the database connection details manually in the Host, Port, Database, Username and Password fields.

If you have centralized your connection information to the database in the Metadata > DB Connections node of the Repository, you can select Repository from the Property Type list and browse to the centralized connection to have the fields automatically filled in. For more information about storing metadata, see Talend Studio User Guide.
3. Fill in the **Table** field with the target database table name, *users* in this example.

4. Select the actions to be carried out on the database table and data according to your needs from the corresponding lists. In this example, the target table will be created if it does not exist in the specified database, and data from client requests will be inserted, or updated if it already exists, to the database table.

5. Click the **Sync columns** button to synchronize the table schema with the input schema.

6. Double-click the **tXMLMap** component to open the Map Editor.

7. Rename the root node in the output table: right-click the node, select **Rename** from the contextual menu, and specify a new name in the pop-up dialog box, *user* in this example.

8. Select all the three columns in the input table and drop them onto the *user* node, and select the **Create as sub-element of target node** option from the pop-up dialog box to set these columns as sub-elements of the *user* node. When done, click **OK** to validate the mappings and close the Map Editor.

9. Double-click the **tRESTResponse** component and set the response parameters according to your needs. In this example, we keep the default settings for all the parameters.

**Configuring result display**

**Procedure**

1. Double-click the **tMysqlInput** component to open its **Basic settings** view.
2. Specify the database connection details, table name and table schema, which are the same as in the tMysqlOutput component.

3. Click the Guess Query button to fill the Query field with the query statement.

4. Double-click the tLogRow component and select the Table option to display the content of the database in table cells.

**Saving the executing the Job**

**Procedure**

1. Press Ctrl+S to save your Job.

2. Click the Run button on the Run tab or press F6 to run it.

The console displays the service implementation information, including the service URL.

When an HTTP POST request is received from a client, the console displays the relevant exchange information and the database update result.
Scenario 4: REST service accepting HTTP POST requests and sending responses

This scenario applies only to a Talend solution with ESB.

This scenario describes how to build a REST service that accepts HTTP POST requests of Document type from the client, processes it and sends the response back. To do this, two Jobs are built: one to create the REST service and the other to call it.

Creating the REST service Job

Drag and drop the following components from the Palette onto the design workspace: a tRESTRequest, a tXMLMap and a tRESTResponse.
Configuring the tRESTRequest component

Procedure

1. Double-click **tRESTRequest** in the design workspace to display its **Basic settings** view.

2. In the **REST Endpoint** field, keep the default URI "http://localhost:8088/" where the REST-ful web service will be accessible for requests.

3. Click the [+] button to add one line in the **REST API Mapping** table.

4. Select the newly-added line and click the [...] button in the **Output Flow** column to add a schema for the output flow. Give the name for the schema **UserInfo** in this scenario.
   
The schema editor opens. Click the [+] button to add a new line **body of Document type** and click **OK** to save the schema.
5. Back to tRESTRequest Basic settings view, select POST from the list in the HTTP Verb column.
6. Fill the field in the URI Pattern column with "/UserInfo". Keep the default settings of the other options.

Configuring the body of the response

Procedure

1. Connect tRESTRequest to tXMLMap using the Row > UserInfo connection.
2. Double-click tXMLMap in the design workspace to open the Map Editor.
3. Right-click on the root node of the input table and select Create Sub-Element. Name the sub-element as person in the popup dialog box.

4. Right-click on the person node created in the previous step and select As loop element.

5. Create two sub-elements to the person node by selecting Create Sub-Element in the contextual menu, id and name in this use case.

6. Click the [+] button on the top right to add an output and name it as Response.

7. Click the [+] button on the bottom right to add a column body of Document type for the output.

8. Right-click the node root in the output table and select Create Sub-Element. Name the sub-element as person in the popup dialog box.

9. Right-click the person node created in the previous step and select As loop element.

10. Create three sub-elements to the person node by selecting Create Sub-Element in the contextual menu, id, name and company in this use case.

11. Select the id column from the input table and drop it onto the Expression field of the id node of the output table.

12. Select the name column from the input table and drop it onto the Expression field of the name node in the output table.

   Click the Expression field of the name node in the output table, and click [...] in this field to show the [Expression Builder] wizard.

   In the Expression area, enter StringHandling.UPCASE([UserInfo.body:/root/person/name]) to convert the name of the user to upper case. Click OK to close the wizard.

   ![Expression Builder](image)

   For further information about using the Expression Builder, see Talend Studio User Guide.

13. In the Expression field of the company node, enter "Talend".

14. Click OK to save the settings.

Configuring the tRESTResponse component

Procedure

1. Connect tXMLMap to a tRESTResponse using Row > Response connection.

   The schema defined in tXMLMap is retrieved in tRESTResponse automatically.
2. Select **OK(200)** from the Return status code list.

3. Leave the rest of the settings as they are.

**Launching the service**

Save the Job and press **F6** to execute it. The service is started.

**Creating the consumer Job**

Drag and drop the following components from the Palette onto the design workspace: a \texttt{tFixedFlowInput}, a \texttt{tXMLMap}, a \texttt{tRESTClient} and a \texttt{tLogRow}.

**Configuring the \texttt{tFixedFlowInput} component**

**Procedure**

1. Double-click \texttt{tFixedFlowInput} in the design workspace to display its Basic settings view.
2. Click **Edit schema** to show the schema editor. In the schema editor, click the [+ ] button to add two columns of **String** type, **id** and **name**. Click **Ok** to close the schema editor.

3. Back to **tFixedFlowInput Basic settings** view, in the **Mode** area, select the **Use Inline Content** option.

4. In the **Content** box, enter the **id** and **name** of three users, for example:

```
1;ford
2;smith
3;thomson
```

**Configuring the tXMLMap component**

**Procedure**

1. Connect **tFixedFlowInput** to **tXMLMap** using the **Row > Main** connection.

2. Connect **tXMLMap** to **tRESTClient** using the **Row > Main** connection, and name the output flow **request** in this example.

3. Double-click **tXMLMap** in the design workspace to open the **Map Editor**.
4. Right-click on the node root in the output table and select Create Sub-Element. Name the sub-element as person in the popup dialog box.

5. Right-click on the person node created in the previous step and select As loop element.

6. Create two sub-elements to the person node by selecting Create Sub-Element in the contextual menu, id, and name in this use case.

7. Select the id column from the input table and drop it onto the Expression field of the id node of the output table.

8. Select the name column from the input table and drop it onto the Expression field of the name node in the output table.

9. Click OK to save the settings.

Configuring the tRESTClient component

Procedure

1. Double-click the tRESTClient component to open its Basic settings view.
2. Fill the **URL** field with the URL of the REST service built in the service Job, “http://localhost:8088/”.
3. Fill the **Relative Path** with the “UserInfo”.
4. From the **HTTP Method** list, select **POST**.
5. Leave the rest of the settings as they are.
6. Connect **tRESTClient** to **tLogRow** using the **Row > Response** connection. Keep the default settings of the **tLogRow** to monitor the message exchanges.

**Saving and executing the Job**

Save the Job and press **F6** to execute it. The user information is shown in the console, including **id**, **name**, and **company**. The name of the user has been converted to upper case.
Scenario 5: REST service accepting HTTP POST requests in an HTML form

This scenario applies only to a Talend solution with ESB.

This scenario describes how to upload data to a REST service using HTTP POST in a HTML form file. To do so, a Job is created to accept HTTP POST requests using the tRESTRequest component.

A predefined HTML form UploadFile.html is used to upload data to the REST service:

```
<form action="http://localhost:8088/UserInfo" method="post" enctype="multipart/form-data">
  <input type="file" name="id" />
  <button>upload</button>
</form>
```

The customer.xml that contains a user ID will be uploaded:

```
<customer>
  <id>100</id>
</customer>
```

Setting up the Job

Drop the following components from the Palette onto the design workspace: a tRESTRequest, a tJavaRow, a tXMLMap and a tRESTResponse.
Configuring the tRESTRequest component

Procedure

1. Double-click tRESTRequest in the design workspace to display its Basic settings view.

2. In the REST Endpoint field, keep the default URI "http://localhost:8088/" where the REST-ful web service will be accessible for requests.

3. Click the [+ ] button to add one line in the REST API Mapping table.

4. Select the newly-added line and click the [...] button in the Output Flow column to add a schema for the output flow. Give the name for the schema UserInfo in this scenario.

   The schema editor opens. Click the [+ ] button to add a new line id of byte[] type and enter multipart in the Comment field. Click OK to save the schema.

5. Back to tRESTRequest Basic settings view, select POST from the list in the HTTP Verb column.

6. Fill the field in the URI Pattern column with "/UserInfo".

7. Select Multipart in the Consumes list. Keep the default settings of the other options.
Configuring the tJavaRow component

Procedure

1. Connect tRESTRequest to tJavaRow using the Row > UserInfo connection.
2. Double-click tJavaRow in the design workspace to display its Basic settings view.

3. Enter the following code in the Code box to convert the message into Document type and print it in the console.

```java
String result = new String(input_row.id, 0, input_row.id.length);
routines.system.Document doc = new routines.system.Document();
doc.setDocument(org.dom4j.DocumentHelper.parseText(result));
output_row.id = doc;
System.out.println(result);
```

Configuring the tXMLMap component

Procedure

1. Connect tJavaRow to tXMLMap using the Row > Main connection.
2. Double-click tXMLMap in the design workspace to open the Map Editor.
3. Click the [+] button on the bottom left to add a column id of Document type for the input.

4. Right-click the root node of the input table and select Rename in the contextual menu and rename it customer.

5. Create a sub-element to the customer node by selecting Create Sub-Element in the contextual menu. Name the sub-element as id in the pop-up dialog box.

6. Click the [+] button on the top right to add an output and name it as response.

7. Click the [+] button on the bottom right to add a column body of Document type for the output.

8. Right-click the root node of the input table and select Rename in the contextual menu and rename it customer.

9. Create a sub-element to the customer node by selecting Create Sub-Element in the contextual menu. Name the sub-element as id in the pop-up dialog box.

10. Select the id column from the input table and drop it onto the Expression field of the id node of the output table.

11. Click OK to save the settings.

**Configuring the tRESTResponse component**

**Procedure**

1. Connect tXMLMap to a tRESTResponse using Row > response connection.

   The schema defined in tXMLMap is retrieved in tRESTResponse automatically.
2. Select **OK(200)** from the **Return status code** list.
3. Leave the rest of the settings as they are.

**Saving and executing the Job**

**Procedure**

1. Save the Job and press **F6** to execute it.

2. Run the **UploadFile.html** using a web browser.

3. Click the **Browse** button to navigate to the **customer.xml** that contains the user ID and click **upload**.
4. The HTTP POST request is accepted by the REST service and the user ID is sent back to the server.

You can also view the response in the page source.

5. The content of the input file is printed in the execution console.

tRESTResponse

Returns a specific HTTP status code to the client end as a response to the HTTP and/or HTTP requests.

**Note:**
To enable the HTTPS support, you have to generate a keystore and add some HTTPS security configuration properties in the `org.ops4j.pax.web.cfg` file of your Runtime container. For more information, see the *Talend ESB Container Administration Guide*.

### tRESTResponse Standard properties

These properties are used to configure tRESTResponse running in the Standard Job framework. The Standard tRESTResponse component belongs to the ESB family.

*This component is relevant only when used with one of the Talend solutions with ESB, as it should be used with the Service Repository node and the Data Service creation related wizard(s).*

#### Basic settings

<table>
<thead>
<tr>
<th>Return Body Type</th>
<th>Select a response body type from Document, String, and Byte[] in the list.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Return status code</td>
<td>Select a status code from the list to indicate the request status.</td>
</tr>
<tr>
<td></td>
<td>- &lt;&lt;Custom&gt;&gt;: This option allows you to customize the status code. Enter the status code of your choice in the field.</td>
</tr>
<tr>
<td></td>
<td>- Bad Request (400): The request had bad syntax or was inherently impossible to be satisfied.</td>
</tr>
<tr>
<td></td>
<td>- Internal Server Error (500): The server encountered an unexpected condition which prevented it from fulfilling the request.</td>
</tr>
<tr>
<td></td>
<td>- OK (200): The request was fulfilled.</td>
</tr>
<tr>
<td></td>
<td>- Resource Not Found (404): The server has not found anything matching the URI given.</td>
</tr>
<tr>
<td>Schema and Edit schema</td>
<td>A schema is a row description, that is, it defines the number of fields to be processed and passed on to the next component.</td>
</tr>
<tr>
<td></td>
<td>The schema mode is Built-in: it is created and stored locally for this component.</td>
</tr>
<tr>
<td></td>
<td>Click Edit schema to make changes to the schema.</td>
</tr>
<tr>
<td></td>
<td>The input flow is retrieved from the previous component connected to tRESTResponse. Any change of the input flow in tRESTResponse will also be propagated to the previous component automatically.</td>
</tr>
</tbody>
</table>
The output flow of **tRESTResponse** is a hard-coded field named **body**, the type of which is defined in the **Return Body Type** list.

### Advanced settings

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Response Headers</strong></td>
<td>Type in the name-value pair(s) to pass additional information about the response. For more information about response headers, see the site <a href="http://www.w3.org/Protocols/rfc2616/rfc2616-sec6.html#sec6.2">http://www.w3.org/Protocols/rfc2616/rfc2616-sec6.html#sec6.2</a>.</td>
</tr>
<tr>
<td><strong>Drop JSON Response Root</strong></td>
<td>Select this check box to drop the root JSON element in the response.</td>

<tr>
<td></td>
<td><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string.</td>
</tr>
<tr>
<td></td>
<td>This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td></td>
<td>For further information about variables, see <a href="http://www.talend.com">Talend Studio User Guide</a>.</td>
</tr>
</tbody>
</table>

### Usage

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Usage rule</strong></td>
<td>This component covers the possibility that a Talend Job can be wrapped as a service, with the ability to input a request to a service into a Job</td>
</tr>
</tbody>
</table>
**tRiakBucketList**

Retrieves a list of buckets from a Riak cluster and iterates on it.

**tRiakBucketList Standard properties**

These properties are used to configure tRiakBucketList running in the Standard Job framework.

The Standard tRiakBucketList component belongs to the Big Data and the Databases families.

The component in this framework is available when you are using one of the Talend solutions with Big Data.

**Basic settings**

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. If you select the Use an existing connection check box, the Nodes table will not be available.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Nodes</td>
<td>Fill in the information required for a connection to a Riak cluster. • <strong>Host</strong>: enter the IP address or hostname of a Riak node in the Riak cluster that you want to connect to. • <strong>Port</strong>: enter the listening port number of a Riak node. You can leave this field empty to use its default value 8098. • <strong>Riak path</strong>: enter the Riak path for accessing a Riak node. You can leave this field empty to use its default value <code>riak</code>. One example of the URL for accessing a Riak node is <code>http://127.0.0.1:8098/riak</code>. For more information about the concepts related to Riak, see <a href="http://docs.basho.com/riak/latest/theory/concepts/">http://docs.basho.com/riak/latest/theory/concepts/</a>.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global Variables**

| Global Variables | **CURRENT_BUCKET_NAME**: the current bucket name. This is a Flow variable and it returns a string. **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer. |
**Usage**

| Usage rule                  | This component can be used as a standalone component. |

**Related scenarios**

No scenario is available for the Standard version of this component yet.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*. 
tRiakClose

Closes an active connection to a Riak cluster so as to release occupied resources.

**tRiakClose Standard properties**

These properties are used to configure tRiakClose running in the Standard Job framework.

The Standard tRiakClose component belongs to the Big Data and the Databases families.

The component in this framework is available when you are using one of the *Talend* solutions with Big Data.

**Basic settings**

| Component List | Select an active connection to a Riak cluster to be closed. |

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global Variables**

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
For further information about variables, see *Talend Studio User Guide*. |

**Usage**

| Usage rule | This component is generally used with other Riak components, particularly tRiakConnection. |

**Related Scenario**

For a scenario in which tRiakClose is used, see *Scenario: Exporting data from a Riak bucket to a local file* on page 3255.
tRiakConnection

Opens and reuses of the connection it creates to a Riak cluster.

**tRiakConnection Standard properties**

These properties are used to configure tRiakConnection running in the Standard Job framework.

The Standard tRiakConnection component belongs to the Big Data and the Databases families.

The component in this framework is available when you are using one of the Talend solutions with Big Data.

**Basic settings**

| Nodes | Fill in the information required for a connection to a Riak cluster.

- **Host**: enter the IP address or hostname of a Riak node in the Riak cluster that you want to connect to.
- **Port**: enter the listening port number of a Riak node.
  You can leave this field empty to use its default value 8098.
- **Riak path**: enter the Riak path for accessing a Riak node.
  You can leave this field empty to use its default value riak.

One example of the URL for accessing a Riak node is http://127.0.0.1:8098/riak.

For more information about the concepts related to Riak, see http://docs.basho.com/riak/latest/theory/concepts/.

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

**Global Variables**

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.
For further information about variables, see *Talend Studio User Guide*.

### Usage

| Usage rule | This component is generally used with other Riak components, particularly *tRiakClose*. |

### Related scenario

For a scenario in which *tRiakConnection* is used, see *Scenario: Exporting data from a Riak bucket to a local file* on page 3255.
tRiakInput

Extracts the desired data from a bucket in a Riak node so as to store or apply changes to the data.
tRiakInput reads data from a Riak bucket and send data in the Talend flow.

**tRiakInput Standard properties**

These properties are used to configure tRiakInput running in the Standard Job framework.
The Standard tRiakInput component belongs to the Big Data and the Databases families.
The component in this framework is available when you are using one of the Talend solutions with Big Data.

</tbody>
</table>

**Usage**

| Usage rule | This component always needs an output link. |

**Scenario: Exporting data from a Riak bucket to a local file**

This scenario applies only to a Talend solution with Big Data.
The following scenario describes a Job which reads data from a Riak bucket and writes it into a local `.txt` file.

**Prerequisites:** The Riak bucket from which you want to export data already exists. In this example, the data from the bucket *computer* will be exported and the bucket has already imported the following data:

```
id; company; brand; price; owner
001; Dell; Inspiron 15; 299; Amanda
002; Dell; Inspiron 15R; 549; Linda
003; HP; Pavilion 500-210qe; 539; Marina
004; HP; Pavilion 500-075; 599; Diana
```

**Dropping and linking components**

**Procedure**

1. Drop the following components from the **Palette** to the design workspace: `tRiakConnection`, `tRiakInput`, `tFileOutputDelimited`, and `tRiakClose`.
2. Connect `tRiakConnection` to `tRiakInput` using a **Trigger > On Subjob Ok** link.
3. Connect `tRiakInput` to `tFileOutputDelimited` using a **Row > Main** link.
4. Connect `tFileOutputDelimited` to `tRiakClose` using a **Trigger > On Component Ok** link.

**Configuring the components**

**Opening a connection to Riak**

**Procedure**

1. Double-click `tRiakConnection` to open its **Basic settings** view in the **Component** tab.

   ![tRiakConnection Basic Settings](image)

   **Connection Nodes**

   2. In the **Nodes** table, enter the information of a Riak cluster you want to connect to.
Exporting data from a Riak bucket to a local file

Procedure

1. Double-click \texttt{tRiakInput} to open its Basic settings view in the Component tab.

2. Click Edit schema to define the structure of exported data. In this example, three columns are defined: \texttt{id}, \texttt{company}, and \texttt{price}.

3. Select the \textbf{Use an existing connection} check box and then select the connection you have configured earlier. In this example, it is \texttt{tRiakConnection_1}.

4. In the Bucket field, enter the name of the bucket from which the data will be exported, \texttt{computer} in this example.
5. Select the **Output key to column** check box, and select the desired column from the list. *id* is selected in this example.

6. In the **Value columns** table, click twice the button and select *company* and *price* from the list respectively.

**Writing data into a local file**

**Procedure**

1. Double-click **tFileOutputDelimited** to open its **Basic settings** view in the **Component** tab.

2. In the **File Name** field, enter the full path to the local file in which you want to store the exported data, *D:/Output/computer.txt* in this example.

3. Select the **Include Header** check box.

4. Leave other settings as they are.

**Closing the connection to Riak**

**Procedure**

1. Double-click **tRiakClose** to open its **Basic settings** view in the **Component** tab.

2. Select the connection you want to close from the **Component List**, **tRiakConnection_1** in this example.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl+S** to save your Job.

2. Execute the Job by pressing **F6** or clicking **Run** on the **Run** tab.

3. Go to the local directory where the file is stored and check the exported data from the Riak bucket.

</tbody>
</table>

Advanced settings

| tStatCatcher Statistics    | Select this check box to gather the Job processing metadata at the Job level as well as at each component level.                                                                                                                                                |

Global Variables

| Global Variables           | **CURRENT_KEY**: the current key. This is a Flow variable and it returns a string.                                                                                                  |
**tRiakKeyList**

**NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

| Usage rule | This component can be used as a standalone component. |

### Related scenarios

No scenario is available for the Standard version of this component yet.
tRiakOutput

Receives data from the preceding component and writes data into or deletes data from a bucket in a Riak cluster.

**tRiakOutput Standard properties**

These properties are used to configure tRiakOutput running in the Standard Job framework.

The Standard tRiakOutput component belongs to the Big Data and the Databases families.

The component in this framework is available when you are using one of the Talend solutions with Big Data.

**Basic settings**

| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:
| | • **View schema**: choose this option to view the schema only.
| | • **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
| | • **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the [Repository Content] window.
| **Built-In**: You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.
| **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.
| When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.
<p>| You can find more details about how to verify default values in retrieved schema in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>). |</p>
<table>
<thead>
<tr>

### Usage

| Usage rule | This component is used as an output component and it always needs an incoming link. |

### Related scenarios

No scenario is available for the Standard version of this component yet.
**tRouteFault**

Sends messages from a Data Integration Job to a Mediation Route and mark the message as fault.

**tRouteFault Standard properties**

These properties are used to configure tRouteFault running in the Standard Job framework.

The Standard tRouteFault component belongs to the ESB family.

*This component is relevant only when used with one of the *Talend* solutions with ESB, as it should be used with the Service Repository node and the Data Service creation related wizard(s).*

### Basic settings

| **Output Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
  • **View schema**: choose this option to view the schema only.  
  • **Change to built-in property**: choose this option to change the schema to Built-in for local changes.  
  • **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the [Repository Content] window.  
Click Sync columns to retrieve the schema from the previous component connected in the Job. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-in</strong>: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td><strong>Repository</strong>: Select the Repository file where Properties are stored.</td>
<td></td>
</tr>
<tr>
<td><strong>Camel</strong></td>
<td>Enter the message parameters corresponding to the columns you defined in the schema dialog box via the Edit schema button.</td>
</tr>
</tbody>
</table>
| **Type** | Select between:  
  • **Body**: Used to set the body of a Route, equals the code exchange.getOut().setBody(...).  
  • **Property**: Used to set the property of a Route, equals the code exchange.setProperty(name, value).  
  • **System**: Used to set the system property, equals the code System.setProperty(name, value). |
### Header

Used the set the output header, equals the code `exchange.getOut().setHeader(name, value)`.

| Name | This column is used to set the name for the parameter when its type is either Property, System or Header. This column is ignored when the type is Body. |

### Advanced settings

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

### Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

### Usage

| Usage rule | This component can be used as the end component and thus requires an input component. |

| Limitation | The Job using a tRouteFault must be launched only within a Route using the cTalendJob component. |

### Scenario: Exchanging messages between a Job and a Route

This scenario applies only to a Talend solution with ESB.

This scenario describes how to exchange messages between a Job and a Route using the tRouteInput and the tRouteFault component. To do this, a Job is created to receive the message from the Route and mark the message as fault. Then a Route is built to send the message to the Job and handle the fault message.

### Creating an Data Integration Job

In this section, a Job named RouteCommunication_tRouteFault is built.
Arranging the flow of the message

About this task

1. Drag and drop a tRouteInput and a tRouteFault from the Palette onto the design workspace.
2. Right-click the tRouteInput component, select Row > Main from the contextual menu and click the tRouteFault component.

Configuring how the message is processed

1. Double-click the tRouteInput component to open its Basic settings view in the Component tab.
2. Click the three-dot button next to Edit Schema. In the schema dialog box, click the plus button to add a new line of String type and name it body. Click OK to close the dialog box.
3. In the **Simple Expression** field for the *body* element, enter "\${in.body}" to get the body of the input message from the Route.

4. Double-click the **tRouteFault** component to display its **Basic settings** view in the **Component** tab.

5. Make sure that **tRouteFault** has one element *body*. Set its type to **Body**.

6. Press **Ctrl+S** to save your Job.

### Creating a Mediation Route

In this section, we will create a Route to send a message to the Job and handle the fault message.

#### Dropping and linking the components

**About this task**

**Procedure**

1. Drag and drop a **cTimer**, a **cSetBody**, a **cJavaDSLProcessor**, a **cTalendJob**, a **cOnException** and a **cProcessor** component from the **Palette** onto the design workspace.

2. Link the components with the **Row > Route** connection as shown above.

3. Label the components for better identification of their roles.

**Configuring the components**

**Procedure**

1. Double-click the **cTimer** component to open its **Basic settings** view in the **Component** tab.
2. Enter 1 in the **Repeat** field to trigger a message exchange one time.

3. Double-click the **cSetBody** component to display its **Basic settings** view in the **Component** tab.

4. Select **Simple** from the **Language** list and enter *Hello!* in the **Expression** field.

5. Double-click the **cJavaDSLProcessor** component to open its **Basic settings** view in the **Component** tab.

6. Enter `.handleFault()` in the **Code** box so that the fault message will be caught as an exception.

7. Double-click the **cTalendJob** component to display its **Basic settings** view in the **Component** tab.
8. Select Job `RouteCommunication_tRouteFault` from the repository to call the Job that is created in the previous section.

9. Double click the `cOnException` component to display its Basic settings view in the Component tab.

10. Click [+] to add a line to the Exceptions table, and enter `org.apache.camel.CamelException` in the Exception field to handle the exceptions.

11. Double-click the `cProcessor` component to display its Basic settings view in the Component tab.
12. Customize the code in the Code area to show the message body:

   ```java
   System.out.println(exchange.getIn());
   ```

13. Press Ctrl+S to save your Route.

**Executing the Route**

Click the Run view to display it and click the Run button to launch the execution of your Route. You can also press F6 to execute it.

The message *Hello!* is sent from the Route to the Job and caught as exception:
[statistics] connecting to socket on port 3783
[statistics] connected

 Processed by failure processor:
 FallbackErrorHandler[Channel[DelegateSync[local_project.routefault_0_1.tRouteFault@102511045b]]

Stacktrace

org.apache.camel.CamelException: Hello!
at org.apache.camel.processor.interceptor.HandleFaultInterceptor.handleFault(HandleFaultInterceptor.java:75)
tRouteInput

Accepts messages in a Data Integration Job from a Mediation Route.

tRouteInput Standard properties

These properties are used to configure tRouteInput running in the Standard Job framework.

The Standard tRouteInput component belongs to the ESB family.

This component is relevant only when used with one of the Talend solutions with ESB, as it should be used with the Service Repository node and the Data Service creation related wizard(s).

Basic settings

| Input Schema and Edit schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:
| • View schema: choose this option to view the schema only.
| • Change to built-in property: choose this option to change the schema to Built-in for local changes.
| • Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the [Repository Content] window. |

| Built-in: No property data stored centrally. |

| Repository: Select the Repository file where Properties are stored. |

| Camel | Enter the message parameters corresponding to the columns you defined in the schema dialog box via the Edit schema button using the Simple Expression Language. For more information about the Simple Expression Language, see the site http://camel.apache.org/simple.html. |

Advanced settings

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |
Global Variables

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*. |

Usage

| Usage rule | This component can be used as starter component and has an output. It is mandatory that a **tRouteInput** component is used in the Data Integration Job to be called by a Route using the **cTalendJob** component. The reason for it is that this will prevent the referenced Job from starting automatically when deployed in Talend Runtime. Instead it will only start when it gets called by the Route.

For more information about how to use the **cTalendJob** component, see Talend Help Center (https://help.talend.com). |

| Limitation | The Job using a **tRouteInput** must be launched only within a Route using the **cTalendJob** component. |

Scenario: Exchanging messages between a Job and a Route

This scenario applies only to a Talend solution with ESB.

This scenario describes how to accept messages from a Route using the **tRouteInput** component and send messages to a Route using the **tRouteOutput** component. To do this, we need to build a Job and a Route to call the Job using the **cTalendJob** component.

For more information about how to use the **cTalendJob** component, see Talend Help Center (https://help.talend.com).

Creating an Data Integration Job

In this section, we will build a Job named *RouteCommunication* to accept the message from a Route, change the message body and send the message back to the Route.
Arranging the flow of the message

About this task

Procedure

1. Drag and drop a tRouteInput, a tLogRow, a tReplace and a tRouteOutput from the Palette onto the design workspace.
2. Link the components using the Row > Main connection as shown above.

Configuring how the message is processed

Procedure

1. Double-click the tRouteInput component to open its Basic settings view in the Component tab.

2. Click the three-dot button next to Edit Schema. In the schema dialog box, click the plus button to add a new line of String type and name it body. Click OK to close the dialog box.

3. In the Simple Expression field for the body element, enter "${in.body}" to get the body of the input message from the Route.
4. The **tLogRow** component will monitor the message exchanges and does not need any configuration.

5. Double-click the **tReplace** component to open its **Basic settings** view in the **Component** tab.

6. Click **Sync columns** to retrieve the schema from the **tLogRow**. In the pop-up dialog box, click **Yes** to propagate the schema to the subsequent component.

   Click [+] to add a row to the **Search/Replace** table. Enter *World* in the **Search** column and *Talend* in the **Replace with** column. Clear the **Whole word** check box.

7. Double-click the **tRouteOutput** component to display its **Basic settings** view in the **Component** tab.

8. Make sure that **tRouteOutput** has one element **body**. Set its type to **Body**.

9. Press **Ctrl+S** to save your Job.

**Creating a Mediation Route**

In this section, we will create a Route to send a message to the Job and receive the message sent back to the Route.
Dropping and linking the components

About this task

Procedure

1. Drag and drop a cTimer, a cSetBody, a cTalendJob, and a cLog from the Palette onto the design workspace.

2. Link the components with the Row > Route connection as shown above.

3. Label the components for better identification of their roles.

Configuring the components

Procedure

1. Double-click the cTimer component to open its Basic settings view in the Component tab.

2. In the Repeat field, enter 1 to generate the message exchange one time. Keep the default settings of the other options.

3. Double-click the cSetBody component to display its Basic settings view in the Component tab.

4. Select Simple from the Language list and enter Hello World! in the Expression field.

5. Double-click the cTalendJob component to display its Basic settings view in the Component tab.
6. Select Job *RouteCommunication* from the repository.
7. The *cLog* component will monitor the message exchanges and does not need any configuration.
8. Press **Ctrl+S** to save your Route.

**Executing the Route**

Click the **Run** view to display it and click the **Run** button to launch the execution of your Route. You can also press **F6** to execute it. In the execution log you can see that the message *Hello World!* is sent to the Job. The message body is changed to *Hello Talend!* and sent back to the Route.
tRouteOutput

Sends messages from a Data Integration Job to a Mediation Route.

**tRouteOutput Standard properties**

These properties are used to configure tRouteOutput running in the Standard Job framework.

The Standard tRouteOutput component belongs to the ESB family.

*This component is relevant only when used with one of the Talend solutions with ESB, as it should be used with the Service Repository node and the Data Service creation related wizard(s).*

**Basic settings**

| Output Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
  • View schema: choose this option to view the schema only.  
  • Change to built-in property: choose this option to change the schema to Built-in for local changes.  
  • Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the [Repository Content] window.  
  
  Click Sync columns to retrieve the schema from the previous component connected in the Job. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Built-in: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td>Repository: Select the Repository file where Properties are stored.</td>
<td></td>
</tr>
<tr>
<td>Camel</td>
<td>Enter the message parameters corresponding to the columns you defined in the schema dialog box via the Edit schema button.</td>
</tr>
</tbody>
</table>
| Type | Select between:  
  • **Body**: Used to set the body of a Route, equals the code exchange.getOut().setBody(...).  
  • **Property**: Used to set the property of a Route, equals the code exchange.setProperty(name, value).  
  • **System**: Used to set the system property, equals the code System.setProperty(name, value). |
Header: Used the set the output header, equals the code exchange.getOut().setHeader(name, value).

Name
This column is used to set the name for the parameter when its type is either Property, System or Header. This column is ignored when the type is Body.

Advanced settings

**tStatCatcher Statistics**
Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

Global Variables

**Global Variables**
ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

**Usage rule**
This component can be used as the end component and thus requires an input component. It is mandatory that a tRouteInput component is used in the Data Integration Job to be called by a Route using the cTalendJob component. The reason for it is that this will prevent the referenced Job from starting automatically when deployed in Talend Runtime. Instead it will only start when it gets called by the Route.

For more information about how to use the cTalendJob component, see Talend Help Center (https://help.talend.com).

**Limitation**
The Job using a tRouteOutput must be launched only within a Route using the cTalendJob component.

Related scenario

For a scenario in which tRouteOutput is used, see Scenario: Exchanging messages between a Job and a Route on page 3274.
tRowGenerator

Creates an input flow in a Job for testing purposes, in particular for boundary test sets.
tRowGenerator generates as many rows and fields as are required using random values taken from a list.

tRowGenerator Standard properties

These properties are used to configure tRowGenerator running in the Standard Job framework.
The Standard tRowGenerator component belongs to the Misc family.
The component in this framework is generally available.

Basic settings

| Schema and Edit schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.  
Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:   
• View schema: choose this option to view the schema only.  
• Change to built-in property: choose this option to change the schema to Built-in for local changes.  
• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the [Repository Content] window. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Built-In: You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.</td>
<td></td>
</tr>
<tr>
<td>Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.</td>
<td></td>
</tr>
</tbody>
</table>
| RowGenerator editor | The editor allows you to define the columns and the nature of data to be generated. You can use predefined routines or type in the function to be used to generate the data specified. 
Note that in a Storm Job, the value -1 in the Number of rows for RowGenerator field in the RowGenerator editor means to generate infinite rows of input data. |
Advanced settings

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

Global Variables

| Global Variables | NB.LINE: the number of rows processed. This is an After variable and it returns an integer. |
|                 | ERROR.MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. |
|                 | A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. |
|                 | To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. |
|                 | For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | The tRowGenerator Editor’s ease of use allows users without any Java knowledge to generate random data for test purposes. |

Defining the schema

First you need to define the structure of data to be generated.

- Add as many columns to your schema as needed, using the plus (+) button.
- Type in the names of the columns to be created in the Columns area and select the Key check box if required.
- Make sure you define then the nature of the data contained in the column, by selecting the Type in the list. According to the type you select, the list of Functions offered will differ. This information is therefore compulsory.

<table>
<thead>
<tr>
<th>Column</th>
<th>Key</th>
<th>Type</th>
<th>Nullable</th>
<th>Functions</th>
<th>Preview</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID_employees</td>
<td></td>
<td>int</td>
<td></td>
<td>sequence</td>
<td>2</td>
</tr>
<tr>
<td>First_Name</td>
<td></td>
<td>String</td>
<td></td>
<td>...</td>
<td>Phoebe</td>
</tr>
<tr>
<td>Last_Name</td>
<td></td>
<td>String</td>
<td></td>
<td>getUserName</td>
<td>Eisenhower</td>
</tr>
<tr>
<td>Hire_Date</td>
<td></td>
<td>Day</td>
<td></td>
<td>getRandomDate</td>
<td>2008-08-31</td>
</tr>
</tbody>
</table>
• Some extra information, although not required, might be useful such as Length, Precision or Comment. You can also hide these columns, by clicking on the Columns drop-down button next to the toolbar, and unchecking the relevant entries on the list.

• In the Function area, you can select the predefined routine/function if one of them corresponds to your needs. You can also add to this list any routine you stored in the Routine area of the Repository. Or you can type in the function you want to use in the Function definition panel.

Related topic: see Talend Studio User Guide.

• Click Refresh to have a preview of the data generated.

• Type in a number of rows to be generated. The more rows to be generated, the longer it’ll take to carry out the generation operation.

Defining the function

Select the […] under Function in the Schema definition panel in order to customize the function parameters.

• Select the Function parameters tab

• The Parameter area displays Customized parameter as function name (read-only)

• In the Value area, type in the Java function to be used to generate the data specified.

• Click on the Preview tab and click Preview to check out a sample of the data generated.

Scenario: Generating random java data

The following scenario creates a two-component Job, generating 50 rows structured as follows: a randomly picked-up ID in a 1-to-3 range, a random ascii First Name and Last Name generation and a random date taken in a defined range.

• Drop a tRowGenerator and a tLogRow component from the Palette to the design workspace.

• Right-click tRowGenerator and select Row > Main. Drag this main row link onto the tLogRow component and release when the plug symbol displays.

• Double click tRowGenerator to open the Editor.

• Define the fields to be generated.
• The random ID column is of integer type, the First and Last names are of string type and the Date is of date type.

• In the **Function** list, select the relevant function or set on the three dots for custom function.

• On the **Function parameters** tab, define the Values to be randomly picked up.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>customize parameter</td>
<td>1,2,3</td>
<td></td>
</tr>
</tbody>
</table>

• **First_Name** and **Last_Name** columns are to be generated using the `getAsciiRandomString` function that is predefined in the system routines. By default the length defined is 6 characters long. You can change this if need be.

• The **Date** column calls the predefined `getRandomDate` function. You can edit the parameter values in the **Function parameters** tab.

• Set the **Number of Rows** to be generated to 50.

• Click **OK** to validate the setting.

• Double click **tLogRow** to view the Basic settings. The default setting is retained for this Job.

• Press **F6** to run the Job.

---

Running process with context: Default.

---

...
The 50 rows are generated following the setting defined in the `tRowGenerator` editor and the output is displayed in the Run console.
**tRSSInput**

Reads RSS-Feeds using URLs. tRSSInput makes it possible to keep track of blog entries on websites to gather and organize information for quick and easy access.

**tRSSInput Standard properties**

These properties are used to configure tRSSInput running in the Standard Job framework.

The Standard tRSSInput component belongs to the Internet family.

The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th><strong>Schema and Edit Schema</strong></th>
<th>A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The tRSSInput component has a read-only schema that is made of four columns: TITLE, DESCRIPTION, PUBDATE, and Link.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>RSS URL</strong></td>
<td>Enter the URL for the RSS_Feed to read.</td>
</tr>
<tr>
<td><strong>Read articles from</strong></td>
<td>If selected, tRSSInput reads articles on the RSS_Feed from the date set through the three-dot [...] button next to the date time field.</td>
</tr>
<tr>
<td><strong>Max number of articles</strong></td>
<td>If selected, tRSSInput reads as many articles as the number entered in the max amount field.</td>
</tr>
<tr>
<td><strong>Die on error</strong></td>
<td>This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows.</td>
</tr>
</tbody>
</table>

**Global Variables**

| **Global Variables** | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  
|----------------------|---------------------------------------------------------------------------------------------------|
|                      | **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.  
|                      | A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
|                      | To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. |
Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is generally used as an input component. It requires an output component.</th>
</tr>
</thead>
</table>

| Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |

Scenario: Fetching frequently updated blog entries.

This two-component scenario aims at retrieving frequently updated blog entries from a Talend local news RSS feed using the tRSSInput component.

Procedure

Procedure

1. Drop the following components from the Palette onto the design workspace: tRSSInput and tLogRow.
2. Right-click to connect them using a Row > Main link.
3. In the design workspace, select tRSSInput, and click the Component tab to define the basic settings for tRSSInput.

4. Enter the URL for the RSS_Feed to access. In this scenario, tRSSInput links to the Talend RSS_Feed: http://feeds.feedburner.com/Talend.
5. Select/clear the other check boxes as required. In this scenario, we want to display the information about two articles dated from July 20, 2008.

6. In the design workspace, select tLogRow and click the Component tab to define its basic settings. For more information about tLogRow properties, see tLogRow Standard properties on page 1988.

7. Save the Job and press F6 to execute it.

The tRSSInput component accessed the RSS feed of Talend website on your behalf and organized the information for you.

Two blog entries are displayed on the console. Each entry has its own title, description, publication date, and the corresponding RSS feed URL address. Blogs show the last entry first, and you can scroll down to read earlier entries.
tRSSOutput

Creates and writes XML files that hold RSS or Atom feeds.

### tRSSOutput Standard properties

These properties are used to configure tRSSOutput running in the Standard Job framework.

The Standard tRSSOutput component belongs to the Internet family.

The component in this framework is generally available.

#### Basic settings

<table>
<thead>
<tr>
<th>File name</th>
<th>Name or path to the XML file to be processed and/or the variable to be used. For further information about how to define and use a variable in a Job, see <a href="#">Talend Studio User Guide</a>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Encoding</td>
<td>Select an encoding type from the list, or select Custom and define it manually. This field is compulsory for DB data handling.</td>
</tr>
<tr>
<td>Append</td>
<td>Select this check box to add the new rows to the end of the file.</td>
</tr>
<tr>
<td>Mode</td>
<td>Select between RSS or ATOM according to the feed you want to generate.</td>
</tr>
</tbody>
</table>

**Channel (in RSS mode)**

- **Title**: Enter a meaningful title.
- **Description**: Enter a description that you think will describe your content.
- **Publication date**: Enter the relevant date.
- **Link**: Enter the relevant URL.

**Note:**

The information to be typed in here concerns your entire input data, site etc, rather than a particular item.

**Feed (in ATOM mode)**

- **Title**: Enter a meaningful title.
- **Link**: Enter the relevant URL.
- **Id**: Enter the valid URL corresponding to the Link.
- **Update date**: Enter the relevant date.
- **Author name**: Enter the relevant name.

**Optionnal Channel Elements**

Click the [+I button below the table to add new lines and enter the information relative to the RSS flow metadata:

- **Element Name**: name of the metadata.
- **Element Value**: content of the metadata.
### Schema and Edit Schema

A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either **Built-in** or stored remotely in the **Repository**.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.

By default, the schema of **tRSSOutput** is made of five read-only columns: **id**, **title**, **link**, **updated**, and **summary**. You can add new columns or click **Syn columns** to retrieve the schema structure from the preceding component.

### Advanced settings

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
<th>Select this check box to gather the Job processing metadata at a Job level as well as at each component level.</th>
</tr>
</thead>
</table>

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>NB_LINE</strong>: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press <strong>Ctrl + Space</strong> to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td></td>
<td>For further information about variables, see <a href="#">Talend Studio User Guide</a>.</td>
</tr>
</tbody>
</table>
Usage

| Usage rule | This component must be linked to an input or intermediary component. |

Scenario 1: Creating an RSS flow and storing files on an FTP server

In this scenario we:

- create an RSS flow for files that you would like to share with other people, and
- store the complete files on an FTP server.

This scenario writes an RSS feed XML file about a Mysql table holding information about books. It adds links to the files stored on an FTP server in case users want to have access to the complete files.

Dropping and linking components

Procedure

1. Drop the following components from the Palette onto the design workspace: tMysqlInput, tRSSOutput, and tFTPPut.
2. Right-click tMysqlInput and connect it to tRSSOutput using a Row > Main link.
3. Right-click tMysqlInput and connect it to tFTPPut using a Trigger > OnSubjobOk link.

Defining the data source

Procedure

1. In the design workspace, select tMysqlInput, and click the Component tab to define the basic settings for tMysqlInput.
2. Set the **Property type** to **Repository** and click the three-dots button [...] to select the relevant DB entry from the list. The connection details along with the schema get filled in automatically.

3. In the **Table Name** field, either type your table name or click the three dots button [...] and select your table name from the list. In this scenario, the Mysql input table is called "rss_talend" and the schema is made up of four columns, **TITLE**, **Description**, **PUBDATE**, and **LINK**.

4. In the **Query** field, enter your DB query paying particular attention to properly sequence the fields in order to match the schema definition, or click **Guess Query**.

**Creating an RSS flow**

**Procedure**

1. In the design workspace, select **tRSSOutput**, and click the **Component** view to define the basic settings for **tRSSOutput**.
2. In the File name field, use the by default file name and path, or browse to set your own for the output XML file.

3. Select the encoding type on the Encoding Type list.

4. In the Mode area, select RSS.

5. In the Channel panel, enter a title, a description, a publication date, and a link to define your input data as a whole.

6. Click Edit Schema to modify the schema if necessary.

   **Note:**
   
   You can click Sync columns to retrieve the generated schema from the preceding component.

7. Save your Job and press F6 to execute this first part.
The **tRSSOutput** component created an output RSS flow in an XML format for the defined files.

**Writing the complete files to an FTP server**

**About this task**

To store the complete files on an FTP server:

**Procedure**

1. In the design workspace, select **FTPPut**, and click the **Component** tab to define the basic settings for **tFTPPut**.
2. Enter the host name and the port number in their corresponding fields.
3. Enter your connection details in the corresponding **Username** and **Password** fields.
4. Browse to the local directory, or enter it manually in the **Local directory** field.
5. Enter the details of the remote server directory.
6. Select the transfer mode from the **Transfer mode** list.
7. On the **Files** panel, click on the plus button to add new lines and fill in the filemasks of all files to be copied onto the remote directory. In this scenario, the files to be saved on the FTP server are all text files.
8. Save your Job and press **F6** to execute it.

   Files defined in the Filemask are copied on the remote server.

### Scenario 2: Creating an RSS flow that contains metadata

This scenario describes a two-component Job that creates an RSS flow that holds metadata and then redirects the obtained information in an XML file of the output RSS flow.

### Dropping and linking components

**Procedure**

1. Drop **tRSSInput** and **tRSSOutput** from the **Palette** to the design workspace.
2. Connect the two components together using a **Row > Main** link.

### Configuring the components

**Procedure**

1. Double-click **tRSSInput** to open its **Basic settings** view and define the component properties.
2. Enter the URL for the RSS Feed to access. In this scenario, tRSSInput links to the Talend RSS_Feed: http://feeds.feedburner.com/Talend.

3. In the design workspace, double-click tRSSOutput to display its Basic settings view and define the component properties.

4. In the File name field, use the by default file name and path, or browse to set your own for the output XML file.

5. Select the encoding type on the Encoding Type list.

6. In the Mode area, select RSS.

7. In the Channel panel, enter a title, a description, a publication date and a link to define your input data as a whole.

8. In the Optional Channel Element, define the RSS flow metadata. In this example, the flow has two metadata: copyright, which value is tos, and language which value is en_us.

9. Click Edit Schema to modify the schema if necessary.

Note:

You can click Sync Column to retrieve the generated schema from the preceding component.
Saving and executing the Job

Procedure

1. Press Ctrl+S to save your Job.
2. Press F6 or click Run on the Run tab to execute the Job.

![Output XML file](image)

The defined files are copied in the output XML file and the metadata display under the `<channel>` node above the information about the RSS flow.

Scenario 3: Creating an ATOM feed XML file

This scenario describes a two component Job that generates data and writes them in an ATOM feed XML file.

Dropping and linking components

Procedure

1. Drop the following components from the Palette onto the design workspace: tFixedFlowInput of the Misc component group and tRSSOutput of the Internet component group.
2. Right-click tFixedFlowInput and connect it to tRSSOutput using a Row Main link.
3. When asked whether you want to pass on the schema of tRSSOutput to tFixedFlowInput, click Yes.
Configuring the components

Procedure

1. In the design workspace, double-click tFixedFlowInput to display its corresponding Component view and define its basic settings.

![tFixedFlowInput_1](image)

- **Basic settings**
  - **Schema**: Built-In
  - **Number of rows**: 1
- **Dynamic settings**
  - **Mode**: Use Single Table
  - **Values**: ID "urn:uuid:1225c6b95-cdb8-4abb-aaaa-80da344efa69", Title "Job using tRSSOutput in Talend Open Studio", Link "http://feeds.feedburner.com/Talend")", Updated "2010-09-07T15:43:02Z", Summary "This is a Job made in Talend Open Studio and usn..."

2. In the **Number of rows** field, leave the default setting to 1 to only generate one line of data.
3. In the **Mode** area, leave the **Use Single Table** option selected and fill in the **Values** table. Note that the **Column** field of the **Values** table is filled in by the columns of the schema defined in the component.
4. In the **Value** field of the **Values** table, type in the data you want to be sent to the following component.
5. In the design workspace, double-click tRSSOutput to display its corresponding Component view and define its basic settings.
6. Click the [...] button next to the File Name field to set the output XML file directory and name.

7. In the Mode area, select ATOM to generate an ATOM feed XML file.

   **Warning:**
   
   As the ATOM feed format is strict, some default information is required to create the XML file. So, the schema tRSSOutput contains default columns that will contain those information. Those default columns are greyed out to indicate that they must not be modified. If you choose to modify the schema of the component, the ATOM XML file created will not be valid.

8. In the Feed area, enter a title, link, id, update date, author name to define your input data as a whole.

**Saving and executing the Job**

**Procedure**

1. Press Ctrl+S to save your Job.
2. Press F6 or click Run on the Run tab to execute the Job.
The `tRSSOutput` component creates an output ATOM flow in an XML format.
**tRunJob**

Manages complex Job systems which need to execute one Job after another.

tRunJob executes the Job called in the component’s properties, in the frame of the context defined.

**tRunJob Standard properties**

These properties are used to configure tRunJob running in the Standard Job framework.

The Standard tRunJob component belongs to the System and the Orchestration families.

The component in this framework is generally available.

⚠️ **Warning:**

The tRunJob component is supported with limitations, which means that only S4 (Minor) support cases are accepted and no patches are provided. If you use tRunJob within Data Services and Routes (with cTalendJob), support is provided on a "best effort" basis only. In most cases, there are class loading issues which can sometimes be resolved but not always.

This is because tRunJob is not designed to work in a Service/Route style (ESB) deployment, so regular support is not provided if you decide to use it, even though it may work in many cases. If you used tRunJob in the past, it is recommended to change your Job Design to use Joblets instead.

For DI and non-ESB use cases, it is still a valuable component and has support.

**Basic settings**

| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:
- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **[Repository Content]** window.

| **Built-In**: You create and store the schema locally for this component only. Related topic: see **Talend Studio User Guide**. |
Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>Copy Child Job Schema</th>
<th>Click to fetch the child Job schema.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Use dynamic job</strong></td>
<td>Select this check box to allow multiple Jobs to be called and processed. When this option is enabled, only the latest version of the Jobs can be called and processed. An independent process will be used to run the subjob. The Context and the Use an independent process to run subjob options disappear.</td>
</tr>
<tr>
<td><strong>Warning:</strong> The Use dynamic job option is not compatible with the Jobserver cache. Therefore, the execution may fail if you run a Job that contains tRunjob with this check box selected in Talend Administration Center.</td>
<td></td>
</tr>
<tr>
<td><strong>Warning:</strong> This option is incompatible with the Use or register a shared DB Connection option of database connection components. When tRunJob works together with a database connection component, enabling both options will cause your Job to fail.</td>
<td></td>
</tr>
<tr>
<td><strong>Warning:</strong> This option is not supported within ESB Routes or Data Services.</td>
<td></td>
</tr>
<tr>
<td><strong>Context job</strong></td>
<td>This field is visible only when the Use dynamic job option is selected. Enter the name of the Job that you want to call from the list of Jobs selected.</td>
</tr>
<tr>
<td><strong>Job</strong></td>
<td>Select the Job to be called in and processed. Make sure you already executed once the Job called, beforehand, in order to ensure a smooth run through tRunJob.</td>
</tr>
<tr>
<td><strong>Version</strong></td>
<td>Select the child Job version that you want to use.</td>
</tr>
<tr>
<td><strong>Context</strong></td>
<td>If you defined contexts and variables for the Job to be run by the tRunJob, select the applicable context entry on the list.</td>

<tr>
<td><strong>Warning:</strong> This option is not compatible with the Jobserver cache. Therefore, the execution may fail if you run a Job that contains tRunjob with this check box selected in Talend Administration Center.</td>
<td></td>
</tr>
<tr>
<td><strong>Warning:</strong> This option is incompatible with the Use or register a shared DB Connection option of database connection components. When tRunJob works together with a database connection component, enabling both options will cause your Job to fail.</td>
<td></td>
</tr>
</tbody>
</table>
### Die on child error
Clear this check box to execute the parent Job even though there is an error when executing the child Job.

### Transmit whole context
Select this check box to get all the context variables from the parent Job. Deselect it to get all the context variables from the child Job.

If this check box is selected when the parent and child Jobs have the same context variables defined:
- variable values for the parent Job will be used during the child Job execution if no relevant values are defined in the Context Param table.
- otherwise, values defined in the Context Param table will be used during the child Job execution.

### Context Param
You can change the value of selected context parameters. Click the [+ ] button to add the parameters defined in the Context tab of the child Job. For more information on context parameters, see Talend Studio User Guide.

The values defined here will be used during the child Job execution even if Transmit whole context is selected.

### Advanced settings

#### Propagate the child result to the output schema
Select this check box to propagate the output data stored in the buffer memory via the tBufferOutput component in the child Job to the output component in the parent Job.

This check box is cleared by default. It is invisible when the Use dynamic Job or Use an independent process to run subjob check box is selected.

#### Print Parameters
Select this check box to display the internal and external parameters in the Console.

#### tStatCatcher Statistics
Select this check box to gather the processing metadata at the Job level as well as at each component level.

### Global Variables

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

**CHILD_RETURN_CODE**: the return code of a child Job. This is an After variable and it returns an integer.

**CHILD_EXCEPTION_STACKTRACE**: the exception stack trace from a child Job. This is an After variable and it returns a string.
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>This component can be used as a standalone Job or can help clarifying complex Job by avoiding having too many sub-jobs all together in one Job.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Connections</th>
<th>Outgoing links (from this component to another):</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Row</strong>: Main.</td>
<td></td>
</tr>
<tr>
<td><strong>Trigger</strong>: On Subjob Ok; On Subjob Error; Run if; On Component Ok; On Component Error</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Connections</th>
<th>Incoming links (from one component to this one):</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Row</strong>: Main; Reject; Iterate.</td>
<td></td>
</tr>
<tr>
<td><strong>Trigger</strong>: On Subjob Ok; On Subjob Error; Run if; On Component Ok; On Component Error; Synchronize; Parallelize.</td>

</tr>
</tbody>
</table>

For further information regarding connections, see *Talend Studio User Guide*.

### Calling a Job and passing the parameter needed to the called Job

This scenario describes a two-component Job named **ParentJob** that calls another Job named **ChildJob** to display the content of files specified in the **ParentJob** on the **Run** console.
Setting up the child Job

Procedure

1. Create a new Job ChildJob and add a **tFileInputDelimited** component and a **tLogRow** component to it.
2. Connect the **tFileInputDelimited** component to the **tLogRow** component using a **Row > Main** link.
3. Double-click the **tFileInputDelimited** component to open its **Basic settings** view.

4. Click in the **File Name** field and then press **F5** to open the **New Context Parameter** dialog box and configure the context variable.
5. In the Name field, enter a name for this new context variable, FilePath in this example.
6. In the Default value field, enter the full path to the default input file.
7. Click Finish to validate the context parameter setup and fill the File Name field with the context variable.

You can also create or edit a context parameter in the Context tab view beneath the design workspace. For more information, see Talend Studio User Guide.

8. Click the [...] button next to Edit schema to open the Schema dialog box where you can configure the schema manually.
9. In the dialog box, click the [+ ] button to add columns and name them according to the input file structure.

In this example, this component will actually read files defined in the parent Job, and these files contain up to five columns. Therefore, add five string type columns and name them Column1, Column2, Column3, Column4, and Column5 respectively, and then click OK to validate the schema configuration and close the Schema dialog box.

10. Double-click the tLogRow component and on its Basic settings view, select the Table option to view displayed content in table cells.

Setting up the parent Job

Procedure

1. Create a new Job ParentJob and add a tFileList component and a tRunJob component to it.
2. Connect the tFileList component to the tRunJob component using a Row > Iterate link.
3. Double-click the tFileList component to open its Basic settings view.
4. In the **Directory** field, specify the path to the directory that holds the files to be processed, or click the [...] button next to the field to browse to the directory.

   In this example, the directory is `D:/tRunJob_Input_Files` that holds three delimited files with up to five columns.

5. In the **FileList Type** list, select **Files**.

6. Select the **Use Glob Expressions as Filemask** check box, and then click the [+][+] button to add a line in the **Files** area and define a filter to match files. In this example, enter `"*.csv"` to retrieve all delimited files.

7. Double-click the **tRunJob** component to display its **Basic settings** view.

   8. Click the [...] button next to the **Job** field and in the pop-up dialog box, select the child Job you want to execute and click **OK** to close the dialog box. The name of the selected Job appears in the **Job** field.
9. In the **Context Param** area, click the [+] button to add a line and define the context parameter. The only context parameter defined in the child Job, named `FilePath`, appears in the **Parameters** cell.

10. Click in the **Values** cell, press **Ctrl+Space** on your keyboard to access the list of context variables, and select `tFileList_1.CURRENT_FILEPATH`.

    The corresponding context variable `((String)globalMap.get("tFileList_1_CURRENT_FILEPATH"))` appears in the **Values** cell.

    For more information on context variables, see *Talend Studio User Guide*.

**Executing the parent Job**

**Procedure**

1. Press **Ctrl+S** to save your Jobs.
2. Press **F6** to execute the parent Job.

```
<table>
<thead>
<tr>
<th>statistics</th>
<th>connecting to socket on port 33</th>
</tr>
</thead>
<tbody>
<tr>
<td>tLogRow_1</td>
<td></td>
</tr>
<tr>
<td>Column1</td>
<td>Column2</td>
</tr>
<tr>
<td>1</td>
<td>Jefferson</td>
</tr>
<tr>
<td>2</td>
<td>Washington</td>
</tr>
<tr>
<td>3</td>
<td>Eisenhower</td>
</tr>
<tr>
<td>4</td>
<td>Eisenhower</td>
</tr>
<tr>
<td>5</td>
<td>Arthur</td>
</tr>
</tbody>
</table>
```

The parent Job calls the child Job, which reads the files defined in the parent Job, and the content of the files is displayed on the Run console.
Running a list of child Jobs dynamically

This scenario describes a Job that calls two child Jobs dynamically. When called from the parent Job, each of these simple child Jobs displays a message on the console.

Setting up the child Jobs

Procedure

1. Create a new Job named ChildJob1, and add a tFixedFlowInput component and a tLogRow component to it.

![Diagram of tFixedFlowInput and tLogRow components connected]

2. Connect the tFixedFlowInput component to the tLogRow component using a Row > Main connection.

3. Double-click the tFixedFlowInput component to open its Basic settings view.

![Basic settings view of tFixedFlowInput component]

4. Click the [...] button next to Edit schema and in the pop-up dialog box, define the schema of the input data by adding one column Message of String type. When done, click OK to close the dialog box and click Yes when prompted to propagate the schema to the next component.

5. In the Mode area, select Use Inline Content(delimited file) and enter the message you want to show on the console in the Content field, Hello World! in this example.

6. Double-click the tLogRow component and on its Basic settings view, select the Table mode to display the execution result in table cells.

7. Create copy of this Job and name it ChildJob2, and enter another message in the Content field of the tFixedFlowInput component, Hello Talend! in this example.

Setting up the parent Job

Procedure

1. Create a new Job named ParentJob and add a tFixedFlowInput component, a tFlowToIterate component, and a tRunJob component to it.
2. Connect the **tFixedFlowInput** component to the **tFlowToIterate** component using a **Row > Main** connection and the **tFlowToIterate** component to the **tRunJob** component using a **Row > Iterate** connection.

3. Double-click the **tFixedFlowInput** component to open its **Basic settings** view.

4. Click the [...] button next to **Edit schema** and in the pop-up dialog box, define the schema of the input data by adding one column **JobName** of String type. When done, click **OK** to close the dialog box.

5. In the **Mode** area, select the **Use Inline Content(delimited file)** option and specify the names of the child Jobs to call from the parent Job in the **Content** field.

   - ChildJob1
   - ChildJob2

6. Double-click the **tRunJob** component to open its **Basic settings** view.
7. Select the Use dynamic job check box and in the Conext job field displayed, press Ctrl+Space and from the list of variables select the iterative global variable created by the tFlowTolterate component, tFlowTolterate_1.JobName in this example. The Context job field is then filled with ((String)globalMap.get("row1.JobName")). Upon each iteration, this variable will be resolved as the name of the Job to be called.

8. Click the [...] button next to the Job field and in the [Select Job] dialog box, select all the Jobs you want to run and click OK to close the dialog box. In this example, they are ChildJob1 and ChildJob2.

Executing the parent Job to run the child Jobs dynamically

Procedure

1. Save your child Jobs and parent Job.
2. Press F6 or click the Run button on the Run console to execute the Job.

As shown above, the child Jobs are called one after another and messages specified in the child Jobs are displayed on the console.
Propagating the buffered output data from the child Job to the parent Job

In this scenario, a three-component Job calls a two-component child Job and displays the buffered output data of the child Job, instead of the data from the input flow of the parent Job, on the console.

Setting up the child Job

About this task

Procedure

1. Create a Job named child, and add two components by typing their names on the design workspace or dropping them from the Palette to the design workspace:
   - a tFixedFlowInput, to generate a message
   - a tBufferOutput, to store the generated message in the buffer memory
2. Connect the tFixedFlowInput component to the tBufferOutput component using a Row > Main connection.
3. Double-click the tFixedFlowInput component to open its Basic settings view.
4. Click the [...] button next to Edit schema to open the [Schema] dialog box and define the schema of the input data. In this example, the schema has only one column message of the string type.
When done, click **OK** to validate the changes and then click **Yes** in the pop-up [Propagate] dialog box to propagate the schema to the next component.

5. In the **Mode** area, select **Use Single Table** option, and define the corresponding value for the `message` column in the **Values** table. In this example, the value is "message from the child job".

### Setting up the parent Job

**About this task**

**Procedure**

1. Create a Job, and add three components by typing their names on the design workspace or dropping them from the **Palette** to the design workspace:
   - a **tFixedFlowInput**, to generate a message
   - a **tRunJob**, to call the Job named `child`
   - a **tLogRow**, to display the execution result on the console

2. Connect the **tFixedFlowInput** component to the **tRunJob** component and the **tRunJob** component to the **tLogRow** component using the **Row > Main** connections.

3. Double-click the **tFixedFlowInput** component to open its **Basic settings** view.
4. Click the [...] button next to Edit schema to open the [Schema] dialog box and define the schema of the input data. In this example, the schema has only one column message of the string type.

When done, click OK to validate the changes.

5. In the Mode area, select the Use Single Table option, and define the corresponding value for the message column in the Values table. In this example, the value is "message from the parent job".

6. Click the tRunJob component and then click the Component tab to open its Basic settings view.

7. Click the Sync columns button and then click Yes in the pop-up [Propagate] dialog box to retrieve the schema from the preceding component.
8. Click the [...] button next to the Job field to open the [Repository Content] dialog box.

In the [Repository Content] dialog box, select the Job named child and then click OK to close the dialog box.

9. In the Advanced settings view of the tRunJob component, select the Propagate the child result to the output schema check box. With this check box selected, the buffered output of the child Job will be propagated to the output component.

**Executing the parent Job**

**Procedure**

1. Press Ctrl+S to save the Job.
2. Press F6 or click the Run button on the Run console to execute the Job.

The child Job is called and the message specified in the child Job, rather than the message defined in the parent Job, is displayed on the console.
tS3BucketCreate

Creates a bucket on Amazon S3.

“Bucket” is a term used by AWS for top level folders on S3, which can contain sub folders and store all your data (objects).

**tS3BucketCreate Standard properties**

These properties are used to configure tS3BucketCreate running in the Standard Job framework.

The Standard tS3BucketCreate component belongs to the Cloud family.

The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>Use existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access Key</td>
<td>The Access Key ID that uniquely identifies an AWS Account. For how to get your Access Key and Access Secret, visit Getting Your AWS Access Keys.</td>
</tr>
<tr>
<td>Secret Key</td>
<td>The Secret Access Key, constituting the security credentials in combination with the access Key. To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Inherit credentials from AWS role</td>
<td>Select this check box to obtain AWS security credentials from Amazon EC2 instance metadata. To use this option, the Amazon EC2 instance must be started and your Job must be running on Amazon EC2. For more information, see Using an IAM Role to Grant Permissions to Applications Running on Amazon EC2 Instances.</td>
</tr>
<tr>
<td>Assume role</td>
<td>Select this check box and specify the values for the following parameters used to create a new assumed role session.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Role ARN</strong>: the Amazon Resource Name (ARN) of the role to assume.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Role session name</strong>: an identifier for the assumed role session.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Session duration (minutes)</strong>: the duration (in minutes) for which we want to have the assumed role session to be active.</td>
</tr>
<tr>
<td></td>
<td>For more information on assuming roles, see AssumeRole.</td>
</tr>
<tr>
<td>Region</td>
<td>Specify the AWS region by selecting a region name from the list or entering a region between double quotation marks (e.g. &quot;us-east-1&quot;) in the list. For more information about the AWS Region, see Regions and Endpoints.</td>
</tr>
<tr>
<td>----------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Bucket</td>
<td>Name of the bucket, namely the top level folder, to create.</td>
</tr>
<tr>
<td>Die on error</td>
<td>This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| Config client | Select this check box to configure client parameters.  
**Client parameter**: select client parameters from the list.  
**Value**: enter the parameter value.  
Not available when Use existing connection is selected. |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| STS Endpoint  | Select this check box and in the field displayed, specify the AWS Security Token Service endpoint where session credentials are retrieved from.  
This check box is available only when the Assume role check box is selected. |
| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

**Global Variables**

| ERROR_MESSAGE | The error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is selected. |

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component can be used alone or with other S3 components, e.g. tS3BucketExist.</th>
</tr>
</thead>
</table>
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.  
Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. |
Related scenario

For **tS3BucketCreate** related scenarios, see Scenario: Verifying the absence of a bucket, creating it and listing all the S3 buckets on page 3324.
**tS3BucketDelete**

Deletes an empty bucket from Amazon S3.

“Bucket” is a term used by AWS for top level folders on S3, which can contain sub folders and store all your data (objects).

**tS3BucketDelete Standard properties**

These properties are used to configure tS3BucketDelete running in the Standard Job framework.

The Standard tS3BucketDelete component belongs to the Cloud family.

The component in this framework is generally available.

<td><strong>Secret Key</strong></td>
<td>The Secret Access Key, constituting the security credentials in combination with the access Key. To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Inherit credentials from AWS role</strong></td>
<td>Select this check box to obtain AWS security credentials from Amazon EC2 instance metadata. To use this option, the Amazon EC2 instance must be started and your Job must be running on Amazon EC2. For more information, see Using an IAM Role to Grant Permissions to Applications Running on Amazon EC2 Instances.</td>
</tr>
</tbody>
</table>
| **Assume role**         | Select this check box and specify the values for the following parameters used to create a new assumed role session.  
  - **Role ARN**: the Amazon Resource Name (ARN) of the role to assume.  
  - **Role session name**: an identifier for the assumed role session.  
  - **Session duration (minutes)**: the duration (in minutes) for which we want to have the assumed role session to be active.  
  For more information on assuming roles, see AssumeRole. |
**Region**

Specify the AWS region by selecting a region name from the list or entering a region between double quotation marks (e.g. \"us-east-1\") in the list. For more information about the AWS Region, see [Regions and Endpoints](#).

**Bucket**

Name of the bucket, namely the top level folder, on the S3 server.

**Die on error**

This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

---

**Advanced settings**

**Config client**

Select this check box to configure client parameters.

- **Client parameter**: select client parameters from the list.
- **Value**: enter the parameter value.

Not available when **Use existing connection** is selected.

**STS Endpoint**

Select this check box and in the field displayed, specify the AWS Security Token Service endpoint where session credentials are retrieved from.

This check box is available only when the **Assume role** check box is selected.

**tStatCatcher Statistics**

Select this check box to collect log data at the component level.

---

**Global Variables**

**BUCKET_EXIST**

The existence of a specified bucket. This is a Flow variable and it returns a boolean.

**BUCKET_NAME**

The name of a specified bucket. This is an After variable and it returns a string.

**ERROR_MESSAGE**

The error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is selected.

---

**Usage**

**Usage rule**

This component is usually used with other S3 components, e.g. **tS3BucketCreate**.

**Dynamic settings**

Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment.
where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

### Scenario: Verifying the absence of a bucket, creating it and listing all the S3 buckets

In this scenario, **tS3BucketExist** is used to verify the absence of a bucket, **tS3BucketCreate** to create that bucket upon confirmation, and **tS3BucketList** to list all the buckets on Amazon S3.

### Linking the components

**Procedure**

1. Drop **tS3Connection**, **tS3BucketExist**, **tS3BucketCreate**, **tS3BucketList**, **tIterateToFlow** and **tLogRow** onto the workspace.
2. Link **tS3Connection** to **tS3BucketExist** using the OnSubjobOk trigger.
3. Link **tS3BucketExist** to **tS3BucketCreate** using the Run if trigger.
4. Link **tS3BucketCreate** to **tS3BucketList** using the OnSubjobOk trigger.
5. Link **tS3BucketList** to **tIterateToFlow** using the Row > Iterate connection.
6. Link **tIterateToFlow** to **tLogRow** using the Row > Main connection.

![Diagram](image)

### Configuring the components

**Procedure**

1. Double-click **tS3Connection** to open its Basic settings view.
2. In the **Access Key** and **Secret Key** fields, enter the authentication credentials.

3. Double-click **tS3BucketExist** to open its **Basic settings** view.

4. Select the **Use existing connection** check box to reuse the connection.

5. In the **Bucket** field, enter the bucket name to check if it exists.

6. Double-click the **If** link to define the condition.

7. In the **Condition** box, enter the expression:

   ```java
   !((Boolean)globalMap.get("tS3BucketExist_1_BUCKET_EXIST"))
   ```

   This way, the rest of the Job will be executed if the specified bucket does not exist.

8. Double-click **tS3BucketCreate** to open its **Basic settings** view.

9. Double-click **tS3BucketList** to open its **Basic settings** view.
Select the **Use existing connection** check box to reuse the connection.

10. Double-click `tIterateToFlow` to open its **Basic settings** view.

11. Click **Edit schema** to open the schema editor.

12. In the **Mapping** area, press **Ctrl + Space** in the **Value** field to choose the variable `tS3BucketList_1_CURRENT_BUCKET_NAME`.

13. Double-click `tLogRow` to open its **Basic settings** view.

Select **Table (print values in cells of a table)** for a better display of the results.
Executing the Job

Procedure

1. Press **Ctrl + S** to save the Job.
2. Press **F6** to run the Job.

   ```
   [statistics] connecting to socket on port 3661
   [statistics] connected
   -----------
   tLogRow_1
   =---------
   bucket_list
   =---------
   movies_andy
   | songs-andy
   -----------
   [statistics] disconnected
   ```

   As shown above, the bucket is created and all the buckets are listed.

3. Go to the S3 web console:

   ![S3 web console](image)

   As shown above, the bucket has been created on the S3 server.

4. Refresh the S3 Browser client:

   ![S3 Browser](image)

   This shows that the S3 Create action was performed successfully.
tS3BucketList

Lists all the buckets on Amazon S3.

"Bucket" is a term used by AWS for top level folders on S3, which can contain sub folders and store all your data (objects).

**tS3BucketList Standard properties**

These properties are used to configure tS3BucketList running in the Standard Job framework.

The Standard tS3BucketList component belongs to the Cloud family.

The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>Use existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>
| Assume role             | Select this check box and specify the values for the following parameters used to create a new assumed role session.  
  - **Role ARN**: the Amazon Resource Name (ARN) of the role to assume.  
  - **Role session name**: an identifier for the assumed role session.  
  - **Session duration (minutes)**: the duration (in minutes) for which we want to have the assumed role session to be active.  
  For more information on assuming roles, see AssumeRole. |
Specify the AWS region by selecting a region name from the list or entering a region between double quotation marks (e.g. "us-east-1") in the list. For more information about the AWS Region, see Regions and Endpoints.

### Advanced settings

| Config client | Select this check box to configure client parameters.  
**Client parameter**: select client parameters from the list.  
**Value**: enter the parameter value.  
Not available when Use existing connection is selected. |
| STS Endpoint | Select this check box and in the field displayed, specify the AWS Security Token Service endpoint where session credentials are retrieved from.  
This check box is available only when the Assume role check box is selected. |
| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

### Global Variables

| CURRENT_BUCKET_NAME | The current bucket name. This is a Flow variable and it returns a string. |
| NB_BUCKET | The number of buckets. This is an After variable and it returns an integer. |
| ERROR_MESSAGE | The error message generated by the component when an error occurs. This is an After variable and it returns a string. |

### Usage

| Usage rule | This component can be used alone or with other S3 components, e.g. tS3BucketDelete. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.  
Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.  
For examples on using dynamic parameters, see Scenario: Reading data from databases through context- |
Related scenario

For **tS3BucketList** related scenarios, see **Scenario: Verifying the absence of a bucket, creating it and listing all the S3 buckets** on page 3324.
**tS3Close**

Shuts down a connection to Amazon S3, thus releasing the network resources.

**tS3Close Standard properties**

These properties are used to configure tS3Close running in the Standard Job framework.

The Standard tS3Close component belongs to the Cloud family.

The component in this framework is generally available.

**Basic settings**

| Component List | List of connection components. |

**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

**Global Variables**

| ERROR_MESSAGE | The error message generated by the component when an error occurs. This is an After variable and it returns a string. |

**Usage**

| Usage rule | As an end component, this component is to be used along with other S3 components, e.g. tS3Connection. |

| Dynamic settings | Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |
Related scenario

For **tS3Close** related scenarios, see *Scenario: Listing files with the same prefix from a bucket* on page 3351.
**tS3Connection**

Establishes a connection to Amazon S3 to store and retrieve data.

**tS3Connection Standard properties**

These properties are used to configure tS3Connection running in the Standard Job framework.

The Standard tS3Connection component belongs to the Cloud family.

The component in this framework is generally available.

**Basic settings**

<table>

<tr>
<td>Encrypt</td>
<td>Select this check box and from the <strong>Key type</strong> drop-down list displayed, select one of the following three options for encrypting the data on the client-side before sending</td>
</tr>
</tbody>
</table>
to Amazon S3. For more information, see Protecting Data Using Client-Side Encryption.

- **KMS-managed customer master key**: use a KMS-managed customer master key (CMK) for the client-side data encryption. In the **Key** field, you need to specify the AWS KMS customer master key ID (CMK ID).

- **Symmetric Master Key**: use a symmetric master key (256-bit AES secret key) for the client-side data encryption.
  - **Algorithm**: select the algorithm associated with the key from the list. By default, there is only one algorithm named **AES**.
  - **Encoding**: select the encoding type associated with the key from the list, either **Base64** or **X509**.
  - **Key** or **Key file**: specify the key or the path to the file that stores the key.

- **Asymmetric Master Key**: use an asymmetric master key (a 1024-bit RSA key pair) for the client-side data encryption.
  - **Algorithm**: select the algorithm associated with the key from the list. By default, there is only one algorithm named **RSA**.
  - **Public key file**: specify the path to the public key file.
  - **Private key file**: specify the path to the private key file.

</tr>
</tbody>
</table>

**Server-Side Encryption**
Select this check box to enable server-side encryption with Amazon S3-Managed Encryption Keys (SSE-S3) and use the 256-bit Advanced Encryption Standard (AES-256) cipher to encrypt your data.
For more information about the server-side encryption, see Protecting Data Using Server-Side Encryption.

**Use KMS**
Select this check box to enable server-side encryption with AWS KMS-Managed Keys (SSE-KMS) instead of Amazon S3-Managed Encryption Keys (SSE-S3).
This property is available when the Server-Side Encryption check box is selected.

**Customer Master Key**
Specify your own customer master key (CMK) that is created in the IAM console using AWS Key Management Service for SSE-KMS encryption. If not specified, the default CMK, which is created the first time you add an SSE-KMS encrypted object to the defined bucket in your region, will be used for SSE-KMS encryption.
This property is available when the Use KMS check box is selected.

**Die on error**
Select this check box to stop the execution of the Job when an error occurs.
Clear the check box to skip any rows on error and complete the process for error-free rows.

**Advanced settings**

| **Config client** | Select this check box and specify the client parameter(s) by clicking the [+] button to add as many rows as needed, each row for a client parameter, and then setting the value of the following fields for each parameter:  
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>STS Endpoint</strong></td>
<td>Select this check box and in the field displayed, specify the AWS Security Token Service endpoint where session credentials are retrieved from.</td>
</tr>
</tbody>
</table>
This check box is available only when the **Assume role** check box is selected.

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

**ERROR_MESSAGE**

The error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is selected.

### Usage

**Usage rule**

This component can be used as a standalone component.

### Scenario: Copying an S3 object from one bucket to another

This scenario describes a Job that uploads a new object to an existing empty S3 bucket `bucket-src`, then copies the object from the bucket `bucket-src` to another existing empty S3 bucket `bucket-dst`, finally lists the object in the bucket `bucket-dst` to see whether the object is successfully copied.
Setting up the Job

Procedure

1. Create a new Job and add a **tS3Connection** component, a **tS3Put** component, a **tS3Copy** component, a **tS3List** component, a **tIterateToFlow** component, and a **tLogRow** component by typing their names on the design workspace or dropping them from the Palette.

2. Link the **tS3List** component to the **tIterateToFlow** component using a **Row > Iterate** connection.

3. Link the **tIterateToFlow** component to the **tLogRow** component using a **Row > Main** connection.

4. Link the **tS3Connection** component to the **tS3Put** component using a **Trigger > On Subjob Ok** connection.

5. Do the same to link the **tS3Put** component to the **tS3Copy** component and the **tS3Copy** component to the **tS3List** component.

Configuring the components

Creating a connection to Amazon S3

Procedure

1. Double-click the **tS3Connection** component to open its **Basic settings** view on the **Component** tab.

2. In the **Access Key** and **Secret Key** fields, enter the authentication credentials required to access Amazon S3.

3. From the **Region** drop-down list, select an AWS region where the object will be uploaded and copied. In this example, we keep the default setting.

Uploading an object to an Amazon S3 bucket

Procedure

1. Double-click the **tS3Put** component to open its **Basic settings** view on the **Component** tab.
2. Select the **Use an existing connection** check box to reuse the Amazon S3 connection information you have defined in the **tS3Connection** component.

3. In the **Bucket** field, enter the name of the S3 bucket where the object will be uploaded. In this example, it is `bucket-src` that already exists in Amazon S3.

4. In the **Key** field, enter the key for the object to be uploaded. In this example, it is `tS3Copy_icon32_src.png`.

5. In the **File** field, browse to or enter the path to the object to be uploaded. In this example, it is `D:/tS3Copy_icon32.png`.

**Copying the uploaded object to another Amazon S3 bucket**

**Procedure**

1. Double-click the **tS3Copy** component to open its **Basic settings** view on the **Component** tab.

2. Select the **Use an existing connection** check box to reuse the Amazon S3 connection information you have defined in the **tS3Connection** component.

3. In the **Bucket** field in the **Source Configuration** area, enter the name of the bucket which contains the object to be copied. In this example, it is `bucket-src`.

4. In the **Key** field in the **Source Configuration** area, enter the key of the object to be copied. In this example, it is `tS3Copy_icon32_src.png`.

5. In the **Bucket** field in the **Destination Configuration** area, enter the name of the bucket to which the object will be copied. In this example, it is the empty one `bucket-dst` that already exists in Amazon S3.

6. In the **Key** field in the **Destination Configuration** area, enter the new key for the object after being copied to the destination bucket. In this example, it is `tS3Copy_icon32_dst.png`.

**Listing the object in the destination bucket**

**Procedure**

1. Double-click the **tS3List** component to open its **Basic settings** view on the **Component** tab.
2. Select the **Use an existing connection** check box to reuse the Amazon S3 connection information you have defined in the **tS3Connection** component.

3. Clear the **List all buckets objects** check box, and then click the [+ ] button to add one row in the **Bucket** table displayed and set the value for each column. In this example, *bucket-dist* for the **Bucket name** column and empty value for the **Key prefix** column, this way only the objects in the *bucket-dist* bucket will be listed.

4. Double-click the **tIterateToFlow** component to open its **Basic settings** view on the **Component** tab.

5. Click the [...] button next to **Edit schema** and in the pop-up schema dialog box define the schema by adding one column **ObjectList** of **String** type.

6. Click **OK** to save the changes and in the pop-up dialog box click **Yes** to accept the propagation.

7. Double-click the **tLogRow** component to open its **Basic settings** view on the **Component** tab.
8. In the **Mode** area, select **Table (print values in cells of a table)** for better readability of the result.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl + S** to save the Job.
2. Press **F6** to run the Job.

```plaintext
[statistics] connecting to socket on port 3491
[statistics] connected
---------
| tLogRow_1 |
---------
| ObjectList |
---------
| tS3Copy_icon32_dst.png |
---------
[statistics] disconnected
```

As shown above, the uploaded object has been copied to the destination bucket successfully.
tS3Delete

Deletes a file from Amazon S3.

**tS3Delete Standard properties**

These properties are used to configure tS3Delete running in the Standard Job framework.

The Standard tS3Delete component belongs to the Cloud family.

The component in this framework is generally available.

**Basic settings**

| STS Endpoint | Select this check box and in the field displayed, specify the AWS Security Token Service endpoint where session credentials are retrieved from.  
| This check box is available only when the *Assume role* check box is selected. |
| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

**Global Variables**

| ERROR_MESSAGE | The error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the *Die on error* check box is selected. |

**Usage**

| Usage rule | This component can be used alone or with other S3 components, e.g. *tS3BucketList*. |

| Dynamic settings | Click the [*] button to add a row in the table and fill the *Code* field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.  
|---|---  
| Once a dynamic parameter is defined, the *Component List* box in the *Basic settings* view becomes unusable.  
| For examples on using dynamic parameters, see *Scenario: Reading data from databases through context-based dynamic connections* on page 2497 and *Scenario:* |
Related scenario

For **tS3Delete** related scenarios, see *Scenario: Verifying the absence of a bucket, creating it and listing all the S3 buckets* on page 3324.
tS3Get

Retrieves a file from Amazon S3.

**tS3Get Standard properties**

These properties are used to configure tS3Get running in the Standard Job framework.

The Standard tS3Get component belongs to the Cloud family.

The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>Use existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Access Key</strong></td>
<td>The Access Key ID that uniquely identifies an AWS Account. For how to get your Access Key and Access Secret, visit Getting Your AWS Access Keys.</td>
</tr>
<tr>
<td><strong>Secret Key</strong></td>
<td>The Secret Access Key, constituting the security credentials in combination with the access Key. To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Inherit credentials from AWS role</strong></td>
<td>Select this check box to obtain AWS security credentials from Amazon EC2 instance metadata. To use this option, the Amazon EC2 instance must be started and your Job must be running on Amazon EC2. For more information, see Using an IAM Role to Grant Permissions to Applications Running on Amazon EC2 Instances.</td>
</tr>
<tr>
<td><strong>Assume role</strong></td>
<td>Select this check box and specify the values for the following parameters used to create a new assumed role session.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Role ARN</strong>: the Amazon Resource Name (ARN) of the role to assume.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Role session name</strong>: an identifier for the assumed role session.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Session duration (minutes)</strong>: the duration (in minutes) for which we want to have the assumed role session to be active. For more information on assuming roles, see AssumeRole.</td>
</tr>
<tr>
<td><strong>Region</strong></td>
<td>Specify the AWS region by selecting a region name from the list or entering a region between double quotation marks (e.g. &quot;us-east-1&quot;) in the list. For more information about the AWS Region, see Regions and Endpoints.</td>
</tr>
</tbody>
</table>
Encrypt

Select this check box and from the **Key type** drop-down list displayed, select one of the following three options for encrypting the data on the client-side before sending to Amazon S3. For more information, see [Protecting Data Using Client-Side Encryption](#).

- **KMS-managed customer master key**: use a KMS-managed customer master key (CMK) for the client-side data encryption. In the **Key** field, you need to specify the AWS KMS customer master key ID (CMK ID).

  - **Algorithm**: select the algorithm associated with the key from the list. By default, there is only one algorithm named **AES**.

  - **Encoding**: select the encoding type associated with the key from the list, either **Base64** or **X509**.

  - **Key or Key file**: specify the key or the path to the file that stores the key.

- **Symmetric Master Key**: use a symmetric master key (256-bit AES secret key) for the client-side data encryption.

  - **Algorithm**: select the algorithm associated with the key from the list. By default, there is only one algorithm named **AES**.

- **Asymmetric Master Key**: use an asymmetric master key (a 1024-bit RSA key pair) for the client-side data encryption.

  - **Algorithm**: select the algorithm associated with the key from the list. By default, there is only one algorithm named **RSA**.

  - **Public key file**: specify the path to the public key file.

  - **Private key file**: specify the path to the private key file.

<table>
<thead>
<tr>
<th>Bucket</th>
<th>Name of the bucket, namely the top level folder, on the S3 server.</th>

</tr>
</tbody>
</table>
| Assume role             | Select this check box and specify the values for the following parameters used to create a new assumed role session.  
  • **Role ARN**: the Amazon Resource Name (ARN) of the role to assume.  
  • **Role session name**: an identifier for the assumed role session.  
  • **Session duration (minutes)**: the duration (in minutes) for which we want to have the assumed role session to be active.  
  For more information on assuming roles, see AssumeRole. |
| Region                  | Specify the AWS region by selecting a region name from the list or entering a region between double quotation marks (e.g. 'us-east-1') in the list. For more information about the AWS Region, see Regions and Endpoints. |
### List all bucket objects

Select this check box to list all the files on the S3 server.

**Key prefix:** enter the prefix of files to be listed. This way, only files with that prefix will be listed.

### Bucket

Click the [+] button to add one or more lines for defining the buckets and file prefixes.

**Bucket name:** name of the bucket, namely the top level folder, whose files will be listed.

**Key prefix:** prefix of files to be listed.

Not available when **List all bucket objects** is selected.

### Die on error

This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

### Advanced settings

#### Config client

Select this check box to configure client parameters.

**Client parameter:** select client parameters from the list.

**Value:** enter the parameter value.

Not available when **Use existing connection** is selected.

#### STS Endpoint

Select this check box and in the field displayed, specify the AWS Security Token Service endpoint where session credentials are retrieved from.

This check box is available only when the **Assume role** check box is selected.

#### tStatCatcher Statistics

Select this check box to collect log data at the component level.

### Global Variables

<table>

### Dynamic settings

Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

## Scenario: Listing files with the same prefix from a bucket

In this scenario, **tS3List** is used to list all the files in a bucket which have the same prefix.

There are such files in this bucket:

![S3 Browser](image)

For how to create a bucket and put files into it, see Scenario: Verifying the absence of a bucket, creating it and listing all the S3 buckets on page 3324 and Scenario: File exchanges with Amazon S3 on page 3358.

## Linking the components

### Procedure

1. Drop **tS3Connection**, **tS3List**, **tIterateToFlow**, **tLogRow** and **tS3Close** onto the workspace.
2. Link **tS3Connection** to **tS3List** using the **OnSubjobOk** trigger.
3. Link `tS3List` to `tIterateToFlow` using the `Row > Iterate` connection.
4. Link `tIterateToFlow` to `tLogRow` using the `Row > Main` connection.
5. Link `tS3List` to `tS3Close` using the `OnSubjobOk` trigger.

**Configuring the components**

**Procedure**

1. Double-click `tS3Connection` to open its **Basic settings** view.

2. In the **Access Key** and **Secret Key** fields, enter the authentication credentials.

3. Double-click `tS3List` to open its **Basic settings** view.
4. Select the **Use existing connection** check box to reuse the connection.

5. In the **Bucket** area, click the [*] button to add one line.

6. In the **Bucket name** and **Key prefix** fields, enter the bucket name and file prefix. This way, only files with the specified prefix will be listed.

7. Double-click **tIterateToFlow** to open its **Basic settings** view.

8. Click **Edit schema** to open the schema editor.

   Click the [*] button to add one column, namely **file_list** of the String type.
   Click **Ok** to validate the setup and close the schema editor.

9. In the **Mapping** area, press **Ctrl + Space** in the **Value** field to choose the variable `tS3List_1_CURR\_ENT_KEY`.

10. Double-click **tLogRow** to open its **Basic settings** view.
Select **Table (print values in cells of a table)** for a better display of the results.

11. Double-click **tS3Close** to open its **Basic settings** view.

There is no need to select a connection component as the only one is selected by default.

**Executing the Job**

**Procedure**

1. Press **Ctrl + S** to save the Job.
2. Press **F6** to run the Job.

   ![Statistics](image)

   As shown above, only the files with the prefix "in" are listed.
tS3Put

Uploads data onto Amazon S3 from a local file or from cache memory via the streaming mode.

**tS3Put Standard properties**

These properties are used to configure tS3Put running in the Standard Job framework.

The Standard tS3Put component belongs to the Cloud family.

The component in this framework is generally available.

### Basic settings

<table>
<thead>
<tr>
<th>Use existing connection</th>
<th>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access Key</td>

<tr>
<td></td>
<td>• <strong>Role ARN</strong>: the Amazon Resource Name (ARN) of the role to assume.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Role session name</strong>: an identifier for the assumed role session.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Session duration (minutes)</strong>: the duration (in minutes) for which we want to have the assumed role session to be active.</td>
</tr>
<tr>
<td></td>
<td>For more information on assuming roles, see <a href="#">AssumeRole</a>.</td>
</tr>
<tr>
<td>Region</td>
<td>Specify the AWS region by selecting a region name from the list or entering a region between double quotation marks (e.g. &quot;us-east-1&quot;) in the list. For more information about the AWS Region, see <a href="#">Regions and Endpoints</a>.</td>
</tr>
</tbody>
</table>
Encrypt

Select this check box and from the **Key type** drop-down list displayed, select one of the following three options for encrypting the data on the client-side before sending to Amazon S3. For more information, see [Protecting Data Using Client-Side Encryption](#).

- **KMS-managed customer master key**: use a KMS-managed customer master key (CMK) for the client-side data encryption. In the **Key** field, you need to specify the AWS KMS customer master key ID (CMK ID).
  - **Algorithm**: select the algorithm associated with the key from the list. By default, there is only one algorithm named **AES**.
  - **Encoding**: select the encoding type associated with the key from the list, either **Base64** or **X509**.
  - **Key or Key file**: specify the key or the path to the file that stores the key.

- **Symmetric Master Key**: use a symmetric master key (256-bit AES secret key) for the client-side data encryption.
  - **Algorithm**: select the algorithm associated with the key from the list. By default, there is only one algorithm named **AES**.
  - **Encoding**: select the encoding type associated with the key from the list, either **Base64** or **X509**.
  - **Key or Key file**: specify the key or the path to the file that stores the key.

- **Asymmetric Master Key**: use an asymmetric master key (a 1024-bit RSA key pair) for the client-side data encryption.
  - **Algorithm**: select the algorithm associated with the key from the list. By default, there is only one algorithm named **RSA**.
  - **Public key file**: specify the path to the public key file.
  - **Private key file**: specify the path to the private key file.

---

<table>
<thead>
<tr>
<th>Bucket</th>
<th>Name of the bucket, namely the top level folder, on the S3 server.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Key</td>
<td>The name of the file that will hold uploaded data on the S3 server.</td>
</tr>
</tbody>
</table>
| File or Stream | The path to the local file to be uploaded or the input stream from which data will be uploaded.  
For an example of how to use stream, see [Scenario 2: Reading data from a remote file in streaming mode](#) on page 1015. |
| Server-Side Encryption | Select this check box to enable server-side encryption with Amazon S3-Managed Encryption Keys (SSE-S3) and use the 256-bit Advanced Encryption Standard (AES-256) cipher to encrypt your data.  
For more information about the server-side encryption, see [Protecting Data Using Server-Side Encryption](#). |
| Use KMS | Select this check box to enable server-side encryption with AWS KMS-Managed Keys (SSE-KMS) instead of Amazon S3-Managed Encryption Keys (SSE-S3). |
This property is available when the **Server-Side Encryption** check box is selected.

### Customer Master Key

Specify your own customer master key (CMK) that is created in the IAM console using AWS Key Management Service for SSE-KMS encryption. If not specified, the default CMK, which is created the first time you add an SSE-KMS encrypted object to the defined bucket in your region, will be used for SSE-KMS encryption.

This property is available when the **Use KMS** check box is selected.

### Die on error

This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

### Advanced settings

| Config client | Select this check box to configure client parameters.  
**Client parameter:** select client parameters from the list.  
**Value:** enter the parameter value.  
Not available when **Use existing connection** is selected. |
|---|---|
| STS Endpoint | Select this check box and in the field displayed, specify the AWS Security Token Service endpoint where session credentials are retrieved from.  
This check box is available only when the **Assume role** check box is selected. |
| Part size (Mb) | Specify the part size in MB when uploading a large file in parts. For more information about S3 multipart upload, see [Multipart Upload Overview](#). |
| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

### Global Variables

| ERROR_MESSAGE | The error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is selected. |

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component can be used alone or with other S3 components, e.g. <strong>tS3Connection</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic settings</td>
<td>Click the <strong>[+]</strong> button to add a row in the table and fill the <strong>Code</strong> field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. </tr>
</tbody>
</table>
the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

### Scenario: File exchanges with Amazon S3

In this scenario, **tS3Put** is used to send a file to the Amazon S3 server while **tS3Get** is used to get that file.

#### Linking the components

**Procedure**

1. Drop **tS3Connection**, **tS3Put** and **tS3Get** onto the workspace.
2. Link **tS3Connection** to **tS3Put** using the **OnSubjobOk** trigger.
3. Link **tS3Put** to **tS3Get** using the **OnSubjobOk** trigger.

#### Configuring the components

**Procedure**

1. Double-click **tS3Connection** to open its Basic settings view.
2. In the **Access Key** and **Secret Key** fields, enter the authentication credentials.
3. Double-click **tS3Put** to open its **Basic settings** view.

4. Select the **Use existing connection** check box to reuse the connection.
5. In the **Bucket** field, enter the bucket name.
6. In the **Key** field, enter the name of the file to be saved on the S3 server.
7. In the **File** field, enter the file to be uploaded to the S3 server.

8. Double-click **tS3Get** to open its **Basic settings** view.

9. Select the **Use existing connection** check box to reuse the connection.
10. In the **Bucket** field, enter the bucket name.
11. In the **Key** field, enter the name of the file to be retrieved from the S3 server.
12. In the **File** field, enter the local name of the retrieved file.

**Executing the Job**

**Procedure**

1. Press **Ctrl + S** to save the Job.
2. Press **F6** to run the Job.
3. Go to the S3 web console:

As shown above, the file has been put on to the S3 server.

4. Refresh the S3 Browser client:

This shows that the S3 Put action was performed successfully.

5. Go to the folder where the retrieved file is saved locally:

As shown above, the remote file is retrieved to the local disk, proof that the S3 Get action was performed successfully.
tSageX3Input

Extracts data from a given Sage X3 system.

This component leverages the Web service provided by a given Sage X3 Web server to extract data from the Sage X3 system (the X3 server).

**tSageX3Input Standard properties**

These properties are used to configure tSageX3Input running in the Standard Job framework.

The Standard tSageX3Input component belongs to the Business family.

The component in this framework is generally available.

**Basic settings**

| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

Click Edit schema to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **[Repository Content]** window. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-in</strong></td>
<td><strong>No property data stored centrally.</strong></td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td><strong>Select the repository file where properties are stored. The fields that come after are pre-filled in using the fetched data.</strong></td>
</tr>
<tr>
<td><strong>Endpoint address</strong></td>
<td><strong>Type in the address of the Web service provided by the given Sage X3 Web server.</strong></td>
</tr>
</tbody>
</table>
| **Username and Password**| **Type in the Web service user authentication data that you have defined for configuring the Sage X3 Web server.**

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings. |
<table>
<thead>
<tr>
<th><strong>Language</strong></th>
<th>Type in the name of the X3 language code used to start a connection group.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Pool alias</strong></td>
<td>Type in the name of the connection pool that distributes the received requests to available connections. This name was given from the Sage X3 configuration console.</td>
</tr>
</tbody>
</table>
| **Request config** | Type in the configuration string if you want to retrieve the debug or trace information. For example, the string could be:  
RequestConfigDebug="adxwss.trace.on=on";  
If you need to use several strings, separate them with a & for example,  
RequestConfigDebug="adxwss.trace.on=on&adxwss.trace.size=16384";  
**Warning:**  
A third party tool is needed to retrieve this kind of information. |
| **Publication name** | Type in the publication name of the published object, list or sub-program you want your Studio to access. |
| **Action** | Select in the list the action to be carried on.  
• **getAllDetails**: returns the details of all the records.  
• **getSummary**: returns the summary of each record.  
• **getDetail**: returns the details of the records that meet the conditions configured in the **Query condition** table. |
| **Mapping** | Complete this table to map the variable elements of the object, the sub-program or the list set in the given Sage X3 Web server. The columns to be completed include:  
**Column**: the columns defined in the schema editor for this component.  
**Group ID**: the identifier of each variable element group. For example, a variable element group could represent one of attributes of an object.  
**Field name**: the field name of each variable element. |
| **Conditions** | Complete this table to set up the query condition(s). The columns to be completed include:  
**Key**: the names of the variable elements used as the key for data extraction.  
**Value**: the value of the given key field used to extract the corresponding data.  
Available when **getDetail** is selected in the **Action** list. |
| **Query condition** | Select this check box to set up the query condition(s). The columns to be completed include:  
**Key**: the names of the variable elements used as the key for data extraction. |
Value: the value of the given key field used to extract the corresponding data.
Not available when getDetail is selected in the Action list.

Limit
Type in a number to indicate the maximum row count of the data to be extracted.
Not available when getDetail is selected in the Action list.

Advanced settings

Global Variables

Global Variables
ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.
For further information about variables, see Talend Studio User Guide.

Usage

Usage rule
Usually used as a Start component. An output component is required.

Scenario: Using query key to extract data from a given Sage X3 system

This scenario describes a two-component Job used to extract one row of data from a given Sage X3 system. The object method is to be called, that means the variable elements of this object thus are attributes. The data used in this scenario can be found in the example provided by Sage X3.
Setting up the Job

Procedure

1. Drop the tSageX3Input component and the tLogRow components onto the workspace from Palette.
2. Connect the tSageX3Input component to the tLogRow component using a Row > Main link.

Configuring the schema of tSageX3Input

Procedure

1. Double-click tSageX3Input to set its properties in the Basic Settings view.

   ![tSageX3Input_1]

   In the Schema field, select Built-In and click the three-dot button next to Edit schema to open the schema editor.

2. In the Schema field, select Built-In and click the three-dot button next to Edit schema to open the schema editor.
3. In this editor, click the plus button 12 times beneath the schema table to add 12 rows into this table.

4. Type in the names you want to use for each row. In this example, these rows are named after the publication names of the object attributes set in the Sage X3 Web server. These columns are used to map the corresponding attribute fields in the Sage X3 system.

5. In the Type column, click the IMG row to display its drop-down list.

6. From the drop-down list, select List as this attribute appears twice or even more and do the same to switch the types of the TIT2NBLIG row, the ITMLNK row and the ZITMLNK row to List as well for the same reason.

7. Click OK to validate this change and accept the propagation prompted by a pop-up dialog box.

**Configuring the connection to the Sage X3 Web server**

**Procedure**

1. In the Endpoint address field, type in the URL address of the Web service provided by the Sage X3 Web server. In this example, it is http://10.42.20.168:28880/adxwsvc/services/CAdxWebServiceXmlCC

2. In the User field, type in the user name of the given Sage X3. In this example, it is ERP.

3. In the Language field, type in the name of the X3 language code used to start a connection group. In this example, it is FRA.

4. In the Pool alias field, type in the name of connection pool to be used. In this example, this connection pool is called TALEND.

5. In the Publication name field, type in the publication name of the object to be called. In this scenario, the publication name is ITMDET.

**Setting up the mapping and configuring the query condition**

**Procedure**

1. In the Group ID column and the Field name column of the Mapping table, type in values corresponding to the attribute group IDs and the attribute publication names defined in the Sage X3 Web server. In this example, the values are presented in the figure below.
1. In the **Mapping** table, the **Column** column has been filled automatically with the columns you created in the schema editor.

2. Select the **Query condition** check box to activate the **Conditions** table.

3. Under the **Conditions** table, click the plus button to add one row into the table.

4. In the **Key** column, type in the publication name associated with the object attribute you need to extract data from.

5. In the **Value** column, type in the value of the attribute you have selected as the key of the data extraction. In this scenario, it is **CONT000059**, one of the product references.

### Job execution

**Procedure**

1. Press **Ctrl+S** to save your Job.

2. Press **F6** or click **Run** on the **Run** tab to execute the Job.

   The results are displayed on the **Run** console:
tSageX3Output

Writes data into a given Sage X3 system.

This component connects to the Web service provided by a given Sage X3 Web server and therefrom insert, update or delete data in the Sage X3 system (the X3 server).

tSageX3Output Standard properties

These properties are used to configure tSageX3Output running in the Standard Job framework.

The Standard tSageX3Output component belongs to the Business family.

The component in this framework is generally available.

Basic settings

| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.
Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:
- View schema: choose this option to view the schema only.
- Change to built-in property: choose this option to change the schema to Built-in for local changes.
- Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.
Click Sync columns to retrieve the schema from the previous component connected in the Job. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Built-in: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td>Repository: Select the repository file where properties are stored. The fields that come after are pre-filled in using the fetched data.</td>
<td></td>
</tr>
<tr>
<td>Endpoint address</td>
<td>Type in the address of the Web service provided by the given Sage X3 Web server.</td>
</tr>
</tbody>
</table>
| Username and Password | Type in the Web service user authentication data that you have defined for configuring the Sage X3 Web server.
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter |
<table>
<thead>
<tr>
<th><strong>Language</strong></th>
<th>Type in the name of the X3 language code used to start a connection group.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Pool alias</strong></td>
<td>Type in the name of the connection pool that distributes the received requests to available connections. This name was given from the Sage X3 configuration console.</td>
</tr>
</tbody>
</table>
| **Request config** | Type in the configuration string if you want to retrieve the debug or trace information.  
For example, the string could be: "RequestConfigDebug=adxwss.trace.on=on";  
If you need use several strings, separate them with a ", for example,  
RequestConfigDebug=adxwss.trace.on=on&adxwss.trace.size=16384";  
**Warning:**  
A third party tool is needed to retrieve this kind of information. |
| **Publication name** | Type in the publication name of the published object, list or sub-program you want your Studio to access. |
| **Action** | You can do any of the following operations on the data in a Sage X3 system:  
**Insert:** insert data  
**Update:** update data  
**Delete:** delete data |
| **Mapping** | Complete this table to map the variable elements of the object, the list or the sub-program your Studio access. Only the elements you need to conduct the data action of your interest on are selected and typed in for the purpose of mapping. The columns to be completed include:  
**Column:** the columns defined in the schema editor for this component.  
**Key:** the variable element used as key for data insertion, update or deletion. Select the corresponding check box if a variable element is the key.  
**Group ID:** the identifier of each variable element group. For example, a variable element group could represent one of attributes of an object.  
**Field name:** the field name of each selected variable element. |
| **Advanced settings** |  
| **tStatCatcher Statistics** | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |
Global Variables

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

Usage

| Usage rule | Usually used as an output component. An input component is required. |

Scenario: Using a Sage X3 Web service to insert data into a given Sage X3 system

This scenario describes a two-component Job used to generate one row of data and insert the data into a given Sage X3 system. You can find the data used in this scenario in the example provided by Sage X3. The Sage X3 Web service is used to access an object.

Setting up the Job

**Procedure**

1. Drop the **tFixedFlowInput** and the **tSageX3Output** components onto the workspace from **Palette**.
2. Connect the **tFixedFlowInput** component to the **tSageX3Output** component using a **Row > Main** connection.

Configuring the schema for the input data

**Procedure**

1. Double-click the **tFixedFlowInput** component to set its Basic Settings in the Component view.
2. Click the three-dot button next to Edit schema to open the schema editor.

3. In the schema editor and then under the schema table, click the plus button four times to add four rows.

4. Click OK to validate this changes and then accept the propagation prompted by the pop-up dialog box. The four rows appear automatically in the Values table of the Component view.

5. In the Values table within the Mode area, type in the values for each of the four rows in the Value column. In this scenario, the values downward are: CONTS00059, Screen 24" standard 16/10, Screen 24" standard 28/10, 2.

**Warning:**

*These values in the Value column must be put between quotation marks.*

**Setting up the connection to the Sage X3 Web server**

**Procedure**

1. Double-click tSageX3Output to set its properties from the Basic Settings view.
2. In the **Endpoint address** field, type in the URL address of the Web service provided by the Sage X3 Web server. In this example, it is `http://10.42.20.168:28880/adxwsvc/services/CAdxWebServiceXmlCC`.

3. In the **User** field, type in the user name of the given Sage X3. In this example, it is `ERP`.

4. In the **Language** field, type in the name of the X3 language code used to start a connection group. In this example, it is `FRA`.

5. In the **Pool alias** field, type in the name of connection pool to be used. In this example, this connection pool is called `TALEND`.

6. In the **Publication name** field, type in the publication name of the object to be called. In this scenario, the publication name is `ITMDET`.

7. In the **Action** field, select **insert** from the drop-down list.

### Setting up the mapping

#### Procedure

1. In the **Field name** column of the **Mapping** table, type in the field names of the attributes the selected data action is exercised on.

2. In the **Group ID** column of the **Mapping** table, type in values corresponding to group IDs of the selected attributes. These IDs are defined in the Sage X3 Web server.

### Note:
In the **Mapping** table, the **Column** column has been filled automatically with the columns retrieved from the schema of the preceding component.

**Job execution**

Press CTRL+S to save your Job and press **F6** to execute it.

To verify the data that you inserted in this scenario, you can use the **tSageX3Input** component to read the concerned data from the Sage X3 server.

For further information about how to use the **tSageX3Input** component to read data, see Scenario: Using query key to extract data from a given Sage X3 system on page 3363.
tSalesforceBulkExec

Bulk-loads data in a given file into a Salesforce object.

The tSalesforceOutputBulk and tSalesforceBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used to feed the Salesforce database. These two steps are fused together in the tSalesforceOutputBulkExec component. The advantage of using two separate steps is that the data can be transformed before it is loaded into Salesforce.

tSalesforceBulkExec Standard properties

These properties are used to configure tSalesforceBulkExec running in the Standard Job framework. The Standard tSalesforceBulkExec component belongs to the Business and the Cloud families. The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Property Type</strong></td>
<td>Select the way the connection details will be set.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Built-In</strong>: The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Repository</strong>: The connection details stored centrally in Repository &gt; Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up Repository Content dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in.</td>
</tr>
<tr>
<td></td>
<td>This property is not available when other connection component is selected from the Connection Component drop-down list.</td>
</tr>
</tbody>
</table>

| **Connection Component** | Select the component that opens the database connection to be reused by this component. |

| **Connection type** | Select the type of the connection from the drop-down list. The connection properties will vary according to the connection type you choose. |
|                    | • **Basic**: select this option to access Salesforce by entering your Salesforce username and password. |
|                    | • **OAuth**: select this option to access Salesforce using OAuth (Open Authorization) 2.0 protocol to authenticate the user. From the Oauth2 flow type drop-down list displayed, you need to choose an OAuth 2.0 authentication flow type, either Json Web Token Flow or Implicit Flow (Deprecated) (User Agent Flow). This way, you need to create a connected app in Salesforce to configure a Salesforce authentication provider. |
For more information about the OAuth authentication flow, see Authenticate Apps with OAuth.

For more information about how to create a connected app in Salesforce, see Create a Connected App.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Available for</th>

### Advanced settings

| **Salesforce URL** | The Webservice URL required to connect to Salesforce. |
| **API version** | The Salesforce API version. This property is available only when the OAuth connection type is selected. |
| **Bulk Connection** | Select this check box if you need to use bulk data processing function. |
| **Use or save the connection session** | Select this check box and in the **Session directory** field displayed, specify the path to the connection session file to be saved or used. This session file can be shared by different Jobs to retrieve a connection session as long as the correct user ID is provided by the component. This way, you do not need to connect to the server to retrieve the session. When an expired session is detected, if the correct connection information (the user ID, password, and security key) is provided, the component will connect to the server to retrieve the new session information and update the connection session file. This property is available only when the **Basic** connection type is selected. |
| **Need compression** | Select this check box to activate SOAP message compression, which can result in increased performance levels. |
| **Use Http Chunked** | Select this check box to use the HTTP chunked data transfer mechanism. This property is available only when the **Bulk Connection** check box is cleared. |
**tSalesforceConnection**

<table>
<thead>
<tr>
<th><strong>Trace HTTP message</strong></th>
<th>Select this check box to output the HTTP interactions on the console. This property is available only when the <strong>Bulk Connection</strong> check box is selected.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Client Id</strong></td>
<td>Enter the ID of the real user to differentiate between those who use the same account and password to access the Salesforce website.</td>
</tr>
<tr>
<td><strong>Timeout</strong></td>
<td>Enter the intended number of query timeout in milliseconds in Salesforce.</td>
</tr>
<tr>
<td><strong>Use Proxy</strong></td>
<td>Select this check box to use a proxy server, and in the <strong>Host</strong>, <strong>Port</strong>, <strong>User Id</strong>, and <strong>Password</strong> fields displayed, specify the connection parameters of the proxy server.</td>
</tr>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to gather the Job processing metadata at the Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

**Global Variables**

| **ERROR_MESSAGE** | The error message generated by the component when an error occurs. This is an After variable and it returns a string.                                                                                     |

**Usage**

| **Usage rule** | This component is more commonly used with other Salesforce components.                                                                                                                             |

**Connecting to Salesforce using OAuth implicit flow to authenticate the user (deprecated)**

In this scenario, the **OAuth2** (Open Authorization 2.0) method is adopted to authorize **tSalesforceConnection** to access the Salesforce resources. This way, better security is achieved as users do not need entering their Salesforce username/password directly on **tSalesforceConnection**, which is required by the **Basic** login type instead.
Setting up the Job

Procedure
1. Drop a tSalesforceConnection component, a tFixedFlowInput component and a tSalesforceOutput component onto the workspace.
2. Link the tFixedFlowInput component to the tSalesforceOutput component using a Row > Main connection.
3. Link the tSalesforceConnection component to the tFixedFlowInput component using a Trigger > OnSubjobOk connection.

Configuring the components

Procedure
1. Double-click the tSalesforceConnection component to open its Basic settings view.
2. Select OAuth from the Connection type drop-down list and Implicit Flow from the Oauth2 flow type drop-down list.
3. In the Client Id and Client Secret fields, enter the key and secret used by the consumer to access Salesforce respectively.
4. In the Callback Host and Callback Port fields, enter the callback host and port information respectively.
5. In the Token File field, browse to or enter the path to the token file that stores the refresh token used by the OAuth-enabled connected app to obtain new sessions without requiring the user to provide their credentials.
6. Double-click the tFixedFlowInput component to open its Basic settings view.
7. Click the [...] button next to Edit schema and in the pop-up schema dialog box, define the schema by adding one column Name of String type. When done, click OK to save the changes and close the dialog box.
8. In the **Mode** area, select **Use Inline Content (delimited file)**. Then in the **Content** field displayed, enter the data to be written into Salesforce. For example, **Talend**.

9. Double-click the **tSalesforceOutput** component to open its **Basic settings** view.

10. Select the **tSalesforceConnection** component from the **Connection Component** drop-down list to reuse the connection created by it.

11. Click the [...] button next to the **Module Name** field and in the pop-up dialog box, select the object you want to access. In this example, it is **Account**.

12. Click the [...] button next to **Edit schema** to open the schema dialog box. On the right side of the panel, remove all the columns except the column **Name**. When done, click **OK** to save the changes and close the dialog box.

---

**Executing the Job**

**Procedure**

1. Press **Ctrl + S** to save the Job.
2. Press **F6** to run the Job. The Studio console gives the URL (in yellow) for OAuth authorization.
3. Copy the URL to the browser’s address bar. The Salesforce.com login page appears.

4. Fill up the username and password and click **Log in to Salesforce**.
   The authorization response is then shown on the browser at the callback host.

5. Now is the time for the Job to continue running.
As shown above, the Job is successfully executed.

6. Go to the Salesforce.com and check the Account object. You can find that the account whose name is Talend is inserted.

![Image of New Accounts with Talend account inserted]

| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
  • View schema: choose this option to view the schema only.  
  • Change to built-in property: choose this option to change the schema to Built-in for local changes.  
  • Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the [Repository Content] window. Click Sync columns to retrieve the schema from the previous component connected in the Job. |
### Start Date
Click the [...] button next to the field and in the calendar dialog box displayed, select the date and time to collect only the data deleted since the specified time. Note that you can collect only the data deleted in the past 30 days.

### End Date
Click the [...] button next to the field and in the calendar dialog box displayed, select the date and time to collect only the data deleted before the specified time.

Recovering deleted data from Salesforce

This scenario describes a two-component Job that collects the account data deleted over the past five days from Salesforce.

Setting up the Job for recovering deleted data from Salesforce

Procedure

1. Create a new Job and add a `tSalesforceGetDeleted` component and a `tLogRow` component by typing their names on the design workspace or dropping them from the Palette.
2. Connect the `tSalesforceGetDeleted` component to the `tLogRow` component using a Row > Main connection.

Configuring the Job for recovering deleted data from Salesforce

Procedure

1. Double-click the `tSalesforceGetDeleted` component to open its Basic settings view.
2. In the User Id, Password and Security Key fields, enter the user authentication information required to access Salesforce.
3. Click the [...] button next to the Module Name field and in the pop-up dialog box, select the object you want to access. In this example, it is Account. When done, click OK to save the settings and close the dialog box.
4. Click the [...] button next to the Start Date field and in the pop-up calendar dialog box, set the value of the start date and time to collect only the data deleted since the specified time. In this example, it is 2016-06-08 00:00:00.

5. Do the same to set the value of the end date and time in the End Date field to collect only the data deleted before the specified time. In this example, it is 2016-06-13 00:00:00.

6. Double-click the tLogRow component to open its Basic settings view.
7. Click **Sync columns** to retrieve the schema from the preceding component.
8. In the **Mode** area, select **Vertical (each row is a key/value list)** to display the results in a tabular form on the console.

**Executing the Job to recover deleted data from Salesforce**

**Procedure**

1. Press **Ctrl + S** to save your Job.
2. Press **F6** to run your Job.
As shown above, the data deleted during the past five days is collected and displayed in a tabular form on the console.
tSalesforceGetServerTimestamp

Retrieves the current date of the Salesforce server presented in a timestamp format.

**tSalesforceGetServerTimestamp Standard properties**

These properties are used to configure tSalesforceGetServerTimestamp running in the Standard Job framework.

The Standard tSalesforceGetServerTimestamp component belongs to the Business and the Cloud families.

The component in this framework is generally available.

**Basic settings**

<tr>
<td>API version</td>
<td>The Salesforce API version.</td>
</tr>
</tbody>
</table>
**Use or save the connection session**

Select this check box and in the **Session directory** field displayed, specify the path to the connection session file to be saved or used.

This session file can be shared by different Jobs to retrieve a connection session as long as the correct user ID is provided by the component. This way, you do not need to connect to the server to retrieve the session.

When an expired session is detected, if the correct connection information (the user ID, password, and security key) is provided, the component will connect to the server to retrieve the new session information and update the connection session file.

This property is available only when the **OAuth** connection type is selected.

**Need compression**

Select this check box to activate SOAP message compression, which can result in increased performance levels.

**Use Http Chunked**

Select this check box to use the HTTP chunked data transfer mechanism.

**Client Id**

Enter the ID of the real user to differentiate between those who use the same account and password to access the Salesforce website.

**Timeout**

Enter the intended number of query timeout in milliseconds in Salesforce.

**Use Proxy**

Select this check box to use a proxy server, and in the **Host**, **Port**, **User Id**, and **Password** fields displayed, specify the connection parameters of the proxy server.

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

**Global Variables**

<table>
<thead>
<tr>
<th>Variables</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE</strong></td>
<td>The number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>

</tr>
</tbody>
</table>
| **Client Secret** | The OAuth Consumer Secret, generated when your connected app is created and shown in the connected app detail page in Salesforce. For more information, see [Create a Connected App](#).  
This property is available only when the OAuth Implicit Flow type is selected. |
| **Callback Host** | The host value in the OAuth authentication callback URL that is defined during the creation of a connected app and will be shown in the API (Enable OAuth Settings) area of the connected app detail page in Salesforce.  
This property is available only when the OAuth Implicit Flow type is selected. |
| **Callback Port** | The port value in the OAuth authentication callback URL that is defined during the creation of a connected app and will be shown in the API (Enable OAuth Settings) area of the connected app detail page in Salesforce.  
This property is available only when the OAuth Implicit Flow type is selected. |
| **Token File** | The path to the token file that stores the refresh token used to get the access token without authorization.  
This property is available only when the OAuth Implicit Flow type is selected. |
| **Module Name** | Click the [...] button next to the field and in the dialog box displayed, select the module that will be used or select the Use custom object check box and specify the module name in the Object Name field. |
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.  
Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
- View schema: choose this option to view the schema only.  
- Change to built-in property: choose this option to change the schema to Built-in for local changes.  
- Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the [Repository Content] window.  
In this component the schema is related to the Module selected.  
To retrieve a column from a linked module it is necessary to define the column in a particular manner in the Edit schema view, otherwise the relationship query

will not work. The correct syntax is: `NameofCurrentModule_NameofLinkedModule_NameofColumnofInterest`.

| Query Mode | Select the query mode from the drop-down list, either **Query** or **Bulk**.  
|---|---|
| Query | the ordinary query.  
| Bulk | the bulk query used to query large data sets efficiently and reduce the number of API requests.  

| Condition | Enter the query used to select the data to be extracted between double quotation marks, for example, "name='Talend'" or "name like '%talend_user%'".  
This property is not available when the Manual Query check box is selected.  

| Manual Query | Select this check box and in the **Full SOQL query string** field displayed, enter the full SOQL (Salesforce Object Query Language) statement used to select the data to be retrieved between double quotation marks. For more information about the SOQL, see Salesforce Object Query Language (SOQL).  
This property is not available when the Manual Query check box is selected.  

| Guess schema | Click this button to generate the schema columns based on the query specified in the **Full SOQL query string** field.  
This property is available only when the Manual Query check box is selected.  
Note that there are some limitations you should be aware of when using this feature. Please refer to the Know Limitations section in Release Notes for more detailed information.  

| Guess query | Click this button to generate the query in the **Full SOQL query string** field based on the defined module and schema.  
For more information about how to set the module and schema correctly when generating the SOQL queries, see How to set schema for the guess query feature of tSalesforceInput on page 3410.  
This property is available only when the Manual Query check box is selected.  
Note that there are some limitations you should be aware of when using this feature. Please refer to the Know Limitations section in Release Notes for more detailed information.  

| Include deleted records | Select this check box to query all the records, including the deleted ones.  
This property is available only when **Query** is selected from the **Query Mode** drop-down list.

</tr>
<tr>
<td>Column Name Delimiter</td>
<td>Enter the characters, strings or regular expressions used to separate the name of the parent object from the name of the child object when you use a query on the hierarchical relations among the different Salesforce objects. This property is available only when <strong>Query</strong> is selected from the <strong>Query Mode</strong> drop-down list.</td>
</tr>
<tr>
<td>Safety Switch</td>
<td>Clear this check box if the length of any column of the module to be queried is greater than 100,000 characters. By default, this check box is selected to prevent excessive memory usage. This property is available only when <strong>Bulk</strong> is selected from the <strong>Query Mode</strong> drop-down list.</td>
</tr>
<tr>
<td>Complete Job timeout</td>
<td>The timeout value, in seconds, within which your bulk query Job must be completed. By default, the value is set to 0, which means there is no time limit for your Job to complete. Salesforce has its own limit for bulk query. If it takes time longer than Salesforce's timeout limit to process a batch, the batch will be placed in a queue and processed later, and thus it might take too much time for the Job to execute. In this case, you can define the Complete Job timeout value to make your Job end in advance. For more information about Salesforce's own limit, see Bulk API Limits - Batch processing time. This property is available only when <strong>Bulk</strong> is selected from the <strong>Query Mode</strong> drop-down list.</td>
</tr>
<tr>
<td>Enable PK Chunking</td>
<td>Select this check box to enable PK (Primary Key, i.e., the object's record ID) chunking when extracting large amounts of records or when the query consistently times out. In the <strong>Chunk size</strong> field displayed, specify the number of records within the ID boundaries for each chunk. For more information, see Use PK Chunking to Extract Large Data Sets from Salesforce. This property is available only when <strong>Bulk</strong> is selected from the <strong>Query Mode</strong> drop-down list.</td>
</tr>
<tr>
<td>tStatCatcher Statistics</td>
<td>Select this check box to gather the Job processing metadata at the Job level as well as at each component level.</td>
</tr>
<tr>
<td><strong>Global Variables</strong></td>
<td></td>
</tr>
<tr>
<td><strong>NB_LINE</strong></td>
<td>The number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
</tbody>
</table>
The error message generated by the component when an error occurs. This is an After variable and it returns a string.

**Usage**

| Usage rule | This component is usually used as a start component of a Job or Subjob and it always needs an output link. |

### How to set schema for the guess query feature of tSalesforceInput

**tSalesforceInput** allows you to generate SOQL queries, with both standard objects and fields and custom objects and fields, based on the defined module and schema. This section demonstrates how to set the module and schema when generating an SOQL query.

There are two types of SOQL queries: simple query and relationship query.

Simple query retrieves data from only one object. For more information about how to set the module and schema for generating simple queries, see **How to set schema for generating the simple query** on page 3410.

Relationship query retrieves data from more than a single type of object, including child-to-parent and parent-to-child relationship queries.

For more information about how to set the module and schema for generating child-to-parent relationship queries, see **How to set schema for generating the child-to-parent relationship query** on page 3411.

For more information about how to set the module and schema for generating parent-to-child relationship queries, see **How to set schema for generating the parent-to-child relationship query** on page 3412.

Note that before setting the module name and schema columns for generating the relationship query in the **Basic settings** view of **tSalesforceInput**, you need to first identify the relationship type (child-to-parent or parent-to-child) of the query to be generated, because the methods of setting the schema column names for these two kinds of relationship queries are somewhat different. The main difference between the child-to-parent and parent-to-child relationship queries is that the parent-to-child relationship query is specified by using the subquery enclosed in parentheses, while the child-to-parent relationship query is not. For more information about the relationship queries in SOQL and how to identify the relationship queries, see **Relationship Queries**.

### How to set schema for generating the simple query

This section demonstrates how to set the module name and schema columns for generating the simple query.

The following two simple query examples will be used for demonstration purpose in the following steps.

- SELECT Id, Name, BillingCity FROM Account, a simple query with standard object and fields, and
- SELECT Name__c, LastName__c FROM Mother__c, a simple query with custom object and fields.
Procedure

1. Set the module name with the name of the object specified in the FROM clause, Account and Mother__c for above examples.

2. Create a column for each field in the field list (separated by commas) after SELECT in the schema dialog box and set the column name with the field name.

   - For the first example, you need to create three columns Id, Name, and BillingCity for the three fields.
   - For the second example, you need to create two columns Name__c and LastName__c for the two fields.

How to set schema for generating the child-to-parent relationship query

This section demonstrates how to set the module name and schema columns for generating a child-to-parent relationship query.

The following two child-to-parent relationship query examples will be used for demonstration purpose in the following steps.

- SELECT Name, Account.Name, Account.Owner.Name FROM Contact, a child-to-parent relationship query with standard object and fields, and

- SELECT Id, FirstName__c, MotherOfDaughter__r.FirstName__c FROM Daughter__c, a child-to-parent relationship query with custom object and fields.

   Note that here you must use the relationship name with __r instead of __c. For more information, see Understanding Relationship Names, Custom Objects, and Custom Fields.

Procedure

1. Set the module name with the name of the object specified in the FROM clause, Contact and Daughter__c in above examples.

2. Create a column for each field in the field list (separated by commas) after SELECT in the schema dialog box.

   - For the first example, you need to create three columns for the three fields Name, Account.Name, and Account.Owner.Name.
   - For the second example, you need to create three columns for the three fields Id, FirstName__c, and MotherOfDaughter__r.FirstName__c.

3. Set the name of each column with the name of each field and replace all dots in the column name with underscore characters.

   - For the first example, the names of the three columns are set to Name, Account_Name, and Account_Owner_Name.
   - For the second example, the names of the three columns are set to Id, FirstName__c, and MotherOfDaughter__r_FirstName__c.

4. Set the type of each column.

   The schema for the first example should be set like this:
And the schema for the second example should be set like this:

Note that the underscore character '_-' is used as a separator between the relationship name and the field name in Talend schema, so only the underscore character '_' that goes after '__r' or '__c' will be replaced by the dot character '.' when generating the query. If the underscore character '_' is a part of any custom name in the schema, for example, `Contact_custom_field__c`, which should be `Contact.custom_field__c` in the query, you need to replace '_' in the generated query with '.' manually.

**How to set schema for generating the parent-to-child relationship query**

This section demonstrates how to set the module name and schema columns for generating a parent-to-child relationship query.

The following two parent-to-child relationship query examples will be used for demonstration purpose in the following steps.

- SELECT Name, Owner.Name (SELECT CreatedBy.Name FROM Notes) FROM Account, a parent-to-child relationship query with standard object and fields, and
- SELECT LastName__c, (SELECT FirstName__c FROM Daughters__r) FROM Mother__c, a parent-to-child relationship query with custom object and fields.
Note that here you must use the relationship name with __r instead of __c. For more information, see Understanding Relationship Names, Custom Objects, and Custom Fields.

Procedure

1. Set the module name with the name of the object specified in the outer query FROM clause, Account and Mother__c in above examples.

2. Create a column for each field (including the fields in subquery) after SELECT in the schema dialog box.

   For the first example, you need to create three columns for the three fields Name and Owner.Name after the outer SELECT, and one field CreatedBy.Name after the subquery SELECT.

   For the second example, you need to create two columns for the two fields LastName__c after the outer SELECT, and the field FirstName__c after the subquery SELECT.

3. For the fields in the outer SELECT clause, which are outside parentheses, set the name of each column with the name of each field and replace all dots in the column name with underscore characters.

   For the first example, the column names for the two fields Name and Owner.Name in the outer SELECT clause are set to Name and Owner_Name.

   For the second example, there is no dot in the field name, so the column name is same as the field name.

4. For the fields in the subquery SELECT, construct the column names using the pattern <$XXX>_records_<$YYY>, where <$XXX> corresponds to the name of the object specified in the subquery FROM clause, and <$YYY> will be the field name with all dots replaced by underscore characters.

   For the first example, the column name for the field CreatedBy.Name in the subquery is set to Notes_records_CreatedBy_Name.

   For the second example, the column name for the field FirstName__c in the subquery is set to Daughters__r_records_FirstName__c.

5. Set the type of each column.

The schema for the first example should be set like this:
And the schema for the second example should be set like this:

![Schema of tSalesforceInput](image)

Note that the underscore character '_' is used as a separator between the relationship name and the field name in Talend schema, so only the underscore character '_' that goes after '__r' or '__c' will be replaced by the dot character '.' when generating the query. If the underscore character '_' is a part of any custom name in the schema, for example, Contact_custom_field__c, which should be Contact.custom_field__c in the query, you need to replace '_' in the generated query with '.' manually.

**Related scenario**

Upserting Salesforce data based on external IDs on page 3420
tSalesforceOutput

Inserts, updates, upserts, or deletes data in a Salesforce object.

tSalesforceOutput Standard properties

</table>
module as well as the external ID fields in the lookup module.

- **Column name of Talend Schema**: the name of the external ID field in the input flow. It refers to the fields in the schema of the preceding component. Such columns are intended to match against the external ID fields specified in the **External id name** column, which are the fields of the lookup module specified in the **Module name** column.

- **Lookup field name**: the name of the lookup field. It refers to the lookup field of the module specified in the **Module Name** field in the **Basic settings** view. This column needs to be specified when there are NULL input values for it and the **Ignore Null** check box is cleared.

- **Lookup relationship field name**: the name of the lookup relationship field. It refers to the lookup relationship fields of the module specified in the **Module Name** field in the **Basic settings** view and is intended to establish relationship with the lookup module specified in the **Module name** column in this table. For how to define the lookup relationship fields and how to provide their correct names in the **Lookup relationship field name** field, go to the Salesforce website and launch the Salesforce Data Loader application for proper actions and information.

- **Module name**: the name of the lookup module.

- **External id name**: the name of the external ID field in the lookup module specified in the **Module name** column.

This property is available only when **UPSERT** is selected from the **Output Action** drop-down list.

<table>
<thead>
<tr>
<th>Extend Insert</th>
<th>Select this check box to transfer the output data in batches. In the <strong>Commit Level</strong> field displayed, specify the number of lines per batch.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cease on Error</td>
<td>Select the check box to stop the execution of the Job when an error occurs. Clear the check box to skip any rows on error and complete the process for error-free rows. When errors are skipped, you can collect the rows on error using a <strong>Row &gt; Reject</strong> link. The <strong>Extend Insert</strong> check box needs to be cleared when using the <strong>Row &gt; Reject</strong> link to collect the erroneous rows.</td>
</tr>
<tr>
<td>Retrieve Id</td>
<td>Select this check box to allow Salesforce to return the Salesforce ID for the inserted or updated records. This check box is available only when <strong>INSERT</strong> or <strong>UPSERT</strong> is selected from the <strong>Output Action</strong> drop-down list and the <strong>Extend Insert</strong> check box is cleared.</td>
</tr>
</tbody>
</table>
When this check box is selected and the tSalesforceOutput component is linked to another component via a Row > Main connection, the following column(s) will be added to the schema of the data flow:

- **salesforce_id**: the Salesforce ID of the created or updated record.
- **salesforce_upsert_status** (only for UPSERT): the status of the upsert action to indicate whether the record is created or updated.

<table>
<thead>
<tr>
<th>Ignore Null</th>
<th>Select this check box to ignore NULL values. This property is available only when UPDATE or UPSERT is selected from the Output Action drop-down list.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Log File Name</td>
<td>Specify the path to the log file that holds all error logs.</td>
</tr>
<tr>
<td>tStatCatcher Statistics</td>
<td>Select this check box to gather the Job processing metadata at the Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

**Global Variables**

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NB_LINE</td>
<td>The number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>NB_SUCCESS</td>
<td>The number of rows successfully processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>NB_REJECT</td>
<td>The number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>ERROR_MESSAGE</td>
<td>The error message generated by the component when an error occurs. This is an After variable and it returns a string.</td>
</tr>
</tbody>
</table>

**Usage**

**Usage rule**

This component can be used as an end component or an intermediate component of a Job or Subjob and it always needs an input link.

**Upserting Salesforce data based on external IDs**

Here is an example of using Talend components to insert and update Salesforce Contact object data based on the mapping relationship with external IDs of the Account object.

The Job used in this example is composed of the following seven subjobs:

- the first subjob opens a connection to Salesforce,
- the second subjob deletes some Account records based on external IDs,
- the third subjob inserts two Account records with external IDs,
• the fourth subjob inserts three Contact records based on the mapping relationship with the Account object external IDs, and gathers both inserted and erroneous data,

• the fifth subjob updates two inserted Contact records based on the mapping relationship with the Account object external IDs,

• the sixth subjob retrieves the inserted Account records, and

• the seventh subjob retrieves the upserted Contact records.
Creating a Job for upserting Salesforce data based on external IDs

Before you begin

- An external ID custom field `Account_External_ID` has been added for the Account object in your Salesforce, which will be used to map the relationship with the Contact object.

- An external ID custom field `Contact_Talend_ID` has been added for the Contact object in Salesforce, which will be used as the key column for upserting Contact object data.

Procedure

1. Create a new Job and add a `tSalesforceConnection` component, three `tSalesforceInput` components, four `tSalesforceOutput` components, three `tFixedFlowInput` components, and four `tLogRow` components.

2. Connect the first `tSalesforceInput` component to the first `tSalesforceOutput` component using a `Row > Main` connection.

3. Do the same to connect the first `tFixedFlowInput` component to the second `tSalesforceOutput` component, the second `tFixedFlowInput` component to the third `tSalesforceOutput` component, the third `tFixedFlowInput` component to the fourth `tSalesforceOutput` component, and the third `tSalesforceInput` component to the fourth `tLogRow` component.

4. Connect the third `tSalesforceOutput` component to the first `tLogRow` component using a `Row > Main` connection and to the second `tLogRow` component using a `Row > Reject` connection.

5. Connect the `tSalesforceConnection` component to the first `tSalesforceInput` component using a `Trigger > On Subjob Ok` connection.

6. Do the same to connect the first `tSalesforceInput` component to the first `tFixedFlowInput` component, the first `tFixedFlowInput` component to the second `tFixedFlowInput` component, the second `tFixedFlowInput` component to the third `tFixedFlowInput` component, the third `tFixedFlowInput` component to the second `tSalesforceInput` component, and the second `tSalesforceInput` component to the third `tSalesforceInput` component.

Opening a connection to Salesforce

Procedure

1. Double-click the `tSalesforceConnection` component to open its `Basic settings` view on the `Component` tab.

2. Select `Basic` from the `Connection type` drop-down list to connect to Salesforce using your Salesforce account username, password, and security token.

   In this example, you connect to Salesforce using the basic connection type. You can also connect to Salesforce using the OAuth JWT (JSON Web Token) Flow type. For more information, see the
related description of how to connect to Salesforce using OAuth JWT Flow on Talend Help Center (https://help.talend.com).

3. In the User Id field, enter your Salesforce username.

4. Click the [...] button next to the Password field and in the pop-up dialog box, enter your Salesforce password between double quotation marks.

5. Click the [...] button next to the Security Token field and in the pop-up dialog box, enter your Salesforce security token between double quotation marks.

You can use the Salesforce metadata wizard to create a connection to your Salesforce system, save the connection in the Repository, and then reuse the connection configuration defined in the metadata wizard in Salesforce components. For more information, see the related description of centralizing Salesforce metadata.

Deleting Salesforce Account records based on external ID

**Procedure**

1. Double-click the first tSalesforceInput component to open its Basic settings view on the Component tab.
2. Select the component that will create the Salesforce connection from the Connection Component drop-down list, tSalesforceConnection_1 in this example.
3. Click the [...] button next to the Module Name field and in the pop-up dialog box, select the object whose data will be deleted, Account in this example. The schema of the Account object will be automatically filled.
4. Click OK to save the changes and in the pop-up dialog box, click Yes to propagate the schema to the next tSalesforceOutput component.
5. Select Query from the Query Mode drop-down list and specify the condition used to filter data to be deleted. In this example, it is talendlena__Account_External_ID__c like '%talend%'.

   All Salesforce Account records whose talendlena__Account_External_ID__c field contains talend will be deleted.

6. Double-click the first tSalesforceOutput component to open its Basic settings view on the Component tab.
7. Select the component that will create the Salesforce connection from the Connection Component drop-down list, tSalesforceConnection_1 in this example.
8. Click the [...] button next to the Module Name field and in the pop-up dialog box, select the object whose data will be deleted, Account in this example.
9. Select DELETE from the Output Action drop-down list to perform the delete operation on the Account objects filtered by the first tSalesforceInput component.

Inserting Salesforce Account records with external IDs

**Procedure**

1. Double-click the second tSalesforceOutput component to open its Basic settings view on the Component tab.
2. Select the component that will create the Salesforce connection from the Connection Component drop-down list, tSalesforceConnection_1 in this example.
3. Click the [...] button next to the **Module Name** field and in the pop-up dialog box, select the object into which data will be inserted, **Account** in this example. The schema of the Account object will be automatically filled.

4. Click the [...] button next to **Edit schema** and in the pop-up dialog box, remove all schema columns except the two columns **Name** and **talendlena__Account__External__ID__c**. Then click ![arrow] to copy these two columns to the first **tFixedFlowInput** component. When done, click **OK** to close the dialog box.

5. Select **INSERT** from the **Output Action** drop-down list.

6. Double-click the first **tFixedFlowInput** component to open its **Basic settings** view on the **Component** tab.

7. In the **Mode** area, select **Use Inline Table** and in the table displayed, enter the data to be inserted into the Salesforce Account object. In this example, the following two records will be inserted.

   ```
   account_talend;account_talend_exid
   account_talend_doc;account_talend_doc_exid
   ```

   You can also select **Use Inline Content**, and then copy and paste the input data into the **Content** field displayed.

### Inserting Salesforce Contact records upon Account external IDs

**Procedure**

1. Double-click the third **tSalesforceOutput** component to open its **Basic settings** view on the **Component** tab.

2. Select the component that will create the Salesforce connection from the **Connection Component** drop-down list, **tSalesforceConnection_1** in this example.

3. Click the [...] button next to the **Module Name** field and in the pop-up dialog box, select the object into which data will be inserted, **Contact** in this example. The schema of the Contact object will be automatically filled. When done, click **OK** to save the changes and in the pop-up dialog box, click **Yes** to propagate the schema to the next two **tLogRow** components.
4. Click the [...] button next to Edit schema and in the pop-up dialog box, remove all schema columns except the three columns LastName, FirstName, and talendlena__Contact_Talend_ID__c. Then add another column Account_External_ID of String type and copy these four columns to the second tFixedFlowInput component. When done, click OK to close the dialog box and in the pop-up dialog box, click Yes to propagate the schema to the next two tLogRow components.

5. Select UPSERT from the Output Action drop-down list and talendlena__Contact_Talend_ID__c from the Upsert Key Column drop-down list displayed.

6. Go to the Advanced settings view and in the Relationship mapping for upsert table, specify the relationship mapping for the column Account_External_ID by adding one row and setting the value for each table column. In this example, the column Account_External_ID is mapped with the external ID field talendlena__Account_External_ID__c of the Account object, so the value for Column name of Talend Schema is Account_External_ID, the value for Lookup relationship field name and Module name is Account, and the value for External id name is talendlena__Account_External_ID__c.

7. Clear the Extend Insert and Die on Error check boxes so that erroneous data can be gathered via the Row > Reject connection.

8. Double-click the second tFixedFlowInput component to open its Basic settings view on the Component tab.
9. In the Mode area, select Use Inline Table and in the table displayed, enter the data to be inserted into the Salesforce Contact object. In this example, the input data is as follows.

<p>| | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Beckham;David;2018010001;account_talend_exid</td>
<td>Taylor;Swift;2018010002;account_talend_exid</td>
<td></td>
<td></td>
</tr>
<tr>
<td>;</td>
<td></td>
<td>;</td>
<td></td>
</tr>
<tr>
<td>;</td>
<td></td>
<td>;</td>
<td></td>
</tr>
</tbody>
</table>

You can also select Use Inline Content, and then copy and paste the input data into the Content field displayed.

10. Double-click the first tLogRow component and on its Basic settings view, select Table in the Mode area to display the result in a table.

11. Do the same to configure the second tLogRow component.

**Updating Salesforce Contact records upon Account external IDs**

**Procedure**

1. Double-click the fourth tSalesforceOutput component to open its Basic settings view on the Component tab.

2. Select the component that will create the Salesforce connection from the Connection Component drop-down list, tSalesforceConnection_1 in this example.

3. Click the [...] button next to the Module Name field and in the pop-up dialog box, select the object into which data will be inserted, Contact in this example. The schema of the Contact object will be automatically filled.

4. Click the [...] button next to Edit schema and in the pop-up dialog box, remove all schema columns except the three columns Phone, Email, and talendlena__Contact_Talend_ID__c. Then add another column Account_External_ID of String type and copy these four columns to the second tFixedFlowInput component. When done, click OK to close the dialog box.

5. Select UPSERT from the Output Action drop-down list and talendlena__Contact_Talend_ID__c from the Upsert Key Column drop-down list displayed.

6. Go to the Advanced settings view and in the Relationship mapping for upsert table, specify the relationship mapping for the column Account_External_ID by adding one row and setting the value for each table column. In this example, the column Account_External_ID is mapped with the external ID field talendlena__Account_External_ID__c of the Account object, so the value for Column name of Talend Schema is Account_External_ID, the value for Lookup relationship field name and Module name is Account, and the value for External id name is talendlena__Account_External_ID__c.

7. Double-click the third tFixedFlowInput component to open its Basic settings view on the Component tab.
8. In the Mode area, select Use Inline Table and in the table displayed, enter the data used to update the two records inserted into the Salesforce Contact object. In this example, the updated data is as follows. The phone and email values will be added for both two records and the Account external ID value for the second record is updated to account_talend_doc_exid.

+86 13666666666;beckham.david@talend.com;2018010001;account_talend_exid
+86 13888888888;taylor.swift@talend.com;2018010002;account_talend_doc_exid

You can also select Use Inline Content, and then copy and paste the input data into the Content field displayed.

Retrieving inserted Salesforce Account records

Procedure

1. Double-click the second tSalesforceInput component to open its Basic settings view on the Component tab.
2. Select the component that will create the Salesforce connection from the Connection Component drop-down list, tSalesforceConnection_1 in this example.
3. Click the [...] button next to the Module Name field and in the pop-up dialog box, select the object from which data will be retrieved, Account in this example. The schema of the Account object will be automatically filled.
4. Click the [...] button next to Edit schema and in the pop-up dialog box, remove all schema columns except the three columns Id, Name, and talendlena__Account_External_ID__c. When done, click OK to save the changes and in the pop-up dialog box, click Yes to propagate the schema to the next tLogRow component.
5. Select Query from the Query Mode drop-down list and specify the condition used to filter data to be retrieved. In this example, it is Name like '%talend%'.

All Salesforce Account records whose Name field contains talend will be retrieved.
6. Double-click the third tLogRow component and on its Basic settings view, select Table in the Mode area to display the result in a table.

Retrieving updated Salesforce Contact records using SOQL query
Procedure

1. Double-click the third **tSalesforceInput** component to open its **Basic settings** view on the **Component** tab.

2. Select the component that will create the Salesforce connection from the **Connection Component** drop-down list, **tSalesforceConnection_1** in this example.

3. Click the [...] button next to the **Module Name** field and in the pop-up dialog box, select the object from which data will be retrieved, **Contact** in this example. The schema of the Contact object will be automatically filled.

4. Click the [...] button next to **Edit schema** and in the pop-up dialog box, remove all schema columns except the four columns **Name**, **Phone**, **Email**, and **talendlena__Contact_Talend_ID__c**.

5. Add another two columns to retrieve name and external ID of the linked Account object, **Contact_Account_Name** and **Contact_Account_talendlena__Account_External_ID__c** in this example.

   To retrieve data of a linked object column, it is necessary to define the name of the column in a particular manner in the schema editor. The correct syntax is **NameofCurrentObject_NameofLinkedObject_NameofColumnofInterest**. If this syntax is not respected, data from the linked object will not be returned. For more information about how to set schema for the relationship query, see How to set schema for the guess query feature of **tSalesforceInput** on page 3410.

6. Click **OK** to save the changes. In the pop-up dialog box, click **Yes** to propagate the schema to the next **tLogRow** component.

7. Select **Query** from the **Query Mode** drop-down list.

8. Select the **Manual Query** check box and click the **Guess query** button to generate the SOQL query based on the defined module name and schema columns. The generated SOQL query will look like below.

   ```sql
   SELECT Name, Phone, Email, talendlena__Contact_Talend_ID__c,
   Contact.Account.Name, Contact_Account_talendlena__Account_External_ID__c FROM Contact
   ```

9. In the generated SOQL query string, replace each underscore character after the object name in the column name **Contact_Account_talendlena__Account_External_ID__c** with a dot character. Then add the **WHERE** condition clause used to filter data to be retrieved at the end of the generated SOQL query. In this example, it is **talendlena__Contact_Talend_ID__c like**
'201801%' and all Salesforce Contact records whose `talendlena__Contact_Talend_ID__c` field begins with '201801' will be retrieved. The updated SOQL query will look like below.

```sql
SELECT Name, Phone, Email, talendlena__Contact_Talend_ID__c, Contact.Account.Name, Contact.Account.talendlena__Account_External_ID__c FROM Contact WHERE talendlena__Contact_Talend_ID__c like '201801%'
```

10. Double-click the fourth `tLogRow` component and on its Basic settings view, select Table in the Mode area to display the result in a table.

**Executing the Job to upsert Salesforce data based on external ID**

**Procedure**

1. Press Ctrl + S to save your Job.
2. Press F6 to execute your Job.

As shown above, two Account records `account_talend` and `account_talend_doc` are successfully inserted, two Contact records Beckham David and Taylor Swift are successfully inserted and updated based on the mapping relationship with the external IDs in the Account object, and another Contact record missing the value for the required field `LastName` is not inserted.

You can also go to the Salesforce website to double-check the Job execution result.
<table>

</table>
Generates the file to be processed by the tSalesforceBulkExec component for bulk processing. The tSalesforceOutputBulk and tSalesforceBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used to feed the Salesforce database. These two steps are fused together in the tSalesforceOutputBulkExec component. The advantage of using two separate steps is that the data can be transformed before it is loaded into Salesforce.

**tSalesforceOutputBulk Standard properties**

These properties are used to configure tSalesforceOutputBulk running in the Standard Job framework. The Standard tSalesforceOutputBulk component belongs to the Business and the Cloud families. The component in this framework is generally available.

### Basic settings

| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields. Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
- **View schema**: choose this option to view the schema only.  
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window. Click **Sync columns** to retrieve the schema from the previous component connected in the Job. |
| **Bulk File Path** | Specify the path to the file to be generated. |
| **Append** | Select this check box to append new data at the end of the file if it already exists, instead of overwriting the existing data. |
| **Ignore Null** | Select this check box to ignore NULL values. |
### Relationship mapping for upsert

Click the [+] button to add lines as needed and specify the external ID fields in the input flow, the lookup relationship fields in the upsert module, the lookup module as well as the external ID fields in the lookup module.

- **Column name of Talend Schema**: the name of the external ID field in the input flow. It refers to the fields in the schema of the preceding component. Such columns are intended to match against the external ID fields specified in the **External id name** column, which are the fields of the lookup module specified in the **Module name** column.

- **Lookup relationship field name**: the name of the lookup relationship field. It refers to the lookup relationship fields of the module specified in the **Module Name** field in the **Basic settings** view of the tSalesforceBulkExec component and is intended to establish relationship with the lookup module specified in the **Module name** column in this table. For how to define the lookup relationship fields and how to provide their correct names in the **Lookup relationship field name** field, go to the Salesforce website and launch the Salesforce Data Loader application for proper actions and information.

- **Module name**: the name of the lookup module.

- **Polymorphic**: select this check box when and only when polymorphic fields are used for relationship mapping. You will get an error if you keep this check box cleared for a polymorphic field or select it for a field that is not polymorphic. For more information about the polymorphic fields, search **polymorphic** at [http://www.salesforce.com/us/developer/docs/api_asynch/](http://www.salesforce.com/us/developer/docs/api_asynch/).

- **External id name**: the name of the external ID field in the lookup module specified in the **Module name** column.

### tStatCatcher Statistics

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NB_LINE</td>
<td>The number of rows processed. This is an After variable and it returns an integer.</td>

<td>The error message generated by the component when an error occurs. This is an After variable and it returns a string.</td>
</tr>
</tbody>
</table>
Usage

| Usage rule | This component is more commonly used with the tSalesforceBulkExec component. Used together, they gain performance while feeding or modifying information in Salesforce.com. |

Related scenario

No scenario is available for this component yet.
tSalesforceOutputBulkExec

Bulk-loads data in a given file into a Salesforce object.

The tSalesforceOutputBulk and tSalesforceBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used to feed the Salesforce database. These two steps are fused together in the tSalesforceOutputBulkExec component. The advantage of using two separate steps is that the data can be transformed before it is loaded into Salesforce.

**tSalesforceOutputBulkExec Standard properties**

These properties are used to configure tSalesforceOutputBulkExec running in the Standard Job framework.

The Standard tSalesforceOutputBulkExec component belongs to the Business and the Cloud families. The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Select the way the connection details will be set.</th>

| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
  - **View schema**: choose this option to view the schema only.  
  - **Change to built-in property**: choose this option to change the schema to Built-in for local changes.  
  - **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No. |
upon completion and choose this schema metadata again in the [Repository Content] window.

Click **Sync columns** to retrieve the schema from the previous component connected in the Job.

### Output Action

Select one of the following operations to be performed from the drop-down list.

- **INSERT**: insert one or more new records into Salesforce.
- **UPDATE**: update one or more existing records in Salesforce.
- **UPSERT**: create new records and update existing records. In the **Upsert Key Column** field displayed, specify the key column for the upsert operation.
- **DELETE**: delete one or more records in Salesforce.

### Bulk File Path

Specify the path to the file that stores the data to be processed.

### Append

Select this check box to append new data at the end of the file if it already exists, instead of overwriting the existing data.

### Ignore Null

Select this check box to ignore NULL values.

### Advanced settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>

<td>Click the [*] button to add lines as needed and specify the external ID fields in the input flow, the lookup relationship fields in the upsert module, the lookup</td>
</tr>
</tbody>
</table>
module as well as the external ID fields in the lookup module.

- **Column name of Talend Schema**: the name of the external ID field in the input flow. It refers to the fields in the schema of the preceding component. Such columns are intended to match against the external ID fields specified in the **External id name** column, which are the fields of the lookup module specified in the **Module name** column.

- **Lookup relationship field name**: the name of the lookup relationship field. It refers to the lookup relationship fields of the module specified in the **Module Name** field in the **Basic settings** view and is intended to establish relationship with the lookup module specified in the **Module name** column in this table. For how to define the lookup relationship fields and how to provide their correct names in the **Lookup relationship field name** field, go to the Salesforce website and launch the Salesforce Data Loader application for proper actions and information.

- **Module name**: the name of the lookup module.

- **Polymorphic**: select this check box when and only when polymorphic fields are used for relationship mapping. You will get an error if you keep this check box cleared for a polymorphic field or select it for a field that is not polymorphic. For more information about the polymorphic fields, search **polymorphic** at http://www.salesforce.com/us/developer/docs/api_asynch/.

- **External id name**: the name of the external ID field in the lookup module specified in the **Module name** column.

This property is available only when **UPSERT** is selected from the **Output Action** drop-down list.

Inserting bulk data into Salesforce

This scenario describes a four-component Job that bulk-loads data in a file into Salesforce, performs the intended action on the data, and ends up with displaying the Job execution results on the console.

The content of the input file `SalesforceAccount.txt` used in this example is as follows:

Name;ParentId;Phone;Fax  
Burlington Textiles Corp of America;;(336) 222-7000;(336) 222-8000  
Dickenson plc;; (785) 241-6200;(785) 241-6201  
GenePoint;;(650) 867-3450;(650) 867-9895  
Edge Communications;talend;(512) 757-6000;(512) 757-9000  
Grand Hotels & Resorts Ltd;talend;(312) 596-1000;(312) 596-1500

Setting up the Job for inserting bulk data into Salesforce

Procedure

1. Create a new Job and add a `tFileInputDelimited` component, a `tSalesforceOutputBulkExec` component, and two `tLogRow` components by typing their names on the design workspace or dropping them from the Palette.
2. Link the `tFileInputDelimited` component to the `tSalesforceOutputBulkExec` component using a Row > Main connection.
3. Link the `tSalesforceOutputBulkExec` component to the first `tLogRow` component using a Row > Main connection.
4. Link the tSalesforceOutputBulkExec component to the second tLogRow component using a Row > Reject connection.

Configuring the Job for inserting bulk data into Salesforce

Procedure

1. Double-click the tFileInputDelimited component to open its Basic settings view.

   ![FileInputDelimited Basic settings](image1)

   2. In the File name/Stream field, browse to or enter the path to the input data file. In this example, it is D:/SalesforceAccount.txt.

   3. Click the [...] button next to Edit schema and in the pop-up schema dialog box, define the schema by adding four columns Name, ParentId, Phone and Fax of String type. When done, click OK to save the changes and close the dialog box.

   ![Schema of tFileInputDelimited](image2)

4. Double-click the tSalesforceOutputBulkExec component to open its Basic settings view.
5. In the **User Id**, **Password** and **Security Key** fields, enter the user authentication information required to access Salesforce.

6. Click the [...] button next to the **Module Name** field and in the pop-up dialog box, select the object you want to access. In this example, it is *Account*.

7. In the **Bulk File Path** field, browse to or enter the path to the CSV file that stores the data for bulk processing. The bulk file to be processed must be in csv format.

8. Double-click the first `tLogRow` component to open its **Basic settings** view.

9. In the **Mode** area, select **Table (print values in cells of a table)** for better readability of the results.

10. Do the same to configure the second `tLogRow` component.

**Executing the Job to insert bulk data into Salesforce**

**Procedure**

1. Press **Ctrl + S** to save the Job.

2. Press **F6** to execute the Job.

   On the console of the **Run** view, you can check the execution result.
In the tLogRow_1 table, you can read the data inserted into Salesforce.

In the tLogRow_2 table, you can read the rejected data due to the incompatibility with the Account objects you have accessed.

Note that if you want to transform the input data before loading them into Salesforce, you need to use `tSalesforceOutputBulk` and `tSalesforceBulkExec` in cooperation to achieve this purpose.
tSalesforceWaveBulkExec

Loads data into Salesforce Analytics Cloud from a local file.

**tSalesforceWaveBulkExec Standard properties**

These properties are used to configure tSalesforceWaveBulkExec running in the Standard Job framework.

The Standard tSalesforceWaveBulkExec component belongs to the Business and the Cloud families.

The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Either Built-In or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Built-In: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The connection fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level.

**User Name and Password**

Enter the Web service authentication details.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

**End Point**

Enter the WebService URL required to connect to Salesforce. For example, https://login.salesforce.com/services/Soap/u/37.0. Note that the version in the URL should be 32.0 or later.

**Schema and Edit schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

- For the fields of numeric type (for example, byte, short, int, long, float, double, and BigDecimal), their length and precision values need to be specified. The default length and precision values are 10 and 2, and you can also specify their custom values in the schema editor.
- For the fields of date type, you need to specify the format of the date in the schema editor. For more
information about the supported date format, see Analytics Cloud External Data Format Reference.

The Schema list and the Editor schema button disappear if the Custom JSON Metadata check box is selected.

**Built-In:** You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.

**Repository:** You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema:** choose this option to view the schema only.
- **Change to built-in property:** choose this option to change the schema to Built-in for local changes.
- **Update repository connection:** choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the [Repository Content] window.

**Operation**

Select an operation to perform on the dataset:

- **Append:** Append all data to the dataset. Create a dataset if it does not exist.
- **Upsert:** Insert or update rows in the dataset. Create a dataset if it does not exist.
- **Overwrite:** Create a new dataset with the given data, and replace dataset if it already exists.
- **Delete:** Delete the rows from the dataset.

**Note:**

- A metadata JSON file is required for the Append, Upsert, and Delete operations.
- The data and metadata for the Append and Upsert operations must match the dataset on which the operation is happening. All columns, dimensions, and measures must match exactly.
- The Append operation is not allowed if you specify any column as the primary key.
- You must specify one (and only one) column as the primary key on which the Upsert or Delete operation is based. You can do that by clicking Edit schema and
selecting the check box next to the column you want to set as the primary key.

- The metadata for the **Delete** operation must be a subset of the dataset columns.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type in the name of the dataset into which the data will be loaded.</th>
</tr>
</thead>
<tbody>
<tr>

<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Range</td>
<td>Enter a range using the relevant syntax to choose a list of single lines and/or a list of groups of lines.</td>
</tr>
</tbody>
</table>

**Global Variables**

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After |
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

| Usage rule | This component handles flows of data therefore it requires input and output components. |

## Scenario: Filtering rows and groups of rows

This scenario describes a three-component Job. A **tRowGenerator** is used to create random entries which are directly sent to a **tSampleRow** where they will be filtered according to a defined range. In this scenario, we suppose the input flow contains names of salespersons along with their respective number of sold products and their years of presence in the enterprise. The result of the filtering operation is displayed on the **Run** console.

### Dropping and linking the components

**Procedure**

1. Drop the following components from the **Palette** onto the design workspace: **tRowGenerator**, **tSampleRow**, and **tLogRow**.
2. Connect the three components using **Row > Main** links.

### Results

![Diagram of components](image)

### Configuring the components

**Procedure**

1. In the design workspace, select **tRowgenerator**, and click the **Component** tab to define the basic settings for **tRowGenerator**.
2. Click the [...] button next to **Edit Schema** to define the data you want to use as input. In this scenario, the schema is made of five columns.
3. In the **Basic settings** view, click **RowGenerator Editor** to define the data to be generated.

4. In the **RowGenerator Editor**, specify the number of rows to be generated in the **Number of Rows for RowGenerator** field and click **OK**. The **RowGenerator Editor** closes.

5. In the design workspace, select **tSampleRow** and click the **Component** tab to define the basic settings for **tSampleRow**.

6. In the **Basic settings** view, set the **Schema** to **Built-In** and click **Sync columns** to retrieve the schema from the **tRowGenerator** component.

7. In the **Range** panel, set the filter to select your rows using the correct syntax as explained. In this scenario, we want to select the first and fifth lines along with the group of lines between 9 and 12.

8. In the design workspace, select **tLogRow** and click the **Component** tab to define its basic settings. For more information about **tLogRow**, see **tLogRow** on page 1988.
Saving and executing the Job

Procedure

1. Press **Ctrl+S** to save your Job.
2. Press **F6**, or click **Run** on the **Run** tab to execute the Job.

Results

```

| 12  | 1                   | Theodore   | Grant      | 68           |
+-----+---------------------+------------+------------+--------------+
Job sample_Row ended at 11:16 20/08/2008. [exit code=0]
```

The filtering result displayed on the console shows the first and fifth rows and the group of rows between 9 and 12.
tSAPHanaClose

Closes a connection to a SAP Hana database.

**tSAPHanaClose Standard properties**

These properties are used to configure tSAPHanaClose running in the Standard Job framework.

The Standard tSAPHanaClose component belongs to the Databases family.

The component in this framework is available when you are using one of the Talend solutions with Big Data.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tSAPHanaConnection component in the list if more than one connection is planned for the current Job.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is to be used along with SAP Hana components, especially with tSAPHanaConnection and tSAPHanaCommit. |

**Related scenarios**

No scenario is available for the Standard version of this component yet.
tSAPHanaCommit

Commits in one go, using a unique connection, a global transaction instead of doing that on every row or every batch and thus provides gain in performance.

tSAPHanaCommit validates the data processed through the Job into the connected database.

**tSAPHanaCommit Standard properties**

These properties are used to configure tSAPHanaCommit running in the Standard Job framework.

The Standard tSAPHanaCommit component belongs to the Databases family.

The component in this framework is available when you are using one of the *Talend* solutions with Big Data.

**Note:**
This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see [Dynamic database components](#) on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tSAPHanaConnection component in the list if more than one connection is planned for the current Job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Warning:**
If you want to use a Row > Main connection to link tSAPHanaCommit to your Job, your data will be committed row by row. In this case, do not select the Close connection check box or your connection will be closed before the end of your first row commit.

**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is more commonly used with other tSAPHana* components, especially with the |
tSAPHanaCommit

| tSAPHanaConnection and tSAPHanaRollback components. Use this component if the Auto Commit option of the tSAPHanaConnection component is cleared. |

### Related scenario

For a related scenario, see Scenario: Inserting data in mother/daughter tables on page 2476.
tSAPHanaConnection

Establishes a SAP Hana connection to be reused by other SAP Hana components in your Job. tSAPHanaConnection opens a connection to the database for a current transaction.

tSAPHanaConnection Standard properties

These properties are used to configure tSAPHanaConnection running in the Standard Job framework. The Standard tSAPHanaConnection component belongs to the Databases and the ELT families. The component in this framework is available when you are using one of the Talend solutions with Big Data.

Note:
This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
<tr>
<td>DB Version</td>
<td>Select the SAP Hana Database (HDB) version you are using.</td>
</tr>
<tr>
<td>Host</td>
<td>Database server IP address.</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of database server.</td>
</tr>
<tr>
<td>Table Schema</td>
<td>Name of the database schema.</td>
</tr>
</tbody>
</table>
| Username and Password | Database authentication data.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| Additional JDBC Parameters | Specify additional connection properties in the database connection you are creating. |

Advanced settings

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
</table>
| Auto Commit    | Select this check box to commit any changes to the database automatically upon the transaction.  
With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and |
changes must be committed explicitly using the corresponding commit component.

Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component.

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

**Usage**

| Usage rule | This component is more commonly used with other tSAP* components, especially with the tSAPHanaCommit and tSAPHanaRollback components. |

**Related scenarios**

No scenario is available for the Standard version of this component yet.
tSAPHanaInput

Executes a database query with a defined command which must correspond to the schema definition. tSAPHanaInput reads a database and extracts fields based on a query. Then it passes on rows to the next component via a Main row link.

**tSAPHanaInput Standard properties**

These properties are used to configure tSAPHanaInput running in the Standard Job framework. The Standard tSAPHanaInput component belongs to the Databases family.

The component in this framework is available when you are using one of the Talend solutions with Big Data.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td><strong>Note:</strong></td>
<td>When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:</td>
</tr>
<tr>
<td></td>
<td>1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.</td>
</tr>
<tr>
<td></td>
<td>2. In the child level, use a dedicated connection component to read that registered database connection.</td>
</tr>
<tr>
<td>DB Version</td>
<td>Select the SAP Hana Database (HDB) version you are using.</td>
</tr>
<tr>
<td>Host</td>
<td>Database server IP address.</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of database server.</td>
</tr>
<tr>
<td>----------</td>
<td>-----------------------------------------</td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>Name of the database schema.</td>
</tr>
</tbody>
</table>
| **Username and Password** | Database authentication data.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. |
| | **Built-in**: The schema is created and stored locally for this component only. For more information, see Talend Studio User Guide. |
| | **Repository**: The schema already exists and is stored in the Repository, hence can be reused. For more information, see Talend Studio User Guide. |
| | Click **Edit schema** to make changes to the schema. If the current schema is of the Repository type, three options are available:  
• **View schema**: choose this option to view the schema only.  
• **Change to built-in property**: choose this option to change the schema to Built-in for local changes.  
• **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the [Repository Content] window. |
| **Table Name** | Name of the table to be written. Note that only one table can be written at a time. |
| **Query Type** | Either Built-in or Repository. |
| | **Built-in**: Fill in manually the query statement or build it graphically using SQLBuilder. |
| | **Repository**: Select the relevant query stored in the Repository. The Query field gets accordingly filled in. |
| **Guess Query** | Click the Guess Query button to generate the query which corresponds to your table schema in the Query field. |
| **Guess schema** | Click the Guess schema button to retrieve the table schema. |
Query

Enter your database query paying particularly attention to properly sequence the fields in order to match the schema definition.

Advanced settings

<table>
<thead>
<tr>
<th><strong>Additional JDBC Parameters</strong></th>
<th>Specify additional connection properties in the database connection you are creating. This option is not available if you have selected Use an existing connection check box in the Basic settings.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Trim all the String/Char columns</strong></td>
<td>Select this check box to remove leading and trailing whitespaces from all the String/Char columns.</td>
</tr>
</tbody>
</table>
| **Trim column** | Remove leading and trailing whitespaces from defined columns.  

**Note:**  
Clear Trim all the String/Char columns check box to enable this option. |
| **tStatCatcher Statistics** | Select this check box to collect log data at the component level. |

Global Variables

| **Global Variables** | **NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.  
**QUERY**: the query statement being processed. This is a Flow variable and it returns a string.  
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.  
For further information about variables, see Talend Studio User Guide. |

Usage

| **Usage rule** | This component is standalone as it includes the SAP Hana engine. This is a startable component that can initiate a data flow processing. |
| **Dynamic settings** | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple |
connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenarios

No scenario is available for the Standard version of this component yet.
tSAPHanaOutput

Executes the action defined on the table and/or on the data contained in the table, based on the flow incoming from the preceding component in the Job.

tSAPHanaOutput writes, updates, makes changes or suppresses entries in a SAP Hana database.

**tSAPHanaOutput Standard properties**

These properties are used to configure tSAPHanaOutput running in the Standard Job framework.

The component in this framework is available when you are using one of the Talend solutions with Big Data.

**Note:**
This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see [Dynamic database components](#) on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined. <strong>Note:</strong> When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to: 1. In the parent level, register the database connection to be shared in the <strong>Basic settings</strong> view of the connection component which creates that very database connection. 2. In the child level, use a dedicated connection component to read that registered database connection. For an example about how to share a database connection across Job levels, see <a href="#">Talend Studio User Guide</a>.</td>
</tr>
<tr>
<td>DB Version</td>
<td>Select the SAP Hana Database (HDB) version you are using.</td>
</tr>
<tr>
<td>Host</td>
<td>Database server IP address.</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of database server.</td>
</tr>
<tr>
<td>----------</td>
<td>------------------------------------------</td>
</tr>
<tr>
<td><strong>Table Schema</strong></td>
<td>Name of the database schema.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>Database authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td><strong>Table</strong></td>
<td>Name of the table to be written. Note that only one table can be written at a time.</td>
</tr>
</tbody>
</table>
| **Action on table** | On the table defined, you can perform one of the following operations:  
  - **None**: No operation is carried out.  
  - **Drop and create table**: The table is removed and created again.  
  - **Create table**: The table does not exist and gets created.  
  - **Create table if not exists**: The table is created if it does not exist.  
  - **Drop table if exists and create**: The table is removed if it already exists and created again.  
  - **Clear table**: The table content is deleted. |
| **Type of table storage** | This option is only available if you create (with or without drop) the database table. This option allows you to define the way the data is stored in the table. The following types of table storage organization are available:  
  - **Row**: Data is stored in rows. It is preferable to use this table type if the majority of table access involves selecting a few records, with all attributes selected.  
  - **Column**: Data is stored in columns. It is preferable to use this table type if the majority of table access will be through a large number of tuples, with only a few selected attributes.  
  - **History column**: Creates a table with a particular transaction session type called HISTORY. Tables with session type HISTORY support time travel queries. For more information on HISTORY and time travel queries, see [http://help.sap.com/saphelp_hanaplatform/helpdata/en/20/d56cd075191014b7ea9e4e77477aae/content.htm](http://help.sap.com/saphelp_hanaplatform/helpdata/en/20/d56cd075191014b7ea9e4e77477aae/content.htm).  
  - **Global temporary**: The table definition and data can be seen by any user and any connection during the current session. The table is truncated at the end of the session.  
  - **Local temporary**: The table definition and data can only be seen by the user who created the table. |
| Action on data | On the data of the table defined, you can perform: 
**Insert**: Add new entries to the table. If duplicates are found, the Job stops. 
**Update**: Make changes to existing entries. 
**Insert or update**: Insert a new record. If the record with the given reference already exists, an update would be made. 
**Update or insert**: Update the record with the given reference. If the record does not exist, a new record would be inserted. 
**Delete**: Remove entries corresponding to the input flow. 

Note that it is necessary to specify at least one column as a primary key on which the **Update** and **Delete** operations are based. You can do that by clicking **Edit Schema** and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, see **Use filed options** in the **Advanced settings** view. |

| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word **line** when naming the fields. 

**Built-In**: You create and store the schema locally for this component only. Related topic: see **Talend Studio User Guide**. 

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see **Talend Studio User Guide**. 

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually. 

You can find more details about how to verify default values in retrieved schema in Talend Help Center [https://help.talend.com](https://help.talend.com). |

|  | Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available: |
|  | • **View schema**: choose this option to view the schema only. |
|  | • **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes. |
|  | • **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate |
the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.

<table>

</table>

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_LINE: the number of rows processed. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>NB_LINE_UPDATED: the number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>NB_LINE_INSERTED: the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>NB_LINE_DELETED: the number of rows deleted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>NB_LINE_REJECTED: the number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>QUERY: the query statement processed. This is an After variable and it returns a string.</td>
</tr>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component must be connected to an Input component. It allows you to carry out actions on a table or on the data of a table in an SAP Hana database. It also allows you to create reject flows using a Row &gt; Reject link to filter erroneous data.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic settings</td>
<td>Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having</td>
</tr>
</tbody>
</table>
the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see **Scenario: Reading data from databases through context-based dynamic connections** on page 2497 and **Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters** on page 489. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

---

**Related scenarios**

No scenario is available for the Standard version of this component yet.
tSAPHanaRollback

Avoids to commit part of a transaction involuntarily.

`tSAPHanaRollback` cancels the transaction in the connected database.

`tSAPHanaRollback Standard properties

These properties are used to configure `tSAPHanaRollback` running in the Standard Job framework.

The Standard `tSAPHanaRollback` component belongs to the Databases family.

The component in this framework is available when you are using one of the `Talend` solutions with Big Data.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the <code>tSAPHanaConnection</code> component in the list if more than one connection is planned for the current Job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is more commonly used with other `tSAPHana*` components, especially with the `tSAPHanaConnection` and `tSAPHanaCommit` components. |

**Related scenarios**

No scenario is available for the Standard version of this component yet.
tSAPHanaRow

Acts on the actual database structure or on the data (although without handling data).

tSAPHanaRow is the specific component for this database query. It executes the SQL query stated onto the specified database. The row suffix means the component implements a flow in the Job design although it does not provide output.

The SQLBuilder tool helps you write easily your SQL statements.

**tSAPHanaRow Standard properties**

These properties are used to configure tSAPHanaRow running in the Standard Job framework.

The Standard tSAPHanaRow component belongs to the Databases family.

The component in this framework is available when you are using one of the *Talend* solutions with Big Data.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see *Dynamic database components* on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
</table>
| Use an existing connection | Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined.

**Note:**

When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.

2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

**Advanced settings**

| **Additional JDBC Parameters** | Specify additional connection properties in the database connection you are creating. This option is not available if you have selected Use an existing connection check box in the Basic settings. |
| **Propagate QUERY’s recordset** | Select this check box to insert the result of the query into a column of the current flow. Select this column from the use column list. |

**Note:**
This option allows the component to have a different schema from that of the preceding component. Moreover, the column that holds the QUERY’s recordset should be set to the type of Object and this component is usually followed by tParseRecordSet. |

| **Commit every** | Number of rows to be completed before committing batches of rows together into the database. This option ensures transaction quality (but not rollback) and above all better performance on executions. |
| **Use PreparedStatement** | Select this check box if you want to query the database using a PreparedStatement. In the Set PreparedStatement Parameter table, define the parameters represented by “?” in the SQL instruction of the Query field in the Basic Settings tab. |

**Parameter Index:** Enter the parameter position in the SQL instruction. |

**Parameter Type:** Enter the parameter type. |

**Parameter Value:** Enter the parameter value. |

**Note:**
This option is very useful if you need to execute the same query several times. Performance levels are increased.
**tStatCatcher Statistics**

Select this check box to collect log data at the component level.

---

### Global Variables

**Global Variables**

- **QUERY**: the query statement being processed. This is a Flow variable and it returns a string.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

---

### Usage

**Usage rule**

This component offers the flexibility of the database query and covers all possible SQL queries.

---

### Related scenarios

No scenario is available for the Standard version of this component yet.
tSasInput

Executes a DB query with a strictly defined statement which must correspond to the schema definition.

⚠️ **Warning:**

*Before being able to benefit from all functional objectives of the SAS components, make sure to install the following three modules: sas.core.jar, sas.intrnet.javatools.jar and sas.svc.connection.jar in the path lib > java in your Talend Studio directory. You can later verify, if needed whether the modules are successfully installed through the Modules view of the Studio.*

tSasInput reads a database and extracts fields based on a query. Then it passes on the field list to the component that follows via a **Row > Main** connection.

**tSasInput Standard properties**

These properties are used to configure tSasInput running in the Standard Job framework.

The Standard tSasInput component belongs to the Databases family.

The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either <strong>Built-in</strong> or <strong>Repository</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-in</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

![icon]

Click this icon to open a database connection wizard and store the database connection parameters you set in the component **Basic settings** view.

For more information about setting up and storing database connection parameters, see *Talend Studio User Guide*.

**Host name**

SAS server IP address.

**Port**

Listening port number of server.

**Librefs**

Enter the directory name that holds the table to read followed by its access path. For example: `C:/SAS/TpSas`.

**Username** and **Password**

DB user authentication data.

To enter the password, click the `(...)` button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.
## Schema and Edit Schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

### Built-in

The schema is created and stored locally for this component only. Related topic: see *Talend Studio User Guide*.

### Repository

The schema already exists and is stored in the Repository, hence can be reused. Related topic: see *Talend Studio User Guide*.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.

## Table Name

Enter the name of the table to read preceded by the directory name that holds it. For example: "TpSas.Customers".

## Query type

The query can be **Built-in** for a particular job, or for commonly used query, it can be stored in the **Repository** to ease the query reuse.

## Query

If your query is not stored in the Repository, type in your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.

## Advanced settings

**tStatCatcher Statistics**

Select this check box to gather the job processing metadata at a Job level as well as at each component level.

## Global Variables

**Global Variables**

- **NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.
- **QUERY**: the query statement being processed. This is a Flow variable and it returns a string.
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component covers all possible SQL queries for databases using SAS connections.</th>
</tr>
</thead>
</table>

### Limitation

- Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

### Related scenarios

For related topics, see:

- **Scenario**: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489.
tSasOutput

Executes the action defined on the table and/or on the data contained in the table, based on the incoming flow from the preceding component in the Job.

⚠️ Warning:

Before being able to benefit from all functional objectives of the SAS components, make sure to install the following three modules: sas.core.jar, sas.intrnet.javatools.jar and sas.svc.connection.jar in the path lib > java in your Talend Studio directory. You can later verify, if needed whether the modules are successfully installed through the Modules view of the Studio.

tSasOutput writes, updates, makes changes or suppresses entries in a database.

**tSasOutput Standard properties**

These properties are used to configure tSasOutput running in the Standard Job framework.
The Standard tSasOutput component belongs to the Databases family.
The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th><strong>Use an existing connection</strong></th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Note:</strong></td>
<td>When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:</td>
</tr>
<tr>
<td></td>
<td>1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.</td>
</tr>
<tr>
<td></td>
<td>2. In the child level, use a dedicated connection component to read that registered database connection.</td>
</tr>
<tr>
<td></td>
<td>For an example about how to share a database connection across Job levels, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

<p>| <strong>SAS URL</strong> | Enter the URL to connect to the desired DB. |
| <strong>Driver JAR</strong> | In the drop down list, select a desired available driver, or download one from a local directory through clicking the three-dot button. |
| <strong>Class Name</strong> | Type in the Class name to be pointed to in the driver. |</p>
<table>
<thead>
<tr>
<th><strong>Username and Password</strong></th>
<th>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Table</strong></td>
<td>Name of the table to read.</td>
</tr>
<tr>
<td><strong>Action on data</strong></td>
<td>On the data of the table defined, you can perform:</td>
</tr>
<tr>
<td></td>
<td><strong>Insert</strong>: Add new entries to the table. If duplicates are found, job stops.</td>
</tr>
<tr>
<td></td>
<td><strong>Update</strong>: Make changes to existing entries</td>
</tr>
<tr>
<td></td>
<td><strong>Insert or update</strong>: Insert a new record. If the record with the given reference already exists, an update would be made.</td>
</tr>
<tr>
<td></td>
<td><strong>Update or insert</strong>: Update the record with the given reference. If the record does not exist, a new record would be inserted.</td>
</tr>
<tr>
<td></td>
<td><strong>Delete</strong>: Remove entries corresponding to the input flow.</td>
</tr>
<tr>
<td></td>
<td><strong>Warning</strong>: It is necessary to specify at least one column as a primary key on which the <strong>Update</strong> and <strong>Delete</strong> operations are based. You can do that by clicking <strong>Edit Schema</strong> and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the <strong>Advanced settings</strong> view where you can simultaneously define primary keys for the <strong>Update</strong> and <strong>Delete</strong> operations. To do that: Select the <strong>Use field options</strong> check box and then in the <strong>Key in update column</strong>, select the check boxes next to the column names you want to use as a base for the <strong>Update</strong> operation. Do the same in the <strong>Key in delete column</strong> for the <strong>Delete</strong> operation.</td>
</tr>
<tr>
<td><strong>Clear data in table</strong></td>
<td>Select this check box to delete data in the selected table before any operation.</td>
</tr>
<tr>
<td><strong>Schema and Edit Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <strong>line</strong> when naming the fields.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-In</strong>: You create and store the schema locally for this component only. Related topic: see <strong>Talend Studio User Guide</strong>.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see <strong>Talend Studio User Guide</strong>.</td>
</tr>
</tbody>
</table>
| | When the schema to be reused has default values that are integers or functions, ensure that these default }
values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.

**Die on error**

This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a **Row > Rejects** link.

### Advanced settings

**Commit every**

Enter the number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and, above all, better performance at execution.

**Additional Columns**

This option is not offered if you create (with or without drop) the DB table. This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing.

- **Name**: Type in the name of the schema column to be altered or inserted as a new column.
- **SQL expression**: Type in the SQL statement to be executed in order to alter or insert the relevant column data.
- **Position**: Select **Before**, **Replace** or **After** following the action to be performed on the reference column.
- **Reference column**: Type in a column of reference that the **tSasOutput** can use to place or replace the new or altered column.

**Use field options**

Select this check box to customize a request, especially when there is double action on data.
Enable debug mode | Select this check box to display each step during processing entries in a database.

| tStatCatcher Statistics | Select this check box to collect log data at the component level.

Global Variables

| Global Variables | NB_LINE: the number of rows processed. This is an After variable and it returns an integer.
|                  | NB_LINE_UPDATED: the number of rows updated. This is an After variable and it returns an integer.
|                  | NB_LINE_INSERTED: the number of rows inserted. This is an After variable and it returns an integer.
|                  | NB_LINE_DELETED: the number of rows deleted. This is an After variable and it returns an integer.
|                  | NB_LINE_REJECTED: the number of rows rejected. This is an After variable and it returns an integer.
|                  | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

| Usage rule | This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible.
|           | This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in a SAS database. It also allows you to create a reject flow using a Row > Rejects link to filter data in error. For an example of tMySQLOutput in use, see Scenario: Retrieving data in error with a Reject link on page 2529.

Limitation

| Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find
Related scenarios

For scenarios in which `tSasOutput` might be used, see:

- **Scenario: Inserting a column and altering data using `tMysqlOutput`** on page 2521.
tSchemaComplianceCheck

Ensures the data quality of any source data against a reference data source.

tSchemaComplianceCheck validates all input rows against a reference schema or check types, nullability, length of rows against reference values. The validation can be carried out in full or partly.
# tSCPClose

Closes a connection to an SCP protocol. 
tSCPClose closes a connection to a fully encrypted channel.

## tSCPClose Standard properties

These properties are used to configure tSCPClose running in the Standard Job framework. 
The Standard tSCPClose component belongs to the Internet family. 
The component in this framework is generally available.

### Basic settings

<table>
<thead>
<tr>
<th>Component list</th>
<th>If there is more than one connection in the current Job, select tSCPConnection from the list.</th>
</tr>
</thead>
</table>

### Advanced settings

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
<th>Select this check box to gather the Job processing metadata at a Job level as well as at each component level.</th>
</tr>
</thead>
</table>

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide.</th>
</tr>
</thead>
</table>

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>tSCPClose is generally used as a start component. It requires an output component.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic settings</td>
<td>Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your SCP connection dynamically from multiple connections planned in your Job.</td>
</tr>
</tbody>
</table>
Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

### Related scenario

This component is closely related to **tSCPConnection** and **tSCPRollback**. It is generally used with **SCPConnection** as it allows you to close a connection for the transaction which is underway.

For a related scenario, see Scenario: handling a file using SCP on page 3492.
tSCPConnection

Opens an SCP connection to transfer files in one transaction.

**tSCPConnection Standard properties**

These properties are used to configure tSCPConnection running in the Standard Job framework.

The Standard tSCPConnection component belongs to the Internet family.

The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>Host</th>
<th>IP address of the SCP server.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of listening port of the SCP server.</td>
<td></td>
</tr>
<tr>
<td>User name for the SCP server.</td>
<td></td>
</tr>
<tr>
<td>SCP authentication method.</td>
<td></td>
</tr>
<tr>
<td>User password for the SCP server.</td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

**Global Variables**

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |
Usage

| Usage rule | This component is typically used as a single-component sub-job. It is used along with other SCP components. |

Related scenarios

For a related scenario, see Scenario: handling a file using SCP on page 3492.
tSCPDelete

Removes a file from the defined SCP server.
tSCPDelete deletes files from remote hosts over a fully encrypted channel.

**tSCPDelete Standard properties**

These properties are used to configure tSCPDelete running in the Standard Job framework.
The Standard tSCPDelete component belongs to the Internet family.
The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>

</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

**Global Variables**

- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.
- **FILENAME**: the name of the file being processed. This is a Flow variable and it returns a string.
- **STATUS**: the execution result of the component. This is an After variable and it returns a string.
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide.*

### Usage

| Usage rule | This component is typically used as a single-component sub-job but can also be used with other components. |

### Scenario: handling a file using SCP

In this scenario, a six-component Job checks if a defined file exists in a specified directory on a remote SCP server, and returns a message to indicate the result of the verification. If the file doesn’t exist in that directory, the Job will put the local file to the SCP server, and then get the file from the SCP server to another defined local directory to verify that the file has been uploaded correctly.
Dropping and linking the components

Procedure

1. Add the following six components by typing their names on the design workspace or dropping them from the Palette to the design workspace: `tSCPConnection`, `tSCPFileExists`, `tJava`, `tSCPPut`, `tSCPGet`, and `tSCPClose`.
2. Connect the `tSCPConnection` component to the `tSCPFileExists` component using a Trigger > On Subjob Ok connection.
3. Connect the `tSCPFileExists` component to the `tJava` component using a Trigger > On Component Ok connection, and to the `tSCPPut` component using a Trigger > Run if connection.
4. Connect the `tSCPPut` component to the `tSCPGet` component using a Trigger > On Subjob Ok connection.
5. Connect the `tSCPGet` component to the `tSCPClose` component using a Trigger > On Subjob Ok connection.

Configuring the `tSCPConnection` component

Procedure

1. Double-click the `tSCPConnection` component to open its Basic settings view.

   ![tSCPConnection_1](image)

2. Enter the host name or IP address of the SCP server and the port number in the corresponding field.
3. Enter the user name used for connection in the Username field.
4. Select Password from the Authentication method drop-down list.
5. Click the [...] button next to the Password text box, then in the pop-up [Enter a new password] dialog box, enter the password between double quotes and click OK to save the change.
### Configuring file existence verification

**Procedure**

1. Double-click the **tSCPFileExists** component to open its Basic settings view.

![Basic settings view of tSCPFileExists component](image)

2. Select the *Use an existing connection* check box and then select the connection you have configured from the Component List.

3. In the *Filename* field, enter the name of the file to be checked between double quotes. In this example, it is "testscp.txt".

4. Double-click the **Java** component to open its Basic settings view.

![Basic settings view of tJava component](image)

5. In the Code field, enter the following code:

```java
System.out.println((String)globalMap.get("tSCPFileExists_1_FILENAME").
System.out.println((String)globalMap.get("tSCPFileExists_1_STATUS");
```

6. Select the Component tab and click the **If** connection to open its Basic settings view.

![Basic settings view of If component](image)

7. In the Condition field, enter the following code:

```java
!((String)globalMap.get("tSCPFileExists_1_STATUS").equals("File exists.")
```

This way, if the file doesn't exist in the defined directory, the rest of the Job will be executed.

### Configuring the tSCPPut component

**Procedure**

1. Double-click the **tSCPPut** component to open its Basic settings view.
Select the **Use an existing connection** check box and then select the connection you have configured from the **Component List**.

3. Click the [+ ] button to add one row in the **Filelist** table, and enter the full local path of the file to be uploaded in the corresponding **Source** column. In this example, it is "D:/SCPPut/testscp.txt".

### Configuring the tSCPGet component

**Procedure**

1. Double-click the **tSCPGet** component to open its **Basic settings** view.

2. Select the **Use an existing connection** check box and then select the connection you have configured from the **Component List**.

3. In the **Local directory** field, enter or click the [...] button to browse to the directory under which the file will be stored. In this example, it is "D:/SCPGet".

4. Select **append** from the **Overwrite or Append** drop-down list.

5. Click the [+ ] button to add one row in the **Filelist** table, and then enter the path of the file to be retrieved from the SCP server in the corresponding **Source** column. In this example, it is "/testscp.txt".

### Configuring the tSCPClose component

**Procedure**

1. Double-click the **tSCPClose** component to open its **Basic settings** view.
2. Select the connection you have configured from the **Component List**.

**Executing the Job**

**Procedure**

1. Press **Ctrl+S** to save the Job.
2. Make sure the file *testscp.txt* exists in the local directory *D:/SCPPut*, and does not exist in the local directory *D:/SCPGet* and the home directory of the SCP server.
3. Press **F6** to run the Job.

The file verification information is displayed on the **Run** console.

4. Go to the local directory *D:/SCPGet* and the home directory of the SCP server, you will see the file *testscp.txt* there.
tSCPFileList

Lists files from the defined SCP server.
tSCPFileList iterates, over a fully encrypted channel, on files in a given directory on a remote host.

**tSCPFileList Standard properties**

These properties are used to configure tSCPFileList running in the Standard Job framework. The Standard tSCPFileList component belongs to the Internet family. The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specify the host name or IP address of the SCP server.</td>
<td></td>
</tr>
<tr>
<td>Specify the listening port number of the SCP server.</td>
<td></td>
</tr>
<tr>

<tr>
<td><strong>STARTTLS Support</strong></td>
<td>Select this check box to authenticate the server at the client side via a STARTTLS protocol.</td>
</tr>
<tr>
<td><strong>Importance</strong></td>
<td>Select in the list the priority level of your messages.</td>
</tr>
</tbody>
</table>
| **Need authentication / Username and Password** | Select this check box and enter a username and a password in the corresponding fields if this is necessary to access the service.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings. |
| **Die on error**       | This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. |

### Advanced settings

| **MIME subtype from the ‘text’ MIME type** | Select in the list the structural form for the text of the message. |
| **Encoding type** | Select the encoding from the list or select **Custom** and define it manually. |
| **tStatCatcher Statistics** | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

### Global Variables

**Global Variables**

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).
Usage

Usage rule

This component is typically used as one sub-job but can also be used as output or end object. It can be connected to other components with either Row or Iterate links.

Scenario: Email on error

This scenario creates a three-component Job which sends an email to defined recipients when an error occurs.

- Drop the following components from your Palette to the design workspace: tFileInputDelimited, tFileOutputXML, tSendMail.
- Define tFileInputDelimited properties. Related topic: tFileInputDelimited on page 1010.
- Right-click on the tFileInputDelimited component and select Row > Main. Then drag it onto the tFileOutputXML component and release when the plug symbol shows up.
- Define tFileOutputXML properties.
- Drag a Run on Error link from tFileDelimited to tSendMail component.
- Define the tSendMail component properties:
  - Enter the recipient and sender email addresses, as well as the email subject.
  - Enter a message containing the error code produced using the corresponding global variable. Access the list of variables by pressing Ctrl+Space.
  - Add attachments and extra header information if any. Type in the SMTP information.
In this scenario, the file containing data to be transferred to XML output cannot be found. *tSendmail* runs on this error and sends a notification email to the defined recipient.
tServerAlive

Validates the status of the connection to a specified host.

tServerAlive checkes whether the connection to a specified host is up or down, which is indicated by the boolean value returned by the global variable SERVER_ALIVE_RESULT.

**tServerAlive Standard properties**

These properties are used to configure tServerAlive running in the Standard Job framework.

The Standard tServerAlive component belongs to the Misc family.

The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Select either Ping or Telnet from the drop-down list of protocols.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>IP address or host name of the remote server to be checked.</td>
</tr>
<tr>
<td>Timeout Interval (in seconds)</td>
<td>Enter the timeout interval in seconds. If the target host is reached within this time, the component’s global variable SERVER_ALIVE_RESULT will be set to true, otherwise false.</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of the Telnet server. Available when Telnet is selected from the Protocol drop-down list.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

**Global Variables**

| Global Variables | SERVER_ALIVE_RESULT: the status of the connection to a remote host. This is an After variable and it returns a boolean.  
ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. |

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is generally used as a one-component subjob.</th>
</tr>
</thead>
</table>

**Scenario: Validating the status of the connection to a remote host**

In this scenario, **tServerAlive** is used to ping a remote host and the value of its global variable *SERVER_ALIVE_RESULT* is extracted to show the connection status.

**Dropping and linking components**

**Procedure**

1. Drop the following components from the **Palette** onto the design workspace: **tServerAlive**, **tFixedFlowInput**, and **tLogRow**.
2. Connect **tServerAlive** to **tFixedFlowInput** using a **Trigger > On Subjob Ok** connection.
3. Connect **tFixedFlowInput** to **tLogRow** using a **Row > Main** connection.

**Configuring the components**

**Procedure**

1. Double-click **tServerAlive** to open its **Basic settings** view.
2. In the Protocol drop-down list, select **Ping**.
3. In the Host field, enter the IP address of the remote server to ping.
4. In the Timeout Interval field, enter the timeout interval in seconds.
5. Double-click **tFixedFlowInput** to open its Basic settings view.

6. Click the [...] button next to **Edit schema** to open the schema editor.

7. Click the [+•] button to add one column, namely **status**, of the boolean type. Click **OK** to validate the schema and close the editor.
   In the dialog box that appears, click **Yes** to propagate the changes to the subsequent component.
8. In the Values table, press the Ctrl + Space keys in the Value field to select **tServerAlive_1_SERVER_ALIVE_RESULT** from the variable list.
9. Double-click **tLogRow** to open its **Basic settings** view.

10. Select **Table (print values in cells of a table)** for a better display of the results.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl+S** to save your Job.
2. Press **F6** to execute the Job.

```
[statistics] connecting to socket on port 3516
[statistics] connected

|tLogRow_1|
|status:
|true|
```

**Results**

As shown above, the remote server is pingable.
**tServiceNowConnection**

Opens a connection to a ServiceNow instance that can then be reused by other ServiceNow components.

**tServiceNowConnection Standard properties**

These properties are used to configure tServiceNowConnection running in the Standard Job framework.

The Standard tServiceNowConnection component belongs to the Business and the Cloud families.

The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>URL</th>
<th>Enter the URL of the ServiceNow instance to be connected.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Username and Password</strong></td>
<td>Enter the user authentication data to connect to the ServiceNow instance.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press <strong>Ctrl + Space</strong> to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td></td>
<td>For further information about variables, see <strong>Talend Studio User Guide</strong>.</td>
</tr>
</tbody>
</table>
Usage

| Usage rule | This component is more commonly used with other ServiceNow components. |

Related scenario

No scenario is available for the Standard version of this component yet.
**tServiceNowInput**

Accesses ServiceNow and retrieves data from it.

*tServiceNowInput* retrieves data from ServiceNow according to the specified conditions.

**tServiceNowInput Standard properties**

These properties are used to configure *tServiceNowInput* running in the Standard Job framework.

The Standard *tServiceNowInput* component belongs to the Business and the Cloud families.

The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>Use Existing Connection</th>
<th>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Note:</strong></td>
<td>When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:</td>
</tr>
<tr>
<td></td>
<td>1. In the parent level, register the database connection to be shared in the <strong>Basic settings</strong> view of the connection component which creates that very database connection.</td>
</tr>
<tr>
<td></td>
<td>2. In the child level, use a dedicated connection component to read that registered database connection.</td>
</tr>
<tr>
<td></td>
<td>For an example about how to share a database connection across Job levels, see <em>Talend Studio User Guide</em>.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>URL</strong></th>
<th>Enter the URL of the ServiceNow instance to be connected.</th>
</tr>
</thead>
</table>

| **Username and Password** | Enter the user authentication data to connect to the ServiceNow instance. |
|                          | To enter the password, click the […] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |

| **Table**                | Select the name of the table from which the data will be retrieved or select **Use Custom Table** and in the **Custom Table Name** field displayed enter the table name. |

| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the |
next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

- **Built-In**: You create and store the schema locally for this component only. Related topic: see *Talend Studio User Guide*.

- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see *Talend Studio User Guide*.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.

- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.

- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **[Repository Content]** window.

### Conditions

Specify search conditions to retrieve only the data that matches the criteria by clicking the **[+]** button to add as many conditions as needed and then setting the following parameters for each condition:

- **Input column**: click in the cell and select the column of the input schema on which the search condition is to be set.

- **Operator**: click in the cell and select an operator for the search condition.

- **Value**: enter the value for the corresponding column for the search condition.

### Advanced settings

<table>
<thead>
<tr>
<th><strong>Trim all columns</strong></th>
<th>Select this check box to remove the leading and trailing whitespaces from all columns.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Limit</strong></td>
<td>Enter the maximum number of records to be retrieved.</td>
</tr>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to gather the Job processing metadata at the Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

### Global Variables

<table>
<thead>
<tr>
<th><strong>Global Variables</strong></th>
<th><strong>NB_LINE</strong>: the number of rows processed. This is an After variable and it returns an integer.</th>
</tr>
</thead>
</table>
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

---

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is usually used as a start component in a <strong>Talend</strong> flow and it requires an output component.</th>
</tr>
</thead>
</table>

#### Dynamic settings

Click the **[+]** button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see *Scenario: Reading data from databases through context-based dynamic connections* on page 2497 and *Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters* on page 489. For more information on **Dynamic settings** and context variables, see *Talend Studio User Guide*.

---

### Related scenario

No scenario is available for the Standard version of this component yet.
tServiceNowOutput

Performs the defined action on the data on ServiceNow.
tServiceNowOutput inserts or updates data on ServiceNow.

**tServiceNowOutput Standard properties**

These properties are used to configure tServiceNowOutput running in the Standard Job framework. The Standard tServiceNowOutput component belongs to the Business and the Cloud families. The component in this framework is generally available.

**Basic settings**

<table>

<td>• <strong>Update</strong>: update existing data in ServiceNow.</td>
</tr>
</tbody>
</table>
### Table

Select the name of the table to be written or select **Use Custom Table** and in the **Custom Table Name** field displayed enter the table name.

### Schema and Edit schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

- **Built-In**: You create and store the schema locally for this component only. Related topic: see [Talend Studio User Guide](#).
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see [Talend Studio User Guide](#).

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **[Repository Content](#)** window.

### Advanced settings

<table>
<thead>
<tr>
<th>Enable payload debug mode</th>
<th>Select this check box to enable the payload debug mode and logging for the payload of the request message.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable response debug mode</td>
<td>Select this check box to enable the response debug mode and logging for the response message from the log server.</td>
</tr>
<tr>
<td>tStatCatcher Statistics</td>
<td>Select this check box to gather the Job processing metadata at the Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th><strong>NB_LINE</strong></th>
<th>the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>NB_LINE_INSERTED</strong></td>
<td>the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td><strong>NB_LINE_UPDATED</strong></td>
<td>the number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
</tbody>
</table>
**NB_LINE_REJECTED**: the number of rows rejected. This is an After variable and it returns an integer.

**PAYLOAD**: the payload of the JSON request message. This is a Flow variable and it returns an object.

**RESPONSE**: the response message from the log server. This is a Flow variable and it returns an object.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

---

### Usage

<table>
<thead>
<tr>
<th><strong>Usage rule</strong></th>
<th>This component is usually used as an end component in a Talend flow and it requires an input component.</th>
</tr>
</thead>
</table>

#### Dynamic settings

Click the [+ ] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

---

### Related scenario

No scenario is available for the Standard version of this component yet.
tSetEnv

Adds variables temporarily to system environment during the execution of a Job.

tSetEnv creates variables and execute a Job script through communicating the information about the newly created variables between subjobs. After job execution, the newly created variables are deleted.

### tSetEnv Standard properties

These properties are used to configure tSetEnv running in the Standard Job framework.

The Standard tSetEnv component belongs to the System family.

The component in this framework is generally available.

#### Basic settings

<table>
<thead>

</thead>
</table>

#### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>tSetEnv can be used as a start or an intermediate component.</th>
</tr>
</thead>
</table>
Scenario: Modifying a variable during a Job execution

The following scenario is made of two Jobs parent and child. With the tSetEnv component, you can transfer and modify in a child Job a value created in a parent Job. As part of this Job, the tMsgBox components allow you to display, for information purposes only, that a variable is properly set, via an info-box.

To modify the value of the parent Job by using a variable set in the tSetEnv component, do as described in the following sections:

Drop and link components

Procedure

1. Create a first Job named parentJob: right-click on the Job Design node of the Repository, and choose Create a Job.
2. From the Palette, drop a tSetEnv component, two tMsgBox components, and one tRunJob component onto the design workspace.
3. Connect the tSetEnv component to a first tMsgBox component with a OnSubjobOk link : right-click on the start component, select Trigger, then OnSubjobOk. Then click on the end component you want to connect.
4. Connect the first tMsgBox component to the tRunJob with a OnSubjobOk link.
5. Then connect the tRunJob component to the second tMsgBox with a OnSubjobOk link.

![Diagram of Job design](image)

7. From the Palette, drop a tSetEnv component onto the design workspace.
8. Connect the tSetEnv component to the tMsgBox with a OnSubjobOk link: right-click on the start component, select Trigger, then OnSubjobOk. Then click on the end component you want to connect.
Set the components

About this task

In this example, the value set in the parent Job is transferred to the child Job. There, it is modified and adopts the value of the child Job, and then transferred to the parent Job again.

Procedure

1. In parentJob, select the tSetEnv component and click the Component tab. Add a variable row by clicking the [+ ] button to set the initial value of the variable. Type Variable_1 in the Name field, and Parent job value in the Value field.

2. Select the first tMsgBox component, and click the Component tab. In the Message field, type the message displayed in the info-box which confirms that your variable has properly been taken into account. For example: "Parent:"+System.getProperty("Variable_1") displays the variable set in the tSetEnv component (here Parent job value).

3. Select the second tMsgBox component, and click the Component tab. In the Message field, type the "Parent:"+System.getProperty("Variable_1") line again. It makes the variable set in the child Job appear.

4. Select the tRunJob component and click the Component tab. In the Job field, type the name of your child Job, here ChildJob. This will run the child Job when you run the parent Job.

5. Now double-click the tRunJob component to open the child Job ChildJob.
6. Select the **tSetEnv** component, and click the **Component** tab. Add a variable row by clicking the [+ button to set the initial value of the variable. Type **Variable_1** in the **Name** field, and **Child job value** in the **Value** field.

7. Select the **tMsgBox** component and click the **Component** tab. In the **Message** field, type the message displayed in the info-box which confirms that your variable has properly been taken into account. For example: "Son:"+System.getProperty("Variable_1") displays the variable set in the **tSetEnv** component (here **Child job value**).

<table>
<thead>
<tr>
<th>Title</th>
<th>&quot;Talend Open Studio&quot;</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Buttons</strong></td>
<td>OK</td>
</tr>
<tr>
<td><strong>Icon</strong></td>
<td>Icon Information</td>
</tr>
<tr>
<td><strong>Message</strong></td>
<td>&quot;Son:&quot;+System.getProperty(&quot;Variable_1&quot;)</td>
</tr>
</tbody>
</table>

8. Save your Job, go back to *parentJob*, then run the Job by pressing **F6**.

**Run the Job**

Three info-boxes are displayed one after the other:

- **Parent: Parent job value**: parent Job’s value is **Parent job value**.
- **Child: Child job value**: Child Job’s value is **Child job value**.
- **Parent: Child job value**: parent Job’s value was modified by the variable set in the **tSetEnv** of the child Job, then transferred again to the parent Job. parent Job’s value is now the one set in the child Job.
tSetGlobalVar

Facilitates the process of defining global variables.
tSetGlobalVar allows you to define and set global variables in GUI.

**tSetGlobalVar Standard properties**

These properties are used to configure tSetGlobalVar running in the Standard Job framework.
The Standard tSetGlobalVar component belongs to the Custom Code family.
The component in this framework is generally available.

**Basic settings**

| Variables | This table contains two columns.  
| Key: Name of the variable to be called in the code.  
| Value: Value assigned to this variable. |

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

**Global Variables**

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
| A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
| To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
| For further information about variables, see **Talend Studio User Guide**. |

**Usage**

| Usage rule | This component is generally used as a one-component subjob. |
| Limitation | Knowledge of Java language is required. |
**Scenario: Printing out the content of a global variable**

This scenario is a simple Job that prints out the value of a global variable defined in the `tSetGlobalVar` component.

**Setting up the Job**

**Procedure**

1. Drop the following components from the **Palette** onto the design workspace: `tSetGlobalVar` and `tJava`.
2. Connect the `tSetGlobalVar` component to the `tJava` component using a **Trigger > OnSubjobOk** connection.

**Configuring the tSetGlobalVar component**

**Procedure**

1. Double-click the `tSetGlobalVar` component to display its **Basic settings** view.

2. Click the plus button to add a line in the **Variables** table, and fill the **Key** and **Value** fields with `K1` and `20` respectively.

3. Then double-click the `tJava` component to display its **Basic settings** view.

Code:

```java
String foo = "bar";
String K1;
String Result = "The value is:";
Result = Result +
globalMap.get("K1");
System.out.println(Result);
```
4. In the **Code** area, type in the following lines:

```java
String foo = "bar";
String K1;
String Result = "The value is:";

Result = Result + globalMap.get("K1");

System.out.println(Result);
```

In this use case, we use the *Result* variable. To access the global variable list, press **Ctrl + Space** bar on your keyboard and select the relevant global parameter.

**Job execution**

Save your Job and press **F6** to execute it.

The content of global variable *K1* is displayed on the console.

```
Starting job SetGlobalVar at 16:22 25/02/2011
[statistics] connecting to socket on port 3489
[statistics] connected
The value is:20
[statistics] disconnected
Job SetGlobalVar ended at 16:22 25/02/2011.
[exit code=0]
```
tSetKerberosConfiguration

Sets the relevant information for Kerberos authentication.

tSetKerberosConfiguration is designed to configure Kerberos authentication for enhanced security of network communications.

For more information on the Kerberos protocol, go to [http://www.kerberos.org](http://www.kerberos.org).

### tSetKerberosConfiguration Standard properties

These properties are used to configure tSetKerberosConfiguration running in the Standard Job framework.

The Standard tSetKerberosConfiguration component belongs to the Internet family.

The component in this framework is generally available.

#### Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>KDC Server</strong></td>
<td>Address of the Key Distribution Center (KDC) server.</td>

<td><strong>tSetKerberosConfiguration</strong> cannot work with IBM JVM.</td>
</tr>
</tbody>
</table>

**Related scenarios**

No scenario is available for the Standard version of this component yet.
tSetKeystore

Sets the authentication data type between **PKCS 12** and **JKS**.

$tSetKeystore$ submits authentication data of a truststore with or without keystore to validation for the SSL connection.

### tSetKeystore Standard properties

These properties are used to configure $tSetKeystore$ running in the Standard Job framework.

The Standard $tSetKeystore$ component belongs to the Internet family.

The component in this framework is generally available.

#### Basic settings

<table>
<thead>
<tr>
<th><strong>TrustStore type</strong></th>
<th>Select the type of the TrustStore to be used. It may be <strong>PKCS 12</strong> or <strong>JKS</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>TrustStore file</strong></td>
<td>Type in the path, or browse to the certificate TrustStore file (including filename) that contains the list of certificates that the client trusts.</td>
</tr>
<tr>
<td><strong>TrustStore password</strong></td>
<td>Type in the password used to check the integrity of the TrustStore data.</td>
</tr>
<tr>
<td><strong>Need Client authentication</strong></td>
<td>Select this check box to validate the keystore data. Once doing so, you need complete three fields:</td>
</tr>
<tr>
<td></td>
<td>- <strong>KeyStore type</strong>: select the type of the keystore to be used. It may be <strong>PKCS 12</strong> or <strong>JKS</strong>.</td>
</tr>
<tr>
<td></td>
<td>- <strong>KeyStore file</strong>: type in the path, or browse to the file (including filename) containing the keystore data.</td>
</tr>
<tr>
<td></td>
<td>- <strong>KeyStore password</strong>: type in the password for this keystore.</td>
</tr>
<tr>
<td><strong>Check server identity</strong></td>
<td>Select this check box to make the Job verify the match between the hostname of the URL and the hostname of the server. If they mismatch, the verification mechanism asks whether this connection should be allowed.</td>
</tr>
</tbody>
</table>

#### Advanced settings

| **tStatCatcher Statistics** | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

#### Global Variables

| **Global Variables** | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions |
only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is used standalone.</th>
</tr>
</thead>
</table>

### Connections

**Outgoing links (from this component to another):**

- **Trigger:** Run if; On Subjob Ok, On Subjob Error, On Component Ok; On Component Error.

**Incoming links (from one component to this one):**

- **Trigger:** Run if, On Subjob Ok, On Component Ok, On Component Error.

For further information regarding connections, see *Talend Studio User Guide*.

### Limitation

n/a.

### Scenario: Extracting customer information from a private WSDL file

This scenario describes a three-component Job that connects to a private WSDL file in order to extract customer information.

The WSDL file used in this Job accesses the corresponding web service under the SSL protocol. For this purpose, the most relative code in this file reads as follows:

```xml
<wsdl:port name="CustomerServiceHttpSoap11Endpoint" binding="ns:CustomerServiceSoap11Binding">
</wsdl:port>
```

Accordingly, we enter the following code in the *server.xml* file of Tomcat:

```xml
<Connector port="8443" protocol="HTTP/1.1" SSLEnabled="true"
  maxThreads="150" scheme="https" secure="true"
  clientAuth="true" sslProtocol="TLS"
  keystoreFile="D:/server.keystore" keystorePass="password"
  keystoreType="JKS"
  truststoreFile="D:/server.p12" truststorePass="password"
  truststoreType="PKCS12" />
```
So we need keystore files to connect to this WSDL file. To replicate this Job, proceed as follows:

- Drop the following components from the Palette onto the design workspace: tSetKeystore, tWebService, and tLogRow.

- Right-click tSetKeystore to open its contextual menu.
- In this menu, select Trigger > On Subjob Ok to connect this component to tWebService.
- Right-click tWebService to open its contextual menu.
- In this menu, select Row > Main to connect this component to tLogRow.
- Double-click tSetKeystore to open its Basic settings view and define the component properties.

- In the TrustStore type field, select PKCS12 from the drop-down list.
- In the TrustStore file field, browse to the corresponding truststore file. Here, it is server.p12.
- In the TrustStore password field, type in the password for this truststore file. In this example, it is password.
- Select the Need Client authentication check box to activate the keystore configuration fields.
- In the KeyStore type field, select JKS from the drop-down list.
- In the KeyStore file field, browse to the corresponding keystore file. Here, it is server.keystore.
- Double-click tWebService to open the component editor, or select the component in the design workspace and in the Basic settings view, click the three-dot button next to Service configuration.
In the **WSDL** field, browse to the private WSDL file to be used. In this example, it is `CustomerService.wsdl`.

Click the refresh button next to the **WSDL** field to retrieve the WSDL description and display it in the fields that follow.

In the **Port Name** list, select the port you want to use, `CustomerServiceHttpSoap11Endpoint` in this example.

In the **Operation** list, select the service you want to use. In this example the selected service is `getCustomer(parameters):Customer`.

Click **Next** to open a new view in the editor.

In the panel to the right of the **Input mapping** view, the input parameter of the service displays automatically. However, you can add other parameters if you select `[+ parameters]` and then click the
The Web service in this example has only one input parameter, ID.

- In the Expression column of the parameters.ID row, type in the customer ID of your interest between quotation marks. In this example, it is A00001.
- Click Next to open a new view in the editor.

In the Element list to the left of the view, the output parameter of the web service displays automatically. However, you can add other parameters if you select [+ parameters] and then click the plus button on top to display the [Parameter Tree] dialog box where you can select any of the parameters listed.

The Web service in this example has four output parameter: return.address, return.email, return.name and return.phone.

You now need to create a connection between the output parameter of the defined Web service and the schema of the output component. To do so:

- In the panel to the right of the view, click the three-dot button next to Edit Schema to open a dialog box in which you can define the output schema.
In the schema editing dialog box, click the plus button to add four columns to the output schema.

Click in each column and type in the new names, Name, Phone, Email and Address in this example. This will retrieve the customer information of your interest.

Click OK to validate your changes and to close the schema editing dialog box.

In the Element list to the right of the editor, drag each parameter to the field that corresponds to the column you have defined in the schema editing dialog box.

**Note:**

If available, use the Auto map! button, located at the bottom left of the interface, to carry out the mapping operation automatically.

Click OK to validate your changes and to close the editor.

In the design workspace, double-click tLogRow to open its Basic settings view and define its properties.

Click Sync columns to retrieve the schema from the preceding component.

Save your Job and press F6 to execute it.

The information of the customer with ID A00001 is returned and displayed in the console of Talend Studio.

```
<table>
<thead>
<tr>
<th>name</th>
<th>phone</th>
<th>email</th>
<th>address</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rose Gonzalez</td>
<td>(512) 757-9000</td>
<td><a href="mailto:rose@edge.com">rose@edge.com</a></td>
<td>313 Constitution Place Austin, TX 78767 USA</td>
</tr>
</tbody>
</table>
```

Job tSetKeystore ended at 19:01 24/11/2010. [exit code=0]
tSetProxy

Sets the relevant information for proxy setup.

**tSetProxy Standard properties**

These properties are used to configure `tSetProxy` running in the Standard Job framework.

The Standard `tSetProxy` component belongs to the Internet family.

The component in this framework is generally available.

**Basic settings**

</table>
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

| Usage rule          | Typically used as a sub-job by itself. **tSetProxy** is deployed along with other Internet components. |

### Related scenarios

No scenario is available for the Standard version of this component yet.
tSleep

Identifies possible bottlenecks using a time break in the Job for testing or tracking purpose.
tSleep implements a time off in a Job execution. In production, it can be used for any needed pause in the Job to feed input flow for example.

**tSleep Standard properties**

These properties are used to configure tSleep running in the Standard Job framework.
The Standard tSleep component belongs to the Orchestration family.
The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>Pause (in second)</th>
<th>Time in second the Job execution is stopped for.</th>
</tr>
</thead>
</table>

**Global Variables**

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.  
For further information about variables, see Talend Studio User Guide. |
|------------------|--------------------------------------------------------------------------------|

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>tSleep component is generally used as a middle component to make a break/pause in the Job, before resuming the Job.</th>
</tr>
</thead>
</table>
| Connections | Outgoing links (from this component to another):  
**Row:** Main; Iterate.  
**Trigger:** On Subjob Ok; On Subjob Error; Run if; On Component Ok; On Component Error  
Incoming links (from one component to this one):  
**Row:** Main; Reject; Iterate.  
**Trigger:** On Subjob Ok; On Subjob Error; Run if; On Component Ok; On Component Error; Synchronize; Parallelize. |
Related scenarios

For use cases in relation with tSleep, see Procedure on page 1992.
tSnowflakeClose

Closes an active Snowflake connection to release the occupied resources.

**tSnowflakeClose Standard properties**

These properties are used to configure tSnowflakeClose running in the Standard Job framework.

The Standard tSnowflakeClose component belongs to the Cloud family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connection Component</td>
<td>Select the component that opens the connection you need to close from the drop-down list.</td>
</tr>
</tbody>
</table>

**Advanced settings**

<table>

</thead>
</table>

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is more commonly used with other Snowflake components, especially with the <strong>tSnowflakeConnection</strong> component.</th>
</tr>
</thead>
</table>

**Related scenario**

For a related scenario, see Writing data into and reading data from a Snowflake table on page 3548.
tSnowflakeConnection

Opens a connection to Snowflake that can then be reused by other Snowflake components.

**tSnowflakeConnection Standard properties**

These properties are used to configure tSnowflakeConnection running in the Standard Job framework. The Standard tSnowflakeConnection component belongs to the Cloud family. The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property Type</td>
<td>Select the way the connection details will be set.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Built-In</strong>: The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Repository</strong>: The connection details stored centrally in Repository &gt; Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up Repository Content dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in.</td>
</tr>
<tr>
<td>Account</td>
<td>In the <strong>Account</strong> field, enter, within double quotation marks, the name that has been assigned to you by Snowflake.</td>
</tr>
<tr>
<td>User Id and Password</td>
<td>Enter, within double quotation marks, your authentication information to log in Snowflake.</td>
</tr>
<tr>
<td></td>
<td>• In the <strong>User Id</strong> field, enter, within double quotation marks, your login name that has been defined in Snowflake using the LOGIN_NAME parameter of Snowflake. For details, ask the administrator of your Snowflake system.</td>
</tr>
<tr>
<td></td>
<td>• To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td><strong>Warehouse</strong></td>
<td>Enter, within double quotation marks, the name of the Snowflake warehouse to be used. This name is case-sensitive and is normally upper case in Snowflake.</td>
</tr>
<tr>
<td>---------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>Enter, within double quotation marks, the name of the database schema to be used. This name is case-sensitive and is normally upper case in Snowflake.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Enter, within double quotation marks, the name of the Snowflake database to be used. This name is case-sensitive and is normally upper case in Snowflake.</td>
</tr>
</tbody>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th><strong>Login Timeout</strong></th>
<th>Specify how long to wait for a response when connecting to Snowflake before returning an error.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Tracing</strong></td>
<td>Select the log level for the Snowflake JDBC driver. If enabled, a standard Java log is generated.</td>
</tr>
<tr>
<td><strong>Role</strong></td>
<td>Enter, within double quotation marks, the default access control role to use to initiate the Snowflake session. This role must already exist and has been granted to the user ID you are using to connect to Snowflake. If this field is left empty, the PUBLIC role is automatically granted. For further information about the Snowflake access control model, see Snowflake documentation at <a href="#">Understanding the Access Control Model</a>.</td>
</tr>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to gather the Job processing metadata at the Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

**Global variables**

| **ERROR_MESSAGE** | The error message generated by the component when an error occurs. This is an After variable and it returns a string.                                                                                   |

**Usage**

| **Usage rule** | This component is more commonly used with other Snowflake components. It creates a Snowflake connection and works with other Subjobs that reuse this connection using a Trigger link. |

**Related scenario**

For a related scenario, see [Writing data into and reading data from a Snowflake table](#) on page 3548.
tSnowflakeInput

Reads data from a Snowflake table into the data flow of your Job based on an SQL query.

**tSnowflakeInput Standard properties**

These properties are used to configure tSnowflakeInput running in the Standard Job framework.

The Standard tSnowflakeInput component belongs to the Cloud family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Property Type</strong></td>
<td>Select the way the connection details will be set.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Built-In</strong>: The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Repository</strong>: The connection details stored centrally in <strong>Repository &gt; Metadata</strong> will be reused by this component. You need to click the [...] button next to it and in the pop-up <strong>Repository Content</strong> dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in.</td>
</tr>
<tr>
<td></td>
<td>This property is not available when other connection component is selected from the <strong>Connection Component</strong> drop-down list.</td>
</tr>
<tr>
<td><strong>Connection Component</strong></td>
<td>Select the component that opens the database connection to be reused by this component.</td>
</tr>
<tr>
<td><strong>Account</strong></td>
<td>In the <strong>Account</strong> field, enter, within double quotation marks, the name that has been assigned to you by Snowflake.</td>
</tr>
<tr>
<td><strong>User Id</strong> and <strong>Password</strong></td>
<td>Enter, within double quotation marks, your authentication information to log in Snowflake.</td>
</tr>
<tr>
<td></td>
<td>• In the <strong>User ID</strong> field, enter, within double quotation marks, your login name that has been defined in Snowflake using the <strong>LOGIN_NAME</strong> parameter of Snowflake. For details, ask the administrator of your Snowflake system.</td>
</tr>
</tbody>
</table>
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

**Warehouse**
Enter, within double quotation marks, the name of the Snowflake warehouse to be used. This name is case-sensitive and is normally upper case in Snowflake.

**Schema**
Enter, within double quotation marks, the name of the database schema to be used. This name is case-sensitive and is normally upper case in Snowflake.

**Database**
Enter, within double quotation marks, the name of the Snowflake database to be used. This name is case-sensitive and is normally upper case in Snowflake.

**Table**
Click the [...] button and in the displayed wizard, select the Snowflake table to be used.

**Schema and Edit Schema**
A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

- **Built-In**: You create and store the schema locally for this component only. Related topic: see **Talend Studio User Guide**.

- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see **Talend Studio User Guide**.

If the Snowflake data type to be handled is VARIANT, OBJECT or ARRAY, while defining the schema in the component, select **String** for the corresponding data in the **Type** column of the schema editor wizard.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.

- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.

- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **[Repository Content]** window.

Note that if the input value of any non-nullable primitive field is null, the row of data including that field will be rejected.

**Manual query**
Select this check box and in the **Full SQL query string** field, enter, within double quotation marks, the query...
statement to be executed. For more explanations about the Snowflake SQL commands, see SQL Command Reference.

| Condition | Enter, within double quotation marks, the boolean expression to be used to filter data from your Snowflake table. This expression is actually used as WHERE clause in the SELECT query run by tSnowflakeInput. |

**Advanced settings**

| Login Timeout | Specify how long to wait for a response when connecting to Snowflake before returning an error. |
| Tracing | Select the log level for the Snowflake JDBC driver. If enabled, a standard Java log is generated. |
| Role | Enter, within double quotation marks, the default access control role to use to initiate the Snowflake session. This role must already exist and has been granted to the user ID you are using to connect to Snowflake. If this field is left empty, the PUBLIC role is automatically granted. For further information about the Snowflake access control model, see Snowflake documentation at Understanding the Access Control Model. |
| Convert columns and table to uppercase | Select this check box to convert lowercase in the defined table name and schema column names to uppercase. This property is not available when the Manual Query check box is selected. |
| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global Variables**

| NB_LINE | The number of rows processed. This is an After variable and it returns an integer. |
| ERROR_MESSAGE | The error message generated by the component when an error occurs. This is an After variable and it returns a string. |

**Usage**

| Usage rule | This component is start component of a data flow in your Job. It sends data to other components via a Row link. |
Writing data into and reading data from a Snowflake table

Here is an example of using Talend Snowflake components to connect to Snowflake, create a Snowflake table, write data into the table, then read data from this table, finally close the connection to Snowflake.

Creating a Job for writing and reading Snowflake data

Create a Job to connect to Snowflake, create a Snowflake table, write data into the table and then read data from the table, finally close the connection to Snowflake.

Before you begin

- The Snowflake data warehouse to be used is started but not in the Suspended status.
- The Snowflake role assigned to you has read and write permissions to the database to be connected.

If you are not sure about these requirements, ask the administrator of your Snowflake system.

Procedure

1. In the Integration perspective of the Studio, create a new Job from the Job Designs node in the Repository tree view.
2. Add a `tSnowflakeConnection` component, a `tSnowflakeRow` component, a `tFixedFlowInput` component, a `tSnowflakeOutput` component, a `tSnowflakeInput` component, a `tLogRow` component, and a `tSnowflakeClose` component to the Job.

3. Connect the `tFixedFlowInput` component to the `tSnowflakeOutput` component using a Row > Main connection.

4. Do the same to connect the `tSnowflakeInput` component to the `tLogRow` component.

5. Connect the `tSnowflakeConnection` component to the `tSnowflakeRow` component using a Trigger > On Subjob Ok connection.

6. Do the same to connect the `tSnowflakeRow` component to the `tFixedFlowInput` component, the `tFixedFlowInput` component to the `tSnowflakeInput` component, and the `tSnowflakeInput` component to the `tSnowflakeClose` component.

## Connecting to Snowflake

Configure the `tSnowflakeConnection` component to connect to Snowflake.

**Procedure**

1. Double-click the `tSnowflakeConnection` component to open its Basic settings view.
2. In the Account field, enter the account name assigned by Snowflake.
3. In the User Id and the Password fields, enter the authentication information accordingly.
   
   Note that this user ID is your user login name. If you do not know your user login name yet, ask the administrator of your Snowflake system for details.
4. In the Warehouse field, enter the name of the data warehouse to be used in Snowflake.
5. In the Schema field, enter the name of the database schema to be used.
6. In the Database field, enter the name of the database to be used.

## Creating a Snowflake table

Configure the `tSnowflakeRow` component to create a new table.

**Procedure**

1. Double-click the `tSnowflakeRow` component to open its Basic settings view on the Component tab.
2. From the Connection Component drop-down list, select the `tSnowflakeConnection` component to reuse the connection created by it. In this example, it is `tSnowflakeConnection_1`.
3. In the Query field, enter the SQL statement used to create a new table into which the data will be written.
   
   In this example, the following SQL statement is used to create or replace a table `EMPLOYEE` with four columns, `ID` of `INT` type, `NAME` of `VARCHAR` type, `ONBOARD` of `DATE` type, and `SALARY` of `VARIANT` type.

   ```sql
   "CREATE OR REPLACE TABLE EMPLOYEE (" +
   "ID INT NOT NULL primary key," +
   "NAME VARCHAR (50), " +
   "ONBOARD DATE," +
   "SALARY VARIANT" +
   ") COMMENT = 'Created By Doc Team'"
   ```
Writing data into Snowflake

Configure the tFixedFlowInput component and the tSnowflakeOutput component to write data into Snowflake.

Procedure

1. Double-click the tFixedFlowInput component to open its Basic settings view.

2. Click the [...] button next to Edit schema and in the pop-up schema dialog box, define the schema by adding four columns, ID of int type, NAME and SALARY of String type, and ONBOARD of Date type.

3. Click OK to validate these changes and accept the propagation prompted by the pop-up dialog box.

4. In the Number of rows field, enter the number of records to be generated, 5 in this example.

5. In the Mode area, select Use Single Table and specify the value for each column.

   - ID: the automatically incremented number generated by the routine Numeric.sequence("id",1,1).
   - NAME: the random first name generated by the routine TalendDataGenerator.getFirstName().
   - ONBOARD: the random date generated by the routine TalendDate.getRandomDate("2007-09-01","2017-09-01").
• SALARY: the semi-structured JSON data with the format "{"Salary": value}, where the salary value is generated by the routine Numeric.random(100000,200000).

6. Double-click the tSnowflakeOutput component to open its Basic settings view.
7. From the Connection Component drop-down list, select the tSnowflakeConnection component to reuse the connection created by it.
8. Click the [...] button next to the Table field and in the pop-up dialog box, select the Use custom object check box and enter the name of the table into which the data will be written in the Object Name field. In this example, it is EMPLOYEE, the table created by the tSnowflakeRow component. When done, click OK to close the dialog box.
9. From the Output action drop-down list, select Insert to write data to the table EMPLOYEE.

Reading data from Snowflake

Configure the tSnowflakelnput component and the tLogRow component to retrieve data from Snowflake and output the data on the console.

Procedure

1. Double-click the tSnowflakelnput component to open its Basic settings view.
2. From the Connection Component drop-down list, select the tSalesforceConnection component to reuse the connection created by it.
3. Click the [...] button next to the Table field and in the pop-up dialog box, select the Use custom object check box and enter the name of the table from which the data will be retrieved in the Object Name field. In this example, it is EMPLOYEE, the table created by the tSnowflakeRow component. When done, click OK to close the dialog box.
4. Click the [...] button next to Edit schema and in the pop-up schema dialog box, define the schema by adding four columns, ID of int type, NAME and SALARY of String type, and ONBOARD of Date type. This schema is the same as the schema of the tSnowflakeOutput component.
5. Click OK to validate these changes and accept the propagation prompted by the pop-up dialog box.
6. Double-click the tLogRow component to open its Component view.
7. In the Mode area, select Vertical (each row is a key/value list) for better readability of the results.

Closing the Snowflake connection

Configure the tSnowflakeClose component to close the connection to Snowflake.

Procedure

1. Double-click the tSnowflakeClose component to open the Component tab.
2. From the Connection Component drop-down list, select the component that opens the connection you need to close, tSnowflakeConnection_1 in this example.

Executing the Job to write and read data in Snowflake

After setting up the Job and configuring the components used in the Job for writing and reading Snowflake data, you can then execute the Job and verify the Job execution result.
**Procedure**

1. Press **Ctrl + S** to save the Job.
2. Press **F6** to run the Job.

As shown below, the data is written into the table `EMPLOYEE` in Snowflake, then read from this table and outputted on the console in the **Run** view of the Studio.

```
[statistics] connecting to socket on port 3880

```
tSnowflakeOutput

Uses the data incoming from its preceding component to insert, update, upsert or delete data in a Snowflake table.

tSnowflakeOutput uses the bulk loader provided by Snowflake for high performance database operations.

**tSnowflakeOutput Standard properties**

These properties are used to configure tSnowflakeOutput running in the Standard Job framework.

The Standard tSnowflakeOutput component belongs to the Cloud family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>

<td>The error message generated by the component when an error occurs. This is an After variable and it returns a string.</td>
</tr>
</tbody>
</table>
### Usage

| Usage rule | This component is end component of a data flow in your Job. It receives data from other components via a **Row > Main** link. It can also send error messages to other components via a **Row > Rejects** link. The provided information about an error could be:  
- The name of the column in error.  
- The number of the row in error.  
- The category of the error, such as a parsing error or a conversion error.  
- The character offset in the line in error.  
- The related error message.  
- The offset of the byte in error.  
- The number of the line in error.  
- SQLSTATE for the error.  
- Snowflake error code. |

---

### Related scenario

For a related scenario, see [Writing data into and reading data from a Snowflake table](#) on page 3548.
tSnowflakeRow

Executes the SQL command stated onto a specified Snowflake database.

**tSnowflakeRow Standard properties**

These properties are used to configure tSnowflakeRow running in the Standard Job framework.

The Standard tSnowflakeRow component belongs to the Cloud family.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td>Property Type</td>
<td>Select the way the connection details will be set.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Built-In:</strong> The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Repository:</strong> The connection details stored centrally in Repository &gt; Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up Repository Content dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in. This property is not available when other connection component is selected from the Connection Component drop-down list.</td>
</tr>
<tr>
<td>Connection Component</td>
<td>Select the component that opens the database connection to be reused by this component.</td>
</tr>
<tr>
<td>Account</td>
<td>In the <strong>Account</strong> field, enter, within double quotation marks, the name that has been assigned to you by Snowflake.</td>
</tr>
<tr>
<td>User Id and Password</td>
<td>Enter, within double quotation marks, your authentication information to log in Snowflake.</td>
</tr>
<tr>
<td></td>
<td>• In the <strong>User ID</strong> field, enter, within double quotation marks, your login name that has been defined in Snowflake using the LOGIN_NAME parameter of Snowflake. For details, ask the administrator of your Snowflake system.</td>
</tr>
<tr>
<td></td>
<td>• To enter the password, click the [...] button next to the password field, and then in the pop-up dialog</td>
</tr>
</tbody>
</table>

3557
Enter the password between double quotes and click **OK** to save the settings.

**Warehouse**
Enter, within double quotation marks, the name of the Snowflake warehouse to be used. This name is case-sensitive and is normally upper case in Snowflake.

**Schema**
Enter, within double quotation marks, the name of the database schema to be used. This name is case-sensitive and is normally upper case in Snowflake.

**Database**
Enter, within double quotation marks, the name of the Snowflake database to be used. This name is case-sensitive and is normally upper case in Snowflake.

**Table**
Click the [...] button and in the displayed wizard, select the Snowflake table to be used.

**Schema and Edit Schema**
A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word **line** when naming the fields.

**Built-In:** You create and store the schema locally for this component only. Related topic: see *Talend Studio User Guide*.

**Repository:** You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see *Talend Studio User Guide*.

If the Snowflake data type to be handled is VARIANT, OBJECT or ARRAY, while defining the schema in the component, select **String** for the corresponding data in the **Type** column of the schema editor wizard.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema:** choose this option to view the schema only.
- **Change to built-in property:** choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection:** choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Guess Query**
Click the button to generate the query which corresponds to the table and the schema in the **Query** field.

**Query**
Specify the SQL command to be executed.
**For more information about Snowflake SQL commands, see SQL Command Reference.**

| Die on error | Select the check box to stop the execution of the Job when an error occurs. Clear the check box to skip any rows on error and complete the process for error-free rows. When errors are skipped, you can collect the rows on error using a Row > Reject connection. |
| Advanced settings | Specify how long to wait for a response when connecting to Snowflake before returning an error. Select the log level for the Snowflake JDBC driver. If enabled, a standard Java log is generated. Enter, within double quotation marks, the default access control role to use to initiate the Snowflake session. This role must already exist and has been granted to the user ID you are using to connect to Snowflake. If this field is left empty, the PUBLIC role is automatically granted. For further information about the Snowflake access control model, see Snowflake documentation at Understanding the Access Control Model. Select this check box to propagate the result of the SELECT query to the output flow. Select this check box if you want to query the database using a prepared statement. In the Set PreparedStatement Parameters table displayed, specify the value for each parameter represented by a question mark ? in the SQL statement defined in the Query field. Specify the number of rows to be processed before committing batches of rows together into the database. Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

- **Login Timeout**

Dynamic settings

Dynamic settings
Click the [+ ] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NB_LINE</td>
<td>The number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>ERROR_MESSAGE</td>
<td>The error message generated by the component when an error occurs. This is an After variable and it returns a string.</td>
</tr>
</tbody>
</table>

Usage

| Usage rule | This component offers the flexibility of the database query and covers all possible SQL queries. |

Related scenario

For a related scenario, see Writing data into and reading data from a Snowflake table on page 3548.
tSOAP

Calls a method via a Web service in order to retrieve the values of the parameters defined in the component editor.

tSOAP sends the defined SOAP message with the given parameters to the invoked Web service and returns the value as defined, based on the given parameters.

**tSOAP Standard properties**

These properties are used to configure tSOAP running in the Standard Job framework.

The Standard tSOAP component belongs to the Internet family.

The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>Schema and Edit schema</th>
<th>A schema is a row description, it defines the number of fields that will be processed and passed on to the next component. This component always uses a built-in, read-only schema. By default, the schema contains three String type columns: - <strong>Header</strong>: stores the SOAP message header of the response from the server end. - <strong>Body</strong>: stores the SOAP message body of the response from the server end. - <strong>Fault</strong>: stores the error information when an error occurs during the SOAP message processing. If the <strong>Output in Document</strong> check box is selected, the schema then contains only one Document type column named <strong>Soap</strong>, which stores the whole response SOAP message in the XML format. Click <strong>Edit schema</strong> to view the schema structure.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use NTLM</td>
<td>Select this check box if you want to use the NTLM authentication protocol. <strong>Domain</strong>: Name of the client domain.</td>
</tr>
<tr>
<td>Need authentication</td>
<td>Select this check box and enter a user name and a password in the corresponding fields if this is necessary to access the service. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter...</td>
</tr>
<tr>
<td><strong>Use http proxy</strong></td>
<td>Select this check box if you are using a proxy server and fill in the necessary information.</td>
</tr>
<tr>
<td>-------------------</td>
<td>--------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| **Trust server with SSL** | Select this check box to validate the server certificate to the client via an SSL protocol and fill in the corresponding fields:  
**TrustStore file:** enter the path (including filename) to the certificate TrustStore file that contains the list of certificates that the client trusts.  
**TrustStore password:** enter the password used to check the integrity of the TrustStore data. |
| **ENDPOINT** | Type in the URL address of the invoked Web server. |
| **SOAP Action** | Type in the URL address of the SOAPAction HTTP header field to be used to identify the intent of the SOAP HTTP request. |
| **SOAP version** | Select the version of the SOAP system you are using.  
**Warning:**  
The required SOAP Envelope varies among versions. |
| **Use a message from the input schema** | Select this check box to read a SOAP message from the preceding component to send to the invoked Web service.  
When this check box is selected, the SOAP message field becomes a drop-down list allowing you to select a Document type column to read an input XML file.  
**Warning:**  
This option makes sense only when the tSOAP component is connected with an input component the schema of which contains a Document type column to read a valid SOAP message. |
| **Output in Document** | Select this check box to output the response message in XML format. |
| **SOAP message** | Type in the SOAP message to be sent to the invoked Web service. The global and context variables can be used when you write a SOAP message.  
For further information about the context variables, see Talend Studio User Guide. |

**Advanced settings**

| **Use Kerberos** | Select this check box to choose a tSetKerberosConfiguration component from the Kerberos configuration list. |
Note:
The OnSubjobOk trigger of tSetKerberosConfiguration should be used for connection with tSoap.

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
<th>Select this check box to gather the Job processing metadata at a Job level as well as at each component level.</th>
</tr>
</thead>
</table>

Global Variables

**Global Variables**

ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

Usage

**Usage rule**

This component can be used as an input or as an intermediate component.

**Connections**

Outgoing links (from this component to another):

- **Row**: Main; Iterate
- **Trigger**: Run if; On Component Ok; On Component Error.

Incoming links (from one component to this one):

- **Row**: Main; Iterate
- **Trigger**: Run if; On Component Ok; On Component Error.

For further information regarding connections, see *Talend Studio User Guide*.

**Scenario 1: Fetching the country name information using a Web service**

This scenario describes a two-component Job that uses a Web service to retrieve the country name information of a given country code.
Procedure

1. Drop the following components from the Palette onto the design workspace: tSOAP and tLogRow.

![Diagram of tSOAP and tLogRow components connected]

2. Connect tSOAP to tLogRow using a Row > Main link.

3. Double-click tSOAP to open its Basic settings view and define the component properties.

4. In **ENDPOINT** field, type in or copy-paste the URL address of the Web service to be used between the quotation marks: "http://www.webservicex.net/country.asmx".

5. In the **SOAP Action** field, type in or copy-paste the URL address of the SOAPAction HTTP header field that indicates that you want to retrieve the country name information: http://www.webserviceX.NET/GetCountryByCountryCode.

**Note:**

You can see this address by looking at the WSDL for the Web service you are calling. For the Web service of this example, in a web browser, append ?wsdl on the end of the URL of the Web service used in the **ENDPOINT** field, open the corresponding web page, and then see the SOAPAction defined under the operation node:

```xml
<wSDL:operation name="GetCountryByCountryCode">
```
6. From the **SOAP Version** list, select the version of the SOAP system being used. In this scenario, the version is **SOAP 1.1**.

7. In the **SOAP message** field, enter the XML-format message used to retrieve the country name information from the invoked Web service. In this example, `IS` is used as the country code, so the message is:

   ```xml
   <soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
    xmlns:web="http://www.webserviceX.NET">
    <soapenv:Header/>
    <soapenv:Body>
    <web:GetCountryByCountryCode>
      <!--Optional:-->
    </web:GetCountryByCountryCode>
    </soapenv:Body>
   </soapenv:Envelope>
   ```

8. Save your Job and press **F6** to execute it.

   The country name information of the given country code `IS` is returned and displayed on the console of the **Run** view.

---

**Scenario 2: Using a SOAP message from an XML file to get country name information and saving the information to an XML file**

This scenario describes a three-component Job that uses a SOAP message from an input XML file to invoke a Web service for the country name information which corresponds to the country code `IR`, and writes the response to an XML file.

**Dropping and linking the components**

**Procedure**

1. Drop the following components from the **Palette** onto the design workspace: `tFileInputXML`, `tSOAP`, and `tFileOutputXML`.

2. Connect the components using **Row > Main** links.
Configuring the input component

Procedure

1. Double-click the tFileInputXML component to open its Basic settings view.

![tFileInputXML Component](image)

2. Click the [...] button next to Edit schema to open the [Schema] dialog box.

![Schema Dialog Box](image)

3. Click the [+] button to add a column, give it a name, getCountryName in this example, and select Document from the Type list. Then, click OK to close the dialog box.

4. In the File name/Stream field, enter the path to the input XML file that contains the SOAP message to be used, or browse to the path by clicking the [...] button.

The input file contains the following SOAP message and you can see that the given country code is IR:

```xml
<soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
                  xmlns:web="http://www.webserviceX.NET">
  <soapenv:Header/>
  <soapenv:Body>
    <web:GetCountryByCountryCode>
      <web:CountryCode>IR</web:CountryCode>
    </web:GetCountryByCountryCode>
  </soapenv:Body>
</soapenv:Envelope>
```

5. In the Loop XPath query field, enter "/" to define the root as the loop node of the input file structure.
6. In the Mapping table, fill the XPath query column with "." to extract all data from context node of the source, and select the Get Nodes check box to build a Document type data flow.

Configuring the Web service via the tSOAP component

Procedure

1. Double-click the tSOAP component to open its Basic settings view.

2. In ENDPOINT field, enter or copy-paste the URL address of the Web service to be used between the quotation marks: “http://www.webservicex.net/country.asmx”.

3. In the SOAP Action field, enter or copy-paste the URL address of the SOAPAction HTTP header field that indicates that you want to retrieve the country name information: http://www.webserviceX.NET/GetCountryByCountryCode.

4. Select the Use a message from the schema check box, and select a Document type column from the SOAP Message list to read the SOAP message from the input file to send to the Web service. In this example, the input schema has only one column, getCountryName.

5. Select the Output in Document check box to output the response message in XML format.

Configuring the output component

Procedure

1. Double-click the tFileOutputXML component to open its Basic settings view.

2. In the File Name field, enter the path to the output XML file.

3. Select the Incoming record is a document check box to retrieve the incoming data flow as an XML document. Note that a Column list appears allowing you choose a column to retrieve data from. In this example, the schema contains only one column.
Executing the Job

Procedure

1. Press **Ctrl+S** to save your Job.
2. Press **F6**, or click **Run** on the **Run** tab to execute the Job.

The country name information that corresponds to the country code of *IR* is returned and the information is saved in the defined XML file.

```xml
<?xml version="1.0" encoding="ISO-8859-15"?>
<soap:Envelope xmlns:soap="http://schemas.xmlsoap.org/soap/envelope/"
    <soap:Body>
            <GetCountryByCountryCodeResult>&lt;NewDataSet&gt; &lt;Table&gt;
                &lt;countrycode&gt;IR&lt;/countrycode&gt; &lt;name&gt;Iran&lt;/name&gt;
                &lt;/Table&gt;
            &lt;/NewDataSet&gt;</GetCountryByCountryCodeResult>
        </GetCountryByCountryCodeResponse>
    </soap:Body>
</soap:Envelope>
```
tSocketInput

Opens the socket port and listens for the incoming data.

tSocketInput is a listening component, allowing to pass data via a defined port.

**tSocketInput Standard properties**

These properties are used to configure tSocketInput running in the Standard Job framework.
The Standard tSocketInput component belongs to the Internet family.
The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host name</td>
<td>Name or IP address of the Host server</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port to open</td>
</tr>
<tr>
<td>Timeout</td>
<td>Number of seconds for the port to listen before closing.</td>
</tr>
<tr>
<td>Uncompress</td>
<td>Select this check box to unzip the data if relevant</td>
</tr>
<tr>
<td>Die on error</td>
<td>This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a <strong>Row &gt; Rejects</strong> link.</td>
</tr>
<tr>
<td>Field separator</td>
<td>Character, string or regular expression to separate fields.</td>
</tr>
<tr>
<td>Row separator</td>
<td>String (ex: <code>\n</code> on Unix) to distinguish rows.</td>
</tr>
<tr>
<td>Escape Char</td>
<td>Character of the row to be escaped</td>
</tr>
<tr>
<td>Text enclosure</td>
<td>Character used to enclose text.</td>
</tr>
</tbody>
</table>

**Schema type** and **Edit Schema**

A schema is a row description, that is to say, it defines the number of fields to be processed and passed on to the next component. The schema is either **Built-in** or stored remotely in the **Repository**.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No**.
upon completion and choose this schema metadata again in the [Repository Content] window.

**Built-in:** The schema will be created and stored locally for this component only. Related topic: see Talend Studio User Guide.

**Repository:** The schema already exists and is stored in the Repository, hence can be reused in various projects and job flowcharts. Related topic: see Talend Studio User Guide.

**Encoding type**
Select the encoding from the list or select Custom and define it manually. This field is compulsory for DB data handling.

**Advanced settings**

**tStatCatcher Statistics**
Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

**Global Variables**

**Global Variables**

**ERROR_MESSAGE:** the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

**NB_LINE:** the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

**Usage**

**Usage rule**
This component opens a point of access to a workstation or server. This component starts a Job and only stops after the time goes out.

**Limitation**
Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find
Scenario: Passing on data to the listening port

The following scenario describes two Jobs aiming at passing data via a listening port. The first Job (SocketInput) opens the listening port and waits for the data to be sent over. The second Job (SocketOutput) passes delimited data from a file to a defined port number corresponding to the listening port.

Another application for the Socket components would be to allow controlled communication between servers which cannot communicate directly.

Dropping and linking components

Procedure
1. For the first Job, drop a tSocketInput component and a tLogRow component from the Palette to the design workspace, and link them using a Row > Main connection.
2. For the second Job, drop a tFileInputDelimited component and a tSocketOutput component from the Palette to the design workspace, and link them using a Row > Main connection.

Configuring the Jobs

Procedure
1. On the second Job, select the tFileInputDelimited and on the Basic Settings tab of the Component view, set the access parameters to the input file.
2. In File Name, browse to the file, and fill the Row, Field separators, and Header fields according to the input file used.

3. Describe the Schema of the data to be passed on to the tSocketOutput component.

The schema should be propagated automatically to the output component.

4. Select the tSocketOutput component and set the parameters on the Basic Settings tab of the Component view.

5. Define the Host IP address and the Port number where the data will be passed on to.

6. Set the number of retries in the Retry field and the amount of time (in seconds) after which the Job will time out.

7. Now on the other Job (SocketInput) design, define the parameters of the tSocketInput component.

8. Define the Host IP address and the listening Port number where the data are passed on to.

9. Set the amount of time (in seconds) after which the Job will time out.
10. Edit the schema and set it to reflect the whole or part of the other Job's schema.

**Executing the Jobs**

**Procedure**

1. Press **F6** to execute this Job (SocketInput) first, in order to open the listening port and prepare it to receive the passed data.

2. Before the time-out, launch the other Job (SocketOutput) to pass on the data.

   The result displays on the **Run** view, along with the opening socket information.

**Schema and Edit Schema**

A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either Built-in or stored remotely in the Repository.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No.
upon completion and choose this schema metadata again in the [Repository Content] window.

| **Built-in**: The schema will be created and stored locally for this component only. Related topic: see Talend Studio User Guide. |
| **Repository**: The schema already exists and is stored in the Repository, hence can be reused in various projects and job flowcharts. Related topic: see Talend Studio User Guide. |

**Encoding**
- Select the encoding from the list or select Custom and define it manually. This field is compulsory for DB data handling.

**Global Variables**

| **Global Variables** | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. |
| **NB_LINE**: the number of rows processed. This is an After variable and it returns an integer. |

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

**Usage**

| **Usage rule** | This component opens a point of access to a workstation or server. This component starts a Job and only stops after the time goes out. |

| **Limitation** | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |
Related Scenario

For use cases in relation with `tSocketOutput`, see `Scenario: Passing on data to the listening port` on page 3571
tSortRow

Helps creating metrics and classification table. tSortRow sorts input data based on one or several columns, by sort type and order.

**tSortRow Standard properties**

These properties are used to configure tSortRow running in the Standard Job framework.

The Standard tSortRow component belongs to the Processing family.

The component in this framework is generally available.

**Basic settings**

| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
• View schema: choose this option to view the schema only.  
• Change to built-in property: choose this option to change the schema to Built-in for local changes.  
• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the [Repository Content] window.  
Click Sync columns to retrieve the schema from the previous component connected in the Job. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Built-In: You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.</td>
<td></td>
</tr>
<tr>
<td>Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.</td>
<td></td>
</tr>
<tr>
<td>Criteria</td>
<td>Click + to add as many lines as required for the sort to be complete. By default the first column defined in your schema is selected.</td>
</tr>
<tr>
<td>Schema column: Select the column label from your schema, which the sort will be based on. Note that the order is essential as it determines the sorting priority.</td>
<td></td>
</tr>
</tbody>
</table>
**Sort type:** Numerical and Alphabetical order are proposed. More sorting types to come.

**Order:** Ascending or descending order.

**Advanced settings**

**Sort on disk**
- Customize the memory used to temporarily store output data.
- **Temp data directory path:** Set the location where the temporary files should be stored.
- **Create temp data directory if not exists:** Select this check box to create the directory if it does not exist.
- **Buffer size of external sort:** Type in the size of physical memory you want to allocate to sort processing.

**tStatCatcher Statistics**
- Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

**Global Variables**

**Global Variables**
- **ERROR_MESSAGE:** the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.
- A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.
- To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.
- For further information about variables, see *Talend Studio User Guide*.

**Usage**

**Usage rule**
- This component handles flow of data therefore it requires input and output, hence is defined as an intermediary step.

**Sorting entries**

This scenario describes a three-component Job. A **tRowGenerator** is used to create random entries which are directly sent to a **tSortRow** to be ordered following a defined value entry. In this scenario, we suppose the input flow contains names of salespersons along with their respective sales and their years of presence in the company. The result of the sorting operation is displayed on the **Run** console.
• Drop the three components required for this use case: `tRowGenerator`, `tSortRow` and `tLogRow` from the Palette to the design workspace.

• Connect them together using Row main links.

• On the `tRowGenerator` editor, define the values to be randomly used in the Sort component. For more information regarding the use of this particular component, see `tRowGenerator` on page 3281.

• In this scenario, we want to rank each salesperson according to its Sales value and to its number of years in the company.

• Double-click `tSortRow` to display the Basic settings tab panel. Set the sort priority on the Sales value and as secondary criteria, set the number of years in the company.

• Use the plus button to add the number of rows required. Set the type of sorting, in this case, both criteria being integer, the sort is numerical. At last, given that the output wanted is a rank classification, set the order as descending.

• Display the Advanced Settings tab and select the Sort on disk check box to modify the temporary memory parameters. In the Temp data directory path field, type the path to the directory where you want to store the temporary data. In the Buffer size of external sort field, set the maximum buffer value you want to allocate to the processing.

⚠️ Warning:
The default buffer value is 1000000 but the more rows and/or columns you process, the higher the value needs to be to prevent the Job from automatically stopping. In that event, an "out of memory" error message displays.

- Make sure you connected this flow to the output component, `tLogRow`, to display the result in the Job console.

- Press `F6` to run the Job. The ranking is based first on the Sales value and then on the number of years of experience.
**tSplitRow**

Splits one input row into several output rows.

**tSplitRow Standard properties**

These properties are used to configure tSplitRow running in the Standard Job framework.

The Standard tSplitRow component belongs to the Processing family.

The component in this framework is generally available.

### Basic settings

| **Schema and Edit Schema** | A schema is a row description, it defines the number of fields to be processed and passed on to the next component. </tbody>
</table>

Usage

| Usage rule | This component splits one input row into multiple output rows by mapping input columns onto output columns. |

Scenario 1: Splitting one row into two rows

This scenario describes a three-component Job. A row of data containing information of two companies will be split up into two rows.

Procedure

Procedure

1. Drop the following components required for this use case: tFixedFlowInput, tSplitRow and tLogRow from the Palette to the design workspace.
2. Connect them together using Row Main connections.
3. Double-click tFixedFlowInput to open its Basic settings view.
4. Select **Use Inline Content(delimited file)** in the **Mode** area.

5. Fill the **Content** area with the following scripts:

   Talend;LA;California;537;5thAvenue;IT;Lionbridge;Memphis;Tennessee;537;Lincoln Road;IT Service;

6. Click **Edit schema** to open a dialog box to edit the schema for the input data.

7. Click the plus button to add twelve lines for the input columns: **Company, City, State, CountryCode, Street, Industry, Company2, City2, State2, CountryCode2, Street2** and **Industry2**.

8. Click **OK** to close the dialog box.

9. Double-click **tSplitRow** to open its **Basic settings** view.
10. Click **Edit schema** to set the schema for the output data.

11. Click the plus button beneath the **tSplitRow_1(Output)** table to add four lines for the output columns: **Company**, **CountryCode**, **Address** and **Industry**.

12. Click **OK** to close the dialog box. Then an empty table with column names defined in the preceding step will appear in the **Columns mapping** area:

<table>
<thead>
<tr>
<th>Column</th>
<th>Key</th>
<th>Type</th>
<th>✓</th>
<th>N..</th>
</tr>
</thead>
<tbody>
<tr>
<td>Company</td>
<td></td>
<td>String</td>
<td>✓</td>
<td></td>
</tr>
<tr>
<td>City</td>
<td></td>
<td>String</td>
<td>✓</td>
<td></td>
</tr>
<tr>
<td>State</td>
<td></td>
<td>String</td>
<td>✓</td>
<td></td>
</tr>
<tr>
<td>CountryCode</td>
<td></td>
<td>String</td>
<td>✓</td>
<td></td>
</tr>
<tr>
<td>Street</td>
<td></td>
<td>String</td>
<td>✓</td>
<td></td>
</tr>
<tr>
<td>Industry</td>
<td></td>
<td>String</td>
<td>✓</td>
<td></td>
</tr>
<tr>
<td>Company2</td>
<td></td>
<td>String</td>
<td>✓</td>
<td></td>
</tr>
<tr>
<td>City2</td>
<td></td>
<td>String</td>
<td>✓</td>
<td></td>
</tr>
<tr>
<td>State2</td>
<td></td>
<td>String</td>
<td>✓</td>
<td></td>
</tr>
<tr>
<td>CountryCode2</td>
<td></td>
<td>String</td>
<td>✓</td>
<td></td>
</tr>
<tr>
<td>Street2</td>
<td></td>
<td>String</td>
<td>✓</td>
<td></td>
</tr>
<tr>
<td>Industry2</td>
<td></td>
<td>String</td>
<td>✓</td>
<td></td>
</tr>
</tbody>
</table>

13. Click the plus button beneath the empty table in the **Columns mapping** area to add two lines for the output rows.

14. Fill the table in the **Columns mapping** area by columns with the following values:
   - **Company**: row1.Company, row1.Company2;
Industry: row1.Industry, row1.Industry2;

Columns mapping

<table>
<thead>
<tr>
<th>Company</th>
<th>CountryCode</th>
<th>Address</th>
<th>Industry</th>
</tr>
</thead>
</table>

Note:
The value in Address column, for example, row1.Street+","+row1.City+","+row1.State, will display an absolute address by combining values in Street column, City column and State column together. The "row1" used in the values of each column refers to the input row from tFixedFlowInput.

15. Double-click tLogRow to open its Basic settings view.

16. Click Sync columns to retrieve the schema defined in the preceding component.

17. Select Table in the Mode area.

18. Save the Job and press F6 to run it.

Job Split ended at 16:21 27/10/2011. [exit code=0]

The input data in one row is split into two rows of data containing the same company information.
**tSplunkEventCollector**

Sends the event data to Splunk through Splunk HTTP Event Collector.

`tSplunkEventCollector` collects and sends the event data to Splunk.

**tSplunkEventCollector Standard properties**

These properties are used to configure `tSplunkEventCollector` running in the Standard Job framework. The Standard `tSplunkEventCollector` component belongs to the Business Intelligence family. The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th><strong>Schema and Edit schema</strong></th>
<th>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <code>line</code> when naming the fields.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• <strong>Built-In</strong>: You create and store the schema locally for this component only. Related topic: see <em>Talend Studio User Guide</em>.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Repository</strong>: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see <em>Talend Studio User Guide</em>.</td>
</tr>
</tbody>
</table>

Note that the schema of this component has been set by default with the following fields. You can click the [...] button next to **Edit schema** to view and change the predefined schema.

- **time**: the event time. Note that the input data is in Java Date format, and it will be transformed to the epoch time format required by Splunk before sending to Splunk HTTP Event Collector.
- **source**: the source value of the event data. It is usually the file or directory path, network port, or script from which the event originated.
- **sourcetype**: the source type of the event data. It tells what kind of data it is.
- **host**: the host of the event data. It is usually the host name, IP address, or fully qualified domain name of the network machine from which the event originated.
- **index**: the name of the index by which the event data is to be indexed. It must be within the list of allowed indexes if the token has the `indexes` parameter set.

For more information about the format of the event data sent to Splunk HTTP Event Collector, see *About the JSON event protocol in HTTP Event Collector*. 
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.

- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.

- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.

<table>
<thead>
<tr>
<th>Splunk Server URL</th>
<th>Enter the URL used to access the Splunk Web Server.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Token</td>
<td>Specify the Event Collector token used to authenticate the event data. For more information, see <a href="#">HTTP Event Collector token management</a>.</td>
</tr>
</tbody>
</table>

### Advanced settings

**Extended output**

Select this check box to send the event data to Splunk in batch mode. In the field displayed, enter the number of events to be processed in each batch.

By default, this check box is selected and the number of events to be processed in each batch is 100.

| tStatCatcher Statistics      | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

### Global Variables

**Global Variables**

- **NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.

- **RESPONSE_CODE**: the response code from Splunk. This is an After variable and it returns an integer.

- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).
## Usage

| Usage rule | This component is usually used as an end component of a Job or Subjob and it always needs an input link. |

### Related scenario

No scenario is available for this component yet.
tSPSSInput

Addresses SPSS .sav data to write it for example in another file.
tSPSSInput reads data from an SPSS .sav file.

**tSPSSInput Standard properties**

These properties are used to configure tSPSSInput running in the Standard Job framework.
The Standard tSPSSInput component belongs to the Business Intelligence family.
The component in this framework is generally available.

**Basic settings**

<table>
<thead>

</tr>
</tbody>
</table>
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

Usage

**Usage rule**

This component is used as a start component. It requires an output flow.

**Warning:**

Before being able to benefit from all functional objectives of the SPSS components, make sure to do the following:
- If you have already installed SPSS, add the path to the SPSS directory as the following: `SET PATH=%PATH%;<DR>:\program\SPSS`, or
- If you have not installed SPSS, you must copy the SPSS IO “spssio32.dll” lib from the SPSS installation CD and paste it in *Talend* root directory.

**Limitation**

Oracle provides two kinds of JVM platforms (32-bit and 64-bit). By default, the JVM used in a 64-bit operating system is the 64-bit version of the JVM. Since the JSPSS.dll file used by this component is compiled in the 32-bit JVM, it is needed to configure the 32-bit JVM for Job execution in *Talend Studio* installed on a 64-bit operating system.

To do so, perform the following:

1. Open the relevant Job in the workspace.
2. Click the **Run** tab and enter the **Advanced settings** view.
3. Select the **Use specific JVM arguments** check box and click the **New...** button.
4. In the **Set the VM argument** box, enter `-d32` and click **Ok** for validation.

Scenario: Displaying the content of an SPSS .sav file

The following scenario creates a two-component Job, which aims at reading each row of a .sav file and displaying the output on the log console.

Setting up the Job

**Procedure**

1. Drop a **tSPSSInput** component and a **tLogRow** component from the **Palette** onto the design workspace.
2. Right-click on tSPSSInput and connect it to tLogRow using a Main Row link.

**Configuring the input component**

**Procedure**

1. Click tSPSSInput to display its Basic settings view and define the component properties.

2. Click the three-dot button next to the Filename field and browse to the SPSS .sav file you want to read.

3. Click the three-dot button next to Sync schema. A message opens up prompting you to accept retrieving the schema from the defined SPSS file.

4. Click Yes to close the message and proceed to the next step.

5. If required, click the three-dot button next to Edit schema to view the pre-defined data structure of the source SPSS file.
6. Click **OK** to close the dialog box.

**Job execution**

Save the Job and press **F6** to execute it.

The SPSS file is read row by row and the extracted fields are displayed on the log console.

```
Starting job SPSS at 10:28 20/01/2010.
[statistics] connecting to socket on port 3802
[statistics] connected

Job SPSS ended at 10:28 20/01/2010. [exit code=0]
```

**Translating the stored values**

**About this task**

To translate the stored values, complete the following:

**Procedure**

1. In the **Basic settings** view, select the **Translate label** check box.
2. Click **Sync Schema** a second time to retrieve the schema after translation.
   - A message opens up prompting you to accept retrieving the schema from the defined SPSS file.
3. Click **Yes** to close the message and proceed to the next step.
   - A second message opens up prompting you to accept propagating the changes.
4. Click **Yes** to close the message and proceed to the next step.
5. Save the Job and press **F6** to execute it.

**Results**

The SPSS file is read row by row and the extracted fields are displayed on the log console after translating the stored values.

</tr>
</tbody>
</table>
Append: writes the new data at the end of the existing data.

Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

Global Variables

| Global Variables | NB_LINE: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer. ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | This component can not be used as start component. It requires an input flow. Warning: Before being able to benefit from all functional objectives of the SPSS components, make sure to do the following: -If you have already installed SPSS, add the path to the SPSS directory as the following: SET PATH=%PATH%;<DR>:\program\SPSS, or -If you have not installed SPSS, you must copy the SPSS IO "spssio32.dll" lib from the SPSS installation CD and paste it in Talend root directory. |

| Limitation | Oracle provides two kinds of JVM platforms (32-bit and 64-bit). By default, the JVM used in a 64-bit operating system is the 64-bit version of the JVM. Since the JSPSS.dll file used by this component is compiled in the 32-bit JVM, it is needed to configure the 32-bit JVM for Job execution in Talend Studio installed on a 64-bit operating system. To do so, perform the following: 1. Open the relevant Job in the workspace. |
Scenario: Writing data in an .sav file

This Java scenario describes a very simple Job that writes data entries in an .sav file.

Setting up the Job

Procedure

1. Drop a tRowGenerator component and a tSPSSOutput component from the Palette onto the design workspace.
2. Right-click on tRowGenerator and connect it to tSPSSOutput using a Main Row link.

Configuring the input component

Procedure

1. In the design workspace, double click tRowGenerator to display its Basic Settings view and open its editor. Here you can define your schema.
2. Click the plus button to add the columns you want to write in the .sav file.
3. Define the schema and set the parameters to the columns.

⚠️ **Warning:**

*Make sure to define the length of your columns. Otherwise, an error message will display when building your Job.*

4. Click **OK** to validate your schema and close the editor.

**Configuring the output component**

**Procedure**

1. Click **tSPSSOutput** to display its **Basic settings** view and define the component properties.

2. Click the three-dot button next to the **Filename** field and browse to the SPSS .sav file in which you want to write data.

3. Click the three-dot button next to **Sync columns** to synchronize columns with the previous component. In this example, the schema to be inserted in the .sav file consists of the two columns: *id* and *country*.

4. If required, click **Edit schema** to view/edit the defined schema.

5. From the **Write Type** list, select **Write** or **Append** to simply write the input data in the .sav file or add it to the end of the .sav file.
Job execution

Save the Job and press **F6** to execute it.

The data generated by the `tRowGenerator` component is written in the defined .sav file.
tSPSSProperties

Obtains information about the main properties of a defined SPSS .sav file.
tSPSSProperties describes the properties of a defined SPSS .sav file.

tSPSSProperties Standard properties

These properties are used to configure tSPSSProperties running in the Standard Job framework.
The Standard tSPSSProperties component belongs to the Business Intelligence family.
The component in this framework is generally available.

Basic settings

| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.
The schema metadata in this component is predefined and thus read-only. You can click Edit schema to view the predefined metadata. |
<table>
<thead>
<tr>

<td>Name or path of the .sav file to be processed.</td>
</tr>
</tbody>
</table>

Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

Global Variables

| Global Variables | IS_VALID_FILE: the result of the file validation. This is an After variable and it returns a boolean. ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. |

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule

Use this component as a start component. It needs an output flow.

⚠️ Warning:

In order to benefit from all of the functional objectives of the SPSS components, do the following: -If you have already installed SPSS, add the path to the SPSS directory as the following: SET PATH=%PATH%;<DR>:\program \SPSS, or -If you have not installed SPSS, you must copy the SPSS IO “spssio32.dll” lib from the SPSS installation CD and paste it in the Talend root directory.

Limitation

Oracle provides two kinds of JVM platforms (32-bit and 64-bit). By default, the JVM used in a 64-bit operating system is the 64-bit version of the JVM. Since the JSPSS.dll file used by this component is compiled in the 32-bit JVM, it is needed to configure the 32-bit JVM for Job execution in Talend Studio installed on a 64-bit operating system.

To do so, perform the following:

1. Open the relevant Job in the workspace.
2. Click the Run tab and enter the Advanced settings view.
3. Select the Use specific JVM arguments check box and click the New... button.
4. In the Set the VM argument box, enter -d32 and click Ok for validation.

Related scenarios

For related topics, see:

- Reading master data from an MDM hub on page 2149.
- Scenario: Writing data in an .sav file on page 3596.
tSPSSStructure

Retrieves information about the variables inside .sav files.

tSPSSStructure addresses variables inside .sav files. You can use this component in combination with tFileList to gather information about existing *.sav files to further analyze or check the findings.

**tSPSSStructure Standard properties**

These properties are used to configure tSPSSStructure running in the Standard Job framework.

The Standard tSPSSStructure component belongs to the Business Intelligence family.

The component in this framework is generally available.

**Basic settings**

| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.
|                       | The schema metadata in this component is predefined and thus read-only. It is based on the internal SPSS convention. You can click Edit schema to view the predefined metadata. |

**Related scenarios**

For related topics, see:

- Reading master data from an MDM hub on page 2149.
- Scenario: Writing data in an .sav file on page 3596.
tSQLDWHBulkExec

Loads data into an Azure SQL Data Warehouse table from either Azure Blob Storage or Azure Data Lake Store.

For more information about loading data into Azure SQL Data Warehouse, see Designing Extract, Load, and Transform (ELT) for Azure SQL Data Warehouse.

tSQLDWHBulkExec Standard properties

These properties are used to configure tSQLDWHBulkExec running in the Standard Job framework. The Standard tSQLDWHBulkExec component belongs to two families: Cloud and Databases. The component in this framework is generally available.

Basic settings

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to: 1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection. 2. In the child level, use a dedicated connection component to read that registered database connection. For an example about how to share a database connection across Job levels, see Talend Studio User Guide.</td>
</tr>
<tr>
<td>JDBC Provider</td>
<td>Select the provider of the JDBC driver to be used.</td>
</tr>
<tr>
<td>Host</td>
<td>Specify the IP address or hostname of the Azure SQL Data Warehouse to be used.</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Specify the listening port number of the Azure SQL Data Warehouse to be used.</td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>Enter the name of the Azure SQL Data Warehouse schema.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Specify the name of the Azure SQL Data Warehouse to be used.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>Enter the user authentication data to access the Azure SQL Data Warehouse. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Additional JDBC Parameters</strong></td>
<td>Specify additional connection properties for the database connection you are creating. The properties are separated by semicolon and each property is a key-value pair. For example, <code>encrypt=true;trustServerCertificate=false;hostNameInCertificate=*.database.windows.net;loginTimeout=30;</code> for Azure SQL database connection.</td>
</tr>
<tr>
<td><strong>Table</strong></td>
<td>Specify the name of the SQL Data Warehouse table into which data will be loaded.</td>
</tr>
<tr>
<td><strong>Action on table</strong></td>
<td>Select an operation to be performed on the table defined.</td>
</tr>
<tr>
<td></td>
<td>- <strong>None</strong>: No operation is carried out.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Drop and create table</strong>: The table is removed and created again.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Create table</strong>: The table does not exist and gets created.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Create table if not exists</strong>: The table is created if it does not exist.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Drop table if exists and create</strong>: The table is removed if it already exists and created again.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Clear table</strong>: The table content is deleted. You have the possibility to rollback the operation.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Truncate table</strong>: The table content is deleted. You do not have the possibility to rollback the operation.</td>
</tr>
<tr>
<td><strong>Schema and Edit schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <code>line</code> when naming the fields.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Built-In</strong>: You create and store the schema locally for this component only. Related topic: see <em>Talend Studio User Guide</em>.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Repository</strong>: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see <em>Talend Studio User Guide</em>.</td>
</tr>
</tbody>
</table>
Click **Edit schema** to make changes to the schema. Note that if you make changes, the schema automatically becomes built-in.

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.

<td>Enter your application ID (also called client ID). This property is available when <strong>Data Lake Store</strong> is selected from the <strong>Azure Storage</strong> drop-down list.</td>
</tr>
<tr>
<td>OAuth 2.0 token endpoint</td>
<td>Copy-paste the OAuth 2.0 token endpoint that you can obtain from the Endpoints list accessible on the App registrations page. This property is available when <strong>Data Lake Store</strong> is selected from the <strong>Azure Storage</strong> drop-down list.</td>
</tr>
<tr>
<td>Azure Storage Location</td>
<td>Specify the location where your Azure Blob Storage or Azure Data Lake Store account is created.</td>
</tr>
</tbody>
</table>
### Advanced settings

<table>
<thead>
<tr>
<th><strong>File format</strong></th>
<th>Select the file format that defines external data stored in your Azure Blob Storage or Azure Data Lake Store, Delimited Text, Hive RCFile, Hive ORC, or Parquet. For more information about the file formats, see CREATE EXTERNAL FILE FORMAT.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Field separator</strong></td>
<td>Specify the character(s) that indicate the end of each field in the delimited text file. This property is available when Delimited Text is selected from the File format drop-down list.</td>
</tr>
<tr>
<td><strong>Enclosed by</strong></td>
<td>Select this check box and in the field next to it, specify the character that encloses the string in the delimited file. This property is available when Delimited Text is selected from the File format drop-down list.</td>
</tr>
<tr>
<td><strong>Date format</strong></td>
<td>Select this check box and in the field next to it, specify the custom format for all date and time data in the delimited file. For more information about the date format, see CREATE EXTERNAL FILE FORMAT. This property is available when Delimited Text is selected from the File format drop-down list.</td>
</tr>
<tr>
<td><strong>Use type default</strong></td>
<td>Select this check box to store each missing value using the default value of the data type of the corresponding column. Clear this check box to store each missing value in the delimited file as NULL. This property is available when Delimited Text is selected from the File format drop-down list.</td>
</tr>
<tr>
<td><strong>Serde Method</strong></td>
<td>Select a Hive serializer and deserializer method. This property is available when Hive RCFile is selected from the File format drop-down list.</td>
</tr>
<tr>
<td><strong>Compressed by</strong></td>
<td>Select this check box if external data is compressed, and from the drop-down list displayed next to it, select the compression method.</td>
</tr>
</tbody>
</table>
| **Data import reject options** | Select this check box to specify the following reject options.  
  - **Reject type**: Specify how you want to deal with reject rows.  
  - **Value**: If the number of rejected rows exceeds the value specified in the Reject value field, the load fails.  
  - **Percentage**: If the percentage of rejected rows exceeds the value specified in the Reject value field, the load fails. |
- **Reject value**: The reject value according to the reject type. For percentage, it is the percent value without the symbol %.
- **Reject sample value**: The reject percentage sample value.

For more information about the reject options, see CREATE EXTERNAL TABLE.

### Distribution Option

Select the sharding pattern used to distribute data in the table, Round Robin, Hash, or Replicate. For more information about the sharding pattern supported by Azure SQL Data Warehouse, see Azure SQL Data Warehouse - Massively parallel processing (MPP) architecture.

This property is available when any option related to table creation is selected from the Action on table drop-down list.

### Distribution Column Name

The name of the distribution column for a hash-distribution table.

This property is available when Hash is selected from the Distribution Option drop-down list.

### Table Option

Select the index type of the table, Clustered Columnstore Index, Heap, or Clustered Index. For more information, see Indexing tables in SQL Data Warehouse.

This property is available when any option related to table creation is selected from the Action on table drop-down list.

### Index column(s)

Specify the name of one or more key columns in the index. If multiple columns are specified, separate them with comma.

This property is available when Clustered Index is selected from the Table Option drop-down list.

### Partition

Select this check box to specify the following partition options:

- **Partition column name**: Specify the name of the column used to partition the table.
- **Range**: Specify how the limit value is included in the range of the limit.
  - **Left**: The limit value is included in the left range of the limit.
  - **Right**: The limit value is included in the right range of the limit.
- **Partition For Values**: Specify the values (separated by comma) used for partition.

For more information about the table partition, see Partitioning tables in SQL Data Warehouse.
tSQLDWHBulkExec

This property is available when any option related to table creation is selected from the **Action on table** drop-down list.

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
<th>Select this check box to gather the Job processing metadata at the Job level as well as at each component level.</th>

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is more commonly used with other Azure SQL Data Warehouse components, especially with the tSQLDWHConnection and tSQLDWHCommit components.</th>
</tr>
</thead>
</table>

**Dynamic settings**

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using...
| Limitation | Note that some features that are supported by other databases are not supported by Azure SQL Data Warehouse. For more information, see [Unsupported table features](#). |

**Related scenario**

No scenario is available for this component yet.
tSQLDWHCommit

Commits in one go a global transaction instead of doing that on every row or every batch and thus provides gain in performance.

If you need to commit each statement as an individual transaction, you have to use the **Auto Commit** function available in the connection component.

**tSQLDWHCommit Standard properties**

These properties are used to configure tSQLDWHCommit running in the Standard Job framework.

The Standard tSQLDWHCommit component belongs to two families: Cloud and Databases.

The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>Component List</th>
<th>Select the tSQLDWHConnection component in the list if more than one connection are planned for the current Job.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task. Note that if you want to use a Row &gt; Main connection to link tSQLDWHCommit to your Job, your data will be committed row by row. In this case, do not select the Close connection check box or your connection will be closed before the end of your first row commit.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global Variables**

| ERROR_MESSAGE | The error message generated by the component when an error occurs. This is an After variable and it returns a string. |

**Usage**

| Usage rule | This component is more commonly used with other Azure SQL Data Warehouse components, especially with the tSQLDWHConnection and tSQLDWHRollback components. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |
| Limitation | Note that some features that are supported by other databases are not supported by Azure SQL Data Warehouse. For more information, see Unsupported table features. |

### Related scenario

No scenario is available for this component yet.
tSQLDWHConnection

Opens a connection to an Azure SQL Data Warehouse database.

**tSQLDWHConnection Standard properties**

These properties are used to configure tSQLDWHConnection running in the Standard Job framework. The Standard tSQLDWHConnection component belongs to two families: Cloud and Databases. The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Property Type</strong></td>
<td>Select the way the connection details will be set.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Built-In:</strong> The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Repository:</strong> The connection details stored centrally in Repository &gt; Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up Repository Content dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in.</td>
</tr>
<tr>
<td><strong>JDBC Provider</strong></td>
<td>Select the provider of the JDBC driver to be used.</td>
</tr>
<tr>
<td><strong>Host</strong></td>
<td>Specify the IP address or hostname of the Azure SQL Data Warehouse to be used.</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Specify the listening port number of the Azure SQL Data Warehouse to be used.</td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>Enter the name of the Azure SQL Data Warehouse schema.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Specify the name of the Azure SQL Data Warehouse to be used.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>Enter the user authentication data to access the Azure SQL Data Warehouse. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Additional JDBC Parameters</strong></td>
<td>Specify additional connection properties for the database connection you are creating. The properties are separated by semicolon and each property is a key-value pair. For example, encrypt=true;trustServerCertificate=false;hostNameInCertificate=*.database.windows.net;loginTimeout=30; for Azure SQL database connection.</td>
</tr>
</tbody>
</table>
### Use or register a shared DB Connection
Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the **Shared DB Connection Name** field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child.

This option is incompatible with the **Use dynamic job** and **Use an independent process to run subjob** options of the `tRunJob` component. Using a shared connection together with a `tRunJob` component with either of these two options enabled will cause your Job to fail.

This check box is not available when the **Specify a data source alias** check box is selected.

### Specify a data source alias
Select this check box and in the **Data source alias** field displayed, specify the alias of a data source created on Talend Runtime side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in Talend Runtime. For a related use case, see *Scenario: Deploying your Job on Talend Runtime to retrieve data from a MySQL database* on page 2503.

This check box is not available when the **Use or register a shared DB Connection** check box is selected.

### Advanced settings

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Auto Commit</strong></td>
<td>Select this check box to commit any changes to the database automatically upon the transaction.</td>
</tr>
<tr>
<td></td>
<td>With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component. Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component.</td>
</tr>
<tr>
<td><strong>Share identity insert in multi table</strong></td>
<td>Select this check box to share IDENTITY_INSERT with multiple tables in one connection.</td>
</tr>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to gather the Job processing metadata at the Job level as well as at each component level.</td>
</tr>
</tbody>
</table>
Global Variables

| ERROR_MESSAGE | The error message generated by the component when an error occurs. This is an After variable and it returns a string. |

Usage

| Usage rule | This component is more commonly used with other Azure SQL Data Warehouse components and it opens a connection that can be reused by them. |
| Limitation | Note that some features that are supported by other databases are not supported by Azure SQL Data Warehouse. For more information, see Unsupported table features. |

Related scenario

No scenario is available for this component yet.
tSQLDWHInput

Reads data and extracts fields based on a query from an Azure SQL Data Warehouse database.

**tSQLDWHInput Standard properties**

These properties are used to configure tSQLDWHInput running in the Standard Job framework.

The Standard tSQLDWHInput component belongs to two families: Cloud and Databases.

The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>

</tbody>
</table>
**Dynamic settings**

Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

**Limitation**

Note that some features that are supported by other databases are not supported by Azure SQL Data Warehouse. For more information, see Unsupported table features.

### Related scenario

No scenario is available for this component yet.
tSQLDWHOutput

Writes, updates, makes changes or suppresses entries in an Azure SQL Data Warehouse database.

**tSQLDWHOutput Standard properties**

These properties are used to configure tSQLDWHOutput running in the Standard Job framework. The Standard tSQLDWHOutput component belongs to two families: Cloud and Databases. The component in this framework is generally available.

**Basic settings**

| Use an existing connection | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:
|**1.** In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
|**2.** In the child level, use a dedicated connection component to read that registered database connection.
For an example about how to share a database connection across Job levels, see Talend Studio User Guide. |
| Property Type | Select the way the connection details will be set.
|**Built-In:** The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.
|**Repository:** The connection details stored centrally in Repository > Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up Repository Content dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in. |
| JDBC Provider | Select the provider of the JDBC driver to be used. |
| Host | Specify the IP address or hostname of the Azure SQL Data Warehouse to be used. |
| Port | Specify the listening port number of the Azure SQL Data Warehouse to be used. |
| **Schema** | Enter the name of the Azure SQL Data Warehouse schema. |
| **Database** | Specify the name of the Azure SQL Data Warehouse to be used. |
| **Username and Password** | Enter the user authentication data to access the Azure SQL Data Warehouse. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| **Table** | Specify the name of the table to be used. |
| **Action on table** | Select an operation to be performed on the table defined.  
- **Default**: No operation is carried out.  
- **Drop and create table**: The table is removed and created again.  
- **Create table**: The table does not exist and gets created.  
- **Create table if does not exist**: The table is created if it does not exist.  
- **Drop table if exist and create**: The table is removed if it already exists and created again.  
- **Clear table**: The table content is deleted. You have the possibility to rollback the operation.  
- **Truncate**: The table content is deleted. |
| **Turn on identity insert** | Select this check box to use your own sequence for the identity value of the inserted records (instead of having the SQL Server pick the next sequential value). |
| **Action on data** | Select an action to be performed on data of the table defined.  
- **Insert**: Add new entries to the table. If duplicates are found, job stops.  
- **Single Insert Query**: Add entries to the table in a batch.  
- **Update**: Make changes to existing entries.  
- **Insert or update**: Insert a new record. If the record with the given reference already exists, an update would be made.  
- **Update or insert**: Update the record with the given reference. If the record does not exist in the index pool, a new record would be inserted.  
- **Delete**: Remove entries corresponding to the input flow.  
- **Insert if not exist**: Add new entries to the table if they do not exist. |
It is necessary to specify at least one column as a primary key on which the Update and Delete operations are based. You can do that by clicking Edit Schema and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the Advanced settings view where you can simultaneously define primary keys for the Update and Delete operations. To do that, select the Use field options check box and then in the Key in update column, select the check boxes next to the column names you want to use as a base for the Update operation. Do the same in the Key in delete column for the Delete operation.

The dynamic schema feature can be used in the following modes: Insert, Update, Insert or update, Update or insert, and Delete.

### Specify identity field

Select this check box to specify the identity field, which is made up of an automatically incrementing identification number.

When this check box is selected, three other fields are displayed:

- **Identity field**: select the column you want to define as the identity field from the list.
- **Start value**: type in a start value, used for the very first row loaded into the table.
- **Step**: type in an incremental value, added to the value of the previous row that was loaded.

This check box is available only when you select Drop and create table, Create table, Create table if not exists, or Drop table if exists and create from the Action on table list, and will disappear if you select the Enable parallel execution check box in the Advanced settings view. If you select this check box with the Turn on identity insert check box cleared and the Create table if not exists option selected from the Action on table list and if the specified table does not exist, only a table will be created without inserting data into it.

Note that you can also specify the identity field from the schema of the component. To do so, set the DB Type of the relevant column to INT IDENTITY.

When the Specify identity field check box is selected, the DB Type INT IDENTITY in the schema is ignored.

### Schema and Edit schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

- **Built-In**: You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in
various projects and Job designs. Related topic: see *Talend Studio User Guide*.

Click **Edit schema** to make changes to the schema. Note that if you make changes, the schema automatically becomes built-in.

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to *Built-in* for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the *Repository Content* window.

### Specify a data source alias
Select this check box and in the **Data source alias** field displayed, specify the alias of a data source created on Talend Runtime side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in Talend Runtime. For a related use case, see *Scenario: Deploying your Job on Talend Runtime to retrieve data from a MySQL database* on page 2503.

This check box is not available when the **Use an existing Connection** check box is selected.

### Die on error
Select the check box to stop the execution of the Job when an error occurs.

Clear the check box to skip any rows on error and complete the process for error-free rows.

### Advanced settings

#### Additional JDBC Parameters
Specify additional connection properties for the database connection you are creating. The properties are separated by semicolon and each property is a key-value pair. For example, `encrypt=true;trustServerCertificate=false;hostNameInCertificate=*.database.windows.net;loginTimeout=30;` for Azure SQL database connection.

#### Commit every
Enter the number of rows to be completed before committing batches of rows together into the database. This option ensures transaction quality (but not rollback) and above all better performance on executions.

#### Additional Columns
This option is not offered if you create (with or without drop) the database table. This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing.

- **Name**: Type in the name of the schema column to be altered or inserted as new column.
<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>SQL expression</strong></td>
<td>Type in the SQL statement to be executed in order to alter or insert the relevant column data.</td>
</tr>
<tr>
<td><strong>Position</strong></td>
<td>Select Before, Replace or After following the action to be performed on the reference column.</td>
</tr>
<tr>
<td><strong>Reference column</strong></td>
<td>Type in a column of reference that can be used to place or replace the new or altered column.</td>
</tr>
<tr>
<td><strong>Use field options</strong></td>
<td>Select this check box to customize a request, especially when there is double action on data.</td>
</tr>
<tr>
<td><strong>Ignore date out of range</strong></td>
<td>Select this check box to ignore the date validation and insert the data directly into the database for the data types of DATE, DATETIME, DATETIME2 and DATETIMEOFFSET.</td>
</tr>
<tr>
<td><strong>Enable debug mode</strong></td>
<td>Select this check box to display each step during processing entries in a database.</td>
</tr>
<tr>
<td><strong>Support null in “SQL WHERE” statement</strong></td>
<td>Select this check box if you want to deal with the Null values contained in a database table. Make sure that the Nullable check box is selected for the corresponding columns in the schema.</td>
</tr>
<tr>
<td><strong>Use Batch</strong></td>
<td>Select this check box to activate the batch mode for data processing. This check box is available only when you have selected the Insert, the Update, the Single Insert Query or the Delete option in the Action on data list.</td>
</tr>
<tr>
<td><strong>Batch Size</strong></td>
<td>Specify the number of records to be processed in each batch. This field appears only when the Use batch mode check box is selected.</td>
</tr>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to gather the Job processing metadata at the Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

**Global Variables**

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERROR_MESSAGE</td>
<td>The error message generated by the component when an error occurs. This is an After variable and it returns a string.</td>
</tr>
<tr>
<td>NB_LINE</td>
<td>The number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>Table</td>
<td>Description</td>
</tr>
<tr>
<td>-------</td>
<td>-------------</td>
</tr>
<tr>
<td>NB_LINE_UPDATED</td>
<td>The number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>NB_LINE_INSERTED</td>
<td>The number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>NB_LINE_DELETED</td>
<td>The number of rows deleted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>NB_LINE_REJECTED</td>
<td>The number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
</tbody>
</table>

**Usage**

**Usage rule**

This component is usually used as an end component of a Job or Subjob and it always needs an input link.

**Dynamic settings**

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

**Limitation**

When the Single Insert Query option is selected in the Action on data list, an SQL Prepared Statement is generated, for example, `INSERT INTO table (col1, col2, col3) VALUES (?, ?, ?), (?, ?, ?), (?, ?, ?), (?, ?, ?)`. Within brackets are the groups of parameters the number of which cannot exceed 2000, generally, depending on the JDBC driver. Therefore, the batch size should be set so that this limit is respected.

Note that some features that are supported by other databases are not supported by Azure SQL Data Warehouse. For more information, see Unsupported table features.

Also note that when creating or deleting a table with this component, it is recommended to use the auto commit function by reusing the database connection.
Related scenario

No scenario is available for this component yet.
**tSQLDWHRollback**

Cancels the transaction commit in the connected Azure SQL Data Warehouse database to prevent partial transaction commit if an error occurs.

**tSQLDWHRollback Standard properties**

These properties are used to configure tSQLDWHRollback running in the Standard Job framework. The Standard tSQLDWHRollback component belongs to two families: Cloud and Databases. The component in this framework is generally available.

### Basic settings

<table>
<thead>
<tr>
<th>Component List</th>
<th>Select the <strong>tSQLDWHConnection</strong> component in the list if more than one connection are planned for the current Job.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the operation is done. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

### Advanced settings

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

### Global Variables

| ERROR_MESSAGE | The error message generated by the component when an error occurs. This is an After variable and it returns a string. |

### Usage

| Usage rule | This component is more commonly used with other Azure SQL Data Warehouse components, especially with the **tSQLDWHConnection** and **tSQLDWHRollback** components. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, |
when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

| Limitation | Note that some features that are supported by other databases are not supported by Azure SQL Data Warehouse. For more information, see Unsupported table features. |

**Related scenario**

No scenario is available for this component yet.
tSQLDWHRow

Executes an SQL query stated on an Azure SQL Data Warehouse database.

**tSQLDWHRow Standard properties**

These properties are used to configure tSQLDWHRow running in the Standard Job framework.

The Standard tSQLDWHRow component belongs to two families: Cloud and Databases.

The component in this framework is generally available.

**Basic settings**

| Use an existing connection | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.

2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide. |
| --- | --- |
| Property Type | Select the way the connection details will be set.

- **Built-In:** The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.

- **Repository:** The connection details stored centrally in Repository > Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up Repository Content dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in. |
| JDBC Provider | Select the provider of the JDBC driver to be used. |
| Host | Specify the IP address or hostname of the Azure SQL Data Warehouse to be used. |
| Port | Specify the listening port number of the Azure SQL Data Warehouse to be used. |
| **Schema** | Enter the name of the Azure SQL Data Warehouse schema. |
| **Database** | Specify the name of the Azure SQL Data Warehouse to be used. |
| **Username and Password** | Enter the user authentication data to access the Azure SQL Data Warehouse. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings. |
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word **line** when naming the fields.  
  - **Built-In**: You create and store the schema locally for this component only. Related topic: see [Talend Studio User Guide](#).  
  - **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see [Talend Studio User Guide](#).  
Click **Edit schema** to make changes to the schema. Note that if you make changes, the schema automatically becomes built-in.  
  - **View schema**: choose this option to view the schema only.  
  - **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
  - **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window. |
| **Table name** | Specify the name of the table to be used. |
| **Turn on identity insert** | Select this check box to use your own sequence for the identity value of the inserted records (instead of having the SQL Server pick the next sequential value). |
| **Query Type** | Select the way the query will be set.  
  - **Built-in**: Fill in manually the query statement or build it graphically using SQLBuilder.  
  - **Repository**: Select the relevant query stored in the Repository. The **Query** field gets accordingly filled in. |
<table>
<thead>
<tr>
<th><strong>Guess Query</strong></th>
<th>Click the <strong>Guess Query</strong> button to generate the query which corresponds to your table schema in the <strong>Query</strong> field.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Query</strong></td>
<td>Specify your database query paying particularly attention to properly sequence the fields in order to match the schema definition.</td>
</tr>
<tr>
<td><strong>Specify a data source alias</strong></td>
<td>Select this check box and in the <strong>Data source alias</strong> field displayed, specify the alias of a data source created on Talend Runtime side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in Talend Runtime. For a related use case, see Scenario: Deploying your Job on Talend Runtime to retrieve data from a MySQL database on page 2503. This check box is not available when the <strong>Use an existing Connection</strong> check box is selected.</td>
</tr>
<tr>
<td><strong>Die on error</strong></td>
<td>Select the check box to stop the execution of the Job when an error occurs. Clear the check box to skip any rows on error and complete the process for error-free rows. When errors are skipped, you can collect the rows on error using a <strong>Row &gt; Reject</strong> connection.</td>
</tr>
</tbody>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th><strong>Advanced settings</strong></th>
<th>Specify additional connection properties for the database connection you are creating. The properties are separated by semicolon and each property is a key-value pair. For example, <code>encrypt=true;trustServerCertificate=false;hostNameInCertificate=*.database.windows.net;loginTimeout=30;</code> for Azure SQL database connection.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Additional JDBC Parameters</strong></td>
<td>Select this check box to insert the result of the query into a column of the current flow. Select this column from the <strong>use column</strong> list. This option allows the component to have a different schema from that of the preceding component. Moreover, the column that holds the QUERY’s recordset should be set to the type of Object and this component is usually followed by <strong>tParseRecordSet</strong>.</td>
</tr>
<tr>
<td><strong>Propagate QUERY’s recordset</strong></td>
<td>Select this check box if you want to query the database using a PreparedStatement. In the <strong>Set PreparedStatement Parameters</strong> table, define the parameters represented by “?” in the SQL instruction of the <strong>Query</strong> field in the <strong>Basic Settings</strong> tab.</td>
</tr>
<tr>
<td><strong>Use PreparedStatement</strong></td>
<td><strong>Parameter Index</strong>: Enter the parameter position in the SQL instruction.</td>
</tr>
<tr>
<td></td>
<td><strong>Parameter Type</strong>: Enter the parameter type.</td>
</tr>
<tr>
<td></td>
<td><strong>Parameter Value</strong>: Enter the parameter value.</td>
</tr>
</tbody>
</table>
This option is very useful if you need to execute the same query several times. Performance levels are increased.

<table>
<thead>
<tr>
<th>Commit every</th>
<th>Enter the number of rows to be completed before committing batches of rows together into the database. This option ensures transaction quality (but not rollback) and above all better performance on executions.</th>
</tr>
</thead>
<tbody>
<tr>
<td>tStatCatcher Statistics</td>
<td>Select this check box to gather the Job processing metadata at the Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

### Global Variables

<table>
<thead>
<tr>
<th>ERROR_MESSAGE</th>
<th>The error message generated by the component when an error occurs. This is an After variable and it returns a string.</th>
</tr>
</thead>
<tbody>
<tr>
<td>QUERY</td>
<td>The query statement being processed. This is a Flow variable and it returns a string.</td>
</tr>
</tbody>
</table>

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component offers the flexibility of the DB query and covers all possible SQL queries.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic settings</td>
<td>Click the [+ button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

### Limitation

| Limitation | Note that some features that are supported by other databases are not supported by Azure SQL Data Warehouse. For more information, see Unsupported table features. |
Also note that when creating or deleting a table with this component, it is recommended to use the auto commit function by reusing the database connection created by a `tSQLDWHConnection` component and selecting the `Auto Commit` check box on the `Advanced settings` view of the `tSQLDWHConnection` component, instead of using a `tSWLDWHCommit` component.

### Related scenario

No scenario is available for this component yet.
tSQLiteClose

Closes a transaction committed in the connected DB.

**tSQLiteClose Standard properties**

These properties are used to configure tSQLiteClose running in the Standard Job framework.

The Standard tSQLiteClose component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tSQLiteConnection component in the list if more than one connection are planned for the current Job.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is to be used along with SQLite components, especially with tSQLiteConnection and tSQLiteCommit. |
| Dynamic settings | Click the [*] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Scenario: Reading data from databases through context- |
Related scenarios

No scenario is available for the Standard version of this component yet.
tSQLiteCommit

Commits in one go, using a unique connection, a global transaction instead of doing that on every row or every batch and thus provides gain in performance.

TSQLiteCommit validates the data processed through the Job into the connected DB

TSQLiteCommit Standard properties

These properties are used to configure tSQLiteCommit running in the Standard Job framework.

The Standard tSQLiteCommit component belongs to the Databases family.

The component in this framework is generally available.

Note:
This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tSQLiteConnection component in the list if more than one connection are planned for the current Job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task. Warning: If you want to use a Row &gt; Main connection to link tSQLiteCommit to your Job, your data will be committed row by row. In this case, do not select the Close connection check box or your connection will be closed before the end of your first row commit.</td>
</tr>
</tbody>
</table>

Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

Usage

| Usage rule | This component is more commonly used with other tSQLite* components, especially with the tSQLiteConnection and tSQLiteRollback components. |
Dynamic settings

Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see **Scenario: Reading data from databases through context-based dynamic connections** on page 2497 and **Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters** on page 489. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

**Related scenario**

For **tSQLiteCommit** related scenario, see **Scenario: Inserting data in mother/daughter tables** on page 2476.
tSQLiteConnection

Opens a connection to the database for a current transaction.

**tSQLiteConnection Standard properties**

These properties are used to configure tSQLiteConnection running in the Standard Job framework.

The Standard tSQLiteConnection component belongs to the Databases and the ELT families.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see [Dynamic database components](#) on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td><strong>Property type</strong></td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database.</td>
</tr>
</tbody>
</table>
| **Use or register a shared DB Connection** | Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the **Shared DB Connection Name** field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child.

This option is incompatible with the **Use dynamic job** and **Use an independent process to run subjob** options of the tRunJob component. Using a shared connection together with a tRunJob component with either of these two options enabled will cause your Job to fail.

**Advanced settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Auto Commit</strong></td>
<td>Select this check box to commit any changes to the database automatically upon the transaction. With this check box selected, you cannot use the corresponding commit component to commit changes</td>
</tr>
</tbody>
</table>
to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component.

Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component.

| tStatCatcher Statistics | Select this check box to gather the job processing metadata at a Job level as well as at each component level. |

**Usage**

| Usage rule | This component is more commonly used with other tSQLite* components, especially with the tSQLiteCommit and tSQLiteRollback components. |

**Related scenarios**

For **tSQLiteConnection** related scenario, see **tMysqlConnection** on page 2475.
tSQLiteInput

Executes a DB query with a defined command which must correspond to the schema definition. It passes on rows to the next component via a Main row link.
tSQLiteInput reads a database file and extracts fields based on an SQL query. As it embeds the SQLite engine, no need of connecting to any database server.

**tSQLiteInput Standard properties**

These properties are used to configure tSQLiteInput running in the Standard Job framework.
The Standard tSQLiteInput component belongs to the Databases family.
The component in this framework is generally available.

*i Note:*

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
</tbody>
</table>

- **Built-in:** No property data stored centrally.
- **Repository:** Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
</table>

*i Note:*

When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.
For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

Click this icon to open a database connection wizard and store the database connection parameters you set in the component **Basic settings** view.

For more information about setting up and storing database connection parameters, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th><strong>Database</strong></th>
<th>Filepath to the SQLite database file.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Schema and Edit Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <em>line</em> when naming the fields.</td>
</tr>
<tr>
<td><strong>Built-in</strong></td>
<td>The schema is created and stored locally for this component only. Related topic: see <em>Talend Studio User Guide</em>.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>The schema already exists and is stored in the Repository, hence can be reused. Related topic: see <em>Talend Studio User Guide</em>.</td>
</tr>
</tbody>
</table>

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the *[Repository Content]* window.

<table>
<thead>
<tr>
<th><strong>Query type</strong></th>
<th>Either Built-in or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Query</strong></td>
<td>If your query is not stored in the Repository, type in your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.</td>

### Global Variables

| Global Variables | **NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.  
**QUERY**: the query statement being processed. This is a Flow variable and it returns a string.  
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
For further information about variables, see *Talend Studio User Guide*. |

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is standalone as it includes the SQLite engine. This is a startable component that can initiate a data flow processing.</th>
</tr>
</thead>
</table>

| Dynamic settings | Click the [+ ] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.  
The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.  
For examples on using dynamic parameters, see *Scenario: Reading data from databases through context-based dynamic connections* on page 2497 and *Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters* on page 489. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide. |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------|
Scenario: Filtering SQLite data

This scenario describes a rather simple job which uses a select statement based on a filter to extract rows from a source SQLite Database and feed an output SQLite table.

- Drop from the Palette, a tSQLiteInput and a tSQLiteOutput component from the Palette to the design workspace.
- Connect the input to the output using a row main link.
- On the tSQLiteInput Basic settings, type in or browse to the SQLite Database input file.

<table>

</tbody>
</table>

The data queried is returned in the defined SQLite file.
tSQLiteOutput

Executes the action defined on the table and/or on the data contained in the table, based on the flow incoming from the preceding component in the job.

tSQLiteOutput writes, updates, makes changes or suppresses entries in an SQLite database. As it embeds the SQLite engine, no need of connecting to any database server.

**tSQLiteOutput Standard properties**

These properties are used to configure tSQLiteOutput running in the Standard Job framework.

The Standard tSQLiteOutput component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <a href="#">Apply</a>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <a href="#">Built-in</a> or <a href="#">Repository</a>.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

**Note:**

When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.
For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

Click this icon to open a database connection wizard and store the database connection parameters you set in the component **Basic settings** view.

For more information about setting up and storing database connection parameters, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th>Database</th>
<th>Filepath to the Database file</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>Name of the table to be written. Note that only one table can be written at a time</td>
</tr>
<tr>
<td><strong>Action on table</strong></td>
<td>On the table defined, you can perform one of the following operations:</td>
</tr>
<tr>
<td></td>
<td><strong>None</strong>: No operation is carried out.</td>
</tr>
<tr>
<td></td>
<td><strong>Drop and create a table</strong>: The table is removed and created again.</td>
</tr>
<tr>
<td></td>
<td><strong>Create a table</strong>: The table does not exist and gets created.</td>
</tr>
<tr>
<td></td>
<td><strong>Create a table if not exists</strong>: The table is created if it does not exist.</td>
</tr>
<tr>
<td></td>
<td><strong>Drop a table if exists and create</strong>: The table is removed if it already exists and created again.</td>
</tr>
<tr>
<td></td>
<td><strong>Clear a table</strong>: The table content is deleted.</td>
</tr>
<tr>
<td><strong>Action on data</strong></td>
<td>On the data of the table defined, you can perform:</td>
</tr>
<tr>
<td></td>
<td><strong>Insert</strong>: Add new entries to the table. If duplicates are found, job stops.</td>
</tr>
<tr>
<td></td>
<td><strong>Update</strong>: Make changes to existing entries</td>
</tr>
<tr>
<td></td>
<td><strong>Insert or update</strong>: Insert a new record. If the record with the given reference already exists, an update would be made.</td>
</tr>
<tr>
<td></td>
<td><strong>Update or insert</strong>: Update the record with the given reference. If the record does not exist, a new record would be inserted.</td>
</tr>
<tr>
<td></td>
<td><strong>Delete</strong>: Remove entries corresponding to the input flow.</td>
</tr>
</tbody>
</table>

**Warning:**

*It is necessary to specify at least one column as a primary key on which the Update and Delete operations are based.* You can do that by clicking **Edit Schema** and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the **Advanced settings** view where you can simultaneously define primary keys for the Update and Delete operations. To do that: Select the **Use field options** check box and then in the **Key in update column**, select the check boxes next to the column names you want to use as a base for the
**Schema and Edit Schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

**Built-In:** You create and store the schema locally for this component only. Related topic: see [Talend Studio User Guide](https://help.talend.com).

**Repository:** You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see [Talend Studio User Guide](https://help.talend.com).

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema:** choose this option to view the schema only.
- **Change to built-in property:** choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection:** choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.

**Die on error**

This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a **Row > Rejects** link.

**Advanced settings**

**Commit every**

Enter the number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and, above all, better performance at execution.

**Additional Columns**

This option is not offered if you create (with or without drop) the DB table. This option allows you to call SQL functions to perform actions on columns, which are...
not insert, nor update or delete actions, or action that require particular preprocessing.

| Name: | Type in the name of the schema column to be altered or inserted as new column |
| SQL expression: | Type in the SQL statement to be executed in order to alter or insert the relevant column data. |
| Position: | Select Before, Replace or After following the action to be performed on the reference column. |
| Reference column: | Type in a column of reference that the tDBoutput can use to place or replace the new or altered column. |

Use field options
Select this check box to customize a request, especially when there is double action on data.

Enable debug mode
Select this check box to display each step during processing entries in a database.

Use Batch
Select this check box to activate the batch mode for data processing.

**Note:**
This check box is available only when you have selected the Insert, Update, or Delete option in the Action on data option.

Batch Size
Specify the number of records to be processed in each batch.
This field appears only when the Use batch mode check box is selected.

**tStat Catcher Statistics**
Select this check box to collect log data at the component level.

---

**Global Variables**

| Global Variables | NB_LINE: the number of rows processed. This is an After variable and it returns an integer. |
| NB_LINE_UPDATED: the number of rows updated. This is an After variable and it returns an integer. |
| NB_LINE_INSERTED: the number of rows inserted. This is an After variable and it returns an integer. |
| NB_LINE_DELETED: the number of rows deleted. This is an After variable and it returns an integer. |
| NB_LINE_REJECTED: the number of rows rejected. This is an After variable and it returns an integer. |
| QUERY: the query statement processed. This is an After variable and it returns a string. |
| ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. |
variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

#### Usage rule

This component must be connected to an Input component. It allows you to carry out actions on a table or on the data of a table in an SQLite database. It also allows you to create reject flows using a **Row > Reject** link to filter erroneous data. For an example of **tSQLiteOutput** in use, see *Scenario: Retrieving data in error with a Reject link* on page 2529.

#### Dynamic settings

Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see *Scenario: Reading data from databases through context-based dynamic connections* on page 2497 and *Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters* on page 489. For more information on **Dynamic settings** and context variables, see *Talend Studio User Guide*.

### Related Scenario

For scenarios related to **tSQLiteOutput**, see *Scenario: Retrieving data in error with a Reject link* on page 2529.
tSQLiteRollback

Cancels the transaction committed in the SQLite database.

### tSQLiteRollback Standard properties

These properties are used to configure tSQLiteRollback running in the Standard Job framework.

The Standard tSQLiteRollback component belongs to the Databases family.

The component in this framework is generally available.

#### Note:

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tSQLiteConnection component in the list if more than one connection are planned for the current Job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

### Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

### Usage

| Usage rule | This component is more commonly used with other tSQLite* components, especially with the tSQLiteConnection and tSQLiteCommit components. |
| Dynamic settings | Click the [+ ] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. |
For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenarios

For tSQLiteRollback related scenario, see Scenario: Rollback from inserting data in mother/daughter tables on page 2480.
tSQLiteRow

Executes the defined query onto the specified database and uses the parameters bound with the column.

A prepared statement uses the input flow to replace the placeholders with the values for each parameters defined. This component can be very useful for updates.

**tSQLiteRow Standard properties**

These properties are used to configure tSQLiteRow running in the Standard Job framework.

The Standard tSQLiteRow component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td><strong>Property type</strong></td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined.

**Note:**

When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.

2. In the child level, use a dedicated connection component to read that registered database connection.
For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

**Schema and Edit Schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word **line** when naming the fields.

**Built-in**: The schema is created and stored locally for this component only. Related topic: see *Talend Studio User Guide*.

**Repository**: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see *Talend Studio User Guide*.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.

**Query type**

Either **Built-in** or **Repository**.

- **Built-in**: Fill in manually the query statement or build it graphically using SQLBuilder
- **Repository**: Select the relevant query stored in the Repository. The Query field gets accordingly filled in.

**Query**

Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.

**Die on error**

Clear this check box to skip the row on error and complete the process for error-free rows.

**Advanced settings**

**Propagate QUERY’s recordset**

Select this check box to insert the result of the query into a **COLUMN** of the current flow. Select this column from the **use column** list.

**Note:**

This option allows the component to have a different schema from that of the preceding
component. Moreover, the column that holds the QUERY’s recordset should be set to the type of Object and this component is usually followed by tParseRecordSet.

Use PreparedStatement

Select this check box if you want to query the database using a PreparedStatement. In the Set PreparedStatement Parameter table, define the parameters represented by "?" in the SQL instruction of the Query field in the Basic Settings tab.

Parameter Index: Enter the parameter position in the SQL instruction.

Parameter Type: Enter the parameter type.

Parameter Value: Enter the parameter value.

Note: This option is very useful if you need to execute the same query several times. Performance levels are increased.

Commit every

Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions.

tStat Catcher Statistics

Select this check box to collect log data at the component level.

Global Variables

QUERY: the query statement being processed. This is a Flow variable and it returns a string.

ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule

This component offers the flexibility of the DB query and covers all possible SQL queries.

Dynamic settings

Click the [*] button to add a row in the table and fill the Code field with a context variable to choose.
your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Scenario: Updating SQLite rows

This scenario describes a job which updates an SQLite database file based on a prepared statement and using a delimited file.

- Drop a tFileInputDelimited and a tSQLiteRow component from the Palette to the design workspace.
- On the tFileInputDelimited Basic settings panel, browse to the input file that will be used to update rows in the database.
- There is no Header nor Footer. The Row separator is a carriage return and the Field separator is a semi-colon.
- Click the [...] button next to Edit schema and define the schema structure in case it is not stored in the Repository.
• Make sure the length and type are respectively correct and large enough to define the columns.

• Then in the tSQLiteRow Basic settings panel, set the Database filepath to the file to be updated.

• The schema is read-only as it is required to match the input schema.

• Type in the query or retrieve it from the Repository. In this use case, we updated the type_os for the id defined in the Input flow. The statement is as follows: "Update download set type_os=? where id=?".

• Then select the Use PreparedStatement check box to display the placeholders’ parameter table.
In the Input parameters table, add as many lines as necessary to cover all placeholders. In this scenario, `type_os` and `id` are to be defined.

Set the `Commit every` field.

Save the job and press F6 to run it.

The download table from the SQLite database is thus updated with new `type_os` code according to the delimited input file.

**Related scenarios**

For a related scenario, see:

- Scenario: Combining two flows for selective output on page 2558
tSQLTemplate

Executes the common database actions or customized SQL statement templates, for example to drop/create a table.

tSQLTemplate offers a range of SQL statement templates for a number of DBMSs to facilitate some of the most common database actions. These templates are accessible via the SQL Template view. Additionally, you are allowed to customize the SQL statement templates as needed.

tSQLTemplate Standard properties

These properties are used to configure tSQLTemplate running in the Standard Job framework.

The Standard tSQLTemplate component belongs to the ELT family.

The component in this framework is generally available.

Basic settings

<table>
<thead>
<tr>
<th>Database Type</th>
<th>Select the database type you want to connect to from the list.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component List</td>
<td>Select the relevant database connection component in the list if you use more than one connection in the current Job.</td>

</tr>
<tr>
<td>Table name</td>
<td>Name of the table on which the SQL statement templates will be executed.</td>
</tr>
</tbody>
</table>

Schema and Edit schema

A schema is a row description, that is to say, it defines the number of fields that will be processed and passed on to the next component. The schema is either built-in or remote in the Repository.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the [Repository Content] window.

**Built-in**: You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.
Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job flowcharts. Related topic: see *Talend Studio User Guide*.

### Advanced settings

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

### Global Variables

**Global Variables**

- **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.
- **QUERY**: the query statement being processed. This is a Flow variable and it returns a string.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the *Die on error* check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press `Ctrl + Space` to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

**Usage rule**

As a start component, this component is used with other database components, especially the database connection and commit components.

**SQL Template**

**SQL Template List**

**Dynamic settings**

Click the `[+]` button to add a row in the table and fill the **Code** field with a context variable to choose your HDFS connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access files in different HDFS systems or different distributions, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of *Talend Studio*.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defin
ed, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenarios

For a related scenario, see Scenario: Filtering and aggregating table columns directly on the DBMS on page 3663.
tSQLTemplateAggregate

Provide a set of matrix based on values or calculations.

tSQLTemplateAggregate collects data values from one or more columns with the intent to manage the collection as a single unit. This component has real-time capabilities since it runs the data transformation on the DBMS itself.

**tSQLTemplateAggregate Standard properties**

These properties are used to configure tSQLTemplateAggregate running in the Standard Job framework.

The Standard tSQLTemplateAggregate component belongs to the ELT family.

The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>Database Type</th>
<th>Select the database type you want to connect to from the list.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component List</td>
<td>Select the relevant DB connection component in the list if you use more than one connection in the current Job.</td>
</tr>
<tr>
<td>Database name</td>
<td>Name of the database.</td>
</tr>
<tr>
<td>Source table name</td>
<td>Name of the table holding the data you want to collect values from.</td>
</tr>
<tr>
<td>Target table name</td>
<td>Name of the table you want to write the collected and transformed data in.</td>
</tr>
</tbody>
</table>

**Schema and Edit schema**

A schema is a row description, that is to say, it defines the number of fields that will be processed and passed on to the next component. The schema is either built-in or remote in the Repository.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **[Repository Content]** window.
### Built-in
You create and store the schema locally for this component only. Related topic: see *Talend Studio User Guide*.

### Repository
You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job flowcharts. Related topic: see *Talend Studio User Guide*.

### Operations
Select the type of operation along with the value to use for the calculation and the output field.

#### Output Column
Select the destination field in the list.

#### Function
Select any of the following operations to perform on data: **count**, **min**, **max**, **avg**, **sum**, and **count (distinct)**.

#### Input column position
Select the input column from which you want to collect the values to be aggregated.

### Group by
Define the aggregation sets, the values of which will be used for calculations.

#### Output Column
Select the column label in the list offered according to the schema structure you defined. You can add as many output columns as you wish to make more precise aggregations.

#### Input column position
Match the input column label with your output columns, in case the output label of the aggregation set needs to be different.

### Advanced settings

#### tStatCatcher Statistics
Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

### Global Variables

#### Global Variables
**NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.

**QUERY**: the query statement being processed. This is a Flow variable and it returns a string.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

### Usage

<table>
<thead>

<td>SQL Template</td>
<td>SQL Template List</td>
</tr>
</tbody>
</table>

**Scenario: Filtering and aggregating table columns directly on the DBMS**

The following scenario creates a Job that opens a connection to a Mysql database and:

- instantiates the schemas from a database table whose rows match the column names specified in the filter,
- filters a column in the same database table to have only the data that matches a WHERE clause,
- collects data grouped by specific value(s) from the filtered column and writes aggregated data in a target database table.

To filter and aggregate database table columns:

- Drop the following components from the **Palette** onto the design workspace: tELTMysqlconnection, tSQLTemplateFilterColumns, tSQLTemplateFilterRows, tSQLTemplateAggregate, tSQLTemplateCommit, and tSQLTemplateRollback.
- Connect the five first components using **OnComponentOk** links.
- Connect **tSQLTemplateAggregate** to **tSQLTemplateRollback** using an **OnComponentError** link.
- In the design workspace, select **tMysqlConnection** and click the **Component** tab to define the basic settings for **tMysqlConnection**.
• In the **Basic settings** view, set the database connection details manually or select **Repository** from the **Property Type** list and select your DB connection if it has already been defined and stored in the **Metadata** area of the **Repository** tree view.

For more information about Metadata, see *Talend Studio User Guide*.

• In the design workspace, select **tSQLTemplateFilterColumns** and click the **Component** tab to define its basic settings.

  ![tSQLTemplateFilterColumns_1](image)

  - On the **Database type** list, select the relevant database.
  - On the **Component list**, select the relevant database connection component if more than one connection is used.
  - Enter the names for the database, source table, and target table in the corresponding fields and click the three-dot buttons next to **Edit schema** to define the data structure in the source and target tables.

    **Note:**

    When you define the data structure for the source table, column names automatically appear in the **Column** list in the **Column filters** panel.

    In this scenario, the source table has five columns: `id`, `First_Name`, `Last_Name`, `Address`, and `id_State`.
  
• In the **Column filters** panel, set the column filter by selecting the check boxes of the columns you want to write in the source table.
In this scenario, the tSQLTemplateFilterColumns component instantiates only three columns: id, First_Name, and id_State from the source table.

**Note:**

In the Component view, you can click the SQL Template tab and add system SQL templates or create your own and use them within your Job to carry out the coded operation. For more information, see tSQLTemplateFilterColumns Standard properties on page 3669.

- In the design workspace, select tSQLTemplateFilterRows and click the Component tab to define its basic settings.

  ![tSQLTemplateFilterRows_1](image)

- On the Database type list, select the relevant database.

- On the Component list, select the relevant database connection component if more than one connection is used.

- Enter the names for the database, source table, and target table in the corresponding fields and click the three-dot buttons next to Edit schema to define the data structure in the source and target tables.

In this scenario, the source table has the three initially instantiated columns: id, First_Name, and id_State and the source table has the same three-column schema.

- In the Where condition field, enter a WHERE clause to extract only those records that fulfill the specified criterion.

In this scenario, the tSQLTemplateFilterRows component filters the First_Name column in the source table to extract only the first names that contain the ‘a’ letter.

- In the design workspace, select tSQLTemplateAggregate and click the Component tab to define its basic settings.

- On the Database type list, select the relevant database.

- On the Component list, select the relevant database connection component if more than one connection is used.

- Enter the names for the database, source table, and target table in the corresponding fields and click the three-dot buttons next to Edit schema to define the data structure in the source and target tables.

The schema for the source table consists of the three columns: id, First_Name, and id_State. The schema for the target table consists of two columns: customers_status and customers_number. In this scenario, we want to group customers by their marital status and count customer number in each marital group. To do that, we define the Operations and Group by panels accordingly.
• In the Operations panel, click the plus button to add one or more lines and then click in the Output column line to select the output column that will hold the counted data.

• Click in the Function line and select the operation to be carried on.

• In the Group by panel, click the plus button to add one or more lines and then click in the Output column line to select the output column that will hold the aggregated data.

• In the design workspace, select `tSQLTemplateCommit` and click the Component tab to define its basic settings.

• On the Database type list, select the relevant database.

• On the Component list, select the relevant database connection component if more than one connection is used.

• Do the same for `tSQLTemplateRollback`.

• Save your Job and press F6 to execute it.

A two-column table `aggregate_customers` is created in the database. It groups customers according to their marital status and count customer number in each marital group.

```
customers_status   customers_number
Married            1
Single             3
```
**tSQLTemplateCommit**

Commits a global action in one go using a single connection, instead of doing so for every row or every batch of rows separately. This provides a gain in performance.

tSQLTemplateCommit validates the data processed in a Job in a specified database.

**tSQLTemplateCommit Standard properties**

These properties are used to configure tSQLTemplateCommit running in the Standard Job framework.

The Standard tSQLTemplateCommit component belongs to the ELT family.

The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>Database Type</th>
<th>Select the database type you want to connect to from the list.</th>

<td>SQL Template List</td>
</tr>
</tbody>
</table>

**Related scenario**

For more information on *tSQLTemplateCommit*, see *Scenario: Filtering and aggregating table columns directly on the DBMS* on page 3663.
tSQLTemplateFilterColumns

Homogenizes schemas by reorganizing, deleting or adding new columns.

tSQLTemplateFilterColumns makes specified changes to the defined schema of the database table based on column name mapping. This component has real-time capabilities since it runs the data filtering on the DBMS itself.

**tSQLTemplateFilterColumns Standard properties**

These properties are used to configure tSQLTemplateFilterColumns running in the Standard Job framework.

The Standard tSQLTemplateFilterColumns component belongs to the ELT family.

The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>Database Type</th>
<th>Select the type of database you want to work on from the drop-down list.</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>

**Schema and Edit schema**

A schema is a row description, it defines the number of fields that will be processed and passed on to the next component. The schema is either built-in or remote in the Repository.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.

**Built-in**: You create and store the schema locally for this component only. Related topic: see *Talend Studio User Guide*.
Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job flowcharts. Related topic: see Talend Studio User Guide.

Column Filters

In the table, click the Filter check box to filter all of the columns. To select specific columns for filtering, select the check box(es) which correspond(s) to the column name(s).

Advanced settings

tStatCatcher Statistics

Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

Global Variables

Global Variables

NB_LINE: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.

QUERY: the query statement being processed. This is a Flow variable and it returns a string.

ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule

This component is used as an intermediary component with other relevant DB components, especially DB connection components.

</table>
Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job flowcharts. Related topic: see *Talend Studio User Guide*.

Where condition

Use a WHERE clause to set the criteria that you want the rows to meet.

You can use the WHERE clause to select specific rows from the table that match specified criteria or conditions.

**Advanced settings**

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

**Global Variables**

**Global Variables**

**NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.

**QUERY**: the query statement being processed. This is a Flow variable and it returns a string.

**ERROR MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

**Usage**

**Usage rule**

This component is used as an intermediary component with other DB components, particularly DB connection components.

**SQL Template**

**SQL Template List**

**Related Scenario**

For a related scenario, see *Scenario: Filtering and aggregating table columns directly on the DBMS* on page 3663.
tSQLTemplateMerge

Merges data into a database table directly on the DBMS by creating and executing a MERGE statement.

tSQLTemplateMerge creates an SQL MERGE statement to merge data into a database table.

**tSQLTemplateMerge Standard properties**

These properties are used to configure tSQLTemplateMerge running in the Standard Job framework.

The Standard tSQLTemplateMerge component belongs to the ELT family.

The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database Type</strong></td>
<td>Select the type of database you want to work on from the drop-down list.</td>
</tr>
<tr>
<td><strong>Component list</strong></td>
<td>Select the relevant DB connection component from the list if you use more than one connection in the current Job.</td>
</tr>
<tr>
<td><strong>Source table name</strong></td>
<td>Name of the database table holding the data you want to merge into the target table.</td>
</tr>
<tr>
<td><strong>Target table name</strong></td>
<td>Name of the table you want to merge data into.</td>
</tr>
</tbody>
</table>

**Schema and Edit schema**

This component involves two schemas: source schema and target schema.

A schema is a row description, that is to say, it defines the number of fields to be processed and passed on to the next component. The schema is either built-in or remotely stored in the Repository.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.

**Built-in**: The schema is created and stored locally for this component only. Related topic: see *Talend Studio User Guide*. 
Repository: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide.

| **Merge ON** | Specify the target and source columns you want to use as the primary keys. |
| **Use UPDATE (WHEN MATCHED)** | Select this check box to update existing records. With the check box selected, the **UPDATE Columns** table appears, allowing you to define the columns in which records are to be updated. |
| **Specify additional output columns** | Select this check box to update records in additional columns other than those listed in the **UPDATE Columns** table. With this check box selected, the **Additional UPDATE Columns** table appears, allowing you to specify additional columns. |
| **Specify UPDATE WHERE clause** | Select this check box and type in a WHERE clause in the **WHERE clause** field to filter data during the update operation.  

**Note:** This option may not work with certain database versions, including Oracle 9i. |
| **Use INSERT (WHEN MATCHED)** | Select this check box to insert new records. With the check box selected, the **INSERT Columns** table appears, allowing you to specify the columns to be involved in the insert operation. |
| **Specify additional output columns** | Select this check box to insert records to additional columns other than those listed in the **INSERT Columns** table. With this check box selected, the **Additional INSERT Columns** table appears, allowing you to specify additional columns. |
| **Specify INSERT WHERE clause** | Select this check box and type in a WHERE clause in the **WHERE clause** field to filter data during the insert operation.  

**Note:** This option may not work with certain database versions, including Oracle 9i. |

### Advanced settings

**tStatCatcher Statistics**  
Select this check box to gather the Job processing metadata at a Job level as well as at component level.

### Global Variables

**Global Variables**  
**NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.
### tSQLTemplateMerge

**NB_LINE_MERGED**: the number of rows merged. This is an After variable and it returns an integer.

**QUERY**: the query statement being processed. This is a Flow variable and it returns a string.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

### Usage

<table>
<thead>
<tr>

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>SQL Template</strong></td>
<td>This component is used as an intermediate component with other relevant DB components, especially the DB connection and commit components.</td>
</tr>
</tbody>
</table>

### Scenario: Merging data directly on the DBMS

This scenario describes a simple Job that opens a connection to a MySQL database, merges data from a source table into a target table according to customer IDs, and displays the contents of the target table before and after the merge action. A WHERE clause is used to filter data during the merge operation.
• Drop a tMysqlConnection component, a tSQLTemplateMerge component, two tMysqlInput components and two tLogRow components from the Palette onto the design workspace.

• Connect the tMysqlConnection component to the first tMysqlInput component using a Trigger > OnSubjobOK connection.

• Connect the first tMysqlInput component to the first tLogRow component using a Row > Main connection. This row will display the initial contents of the target table on the console.

• Connect the first tMysqlInput component to the tSQLTemplateMerge component, and the tSQLTemplateMerge component to the second tMysqlInput component using Trigger > OnSubjobOK connections.

• Connect the second tMysqlInput component to the second tLogRow component using a Row > Main connection. This row will display the merge result on the console.

• Double-click the tMysqlConnection component to display its Basic settings view.

• Set the database connection details manually or select Repository from the Property Type list and select your DB connection if it has already been defined and stored in the Metadata area of the Repository tree view.
For more information about Metadata, see *Talend Studio User Guide*.

- Double-click the first **tMysqlInput** component to display its **Basic settings** view.

- Select the **Use an existing connection** check box. If you are using more than one DB connection component in your Job, select the component you want to use from the **Component List**.

- Click the three-dot button next to **Edit schema** and define the data structure of the target table, or select **Repository** from the **Schema** list and select the target table if the schema has already been defined and stored in the **Metadata** area of the **Repository** tree view.

  In this scenario, we use built-in schemas.

- Define the columns as shown above, and then click **OK** to propagate the schema structure to the output component and close the schema dialog box.

- Fill the **Table Name** field with the name of the target table, *customer_info_merge* in this scenario.

- Click the **Guess Query** button, or type **"SELECT * FROM customer_info_merge"** in the **Query** area, to retrieve all the table columns.
• Define the properties of the second `tMysqlInput` component, using exactly the same settings as for the first `tMysqlInput` component.

• In the Basic settings view of each `tLogRow` component, select the Table option in the Mode area so that the contents will be displayed in table cells on the console.

• Double-click the `tSQLTemplateMerge` component to display its Basic settings view.

• Type in the names of the source table and the target table in the relevant fields.

In this scenario, the source table is `new_customer_info`, which contains eight records; the target table is `customer_info_merge`, which contains five records, and both tables have the same data structure.

Note:

The source table and the target table may have different schema structures. In this case, however, make sure that the source column and target column specified in each line of the Merge ON table, the UPDATE Columns table, and the INSERT Columns table are identical in data type and the target column length allows the insertion of the data from the corresponding source column.

• Define the source schema manually, or select Repository from the Schema list and select the relevant table if the schema has already been defined and stored in the Metadata area of the Repository tree view.

In this scenario, we use built-in schemas.
• Define the columns as shown above and click **OK** to close the schema dialog box, and do the same for the target schema.

• Click the green plus button beneath the **Merge ON** table to add a line, and select the **ID** column as the primary key.

```
<table>
<thead>
<tr>

**Warning:**

The columns defined as the primary key CANNOT and MUST NOT be made subject to updates.

• Select the **Specify UPDATE WHERE clause** check box and type in `customer_info_merge.ID >= 4` within double quotation marks in the **WHERE clause** field so that only those existing records with an ID equal to or greater than 4 will be updated.

```
Use UPDATE (WHEN MATCHED)
```

In this scenario, we want to update all the columns according to the customer IDs. Therefore, we select all the columns except the **ID** column.

**Warning:**

The columns defined as the primary key CANNOT and MUST NOT be made subject to updates.
• Select the **Use INSERT (WHEN MATCHED)** check box and define the columns to take data from and insert data to in the **INSERT Columns** table.

In this example, we want to insert all the records that do not exist in the target table.

• Select the **SQL Template** view to display and add the SQL templates to be used.

By default, the **SQLTemplateMerge** component uses two system SQL templates: **MergeUpdate** and **MergeInsert**.

**Note:**
In the **SQL Template** tab, you can add system SQL templates or create your own and use them within your Job to carry out the coded operation. For more information, see **tSQLTemplateFilterColumns Standard properties** on page 3669.
- Click the **Add** button to add a line and select **Commit** from the template list to commit the merge result to your database.

Alternatively, you can connect the **tSQLTemplateMerge** component to a **tSQLTemplateCommit** or **tMysqlCommit** component using a **Trigger > OnSubjobOK** connection to commit the merge result to your database.

- Save your Job and press **F6** to run it.

Both the original contents of the target table and the merge result are displayed on the console. In the target table, records No. 4 and No. 5 contain the updated information, and records No. 6 through No. 8 contain the inserted information.

```
Starting job MergeData at 10:56 01/04/2011

**Job MergeData ended at 10:56 01/04/2011. [exit code=0]**
tSQLTemplateRollback

Cancels the transaction committed in the SQLTemplate database.

**tSQLTemplateRollback Standard properties**

These properties are used to configure tSQLTemplateRollback running in the Standard Job framework.

The Standard tSQLTemplateRollback component belongs to the ELT family.

The component in this framework is generally available.

### Basic settings

<table>
<thead>
<tr>
<th><strong>Database Type</strong></th>
<th>Select the database type you want to connect to from the list.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Component List</strong></td>
<td>Select the ELT database connection component in the list if more than one connection is planned for the current Job.</td>
</tr>
<tr>
<td><strong>Close Connection</strong></td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

### Advanced settings

| **tStatCatcher Statistics** | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

### Global Variables

| **Global Variables** | **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.  
**QUERY**: the query statement being processed. This is a Flow variable and it returns a string.  
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
For further information about variables, see Talend Studio User Guide. |

Usage

<table>

</table>

Related scenarios

For a \texttt{tSQLTemplateRollback} related scenario, see \texttt{Scenario: Filtering and aggregating table columns directly on the DBMS} on page 3663.
tSqoopExport

Defines the arguments required by Sqoop for transferring data to a RDBMS.

tSqoopExport calls sqoop to transfer data from the Hadoop Distributed File System (HDFS) to a relational database management system (RDBMS).

Please be aware that some features provided by this component are only supported by the latest Sqoop version. For further information about the availability of each feature, see Apache’s documentation about Sqoop.

Note:
Sqoop is typically installed in every Hadoop distribution. But if the Hadoop distribution you need to use have no Sqoop installed, you have to install one on your own and ensure to add the Sqoop command line to the PATH variable of that distribution. For further information about how to install Sqoop, see the documentation of Sqoop.

Additional arguments

</tbody>
</table>
**tSqoopExport Standard properties**

These properties are used to configure tSqoopExport running in the Standard Job framework.

The Standard tSqoopExport component belongs to the Big Data and the File families.

The component in this framework is available when you are using one of the Talend solutions with Big Data.

**Basic settings**

<table>
<thead>
<tr>
<th>Mode</th>
<th>Select the mode in which Sqoop is called in a Job execution.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Use Commandline</strong></td>
<td>the Sqoop shell is used to call Sqoop. In this mode, you have to deploy and run the Job in the host where Sqoop is installed. Therefore, if you are a subscription-based user, we recommend installing and using a Jobserver provided by Talend in that host to run the Job; if you are using one of the Talend solutions with Big Data, you have to ensure that the Studio and the Sqoop to be used are in the same machine.</td>
</tr>
<tr>
<td><strong>Use Java API</strong></td>
<td>the Java API is used to call Sqoop. In this mode, the Job can be run locally in the Studio but you need to configure the connection to the Hadoop distribution to be used. Note that JDK is required to execute the Job in the Java API mode and the versions of the JDK kits installed in both machines must be compatible with each other; for example, the versions are the same or the JDK version of the Hadoop machine is more recent.</td>
</tr>
</tbody>
</table>

---

For further information about the arguments available in the Sqoop commandline mode, see the documentation of Sqoop.

The arguments listed earlier for the Java API mode are subject to updates and changes by Java. For further information about these arguments, see [http://svn.apache.org/repos/asf/sqoop/trunk/src/java/org/apache/sqoop/SqoopOptions.java](http://svn.apache.org/repos/asf/sqoop/trunk/src/java/org/apache/sqoop/SqoopOptions.java)
### Hadoop properties

Either **Built-in** or **Repository**:

- **Built-in**: you enter the configuration information of the Hadoop distribution to be used locally for this component only.

- **Repository**: you have already created the Hadoop connection and stored it in the Repository; therefore, you reuse it directly for the component configuration and the Job design. For further information about how to create a centralized Hadoop connection, see [Talend Open Studio for Big Data Getting Started Guide](https://help.talend.com).

### Distribution

Select the cluster you are using from the drop-down list. The options in the list vary depending on the component you are using. Among these options, the following ones requires specific configuration:

- If available in this Distribution drop-down list, the **Microsoft HD Insight** option allows you to use a Microsoft HD Insight cluster. For this purpose, you need to configure the connections to the HD Insight cluster and the Windows Azure Storage service of that cluster in the areas that are displayed. For detailed explanation about these parameters, search for configuring the connection manually on Talend Help Center (https://help.talend.com).

- If you select **Amazon EMR**, you can find more details about how to configure an Amazon EMR cluster in Talend Help Center (https://help.talend.com).

- The **Custom** option allows you to connect to a cluster different from any of the distributions given in this list, that is to say, to connect to a cluster not officially supported by Talend.

1. Select **Import from existing version** to import an officially supported distribution as base and then add other required jar files which the base distribution does not provide.

2. Select **Import from zip** to import the configuration zip for the custom distribution to be used. This zip file should contain the libraries of the different Hadoop elements and the index file of these libraries.

In Talend Exchange, members of Talend community have shared some ready-for-use configuration zip files which you can download from this Hadoop configuration list and directly use them in your connection accordingly. However, because of the ongoing evolution of the different Hadoop-related projects, you might not be able to find the configuration zip corresponding to your distribution from this list; then it is recommended to use the **Import from existing version** option to take an existing distribution as base to add the jars required by your distribution.
Note that custom versions are not officially supported by **Talend**. **Talend** and its community provide you with the opportunity to connect to custom versions from the Studio but cannot guarantee that the configuration of whichever version you choose will be easy, due to the wide range of different Hadoop distributions and versions that are available. As such, you should only attempt to set up such a connection if you have sufficient Hadoop experience to handle any issues on your own.

**Note:**
In this dialog box, the active check box must be kept selected so as to import the jar files pertinent to the connection to be created between the custom distribution and this component.

For a step-by-step example about how to connect to a custom distribution and share this connection, see [Connecting to a custom Hadoop distribution](#) on page 1589.

<table>
<thead>
<tr>
<th>Hadoop Version</th>
<th>Select the version of the Hadoop distribution you are using. The available options vary depending on the component you are using.</th>
</tr>
</thead>
<tbody>
<tr>
<td>NameNode URI</td>
<td>Type in the URI of the Hadoop NameNode, the master node of a Hadoop system. For example, we assume that you have chosen a machine called <em>masternode</em> as the NameNode, then the location is hdfs://masternode:portnumber. If you are using WebHDFS, the location should be webhdfs://masternode:portnumber; if this WebHDFS is secured with SSL, the scheme should be swebhdfs and you need to use a tLibraryLoad in the Job to load the library required by the secured WebHDFS.</td>
</tr>
</tbody>
</table>
| JobTracker Host | Select this check box and in the displayed field, enter the location of the ResourceManager of your distribution. For example, tal-qa114.tale nd.lan:8050. This property is required when the query you want to use is executed in Windows and it is a Select query. For example, `SELECT your_column_name FROM your_table_name` Then you can continue to set the following parameters depending on the configuration of the Hadoop cluster to be used (if you leave the check box of a parameter clear, then at runtime, the configuration about this parameter in the Hadoop cluster to be used will be ignored):  
  1. Select the **Set resourcemanager scheduler address** check box and enter the Scheduler address in the field that appears.  
  2. Select the **Set jobhistory address** check box and enter the location of the JobHistory server of the |
Hadoop cluster to be used. This allows the metrics information of the current Job to be stored in that JobHistory server.

3. Select the Set staging directory check box and enter this directory defined in your Hadoop cluster for temporary files created by running programs. Typically, this directory can be found under the yarn.app.mapreduce.am.staging-dir property in the configuration files such as yarn-site.xml or mapred-site.xml of your distribution.

4. Allocate proper memory volumes to the Map and the Reduce computations and the ApplicationMaster of YARN by selecting the Set memory check box in the Advanced settings view.

5. Select the Set Hadoop user check box and enter the user name under which you want to execute the Job. Since a file or a directory in Hadoop has its specific owner with appropriate read or write rights, this field allows you to execute the Job directly under the user name that has the appropriate rights to access the file or directory to be processed.

6. Select the Use datanode hostname check box to allow the Job to access datanodes via their hostnames. This actually sets the dfs.client.use.datanode.hostname property to true. When connecting to a S3N filesystem, you must select this check box.

For further information about these parameters, see the documentation or contact the administrator of the Hadoop cluster to be used.

For further information about the Hadoop Map/Reduce framework, see the Map/Reduce tutorial in Apache’s Hadoop documentation on http://hadoop.apache.org.

Use kerberos authentication

If you are accessing the Hadoop cluster running with Kerberos security, select this check box, then, enter the Kerberos principal name for the NameNode in the field displayed. This enables you to use your user name to authenticate against the credentials stored in Kerberos.

- If this cluster is a MapR cluster of the version 5.0.0 or later, you can set the MapR ticket authentication configuration in addition or as an alternative by following the explanation in Connecting to a security-enabled MapR on page 1652.

Keep in mind that this configuration generates a new MapR security ticket for the username defined in the Job in each execution. If you need to reuse an existing ticket issued for the same username, leave both the Force MapR ticket authentication check box and the Use Kerberos authentication check box clear, and then MapR should be able to automatically find that ticket on the fly.

In addition, since this component performs Map/Reduce computations, you also need to authenticate the related services such as the Job history server and the Resource

Use kerberos authentication
manager or Jobtracker depending on your distribution in the corresponding field. These principals can be found in the configuration files of your distribution. For example, in a CDH4 distribution, the Resource manager principal is set in the `yarn-site.xml` file and the Job history principal in the `mapred-site.xml` file.

This check box is available depending on the Hadoop distribution you are connecting to.

| Use a keytab to authenticate | Select the **Use a keytab to authenticate** check box to log into a Kerberos-enabled system using a given keytab file. A keytab file contains pairs of Kerberos principals and encrypted keys. You need to enter the principal to be used in the **Principal** field and the access path to the keytab file itself in the **Keytab** field. This keytab file must be stored in the machine in which your Job actually runs, for example, on a Talend Jobserver.

Note that the user that executes a keytab-enabled Job is not necessarily the one a principal designates but must have the right to read the keytab file being used. For example, the user name you are using to execute a Job is **user1** and the principal to be used is **guest**; in this situation, ensure that **user1** has the right to read the keytab file to be used. |
| Hadoop user name | Enter the user name under which you want to execute the Job. Since a file or a directory in Hadoop has its specific owner with appropriate read or write rights, this field allows you to execute the Job directly under the user name that has the appropriate rights to access the file or directory to be processed. Note that this field is available depending on the distribution you are using. |
| JDBC property | Either **Built-in** or **Repository**:

- **Built-in**: you enter the connection information of the database to be used locally for this component only.

- **Repository**: you have already created the database connection and stored it in the **Repository**; therefore, you reuse it directly for the component configuration and the Job design. For further information about how to create a centralized database connection, see **Talend Studio User Guide**.

Note that only the **General JDBC** connection stored in the **Repository** is supported. |
| Connection | Type in the JDBC URL used to connect to the target database. |
| User name and Password | Type in the authentication information to the target database.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.
If your password is stored in a file, select the **The password is stored in a file** check box and enter the path to that file in the **File path** field that is displayed.

- This file can be stored either in the machine where the Job is to be executed or in the HDFS system of the Hadoop cluster to be used.
- The password stored in this file must not contain `\n` (the newline escape) at the end, that is to say, you must not insert a new line at the end of the password even though this line is empty.

Note that this feature is available depending on the Sqoop version you are using.

<table>
<thead>
<tr>
<th><strong>Driver JAR</strong></th>
<th>In either the <strong>Use Commandline</strong> mode or the <strong>Java API</strong> mode, you must add the driver file of the database to be used to the <strong>lib</strong> folder of the Hadoop distribution you are using. For that purpose, use this <strong>Driver JAR</strong> table to add that driver file for the current Job you are designing.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Table Name</strong></td>
<td>Type in the name of the target table to which data is transferred from HDFS. This table must already exist in the target database. The input files are read and parsed into a set of records according to the user-specified delimiters.</td>
</tr>
<tr>
<td><strong>Export Dir</strong></td>
<td>Enter the path to the source data to be transferred in HDFS.</td>
</tr>
<tr>
<td><strong>Direct</strong></td>
<td>Select this check box to use the export fast path.</td>
</tr>
<tr>
<td><strong>Specify Number of Mappers</strong></td>
<td>Select this check box to indicate the number of map tasks (parallel processes) used to perform the data transfer. If you do not want Sqoop to work in parallel, enter 1 in the displayed field.</td>
</tr>
<tr>
<td><strong>Call a stored procedure</strong></td>
<td>Select this check box to enable the component to call a specific store procedure to write data into the target database. You need to enter the name of the stored procedure to be used in the field that is displayed. Syntax and capabilities of stored procedures vary among different databases; for this reason, you are recommended to consult the documentation of the database you want to use for details about how a given stored procedure could be called.</td>
</tr>
<tr>
<td><strong>Use batch mode</strong></td>
<td>Select this check box to execute the statements in batch mode instead of running a multi-row INSERT statement to write multiple records in the target database.</td>
</tr>
<tr>
<td><strong>Clear staging table</strong></td>
<td>If you are using a specific staging table for the desired data transfer, select this check box to ensure that the staging table is empty when the data transfer runs.</td>
</tr>
</tbody>
</table>
### Define a staging table

Select this check box to create a staging table for the data to be transferred. The transferred data is staged within this table before being written into the target table so as to avoid only a part of the data being committed to the target table when the transfer fails.

For further information about whether a staging table is supported for a given data transfer, see Apache’s documentation for Sqoop.

### Specify how updates are performed when new rows are found with non-match keys in database

Select this check box to determine the action to be taken when a given update key does not have any matching records in the target table. You can then select either of the following options:

- **Update only**: this updates only the records that already exist in the target table.
- **Allow insert**: this works like the SQL UPSERT statement. It writes new records in the table if they do not exist there.

### Use column for update

Select this check box and in the table that is displayed, add the columns to be used as the update key.

### Print Log

Select this check box to activate the **Verbose** check box.

### Verbose

Select this check box to print more information while working, for example, the debugging information.

### Advanced settings

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Use MySQL default delimiters</strong></td>
<td>Select this check box to use MySQL’s default delimiter set. This check box is available only to the Commandline mode.</td>
</tr>
<tr>
<td><strong>Define Java mapping</strong></td>
<td>Sqoop provides default configuration that maps most SQL types to appropriate Java types. If you need to use your custom map to overwrite the default ones at runtime, select this check box and define the map(s) you want to use in the table that appears.</td>
</tr>
<tr>
<td><strong>Additional arguments</strong></td>
<td>Complete this table to use additional arguments if needed. By adding additional arguments, you are able to perform multiple operations in one single transaction. For example, you can use <code>--hive-import</code> and <code>--hive-table</code> in the Commandline mode or <code>hive.import</code> and <code>hive.table.name</code> in the Java API mode to create Hive table and write data in at the runtime of the transaction writing data in HDFS. For further information about the available Sqoop arguments in the Commandline mode and the Java API mode, respectively, see Additional arguments on page 3684.</td>
</tr>
<tr>
<td><strong>Use speed parallel data transfers</strong></td>
<td>Select this check box to enable quick parallel data transfers between the Teradata database and the Hortonworks Hadoop distribution. Then the Specific pa</td>
</tr>
</tbody>
</table>
rams table and the **Use additional params** check box appear to allow you to specify the Teradata parameters required by parallel transfers.

- In the **Specific params** table, two columns are available:
  - **Argument**: select the parameters as needed from the drop-down list. They are the most common parameters for the parallel transfer.
  - **Value**: type in the value of the parameters.

- By selecting the **Additional params** check box, you make the **Specific additional params** field displayed. In this field, you can enter the Teradata parameters that you need to use but are not provided in the **Specific params** table. The syntax for a parameter is `-Dparameter=value` and when you put more than one parameter in this field, separate them using whitespace.

You must ensure that the Hortonworks Connector for Teradata has been installed in your Hortonworks cluster. The latest connector can be downloaded from the website of Hortonworks and installed by following the explanations from [http://hortonworks.com/wp-content/uploads/2014/02/bk_HortonworksConnectorForTeradata.pdf](http://hortonworks.com/wp-content/uploads/2014/02/bk_HortonworksConnectorForTeradata.pdf). In the same document, you can as well find the detailed explanations about each parameter that is available for the parallel transfer purpose.

Available in the **Use Commandline** mode only.

### Hadoop properties

**Talend Studio** uses a default configuration for its engine to perform operations in a Hadoop distribution. If you need to use a custom configuration in a specific situation, complete this table with the property or properties to be customized. Then at runtime, the customized property or properties will override those default ones.

- Note that if you are using the centrally stored metadata from the **Repository**, this table automatically inherits the properties defined in that metadata and becomes uneditable unless you change the **Property type** from **Repository** to **Built-in**.

For further information about the properties required by Hadoop and its related systems such as HDFS and Hive, see the documentation of the Hadoop distribution you are using or see Apache's Hadoop documentation on [http://hadoop.apache.org/docs](http://hadoop.apache.org/docs) and then select the version of the documentation you want. For demonstration purposes, the links to some properties are listed below:

- Typically, the HDFS-related properties can be found in the `hdfs-default.xml` file of your distribution, such as [http://hadoop.apache.org/docs/r2.6.0/hadoop-project-dist/hadoop-hdfs/hdfs-default.xml](http://hadoop.apache.org/docs/r2.6.0/hadoop-project-dist/hadoop-hdfs/hdfs-default.xml).
Apache also provides a page to list the Hive-related properties: https://cwiki.apache.org/confluence/display/Hive/Configuration+Properties.

Mapred job map memory mb and Mapred job reduce memory mb
You can tune the map and reduce computations by selecting the Set memory check box to set proper memory allocations for the computations to be performed by the Hadoop system.

In that situation, you need to enter the values you need in the Mapred job map memory mb and the Mapred job reduce memory mb fields, respectively. By default, the values are both 1000 which are normally appropriate for running the computations.

The memory parameters to be set are Map (in Mb), Reduce (in Mb) and ApplicationMaster (in Mb). These fields allow you to dynamically allocate memory to the map and the reduce computations and the ApplicationMaster of YARN.

Path separator in server
Leave the default value of the Path separator in server as it is, unless you have changed the separator used by your Hadoop distribution’s host machine for its PATH variable or in other words, that separator is not a colon (:). In that situation, you must change this value to the one you are using in that host.

tStatCatcher Statistics
Select this check box to collect log data at the component level.

Global Variables

Global Variables

ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

EXIT_CODE: the exit code of the remote command. This is an After variable and it returns an integer.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule
This component is used standalone. It respects the Sqoop prerequisites. You need necessary knowledge about Sqoop to use it.

We recommend using the Sqoop of version 1.4+ in order to benefit the full functions of these components.
Prerequisites

The Hadoop distribution must be properly installed, so as to guarantee the interaction with Talend Studio. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native. For example, the library for Windows is \lib\native\MapRClient.dll in the MapR client jar file. For further information, see the following link from MapR: http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr.

Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path.

- Set the -Djava.library.path argument, for example, in the Job Run VM arguments area of the Run/Debug view in the [Preferences] dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

Limitation

If you have selected the Use Commandline mode, you need to use the host where Sqoop is installed to run the Job using this component.

Connections

Outgoing links (from this component to another):

**Trigger**: Run if; On Subjob Ok; On Subjob Error.

Incoming links (from one component to this one):

**Row**: Iterate;

**Trigger**: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error

For further information regarding connections, see Talend Studio User Guide.

Related scenarios

No scenario is available for the Standard version of this component yet.
tSqoopImport

Defines the arguments required by Sqoop for writing the data of your interest into HDFS.

tSqoopImport calls Sqoop to transfer data from a relational database management system (RDBMS) such as MySQL or Oracle into the Hadoop Distributed File System (HDFS).

Note:
Sqoop is typically installed in every Hadoop distribution. But if the Hadoop distribution you need to use have no Sqoop installed, you have to install one on your own and ensure to add the Sqoop command line to the PATH variable of that distribution. For further information about how to install Sqoop, see the documentation of Sqoop.

tSqoopImport Standard properties

These properties are used to configure tSqoopImport running in the Standard Job framework.
The Standard tSqoopImport component belongs to the Big Data and the File families.
The component in this framework is available when you are using one of the Talend solutions with Big Data.

Basic settings

<table>
<thead>
<tr>
<th>Mode</th>
<th>Select the mode in which Sqoop is called in a Job execution.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use Commandline</td>
<td>the Sqoop shell is used to call Sqoop. In this mode, you have to deploy and run the Job in the host where Sqoop is installed. Therefore, if you are a subscription-based user, we recommend installing and using a Jobserver provided by Talend in that host to run the Job; if you are using one of the Talend solutions with Big Data, you have to ensure that the Studio and the Sqoop to be used are in the same machine.</td>
</tr>
<tr>
<td>Use Java API</td>
<td>the Java API is used to call Sqoop. In this mode, the Job can be run locally in the Studio but you need to configure the connection to the Hadoop distribution to be used. Note that JDK is required to execute the Job in the Java API mode and the versions of the JDK kits installed in both machines must be compatible with each other; for example, the versions are the same or the JDK version of the Hadoop machine is more recent.</td>
</tr>
</tbody>
</table>

Hadoop properties

Either Built-in or Repository:
- Built-in: you enter the configuration information of the Hadoop distribution to be used locally for this component only.
- Repository: you have already created the Hadoop connection and stored it in the Repository; therefore, you reuse it directly for the component configuration and the Job design. For further information about how to create a centralized
### Distribution

Select the cluster you are using from the drop-down list. The options in the list vary depending on the component you are using. Among these options, the following ones require specific configuration:

- If available in this Distribution drop-down list, the **Microsoft HD Insight** option allows you to use a Microsoft HD Insight cluster. For this purpose, you need to configure the connections to the HD Insight cluster and the Windows Azure Storage service of that cluster in the areas that are displayed. For detailed explanation about these parameters, search for configuring the connection manually on Talend Help Center ([https://help.talend.com](https://help.talend.com)).

- If you select **Amazon EMR**, you can find more details about how to configure an Amazon EMR cluster in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

- The **Custom** option allows you to connect to a cluster different from any of the distributions given in this list, that is to say, to connect to a cluster not officially supported by Talend.

1. Select **Import from existing version** to import an officially supported distribution as base and then add other required jar files which the base distribution does not provide.

2. Select **Import from zip** to import the configuration zip for the custom distribution to be used. This zip file should contain the libraries of the different Hadoop elements and the index file of these libraries.

   In Talend Exchange, members of Talend community have shared some ready-for-use configuration zip files which you can download from this [Hadoop configuration list](https://help.talend.com) and directly use them in your connection accordingly. However, because of the ongoing evolution of the different Hadoop-related projects, you might not be able to find the configuration zip corresponding to your distribution from this list; then it is recommended to use the **Import from existing version** option to take an existing distribution as base to add the jars required by your distribution.

Note that custom versions are not officially supported by Talend. Talend and its community provide you with the opportunity to connect to custom versions from the Studio but cannot guarantee that the configuration of whichever version you choose will be easy, due to the wide range of different Hadoop distributions and versions that are available. As such, you should only attempt to set up such a connection if you have sufficient Hadoop experience to handle any issues on your own.
### Note:
In this dialog box, the active check box must be kept selected so as to import the jar files pertinent to the connection to be created between the custom distribution and this component.

For a step-by-step example about how to connect to a custom distribution and share this connection, see Connecting to a custom Hadoop distribution on page 1589.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Hadoop Version</strong></td>
<td>Select the version of the Hadoop distribution you are using. The available options vary depending on the component you are using.</td>
</tr>
<tr>
<td><strong>NameNode URI</strong></td>
<td>Type in the URI of the Hadoop NameNode, the master node of a Hadoop system. For example, we assume that you have chosen a machine called <code>masternode</code> as the NameNode, then the location is <code>hdfs://masternode:portnumber</code>. If you are using WebHDFS, the location should be <code>webhdfs://masternode:portnumber</code>; if this WebHDFS is secured with SSL, the scheme should be <code>swebhdfs</code> and you need to use a <code>LibraryLoad</code> in the Job to load the library required by the secured WebHDFS.</td>
</tr>
</tbody>
</table>
| **JobTracker Host**    | Select this check box and in the displayed field, enter the location of the ResourceManager of your distribution. For example, `tal-qall4.taled.lan:8050`. This property is required when the query you want to use is executed in Windows and it is a Select query. For example, `SELECT your_column_name FROM your_table_name` Then you can continue to set the following parameters depending on the configuration of the Hadoop cluster to be used (if you leave the check box of a parameter clear, then at runtime, the configuration about this parameter in the Hadoop cluster to be used will be ignored):

1. Select the **Set resourcemanager scheduler address** check box and enter the Scheduler address in the field that appears.
2. Select the **Set jobhistory address** check box and enter the location of the JobHistory server of the Hadoop cluster to be used. This allows the metrics information of the current Job to be stored in that JobHistory server.
3. Select the **Set staging directory** check box and enter this directory defined in your Hadoop cluster for temporary files created by running programs. Typically, this directory can be found under the `yarn.app.mapreduce.am.staging-dir` property in the configuration files such as `yarn-site.xml` or `mapred-site.xml` of your distribution.
4. Allocate proper memory volumes to the **Map** and the **Reduce** computations and the **ApplicationMaster** of YARN by selecting the **Set memory** check box in the **Advanced settings** view.

5. Select the **Set Hadoop user** check box and enter the user name under which you want to execute the Job. Since a file or a directory in Hadoop has its specific owner with appropriate read or write rights, this field allows you to execute the Job directly under the user name that has the appropriate rights to access the file or directory to be processed.

6. Select the **Use datanode hostname** check box to allow the Job to access datanodes via their hostnames. This actually sets the `dfs.client.use.datanode.hostname` property to `true`. When connecting to a S3N filesystem, you must select this check box.

For further information about these parameters, see the documentation or contact the administrator of the Hadoop cluster to be used.

### Use kerberos authentication

If you are accessing the Hadoop cluster running with Kerberos security, select this check box, then, enter the Kerberos principal name for the NameNode in the field displayed. This enables you to use your user name to authenticate against the credentials stored in Kerberos.

- If this cluster is a MapR cluster of the version 5.0.0 or later, you can set the MapR ticket authentication configuration in addition or as an alternative by following the explanation in Connecting to a security-enabled MapR on page 1652.

Keep in mind that this configuration generates a new MapR security ticket for the username defined in the Job in each execution. If you need to reuse an existing ticket issued for the same username, leave both the **Force MapR ticket authentication** check box and the **Use Kerberos authentication** check box clear, and then MapR should be able to automatically find that ticket on the fly.

In addition, since this component performs Map/Reduce computations, you also need to authenticate the related services such as the Job history server and the Resource manager or Jobtracker depending on your distribution in the corresponding field. These principals can be found in the configuration files of your distribution. For example, in a CDH4 distribution, the Resource manager principal is set in the `yarn-site.xml` file and the Job history principal in the `mapred-site.xml` file.

This check box is available depending on the Hadoop distribution you are connecting to.
| **Use a keytab to authenticate** | Select the **Use a keytab to authenticate** check box to log into a Kerberos-enabled system using a given keytab file. A keytab file contains pairs of Kerberos principals and encrypted keys. You need to enter the principal to be used in the **Principal** field and the access path to the keytab file itself in the **Keytab** field. This keytab file must be stored in the machine in which your Job actually runs, for example, on a Talend Jobserver.

Note that the user that executes a keytab-enabled Job is not necessarily the one a principal designates but must have the right to read the keytab file being used. For example, the user name you are using to execute a Job is *user1* and the principal to be used is *guest*; in this situation, ensure that *user1* has the right to read the keytab file to be used. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Hadoop user name</strong></td>
<td>Enter the user name under which you want to execute the Job. Since a file or a directory in Hadoop has its specific owner with appropriate read or write rights, this field allows you to execute the Job directly under the user name that has the appropriate rights to access the file or directory to be processed. Note that this field is available depending on the distribution you are using.</td>
</tr>
</tbody>
</table>
| **JDBC property** | Either **Built-in** or **Repository**:

- **Built-in**: you enter the connection information of the database to be used locally for this component only.

- **Repository**: you have already created the database connection and stored it in the **Repository**; therefore, you reuse it directly for the component configuration and the Job design. For further information about how to create a centralized database connection, see *Talend Studio User Guide*.

Note that only the **General JDBC** connection stored in the **Repository** is supported. |
| **Connection** | Enter the JDBC URL used to connect to the database where the source data is stored. |
| **User name and Password** | Enter the authentication information used to connect to the source database.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

If your password is stored in a file, select the **The password is stored in a file** check box and enter the path to that file in the **File path** field that is displayed.

- This file can be stored either in the machine where the Job is to be executed or in the HDFS system of the Hadoop cluster to be used.

- The password stored in this file must not contain \n (the newline escape) at the end, that is to say, you must not insert a new line at the end of the password even though this line is empty. |
Note that this feature is available depending on the Sqoop version you are using.

| **Driver JAR** | In either the **Use Commandline** mode or the **Java API** mode, you must add the driver file of the database to be used to the \lib\ folder of the Hadoop distribution you are using. For that purpose, use this **Driver JAR** table to add that driver file for the current Job you are designing. |
| **Table Name** | Type in the name of the table to be transferred into HDFS. This field is not available when you are using the free-form query mode by selecting the **Use query** check box. |
| **File format** | Select a file format for the data to be transferred:  
- **textfile**  
- **sequencefile**  
- **Avro file**  
- **Parquet file**: the version of Sqoop must be 1.4.6. |
| **Delete target directory** | Select this check box to remove the target directory of the transfer. |
| **Append** | Select this check box to append transferred data to an existing dataset in HDFS. |
| **Compress** | Select this check box to enable compression. |
| **Direct** | Select this check box to use the import fast path. |
| **Specify columns** | Select this check box to display the column table where you can specify the columns you want to transfer into HDFS. |
| **Use WHERE clause** | Select this check box to use a WHERE clause that controls the rows to be transferred. In the field displayed, you can type in the condition used to select the rows you want. For example, type `id >400` to import only the rows where the `id` column has a value greater than 400. |
| **Use query** | Select this check box to use the free-form query mode provided by Sqoop.  
Once selecting it, you are able to enter the free-form query you need to use.  
Then, you must specify the target directory and if the Sqoop imports data in parallel, specify as well the **Split by** argument.  

**Warning:**  
Once queries are entered here, the value of the argument `--fields-terminated-by` can only be set to `\'\'` in the **Additional arguments** table in the **Advanced settings** tab. |
Specify Target Dir
Select this check box to enter the path to the target location, in HDFS, where you want to transfer the source data to.
This location should be a new directory; otherwise, you must select the Append check box.

Specify Split by
Select this check box, then, enter the table column you need and are able to use as the splitting column to split the workload.
For example, for a table where the id column is the key column, enter tablename.id. Then Sqoop will split the data to be transferred according to their ID values and imports them in parallel.

Specify Number of Mappers
Select this check box to indicate the number of map tasks (parallel processes) used to perform the data transfer.
If you do not want Sqoop to work in parallel, enter 1 in the displayed field.

Print Log
Select this check box to activate the Verbose check box.

Verbose
Select this check box to print more information while working, for example, the debugging information.

Advanced settings

Use MySQL default delimiters
Select this check box to use MySQL’s default delimiter set. This check box is available only to the Commandline mode.

Define Java mapping
Sqoop provides default configuration that maps most SQL types to appropriate Java types. If you need to use your custom map to overwrite the default ones at runtime, select this check box and define the map(s) you want to use in the table that appears.

Define Hive mapping
Sqoop provides default configuration that maps most SQL types to appropriate Hive types. If you need to use your custom map to overwrite the default ones at runtime, select this check box and define the map(s) you want to use in the table that appears.

Additional arguments
Complete this table to use additional arguments if needed be.
By adding additional arguments, you are able to perform multiple operations in one single transaction. For example, you can use --hive-import and --hive-table in the Commandline mode or hive.import and hive.table.name in the Java API mode to create Hive table and write data in at the runtime of the transaction writing data in HDFS. For further information about the availableSqoop arguments in the Commandline mode and the Java API mode, respectively, see Additional arguments on page 3684.
| Use speed parallel data transfers | Select this check box to enable quick parallel data transfers between the Teradata database and the Hortonworks Hadoop distribution. Then the **Specific params** table and the **Use additional params** check box appear to allow you to specify the Teradata parameters required by parallel transfers.

- In the **Specific params** table, two columns are available:
  - **Argument**: select the parameters as needed from the drop-down list. They are the most common parameters for the parallel transfer.
  - **Value**: type in the value of the parameters.
- By selecting the **Additional params** check box, you make the **Specific additional params** field displayed. In this field, you can enter the Teradata parameters that you need to use but are not provided in the **Specific params** table. The syntax for a parameter is `-Dparameter=value` and when you put more than one parameter in this field, separate them using whitespace.

You must ensure that the Hortonworks Connector for Teradata has been installed in your Hortonworks cluster. The latest connector can be downloaded from the website of Hortonworks and installed by following the explanations from [http://hortonworks.com/wp-content/uploads/2014/02/bk_HortonworksConnectorForTeradata.pdf](http://hortonworks.com/wp-content/uploads/2014/02/bk_HortonworksConnectorForTeradata.pdf). In the same document, you can as well find the detailed explanations about each parameter that is available for the parallel transfer purpose.

Available in the **Use Commandline** mode only.

| Hadoop properties | **Talend Studio** uses a default configuration for its engine to perform operations in a Hadoop distribution. If you need to use a custom configuration in a specific situation, complete this table with the property or properties to be customized. Then at runtime, the customized property or properties will override those default ones.

- Note that if you are using the centrally stored metadata from the **Repository**, this table automatically inherits the properties defined in that metadata and becomes uneditable unless you change the **Property type** from **Repository** to **Built-in**.

For further information about the properties required by Hadoop and its related systems such as HDFS and Hive, see the documentation of the Hadoop distribution you are using or see Apache’s Hadoop documentation on [http://hadoop.apache.org/docs](http://hadoop.apache.org/docs) and then select the version of the documentation you want. For demonstration purposes, the links to some properties are listed below:

- Typically, the HDFS-related properties can be found in the `hdfs-default.xml` file of your distribution, such
A Mapred job map memory mb and Mapred job reduce memory mb can be tuned by selecting the Set memory check box to set proper memory allocations for the computations to be performed by the Hadoop system. In that situation, you need to enter the values you need in the Mapred job map memory mb and the Mapred job reduce memory mb fields, respectively. By default, the values are both 1000 which are normally appropriate for running the computations.

The memory parameters to be set are Map (in Mb), Reduce (in Mb) and ApplicationMaster (in Mb). These fields allow you to dynamically allocate memory to the map and the reduce computations and the ApplicationMaster of YARN.

Path separator in server

Leave the default value of the Path separator in server as it is, unless you have changed the separator used by your Hadoop distribution’s host machine for its PATH variable or in other words, that separator is not a colon (:). In that situation, you must change this value to the one you are using in that host.

Global Variables

ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

EXIT_CODE: the exit code of the remote command. This is an After variable and it returns an integer.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

This component is used standalone. It respects the Sqoop prerequisites. You need necessary knowledge about Sqoop to use it.
We recommend using the Sqoop of version 1.4+ in order to benefit the full functions of these components.

For further information about Sqoop, see the Sqoop manual on: [http://sqoop.apache.org/docs/](http://sqoop.apache.org/docs/)

### Prerequisites

The Hadoop distribution must be properly installed, so as to guarantee the interaction with *Talend Studio*. The following list presents MapR related information for example:

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR's documentation, the library or libraries of a MapR client corresponding to each OS version can be found under `MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native`. For example, the library for Windows is `\lib\native\MapRClient.dll` in the MapR client jar file. For further information, see the following link from MapR: [http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr](http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr).

Without adding the specified library or libraries, you may encounter the following error: `no MapRClient in java.library.path`.

- Set the `-Djava.library.path` argument, for example, in the *Job Run VM arguments* area of the *Run/Debug* view in the *Preferences* dialog box in the *Window* menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the *Data viewer* to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

### Limitation

If you have selected the *Use Commandline* mode, you need to use the host where Sqoop is installed to run the Job using this component.

### Connections

Outgoing links (from this component to another):

**Trigger**: Run if; On Subjob Ok; On Subjob Error.

Incoming links (from one component to this one):

**Row**: Iterate;

**Trigger**: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error

For further information regarding connections, see *Talend Studio  User Guide*. 
Scenario: Importing a MySQL table to HDFS

This scenario applies only to a Talend solution with Big Data.

This scenario illustrates how to use `tSqoopImport` to import a MySQL table to a given HDFS system.

The sample data to be used in this scenario reads as follows:

<table>
<thead>
<tr>
<th>id, wage, mod_date</th>
</tr>
</thead>
<tbody>
<tr>
<td>0, 2000, 2008-06-26 04:25:59</td>
</tr>
<tr>
<td>1, 2300, 2011-06-12 05:29:45</td>
</tr>
<tr>
<td>3, 3000, 2010-05-02 15:34:05</td>
</tr>
</tbody>
</table>

The data is stored in a MySQL table called `sqoopmerge`.

Before starting to replicate this scenario, ensure that you have appropriate rights and permissions to access the Hadoop distribution to be used. Then proceed as follows:

### Dropping the component

**Procedure**

1. In the **Integration** perspective of the Studio, create an empty Job from the **Job Designs** node in the **Repository** tree view.
   
   For further information about how to create a Job, see the *Talend Studio User Guide*.

2. Drop `tSqoopImport` onto the workspace.

### Importing the MySQL table

**About this task**

Configuring `tSqoopImport`  

**Procedure**

1. Double-click `tSqoopImport` to open its **Component** view.
2. In the **Mode** area, select **Use Java API**.

3. In the **Version** area, select the Hadoop distribution to be used and its version. If you cannot find from the list the distribution corresponding to yours, select **Custom** so as to connect to a Hadoop distribution not officially supported in the Studio.

   For a step-by-step example about how to use this **Custom** option, see [Connecting to a custom Hadoop distribution](#) on page 1589.

4. In the **NameNode URI** field, enter the location of the master node, the NameNode, of the distribution to be used. If you are using WebHDFS, the location should be `webhdfs://master:portnumber`; if this WebHDFS is secured with SSL, the scheme should be `swebhdfs` and you need to use a `tLibraryLoad` in the Job to load the library required by the secured WebHDFS.
5. In the **Resource Manager** field, enter the location of the ResourceManager of your distribution. Note that the notion Job in this term JobTracker designates the MR or the MapReduce jobs described in Apache's documentation on [http://hadoop.apache.org/](http://hadoop.apache.org/).

6. If the distribution to be used requires Kerberos authentication, select the **Use Kerberos authentication** check box and complete the authentication details. Otherwise, leave this check box clear.

   If you need to use a Kerberos keytab file to log in, select **Use a keytab to authenticate**. A keytab file contains pairs of Kerberos principals and encrypted keys. You need to enter the principal to be used in the **Principal** field and the access path to the keytab file itself in the **Keytab** field. This keytab file must be stored in the machine in which your Job actually runs, for example, on a Talend Jobserver.

   Note that the user that executes a keytab-enabled Job is not necessarily the one a principal designates but must have the right to read the keytab file being used. For example, the user name you are using to execute a Job is *user1* and the principal to be used is *guest*; in this situation, ensure that *user1* has the right to read the keytab file to be used.

7. In the **Connection** field, enter the URI of the MySQL database where the source table is stored. For example, `jdbc:mysql://10.42.10.13/mysql`.

8. In **Username** and **Password**, enter the authentication information.

9. Under the **Driver JAR** table, click the `[+]` button to add one row, then in this row, click the `...` button to display the drop-down list and select the jar file to be used from that list. In this scenario, it is `mysql-connector-java-5.1.30-bin.jar`.

   If the `...` button does not appear, click anywhere in this row to make it displayed.

10. In the **Table Name** field, enter the name of the source table. In this scenario, it is `sqoopmerge`.

11. From the **File format** list, select the format that corresponds to the data to be used, **textfile** in this scenario.

12. Select the **Specify target dir** check box and enter the directory where you need to import the data to. For example, `/user/ychen/target_old`.

### Configuring tSqoopImport

#### Procedure

1. Double-click **tSqoopImport** to open its **Component** view.
2. In the Mode area, select Use Java API.

3. In the Version area, select the Hadoop distribution to be used and its version. If you cannot find from the list the distribution corresponding to yours, select Custom so as to connect to a Hadoop distribution not officially supported in the Studio.

   For a step-by-step example about how to use this Custom option, see Connecting to a custom Hadoop distribution on page 1589.

4. In the NameNode URI field, enter the location of the master node, the NameNode, of the distribution to be used. For example, hdfs://talend-cdh4-namenode:8020. If you are using WebHDFS, the location should be webhdfs://masternode:portnumber; if this WebHDFS is secured with SSL,
the scheme should be swebhdfs and you need to use a tLibraryLoad in the Job to load the library required by the secured WebHDFS.

5. In the JobTracker Host field, enter the location of the JobTracker of your distribution. For example, talend-cdh4-namenode:8021.

Note that the notion Job in this term JobTracker designates the MR or the MapReduce jobs described in Apache's documentation on http://hadoop.apache.org/.

6. If the distribution to be used requires Kerberos authentication, select the Use Kerberos authentication check box and complete the authentication details. Otherwise, leave this check box clear.

If you need to use a Kerberos keytab file to log in, select Use a keytab to authenticate. A keytab file contains pairs of Kerberos principals and encrypted keys. You need to enter the principal to be used in the Principal field and the access path to the keytab file itself in the Keytab field. This keytab file must be stored in the machine in which your Job actually runs, for example, on a Talend Jobserver.

Note that the user that executes a keytab-enabled Job is not necessarily the one a principal designates but must have the right to read the keytab file being used. For example, the user name you are using to execute a Job is user1 and the principal to be used is guest; in this situation, ensure that user1 has the right to read the keytab file to be used.

7. In the Connection field, enter the URI of the MySQL database where the source table is stored. For example, jdbc:mysql://10.42.10.13/mysql.

8. In Username and Password, enter the authentication information.

9. Under the Driver JAR table, click the [+] button to add one row, then in this row, click the [...] button to display the drop-down list and select the jar file to be used from that list. In this scenario, it is mysql-connector-java-5.1.30-bin.jar.

If the [...] button does not appear, click anywhere in this row to make it displayed.

10. In the Table Name field, enter the name of the source table. In this scenario, it is sqoopmerge.

11. From the File format list, select the format that corresponds to the data to be used, textfile in this scenario.

12. Select the Specify target dir check box and enter the directory where you need to import the data to. For example, /user/ychen/target_old.

**Executing the Job**

Then you can press F6 to run this Job.

Once done, you can verify the results in the target directory you have specified, in the web console of the Hadoop distribution used.
Contents of directory /user/ychen/target_old

Goto: [user/ychen/target_old]  go

Go to parent directory

Go back to DFS home

If you need to obtain more details about the Job, it is recommended to use the web console of the Jobtracker provided by the Hadoop distribution you are using.
**tSqoopImportAllTables**

Defines the arguments required by Sqoop for writing all of the tables of a database into HDFS.

*tSqoopImportAllTables* calls Sqoop to transfer all of the tables of a relational database management system (RDBMS) such as MySQL or Oracle into the Hadoop Distributed File System (HDFS).

**Note:**
Sqoop is typically installed in every Hadoop distribution. But if the Hadoop distribution you need to use have no Sqoop installed, you have to install one on your own and ensure to add the Sqoop command line to the PATH variable of that distribution. For further information about how to install Sqoop, see the documentation of Sqoop.

**tSqoopImportAllTables Standard properties**

These properties are used to configure *tSqoopImportAllTables* running in the Standard Job framework. The Standard *tSqoopImportAllTables* component belongs to the Big Data and the File families. The component in this framework is available when you are using one of the *Talend* solutions with Big Data.

**Basic settings**

<table>
<thead>
<tr>
<th>Mode</th>
<th>Select the mode in which Sqoop is called in a Job execution.</th>
</tr>

<tbody>
<tr>
<td>Use Commandline</td>
<td>the Sqoop shell is used to call Sqoop. In this mode, you have to deploy and run the Job in the host where Sqoop is installed. Therefore, if you are a subscription-based user, we recommend installing and using a Jobserver provided by <em>Talend</em> in that host to run the Job; if you are using one of the <em>Talend</em> solutions with Big Data, you have to ensure that the Studio and the Sqoop to be used are in the same machine.</td>
</tr>
<tr>
<td>Use Java API</td>
<td>the Java API is used to call Sqoop. In this mode, the Job can be run locally in the Studio but you need to configure the connection to the Hadoop distribution to be used. Note that JDK is required to execute the Job in the Java API mode and the versions of the JDK kits installed in both machines must be compatible with each other; for example, the versions are the same or the JDK version of the Hadoop machine is more recent.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Hadoop properties</th>
<th>Either <strong>Built-in</strong> or <strong>Repository</strong>:</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Built-in</td>
<td>you enter the configuration information of the Hadoop distribution to be used locally for this component only.</td>
</tr>
<tr>
<td>• Repository</td>
<td>you have already created the Hadoop connection and stored it in the <strong>Repository</strong>; therefore, you reuse it directly for the component configuration and the Job design. For further information about how to create a centralized</td>
</tr>
</tbody>
</table>
Select the cluster you are using from the drop-down list. The options in the list vary depending on the component you are using. Among these options, the following one requires specific configuration:

- If available in this Distribution drop-down list, the Microsoft HD Insight option allows you to use a Microsoft HD Insight cluster. For this purpose, you need to configure the connections to the HD Insight cluster and the Windows Azure Storage service of that cluster in the areas that are displayed. For detailed explanation about these parameters, search for configuring the connection manually on Talend Help Center (https://help.talend.com).

- If you select Amazon EMR, you can find more details about how to configure an Amazon EMR cluster in Talend Help Center (https://help.talend.com).

- The Custom option allows you to connect to a cluster different from any of the distributions given in this list, that is to say, to connect to a cluster not officially supported by Talend.

1. Select Import from existing version to import an officially supported distribution as base and then add other required jar files which the base distribution does not provide.

2. Select Import from zip to import the configuration zip for the custom distribution to be used. This zip file should contain the libraries of the different Hadoop elements and the index file of these libraries.

In Talend Exchange, members of Talend community have shared some ready-for-use configuration zip files which you can download from this Hadoop configuration list and directly use them in your connection accordingly. However, because of the ongoing evolution of the different Hadoop-related projects, you might not be able to find the configuration zip corresponding to your distribution from this list; then it is recommended to use the Import from existing version option to take an existing distribution as base to add the jars required by your distribution.

Note that custom versions are not officially supported by Talend. Talend and its community provide you with the opportunity to connect to custom versions from the Studio but cannot guarantee that the configuration of whichever version you choose will be easy, due to the wide range of different Hadoop distributions and versions that are available. As such, you should only attempt to set up such a connection if you have sufficient Hadoop experience to handle any issues on your own.
<table>
<thead>
<tr>
<th><strong>Hadoop Version</strong></th>
<th>Select the version of the Hadoop distribution you are using. The available options vary depending on the component you are using.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NameNode URI</strong></td>
<td>Type in the URI of the Hadoop NameNode, the master node of a Hadoop system. For example, we assume that you have chosen a machine called <code>masternode</code> as the NameNode, then the location is <code>hdfs://masternode:portnumber</code>. If you are using WebHDFS, the location should be <code>webhdfs://masternode:portnumber</code>; if this WebHDFS is secured with SSL, the scheme should be <code>swebhdfs</code> and you need to use a <code>LibraryLoad</code> in the Job to load the library required by the secured WebHDFS.</td>
</tr>
</tbody>
</table>
| **JobTracker Host** | Select this check box and in the displayed field, enter the location of the ResourceManager of your distribution. For example, `tal-qall4.taland.lan:8050`. This property is required when the query you want to use is executed in Windows and it is a Select query. For example, `SELECT your_column_name FROM your_table_name` Then you can continue to set the following parameters depending on the configuration of the Hadoop cluster to be used (if you leave the check box of a parameter clear, then at runtime, the configuration about this parameter in the Hadoop cluster to be used will be ignored):  
1. Select the **Set resourcemanager scheduler address** check box and enter the Scheduler address in the field that appears.  
2. Select the **Set jobhistory address** check box and enter the location of the JobHistory server of the Hadoop cluster to be used. This allows the metrics information of the current Job to be stored in that JobHistory server.  
3. Select the **Set staging directory** check box and enter this directory defined in your Hadoop cluster for temporary files created by running programs. Typically, this directory can be found under the `yarn.app.mapreduce.am.staging-dir` property in the configuration files such as `yarn-site.xml` or `mapred-site.xml` of your distribution. |
4. Allocate proper memory volumes to the Map and the Reduce computations and the ApplicationMaster of YARN by selecting the Set memory check box in the Advanced settings view.

5. Select the Set Hadoop user check box and enter the user name under which you want to execute the Job. Since a file or a directory in Hadoop has its specific owner with appropriate read or write rights, this field allows you to execute the Job directly under the user name that has the appropriate rights to access the file or directory to be processed.

6. Select the Use datanode hostname check box to allow the Job to access datanodes via their hostnames. This actually sets the dfs.client.use.datanode.hostname property to true. When connecting to a S3N filesystem, you must select this check box.

For further information about these parameters, see the documentation or contact the administrator of the Hadoop cluster to be used.

For further information about the Hadoop Map/Reduce framework, see the Map/Reduce tutorial in Apache's Hadoop documentation on http://hadoop.apache.org.

**Use kerberos authentication**

If you are accessing the Hadoop cluster running with Kerberos security, select this check box, then, enter the Kerberos principal name for the NameNode in the field displayed. This enables you to use your user name to authenticate against the credentials stored in Kerberos.

- If this cluster is a MapR cluster of the version 5.0.0 or later, you can set the MapR ticket authentication configuration in addition or as an alternative by following the explanation in Connecting to a security-enabled MapR on page 1652.

  Keep in mind that this configuration generates a new MapR security ticket for the username defined in the Job in each execution. If you need to reuse an existing ticket issued for the same username, leave both the Force MapR ticket authentication check box and the Use Kerberos authentication check box clear, and then MapR should be able to automatically find that ticket on the fly.

In addition, since this component performs Map/Reduce computations, you also need to authenticate the related services such as the Job history server and the Resource manager or Jobtracker depending on your distribution in the corresponding field. These principals can be found in the configuration files of your distribution. For example, in a CDH4 distribution, the Resource manager principal is set in the yarn-site.xml file and the Job history principal in the mapred-site.xml file.

This check box is available depending on the Hadoop distribution you are connecting to.
### Use a keytab to authenticate

Select the **Use a keytab to authenticate** check box to log into a Kerberos-enabled system using a given keytab file. A keytab file contains pairs of Kerberos principals and encrypted keys. You need to enter the principal to be used in the **Principal** field and the access path to the keytab file itself in the **Keytab** field. This keytab file must be stored in the machine in which your Job actually runs, for example, on a Talend Jobserver.

Note that the user that executes a keytab-enabled Job is not necessarily the one a principal designates but must have the right to read the keytab file being used. For example, the user name you are using to execute a Job is `user1` and the principal to be used is `guest`; in this situation, ensure that `user1` has the right to read the keytab file to be used.

### Hadoop user name

Enter the user name under which you want to execute the Job. Since a file or a directory in Hadoop has its specific owner with appropriate read or write rights, this field allows you to execute the Job directly under the user name that has the appropriate rights to access the file or directory to be processed. Note that this field is available depending on the distribution you are using.

### JDBC property

Either **Built-in** or **Repository**:

- **Built-in**: you enter the connection information of the database to be used locally for this component only.

- **Repository**: you have already created the database connection and stored it in the **Repository**; therefore, you reuse it directly for the component configuration and the Job design. For further information about how to create a centralized database connection, see [Talend Studio User Guide](#).

Note that only the **General JDBC** connection stored in the **Repository** is supported.

### Connection

Enter the JDBC URL used to connect to the database where the source data is stored.

### User name and Password

Enter the authentication information used to connect to the source database.

To enter the password, click the `[...]` button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

If your password is stored in a file, select the **The password is stored in a file** check box and enter the path to that file in the **File path** field that is displayed.

- This file can be stored either in the machine where the Job is to be executed or in the HDFS system of the Hadoop cluster to be used.

- The password stored in this file must not contain `\n` (the newline escape) at the end, that is to say, you must not insert a new line at the end of the password even though this line is empty.
Note that this feature is available depending on the Sqoop version you are using.

### Driver JAR
In either the **Use Commandline** mode or the **Java API** mode, you must add the driver file of the database to be used to the *lib* folder of the Hadoop distribution you are using. For that purpose, use this **Driver JAR** table to add that driver file for the current Job you are designing.

### File format
Select a file format for the data to be transferred:
- `textfile`
- `sequencefile`
- `Avro file`
- `Parquet file`: the version of Sqoop must be 1.4.6.

### Specify Number of Mappers
Select this check box to indicate the number of map tasks (parallel processes) used to perform the data transfer.
If you do not want Sqoop to work in parallel, enter 1 in the displayed field.

### Compress
Select this check box to enable compression.

### Direct
Select this check box to use the import fast path.

### Exclude table
Select this check box and enter the name of the table(s) to be excluded from the import process.

### Print Log
Select this check box to activate the **Verbose** check box.

### Verbose
Select this check box to print more information while working, for example, the debugging information.

### Advanced settings

#### Define Hive mapping
Sqoop provides default configuration that maps most SQL types to appropriate Hive types. If you need to use your custom map to overwrite the default ones at runtime, select this check box and define the map(s) you want to use in the table that appears.

#### Use MySQL default delimiters
Select this check box to use MySQL's default delimiter set. This check box is available only to the Commandline mode.

#### Additional arguments
Complete this table to use additional arguments if needed be.
By adding additional arguments, you are able to perform multiple operations in one single transaction. For example, you can use `--hive-import` and `--hive-table` in the Commandline mode or `hive.import` and `hive.table.name` in the Java API mode to create Hive table and write data in at the runtime of the transaction writing data in HDFS. For further information about the available Sqoop arguments in the
Commandline mode and the Java API mode, respectively, see Additional arguments on page 3684.

| Hadoop properties | Talend Studio uses a default configuration for its engine to perform operations in a Hadoop distribution. If you need to use a custom configuration in a specific situation, complete this table with the property or properties to be customized. Then at runtime, the customized property or properties will override those default ones.  

- Note that if you are using the centrally stored metadata from the Repository, this table automatically inherits the properties defined in that metadata and becomes uneditable unless you change the Property type from Repository to Built-in.  

For further information about the properties required by Hadoop and its related systems such as HDFS and Hive, see the documentation of the Hadoop distribution you are using or see Apache’s Hadoop documentation on http://hadoop.apache.org/docs and then select the version of the documentation you want. For demonstration purposes, the links to some properties are listed below:

- Typically, the HDFS-related properties can be found in the hdfs-default.xml file of your distribution, such as http://hadoop.apache.org/docs/r2.6.0/hadoop-project-dist/hadoop-hdfs/hdfs-default.xml.

- Apache also provides a page to list the Hive-related properties: https://cwiki.apache.org/confluence/display/Hive/Configuration+Properties. |

| Mapred job map memory mb and Mapred job reduce memory mb | You can tune the map and reduce computations by selecting the Set memory check box to set proper memory allocations for the computations to be performed by the Hadoop system.  

In that situation, you need to enter the values you need in the Mapred job map memory mb and the Mapred job reduce memory mb fields, respectively. By default, the values are both 1000 which are normally appropriate for running the computations.  

The memory parameters to be set are Map (in Mb), Reduce (in Mb) and ApplicationMaster (in Mb). These fields allow you to dynamically allocate memory to the map and the reduce computations and the ApplicationMaster of YARN. |

| Path separator in server | Leave the default value of the Path separator in server as it is, unless you have changed the separator used by your Hadoop distribution’s host machine for its PATH variable or in other words, that separator is not a colon (:). In that situation, you must change this value to the one you are using in that host. |

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |
### Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>ERROR_MESSAGE</strong></td>
<td>the error message generated by the component when an error occurs.</td>
</tr>
<tr>
<td></td>
<td>This is an After variable and it returns a string.</td>
</tr>
<tr>
<td></td>
<td>This variable functions only if the <strong>Die on error</strong> check box is cleared.</td>
</tr>
<tr>
<td></td>
<td>If the component has this check box.</td>
</tr>
<tr>
<td><strong>EXIT_CODE</strong></td>
<td>the exit code of the remote command.</td>
</tr>
<tr>
<td></td>
<td>This is an After variable and it returns an integer.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

### Usage

**Usage rule**

This component is used standalone. It respects the Sqoop prerequisites. You need necessary knowledge about Sqoop to use it.

We recommend using the Sqoop of version 1.4+ in order to benefit the full functions of these components.

For further information about Sqoop, see the Sqoop manual on: [http://sqoop.apache.org/docs/](http://sqoop.apache.org/docs/)

### Prerequisites

The Hadoop distribution must be properly installed, so as to guarantee the interaction with [Talend Studio](#). The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR's documentation, the library or libraries of a MapR client corresponding to each OS version can be found under `MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native`. For example, the library for Windows is `\lib\native\MapRClient.dll` in the MapR client jar file. For further information, see the following link from MapR: [http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr](http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr).

    Without adding the specified library or libraries, you may encounter the following error: `no MapRClient in java.library.path`.

    - Set the `-Djava.library.path` argument, for example, in the **Job Run VM arguments** area of the **Run/Debug** view in the **[Preferences]** dialog box in the **Window** menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to
| **tSqoopImportAllTables** | make full use of the **Data viewer** to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using. |
|--------------------------|-------------------------------------------------------------------------------------------------|

**Limitation**

- If you have selected the **Use Commandline** mode, you need to use the host where Sqoop is installed to run the Job using this component.

- The preconditions required by Sqoop for using its `import-all-tables` tool must be satisfied. For further information, please see the manual of Sqoop.

**Connections**

- Outgoing links (from this component to another):
  - **Trigger**: Run if; On Subjob Ok; On Subjob Error.

- Incoming links (from one component to this one):
  - **Row**: Iterate;
  - **Trigger**: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error

- For further information regarding connections, see *Talend Studio User Guide*.

---

**Related scenarios**

No scenario is available for the Standard version of this component yet.
tSqoopMerge

Performs an incremental import that updates an older dataset with newer records. The file types of the newer and the older datasets must be the same.

tSqoopMerge reads two datasets in HDFS and combines them both using a merge class that is able to parse the datasets, with the newer records overwriting the older records.

**Note:**
Sqoop is typically installed in every Hadoop distribution. But if the Hadoop distribution you need to use have no Sqoop installed, you have to install one on your own and ensure to add the Sqoop command line to the PATH variable of that distribution. For further information about how to install Sqoop, see the documentation of Sqoop.

### tSqoopMerge Standard properties

These properties are used to configure tSqoopMerge running in the Standard Job framework.

The Standard tSqoopMerge component belongs to the Big Data and the File families.

The component in this framework is available when you are using one of the Talend solutions with Big Data.

### Distribution

Select the cluster you are using from the drop-down list. The options in the list vary depending on the component you are using. Among these options, the following ones requires specific configuration:

- If available in this **Distribution** drop-down list, the **Microsoft HD Insight** option allows you to use a Microsoft HD Insight cluster. For this purpose, you need to configure the connections to the HD Insight cluster and the Windows Azure Storage service of that cluster in the areas that are displayed. For detailed explanation about these parameters, search for configuring the connection manually on Talend Help Center ([https://help.talend.com](https://help.talend.com)).

- If you select **Amazon EMR**, you can find more details about how to configure an Amazon EMR cluster in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

- The **Custom** option allows you to connect to a cluster different from any of the distributions given in this list, that is to say, to connect to a cluster not officially supported by Talend.

1. Select **Import from existing version** to import an officially supported distribution as base and then add other required jar files which the base distribution does not provide.

2. Select **Import from zip** to import the configuration zip for the custom distribution to be used. This zip file should contain the libraries of the different Hadoop elements and the index file of these libraries.

   In **Talend Exchange**, members of **Talend community** have shared some ready-for-use configuration zip files which you can download from this **Hadoop configuration** list and directly use them in your connection accordingly. However, because of the ongoing evolution of the different Hadoop-related projects, you might not be able to find the configuration zip corresponding to your distribution from this list; then it is recommended to use the **Import from existing version** option to take an existing distribution as base to add the jars required by your distribution.

Note that custom versions are not officially supported by Talend. Talend and its community provide you with the opportunity to connect to custom versions from the Studio but cannot guarantee that the configuration of whichever version you choose will be easy, due to the wide range of different Hadoop distributions and versions that are available. As such, you should only attempt to set up such a connection if you have sufficient information about how to create a centralized Hadoop connection, see **Talend Open Studio for Big Data Getting Started Guide**.
Hadoop experience to handle any issues on your own.

**Note:**
In this dialog box, the active check box must be kept selected so as to import the jar files pertinent to the connection to be created between the custom distribution and this component.

For a step-by-step example about how to connect to a custom distribution and share this connection, see [Connecting to a custom Hadoop distribution](#) on page 1589.

<table>
<thead>
<tr>
<th><strong>Hadoop Version</strong></th>
<th>Select the version of the Hadoop distribution you are using. The available options vary depending on the component you are using.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NameNode URI</strong></td>
<td>Type in the URI of the Hadoop NameNode, the master node of a Hadoop system. For example, we assume that you have chosen a machine called <em>masternode</em> as the NameNode, then the location is <code>hdfs://masternode:portnumber</code>. If you are using WebHDFS, the location should be <code>webhdfs://masternode:portnumber</code>; if this WebHDFS is secured with SSL, the scheme should be <code>swebhdfs</code> and you need to use a <code>tLibraryLoad</code> in the Job to load the library required by the secured WebHDFS.</td>
</tr>
</tbody>
</table>
| **JobTracker Host** | Select this check box and in the displayed field, enter the location of the ResourceManager of your distribution. For example, `tal-qal14.taland.lan:8050`. This property is required when the query you want to use is executed in Windows and it is a Select query. For example, `SELECT your_column_name FROM your_table_name`

Then you can continue to set the following parameters depending on the configuration of the Hadoop cluster to be used (if you leave the check box of a parameter clear, then at runtime, the configuration about this parameter in the Hadoop cluster to be used will be ignored):

1. Select the **Set resourcemanager scheduler address** check box and enter the Scheduler address in the field that appears.

2. Select the **Set jobhistory address** check box and enter the location of the JobHistory server of the Hadoop cluster to be used. This allows the metrics information of the current Job to be stored in that JobHistory server.

3. Select the **Set staging directory** check box and enter this directory defined in your Hadoop cluster for temporary files created by running programs. Typically, this directory can be found under the `yarn.app.mapreduce.am.staging-dir` property in the

---
configuration files such as `yarn-site.xml` or `mapred-site.xml` of your distribution.

4. Allocate proper memory volumes to the Map and the Reduce computations and the ApplicationMaster of YARN by selecting the Set memory check box in the Advanced settings view.

5. Select the Set Hadoop user check box and enter the user name under which you want to execute the Job. Since a file or a directory in Hadoop has its specific owner with appropriate read or write rights, this field allows you to execute the Job directly under the user name that has the appropriate rights to access the file or directory to be processed.

6. Select the Use datanode hostname check box to allow the Job to access datanodes via their hostnames. This actually sets the `dfs.client.use.datanode.hostname` property to true. When connecting to a S3N filesystem, you must select this check box.

For further information about these parameters, see the documentation or contact the administrator of the Hadoop cluster to be used.

### Use kerberos authentication

If you are accessing the Hadoop cluster running with Kerberos security, select this check box, then, enter the Kerberos principal name for the NameNode in the field displayed. This enables you to use your user name to authenticate against the credentials stored in Kerberos.

- If this cluster is a MapR cluster of the version 5.0.0 or later, you can set the MapR ticket authentication configuration in addition or as an alternative by following the explanation in Connecting to a security-enabled MapR on page 1652.

Keep in mind that this configuration generates a new MapR security ticket for the username defined in the Job in each execution. If you need to reuse an existing ticket issued for the same username, leave both the Force MapR ticket authentication check box and the Use Kerberos authentication check box clear, and then MapR should be able to automatically find that ticket on the fly.

In addition, since this component performs Map/Reduce computations, you also need to authenticate the related services such as the Job history server and the Resource manager or Jobtracker depending on your distribution in the corresponding field. These principals can be found in the configuration files of your distribution. For example, in a CDH4 distribution, the Resource manager principal is set in the `yarn-site.xml` file and the Job history principal in the `mapred-site.xml` file.
<table>
<thead>
<tr>
<th><strong>tSqoopMerge</strong></th>
<th>This check box is available depending on the Hadoop distribution you are connecting to.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Use a keytab to authenticate</strong></td>
<td>Select the <strong>Use a keytab to authenticate</strong> check box to log into a Kerberos-enabled system using a given keytab file. A keytab file contains pairs of Kerberos principals and encrypted keys. You need to enter the principal to be used in the <strong>Principal</strong> field and the access path to the keytab file itself in the <strong>Keytab</strong> field. This keytab file must be stored in the machine in which your Job actually runs, for example, on a Talend Jobserver. Note that the user that executes a keytab-enabled Job is not necessarily the one a principal designates but must have the right to read the keytab file being used. For example, the user name you are using to execute a Job is <strong>user1</strong> and the principal to be used is <strong>guest</strong>; in this situation, ensure that <strong>user1</strong> has the right to read the keytab file to be used.</td>

<tr>
<td><strong>Target directory</strong></td>
<td>Enter the directory where you need to put the output of the merging.</td>
</tr>
<tr>
<td><strong>Merge key</strong></td>
<td>Enter the name of the column used as the key of each record for the merging. This primary key must be unique.</td>
</tr>
<tr>
<td><strong>Need to generate the JAR file</strong></td>
<td>Select this check box to generate the merge jar file and the merge class required to parse the datasets to be merged. The default name of the jar file and the class is <strong>SqoopMerge_component_ID</strong>. This <strong>component_ID</strong> is the ID of the <strong>tSqoopMerge</strong> component that generates the jar file and the class, such as <strong>tSqoopMerge_1</strong>, or <strong>tSqoopMerge_2</strong>. As this jar file is generated from the source table of the imported data, selecting this check box displays the corresponding parameters to be set for connecting to that table.</td>
</tr>
</tbody>
</table>
| **JDBC property** | Either **Built-in** or **Repository**:  
  - **Built-in**: you enter the connection information of the database to be used locally for this component only.  
  - **Repository**: you have already created the database connection and stored it in the **Repository**; therefore, you reuse it directly for the component configuration and the Job design. For further |
information about how to create a centralized
database connection, see Talend Studio User Guide.

Note that only the General JDBC connection stored
in the Repository is supported.

| Connection                      | Enter the JDBC URL used to connect to the database
|                                | where the source data is stored.
| **User name and Password**      | Enter the authentication information used to connect to
|                                | the source database.
|                                | To enter the password, click the [...] button next to the
|                                | password field, and then in the pop-up dialog box enter
|                                | the password between double quotes and click OK to
|                                | save the settings.
| **Table Name**                  | Type in the name of the source table.
|                                | This name is used to name the generated jar file.
| **Driver JAR**                  | In either the Use Commandline mode or the Java API
|                                | mode, you must add the driver file of the database to be
|                                | used to the lib folder of the Hadoop distribution you are
|                                | using. For that purpose, use this Driver JAR table to add
|                                | that driver file for the current Job you are designing.
|                                | This driver jar is required only when you need to connect
to the database to be used to generate the merge jar
|                                | file; therefore this Driver JAR table is available only
|                                | when you have selected the Need to generate the JAR
|                                | file check box.
| **JAR file**                    | If a required merge class already exists and is available,
specify the access path to the jar file that contains that
class for reusing the class.
|                                | In this situation, you need to enter the name of the class
|                                | in the Class name field in the Advanced settings tab.
| **Print Log**                   | Select this check box to activate the Verbose check box.
| **Verbose**                     | Select this check box to print more information while
|                                | working, for example, the debugging information.

**Advanced settings**

| **Custom class name**          | Select this check box to display the Class name field
|                                | and enter the name of the merge class you need to use.
|                                | This check box must be clear if you use Generate the
|                                | JAR file in the Basic settings tab.
| **Additional arguments**        | Complete this table to use additional arguments if needs be.
|                                | By adding additional arguments, you are able to perform
|                                | multiple operations in one single transaction. For example,
you can use --hive-import and --hive-table in the Commandline mode or
hive.import and hive.table.name in the Java API mode to
create Hive table and write data in at the runtime of the transaction writing data in HDFS. For further information about the available Sqoop arguments in the Commandline mode and the Java API mode, respectively, see Additional arguments on page 3684.

<table>
<thead>
<tr>
<th>Hadoop properties</th>
</tr>
</thead>
<tbody>
<tr>
<td><em>Talend Studio</em> uses a default configuration for its engine to perform operations in a Hadoop distribution. If you need to use a custom configuration in a specific situation, complete this table with the property or properties to be customized. Then at runtime, the customized property or properties will override those default ones.</td>
</tr>
<tr>
<td>• Note that if you are using the centrally stored metadata from the <em>Repository</em>, this table automatically inherits the properties defined in that metadata and becomes uneditable unless you change the Property type from <em>Repository</em> to <em>Built-in</em>.</td>
</tr>
<tr>
<td>For further information about the properties required by Hadoop and its related systems such as HDFS and Hive, see the documentation of the Hadoop distribution you are using or see Apache’s Hadoop documentation on <a href="http://hadoop.apache.org/docs">http://hadoop.apache.org/docs</a> and then select the version of the documentation you want. For demonstration purposes, the links to some properties are listed below:</td>
</tr>
<tr>
<td>• Typically, the HDFS-related properties can be found in the <em>hdfs-default.xml</em> file of your distribution, such as <a href="http://hadoop.apache.org/docs/r2.6.0/hadoop-project-dist/hadoop-hdfs/hdfs-default.xml">http://hadoop.apache.org/docs/r2.6.0/hadoop-project-dist/hadoop-hdfs/hdfs-default.xml</a>.</td>
</tr>
<tr>
<td>• Apache also provides a page to list the Hive-related properties: <a href="https://cwiki.apache.org/confluence/display/Hive/Configuration+Properties">https://cwiki.apache.org/confluence/display/Hive/Configuration+Properties</a>.</td>
</tr>
</tbody>
</table>

<tr>
<td>Leave the default value of the Path separator in server as it is, unless you have changed the separator used by your Hadoop distribution’s host machine for its PATH variable or in other words, that separator is not a colon (:). In that situation, you must change this value to the one you are using in that host.</td>
</tr>
</tbody>
</table>
tStatCatcher Statistics

Select this check box to collect log data at the component level.

Global Variables

Global Variables

ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

EXIT_CODE: the exit code of the remote command. This is an After variable and it returns an integer.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule

This component is used standalone. It respects the Sqoop prerequisites. You need necessary knowledge about Sqoop to use it.

We recommend using the Sqoop of version 1.4+ in order to benefit the full functions of these components.

For further information about Sqoop, see the Sqoop manual on: http://sqoop.apache.org/docs/

Prerequisites

The Hadoop distribution must be properly installed, so as to guarantee the interaction with Talend Studio. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native. For example, the library for Windows is \lib\native\MapRClient.dll in the MapR client jar file. For further information, see the following link from MapR: http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-map.

Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path.

- Set the -Djava.library.path argument, for example, in the Job Run VM arguments area of the
Run/Debug view in the [Preferences] dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

**Limitation**

If you have selected the Use Commandline mode, you need to use the host where Sqoop is installed to run the Job using this component.

**Connections**

Outgoing links (from this component to another):

Trigger: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error.

Incoming links (from one component to this one):

Row: Iterate;

Trigger: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error.

For further information regarding connections, see Talend Studio User Guide.

---

**Scenario: Merging two datasets in HDFS**

This scenario applies only to a Talend solution with Big Data.

This scenario illustrates how to use **tSqoopMerge** to merge two datasets that are sequentially imported to HDFS from the same MySQL table, with modifications of a record in between.

The first dataset (the old one before the modifications) to be used in this scenario reads as follows:

<table>
<thead>
<tr>
<th>id, wage, mod_date</th>
</tr>
</thead>
<tbody>
<tr>
<td>0, 2000, 2008-06-26 04:25:59</td>
</tr>
<tr>
<td>1, 2300, 2011-06-12 05:29:45</td>
</tr>
<tr>
<td>3, 3000, 2010-05-02 15:34:05</td>
</tr>
</tbody>
</table>

The path to it in HDFS is /user/ychen/target_old.

The second dataset (the new one after the modifications) to be used reads as follows:

<table>
<thead>
<tr>
<th>id, wage, mod_date</th>
</tr>
</thead>
<tbody>
<tr>
<td>1, 2300, 2011-06-12 05:29:45</td>
</tr>
<tr>
<td>3, 3000, 2010-05-02 15:34:05</td>
</tr>
</tbody>
</table>
The path to it in HDFS is /user/ychen/target_new.

These datasets were both imported by tSqoopImport. For a scenario about how to use tSqoopImport, see Scenario: Importing a MySQL table to HDFS on page 3705.

The Job in this scenario merges these two datasets with the newer record overwriting the older one. Before starting to replicate this scenario, ensure that you have appropriate rights and permissions to access the Hadoop distribution to be used. Then proceed as follows:

**Dropping the component**

**Procedure**

1. In the Integration perspective of the Studio, create an empty Job from the Job Designs node in the Repository tree view.
   For further information about how to create a Job, see Talend Studio User Guide.
2. Drop tSqoopMerge onto the workspace.
   In this scenario, the required jar file for the merge is not available, you then need to use tSqoopMerge to generate it at runtime from the source MySQL table.

**Configuring tSqoopMerge**

**Procedure**

1. Double-click tSqoopMerge to open its Component view.
2. In the **Mode** area, select **Use Java API**.

3. In the **Version** area, select the Hadoop distribution to be used and its version. If you cannot find from the list the distribution corresponding to yours, select **Custom** so as to connect to a Hadoop distribution not officially supported in the Studio.

   For a step-by-step example about how to use this **Custom** option, see Connecting to a custom Hadoop distribution on page 1589.

4. In the **NameNode URI** field, enter the location of the master node, the NameNode, of the distribution to be used. For example, `hdfs://talend-cdh4-namenode:8020`. If you are using WebHDFS, the location should be `webhdfs://masternode:portnumber`; if this WebHDFS is secured with SSL, the scheme should be `swebhdfs` and you need to use a `tLibraryLoad` in the Job to load the library required by the secured WebHDFS.

5. In the **Resource Manager** field, enter the location of the ResourceManager of your distribution.
6. If the distribution to be used requires Kerberos authentication, select the Use Kerberos authentication check box and complete the authentication details. Otherwise, leave this check box clear.

If you need to use a Kerberos keytab file to log in, select Use a keytab to authenticate. A keytab file contains pairs of Kerberos principals and encrypted keys. You need to enter the principal to be used in the Principal field and the access path to the keytab file itself in the Keytab field. This keytab file must be stored in the machine in which your Job actually runs, for example, on a Talend Jobserver.

Note that the user that executes a keytab-enabled Job is not necessarily the one a principal designates but must have the right to read the keytab file being used. For example, the user name you are using to execute a Job is user1 and the principal to be used is guest; in this situation, ensure that user1 has the right to read the keytab file to be used.

7. In the Old data directory and the New data directory fields, enter the path, or browse to the directory in HDFS where the older and the newer datasets are stored, respectively.

8. In the Target directory field, enter the path, or browse to the folder you need to store the merge result in.

9. In the Merge key field, enter the column to be used as the key for the merge. In this scenario, the column is id.

10. Select Need to generate the JAR file to display the connection parameters to the source database table.

11. In the Connection field, enter the URI of the MySQL database where the source table is stored. For example, jdbc:mysql://10.42.10.13/mysql.

12. In the Table Name field, enter the name of the source table. In this scenario, it is sqoopmerge.

13. In Username and Password, enter the authentication information.

14. Under the Driver JAR table, click the [+ ] button to add one row, then in this row, click the [...] button to display the drop-down list and select the jar file to be used from that list. In this scenario, it is mysql-connector-java-5.1.30-bin.jar.

   If the [...] button does not appear, click anywhere in this row to make it displayed.

15. If the field delimiter of the source table is not comma (,), you still need to specify the delimiter in the Additional Arguments table in the Advanced settings tab. The argument to be used is codegen.output.delimiters.field for the Use Java API mode or --fields-terminated-by for the Use Commandline mode.

**Executing the Job**

Then you can press F6 to run this Job.

During the execution, the jar file and the class for the merge are generated in the local machine.
Once done, you can verify the results in the target directory you have specified, in the web console of the Hadoop distribution used.

File: /user/ychen/merged/part-r-00000

Go back to dir listing
Advanced view/download options

If you need to obtain more details about the Job, it is recommended to use the web console of the Jobtracker provided by the Hadoop distribution you are using.

If you continue to import updated datasets to HDFS from the same source table, you can reuse the generated merge class to merge the datasets.
tSQSConnection

Opens a connection to Amazon Simple Queue Service that can then be reused by other SQS components.

**tSQSConnection Standard properties**

These properties are used to configure tSQSConnection running in the Standard Job framework.

The Standard tSQSConnection component belongs to the Cloud family.

The component in this framework is generally available.

**Basic settings**

| **Access Key** and **Secret Key** | Specify the access keys (the access key ID in the **Access Key** field and the secret access key in the **Secret Key** field) required to access the Amazon Web Services. For more information on AWS access keys, see Access keys (access key ID and secret access key).

To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings. |
| --- | --- |

<table>
<thead>
<tr>
<th><strong>Inherit credentials from AWS role</strong></th>
<th>Select this check box to leverage the instance profile credentials. These credentials can be used on Amazon EC2 instances, and are delivered through the Amazon EC2 metadata service. To use this option, your Job must be running within Amazon EC2 or other services that can leverage IAM Roles for access to resources. For more information, see Using an IAM Role to Grant Permissions to Applications Running on Amazon EC2 Instances.</th>
</tr>
</thead>
</table>

| **Assume Role** | Select this check box and specify the values for the following parameters used to create a new assumed role session.

- **Role ARN**: the Amazon Resource Name (ARN) of the role to assume.
- **Role session name**: an identifier for the assumed role session.
- **Session duration (minutes)**: the duration (in minutes) for which we want to have the assumed role session to be active.

For more information on assuming roles, see AssumeRole. |
| --- | --- |

| **Region** | Specify the AWS region by selecting a region name from the list or entering a region between double quotation marks (for example "us-east-1") in the list. For more information on AWS Regions, see AWS Regions and Endpoints. |
Advanced settings

| Config client | Select this check box and in the table displayed specify the client configuration parameters. Click the [+] button below the table to add as many rows as needed, each row for a client configuration parameter, and set the value of the following attributes for each parameter:
|               | • Client Parameter: click the cell and select a parameter from the drop-down list.  
|               | • Value: enter the value for the corresponding parameter. |

| STS Endpoint | Select this check box and in the field displayed, specify the AWS Security Token Service endpoint where session credentials are retrieved from. This check box is available only when the Assume role check box is selected. |

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

Global variables

| ERROR_MESSAGE | The error message generated by the component when an error occurs. This is an After variable and it returns a string. |

Usage

| Usage rule | This component can be used as a standalone component of a Job or Subjob. |

Related scenarios

- Delivering messages to an Amazon SQS queue on page 3750
- Listing Amazon SQS queues in an AWS region on page 3766
- Retrieving messages from an Amazon SQS queue on page 3737
tSQSInput

Retrieves one or more messages, with a maximum limit of ten messages, from an Amazon SQS (Simple Queue Service) queue.

**tSQSInput Standard properties**

These properties are used to configure tSQSInput running in the Standard Job framework. The Standard tSQSInput component belongs to the Cloud family. The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Access Key and Secret Key</strong></td>
<td>Specify the access keys (the access key ID in the Access Key field and the secret access key in the Secret Key field) required to access the Amazon Web Services. For more information on AWS access keys, see Access keys (access key ID and secret access key). To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Inherit credentials from AWS role</strong></td>
<td>Select this check box to leverage the instance profile credentials. These credentials can be used on Amazon EC2 instances, and are delivered through the Amazon EC2 metadata service. </tr>
</tbody>
</table>
| **Assume Role** | Select this check box and specify the values for the following parameters used to create a new assumed role session.  
  • **Role ARN**: the Amazon Resource Name (ARN) of the role to assume.  
  • **Role session name**: an identifier for the assumed role session.  
  • **Session duration (minutes)**: the duration (in minutes) for which we want to have the assumed role session to be active.  
  For more information on assuming roles, see AssumeRole. |
| **Region** | Specify the AWS region by selecting a region name from the list or entering a region between double quotation
marks (for example 'us-east-1') in the list. For more information on AWS Regions, see [AWS Regions and Endpoints](https://docs.aws.amazon.com/AmazonSQS/latest/APIReference/).  

<table>
<thead>
<tr>
<th>Queue (Name or URL)</th>
<th>Specify the name or the URL of the queue from which messages will be retrieved.</th>
</tr>
</thead>
</table>
| Schema and Edit schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.  

The schema of this component is predefined with the following four String type message attributes:  

- **MessageId**: the ID of the message.  
- **ReceiptHandle**: the receipt handle of the message.  
- **MD5OfBody**: the MD5 digest of the message body.  
- **Body**: the message body.  

You can click the button next to `Edit schema` to view its schema and edit the schema by removing existing attributes or adding standard SQS attributes and customized user attributes. |
| Read standard attributes | Select this check box to retrieve standard Amazon SQS attributes along with each message. For more information on the Amazon SQS attributes, see [ReceiveMessage > Request Parameters](https://docs.aws.amazon.com/AmazonSQS/latest/APIReference/). |
| Read custom user attributes | Select this check box to retrieve customized user attributes along with each message. |
| Custom visibility timeout | Select this check box and in the field displayed specify the visibility timeout (in seconds) for the received messages. If not specified, the overall visibility timeout for the queue will be used for the received messages. For more information, see [Visibility Timeout](https://docs.aws.amazon.com/AmazonSQS/latest/APIReference/). |
| Custom wait time | Select this check box and in the field displayed specify the duration (in seconds) for which the call will wait for the message to arrive in the queue before returning. |
| Delete the messages while streaming | Select this check box to delete the message while retrieving it from the queue. |
| Read all messages from the queue | Select this check box to retrieve all messages from the queue.  

This check box is not available when the `Delete the messages while streaming` check box is cleared. |
| Max number of message to return per request | Specify the maximum number of messages to return per each request. Valid values are 1 to 10. |
| Die on error | Select the check box to stop the execution of the Job when an error occurs. |
Clear the check box to skip any error and continue the Job execution process.

**Advanced settings**

| Config client | Select this check box and in the table displayed specify the client configuration parameters. Click the [+] button below the table to add as many rows as needed, each row for a client configuration parameter, and set the value of the following attributes for each parameter:
|               | • **Client Parameter**: click the cell and select a parameter from the drop-down list.
|               | • **Value**: enter the value for the corresponding parameter.

| STS Endpoint | Select this check box and in the field displayed, specify the AWS Security Token Service endpoint where session credentials are retrieved from. This check box is available only when the Assume role check box is selected.

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

**Global variables**

| NB_LINE | The number of rows processed. This is an After variable and it returns an integer.

| ERROR_MESSAGE | The error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is selected.

**Usage**

| Usage rule | This component is usually used as a start component of a Job or Subjob and it always needs an output link.

**Retrieving messages from an Amazon SQS queue**

Here’s an example of using Talend components to retrieve all messages from an existing Amazon SQS (Simple Queue Service) queue and then delete the empty queue.

**Creating a Job for retrieving Amazon SQS messages**

Create a Job to open a connection to access Amazon SQS, then retrieve all messages from an existing Amazon SQS queue, finally delete the queue.
Prerequisites: You must deliver the following message creator attribute and message body data to the Amazon SQS queue named talend in order to replicate this scenario.

#Creator;Body
Talend DOC Team;the 1st message from Talend DOC team
Talend DEV Team;the 2nd message from Talend DEV team
Talend QA Team;the 3rd message from Talend QA team

Procedure

1. Create a new Job and add a tSQSConnection component, a tSQSInput component, a tLogRow component, and a tSQSQueueDelete component by typing their names in the design workspace or dropping them from the Palette.
2. Link the tSQSInput component to the tLogRow component using a Row > Main connection.
3. Link the tSQSConnection component to the tSQSInput component using a Trigger > OnSubjobOk connection.
4. Link the tSQSInput component to the tSQSQueueDelete component using a Trigger > OnSubjobOk connection.

Opening a connection to access Amazon SQS

Configure the tSQSConnection component to open a connection to access Amazon SQS.

Procedure

1. Double-click the tSQSConnection component to open its Basic settings view.
2. In the **Access Key** and **Secret Key** fields, specify the authentication information required to access Amazon SQS.

3. Select an AWS region available for Amazon SQS from the **Region** drop-down list. In this example, it is **Asia Pacific (Tokyo)**.

### Retrieving messages from an Amazon SQS queue

Configure the **tSQSInput** component and the **LogRow** component to retrieve all messages from an existing Amazon SQS queue and display the retrieved messages on the console of Talend Studio.

**Procedure**

1. Double-click the **tSQSInput** component to open its **Basic settings** view.

2. Specify the connection details required to access Amazon SQS. In this example, select the **Use an existing connection** check box and from the **Component List** drop-down list displayed, select the connection component to reuse its connection details you have already defined.

3. In the **Queue (Name or URL)** field, enter the name for the queue from which the messages will be retrieved. In this example, it is **talend**.

4. Click the button next to **Edit schema** to open the schema dialog box.
You can see the schema of the `tSQSInput` component is predefined with four columns of String type: `MessageId`, `ReceiptHandle`, `MD5OfBody` and `Body`.

5. Click the button to add five columns of String type, including four Amazon SQS attributes `ApproximateFirstReceiveTimestamp`, `ApproximateReceiveCount`, `SenderId` and `SentTimestamp` and one customized attribute `Creator`.

6. Click OK to save the changes and close the schema dialog box.

7. Select the Read standard attributes and Read custom user attributes check boxes to retrieve the value of four Amazon SQS attributes and one customized user attribute along with each message.

8. Double-click the `tLogRow` component to open its Basic settings view, and then select Table (print values in cells of a table) in the Mode area for better readability of the result.

### Deleting an Amazon SQS queue

Configure the `tSQSQueueDelete` component to create an Amazon SQS queue.

**Procedure**

1. Double-click the `tSQSQueueDelete` component to open its Basic settings view.
2. Specify the connection details required to access Amazon SQS. In this example, select the **Use an existing connection** check box and from the **Component List** drop-down list displayed, select the connection component to reuse its connection details you have already defined.

3. In the **Queue (Name or URL)** field, enter the name for the queue to be deleted. In this example, it is `talend`.

### Executing the Job to retrieve Amazon SQS messages

After setting up the Job and configuring the components used in the Job for retrieving Amazon SQS messages, you can then execute the Job and verify the Job execution result.

#### Procedure

1. Press **Ctrl + S** to save the Job and then **F6** to execute the Job.

As shown above, all three messages and their attributes are retrieved and displayed on the console.

2. View the queue details on the AWS console to validate the Job execution result.
You can see the queue talend has already been deleted and is not on the AWS console any more.
**tSQSMessageChangeVisibility**

Changes the visibility timeout of a specified message in an Amazon SQS (Simple Queue Service) queue.

**tSQSMessageChangeVisibility Standard properties**

These properties are used to configure tSQSMessageChangeVisibility running in the Standard Job framework.

The Standard tSQSMessageChangeVisibility component belongs to the Cloud family.

The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
</table>
| **Access Key and Secret Key** | Specify the access keys (the access key ID in the Access Key field and the secret access key in the Secret Key field) required to access the Amazon Web Services. For more information on AWS access keys, see Access keys (access key ID and secret access key).  
To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| **Inherit credentials from AWS role** | Select this check box to leverage the instance profile credentials. These credentials can be used on Amazon EC2 instances, and are delivered through the Amazon EC2 metadata service. To use this option, your Job must be running within Amazon EC2 or other services that can leverage IAM Roles for access to resources. For more information, see Using an IAM Role to Grant Permissions to Applications Running on Amazon EC2 Instances. |
| **Assume Role** | Select this check box and specify the values for the following parameters used to create a new assumed role session.  
• **Role ARN**: the Amazon Resource Name (ARN) of the role to assume.  
• **Role session name**: an identifier for the assumed role session.  
• **Session duration (minutes)**: the duration (in minutes) for which we want to have the assumed role session to be active.  
For more information on assuming roles, see AssumeRole. |

### Advanced settings

| Config client | Select this check box and in the table displayed specify the client configuration parameters. Click the [+] button below the table to add as many rows as needed, each row for a client configuration parameter, and set the value of the following attributes for each parameter:
| Client Parameter: click the cell and select a parameter from the drop-down list.
| Value: enter the value for the corresponding parameter. |

| STS Endpoint | Select this check box and in the field displayed, specify the AWS Security Token Service endpoint where session credentials are retrieved from.
| This check box is available only when the Assume role check box is selected. |

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

### Global variables

| NB_LINE | The number of rows processed. This is an After variable and it returns an integer. |
| NB_LINE_SUCCESS | The number of rows successfully processed. This is an After variable and it returns an integer. |
| NB_LINE_REJECTED | The number of rows rejected. This is an After variable and it returns an integer. |
| ERROR_MESSAGE | The error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is selected. |

### Usage

| Usage rule | This component is usually used as an end component of a Job or Subjob and it always needs an input link. |

### Delivering messages to an Amazon SQS queue

Here’s an example of using Talend components to create an Amazon SQS (Simple Queue Service) queue, then deliver a couple of messages to the queue, finally get and display the attributes of the queue on the console.

The input messages in this example are as follows, and each message contains the message creator attribute and the message body information.

#Creator;Body
Creating a Job for delivering Amazon SQS messages

Create a Job to open a connection to access Amazon SQS, then create an Amazon SQS queue and deliver a couple of messages to the queue, finally get and display the attributes of the queue on the console.

Procedure

1. Create a new Job and add a `tSQSConnection` component, a `tSQSQueueCreate` component, a `tFixedSizeInput` component, a `tSQSOutput` component, a `tSQSQueueAttributes` component, and a `tLogRow` component by typing their names in the design workspace or dropping them from the Palette.

2. Link the `tFixedSizeInput` component to the `tSQSOutput` component using a Row > Main connection.

3. Do the same to link the `tSQSQueueAttributes` component to the `tLogRow` component.

4. Link the `tSQSConnection` component to the `tSQSQueueCreate` component using a Trigger > OnSubjobOk connection.

5. Do the same to link the `tSQSQueueCreate` component to the `tFixedSizeInput` component and the `tFixedSizeInput` component to the `tSQSQueueAttributes` component.

Opening a connection to access Amazon SQS

Configure the `tSQSConnection` component to open a connection to access Amazon SQS.
Procedure

1. Double-click the **tSQSConnection** component to open its **Basic settings** view.

   ![tSQSConnection](image)

   - **Access Key**: BKIOH3CC7E45S6
   - **Secret Key**: ************
   - **Inherit credentials from AWS role**: unchecked
   - **Assume Role**: unchecked
   - **Region**: Asia Pacific (Tokyo)

2. In the **Access Key** and **Secret Key** fields, specify the authentication information required to access Amazon SQS.

3. Select an AWS region available for Amazon SQS from the **Region** drop-down list. In this example, it is Asia Pacific (Tokyo).

Creating an Amazon SQS queue

Configure the **tSQSQueueCreate** component to create an Amazon SQS queue.

Procedure

1. Double-click the **tSQSQueueCreate** component to open its **Basic settings** view.

   ![tSQSQueueCreate](image)

   - **Connection**: Use an existing connection
   - **Queue (Name or URL)**: talend
   - **Queue Attributes**:
     - **MessageRetentionPeriod**: 86400

2. Specify the connection details required to access Amazon SQS. In this example, select the **Use an existing connection** check box and from the **Component List** drop-down list displayed, select the connection component to reuse its connection details you have already defined.

3. In the **Queue (Name or URL)** field, specify the name for the queue to be created. In this example, it is talend.

4. If needed, specify the attributes for the queue to be created in the **Queue Attributes** table. In this example, the **MessageRetentionPeriod** attribute is added and its value is set to 86400, which means Amazon SQS will retain the messages delivered to the queue for 86400 seconds (1 day) instead of the default 345600 seconds (4 day).
Delivering messages to the Amazon SQS queue

Configure the tFixedFlowInput component and the tSQSOutput component to deliver messages to the new empty Amazon SQS queue.

Procedure

1. Double-click the tSQSOutput component to open its Basic settings view.

2. Specify the connection details required to access Amazon SQS. In this example, select the Use an existing connection check box and from the Component List drop-down list displayed, select the connection component to reuse its connection details you have already defined.

3. In the Queue (Name or URL) field, enter the name for the queue to which the messages will be delivered. In this example, it is talend.

4. Click the button next to Edit schema to open the schema dialog box.

You can see the schema of the tSQSOutput component is predefined with a single String column Body that stores the body of each message to be delivered.

5. Click the button in the right panel to add one column Creator of String type, which will hold the customized creator attribute value of each message.

6. Click the button to copy all columns from the output schema to the input schema. In the pop-up dialog box, click OK to accept the changes.

7. Click OK to close the schema dialog box.

8. Double-click the tFixedFlowInput component to open its Basic settings view.
9. In the Mode area, select Use Inline Content(delimited file). Then in the Content field displayed, enter the creator attribute and body data of the messages to be delivered to Amazon SQS. In this example, it is:

- Talend DOC Team; the 1st message from Talend DOC team
- Talend DEV Team; the 2nd message from Talend DEV team
- Talend QA Team; the 3rd message from Talend QA team

### Getting attributes of the Amazon SQS queue

Configure the tSQSQueueAttributes component and the tLogRow component to get and display the attributes of the Amazon SQS queue on the console.

**Procedure**

1. Double-click the tSQSQueueAttributes component to open its Basic settings view.
2. Specify the connection details required to access Amazon SQS. In this example, select the Use an existing connection check box and from the Component List drop-down list displayed, select the connection component to reuse its connection details you have already defined.
3. In the Queue (Name or URL) field, enter the name for the queue whose attributes will be retrieved. In this example, it is talend.
4. Double-click the tLogRow component to open its Basic settings view.
5. In the Mode area, select Vertical to display each attribute and its value in a row.

### Executing the Job to deliver Amazon SQS messages

After setting up the Job and configuring the components used in the Job for delivering Amazon SQS messages, you can then execute the Job and verify the Job execution result.

**Procedure**

1. Press Ctrl + S to save the Job and then F6 to execute the Job.
As shown above, the Job is executed successfully and the attributes of the queue is displayed on the console.

2. View the queue details on the AWS console to validate the Job execution result.

![AWS Console](image)

You can see the queue talend is created successfully with the retention period for one day, and three messages are now available in the queue.

3. Select the queue talend on the AWS console and then click **Queue Actions > View/Delete Messages** to view messages in the queue.
You can see the three messages are now available in the queue.

4. Click **More Details** for one of the messages to view the detailed information of the message.

You can see the customized Creator attribute value for the message is listed on the **Message Attributes** tab.
**tSQSQueueAttributes**

Gets attributes for a specified Amazon SQS (Simple Queue Service) queue.

**tSQSQueueAttributes Standard properties**

These properties are used to configure tSQSQueueAttributes running in the Standard Job framework.

The Standard tSQSQueueAttributes component belongs to the Cloud family.

The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Use an existing connection</strong></td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td><strong>Access Key and Secret Key</strong></td>
<td>Specify the access keys (the access key ID in the <strong>Access Key</strong> field and the secret access key in the <strong>Secret Key</strong> field) required to access the Amazon Web Services. For more information on AWS access keys, see Access keys (access key ID and secret access key). To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td><strong>Inherit credentials from AWS role</strong></td>
<td>Select this check box to leverage the instance profile credentials. These credentials can be used on Amazon EC2 instances, and are delivered through the Amazon EC2 metadata service. To use this option, your Job must be running within Amazon EC2 or other services that can leverage IAM Roles for access to resources. For more information, see Using an IAM Role to Grant Permissions to Applications Running on Amazon EC2 Instances.</td>
</tr>
<tr>
<td><strong>Assume Role</strong></td>
<td>Select this check box and specify the values for the following parameters used to create a new assumed role session.</td>

<tr>
<td><strong>Region</strong></td>
<td>Specify the AWS region by selecting a region name from the list or entering a region between double quotation marks (for example 'us-east-1') in the list. For more</td>
</tr>
</tbody>
</table>
**Queue (Name or URL)**
Specify the name or the URL of the queue whose attribute information will be retrieved.

**Schema and Edit schema**
A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

The schema of this component is read-only and predefined with a couple of columns that describe the attributes for the specified queue. You can click the [...] button next to `Edit schema` to view its schema. For more information on each attribute, see GetQueueAttributes.

**Die on error**
Select the check box to stop the execution of the Job when an error occurs.
Clear the check box to skip any error and continue the Job execution process.

---

**Advanced settings**

**Config client**
Select this check box and in the table displayed specify the client configuration parameters. Click the [+] button below the table to add as many rows as needed, each row for a client configuration parameter, and set the value of the following attributes for each parameter:

- **Client Parameter**: click the cell and select a parameter from the drop-down list.
- **Value**: enter the value for the corresponding parameter.

**STS Endpoint**
Select this check box and in the field displayed, specify the AWS Security Token Service endpoint where session credentials are retrieved from.

This check box is available only when the Assume role check box is selected.

**tStatCatcher Statistics**
Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

---

**Global variables**

**ERROR_MESSAGE**
The error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is selected.
Usage

| Usage rule | This component is usually used as a start component of a Job or Subjob and it always needs an output link. |

<td>Die on error</td>
<td>Select the check box to stop the execution of the Job when an error occurs. Clear the check box to skip any error and continue the Job execution process.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| Config client       | Select this check box and in the table displayed specify the client configuration parameters. Click the [+] button below the table to add as many rows as needed, each row for a client configuration parameter, and set the value of the following attributes for each parameter:  
|                    | • **Client Parameter**: click the cell and select a parameter from the drop-down list.  
|                    | • **Value**: enter the value for the corresponding parameter. |
| STS Endpoint       | Select this check box and in the field displayed, specify the AWS Security Token Service endpoint where session credentials are retrieved from. This check box is available only when the **Assume role** check box is selected. |
| tStatCatcherStatistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global variables**

| ERROR_MESSAGE | The error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is selected. |

**Usage**

| Usage rule | This component can be used as a standalone component of a Job or Subjob. |

**Related scenario**

Retrieving messages from an Amazon SQS queue on page 3737
tSQSQueueList

Iterates and lists the URL of Amazon SQS (Simple Queue Service) queues in a specified region.

**tSQSQueueList Standard properties**

These properties are used to configure tSQSQueueList running in the Standard Job framework.

The Standard tSQSQueueList component belongs to the Cloud family.

The component in this framework is generally available.

**Basic settings**

<table>
<thead>

<td>Specify the access keys (the access key ID in the <strong>Access Key</strong> field and the secret access key in the <strong>Secret Key</strong> field) required to access the Amazon Web Services. For more information on AWS access keys, see Access keys (access key ID and secret access key). To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Inherit credentials from AWS role</strong></td>
<td>Select this check box to leverage the instance profile credentials. These credentials can be used on Amazon EC2 instances, and are delivered through the Amazon EC2 metadata service. To use this option, your Job must be running within Amazon EC2 or other services that can leverage IAM Roles for access to resources. For more information, see Using an IAM Role to Grant Permissions to Applications Running on Amazon EC2 Instances.</td>
</tr>
</tbody>
</table>
| **Assume Role** | Select this check box and specify the values for the following parameters used to create a new assumed role session.  
  - **Role ARN**: the Amazon Resource Name (ARN) of the role to assume.  
  - **Role session name**: an identifier for the assumed role session.  
  - **Session duration (minutes)**: the duration (in minutes) for which we want to have the assumed role session to be active. For more information on assuming roles, see AssumeRole. |
| **Region** | Specify the AWS region by selecting a region name from the list or entering a region between double quotation marks (for example ‘us-east-1’) in the list. For more
Advanced settings

**Config client**
Select this check box and in the table displayed specify the client configuration parameters. Click the [+] button below the table to add as many rows as needed, each row for a client configuration parameter, and set the value of the following attributes for each parameter:
- **Client Parameter**: click the cell and select a parameter from the drop-down list.
- **Value**: enter the value for the corresponding parameter.

**STS Endpoint**
Select this check box and in the field displayed, specify the AWS Security Token Service endpoint where session credentials are retrieved from.
This check box is available only when the **Assume role** check box is selected.

**tStatCatcher Statistics**
Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

Global variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CURRENT_QUEUE_NAME</td>
<td>The URL of the queue being processed. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td>NB_QUEUE</td>
<td>The number of queues processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>ERROR_MESSAGE</td>
<td>The error message generated by the component when an error occurs. This is an After variable and it returns a string.</td>
</tr>
</tbody>
</table>

Usage

**Usage rule**
This component is usually used as a start component of a Job or Subjob and it always needs an output link.

**Listing Amazon SQS queues in an AWS region**

Here's an example of using Talend components to iterate and list the URLs of all Amazon SQS (Simple Queue Service) queues in an AWS region.

**Creating a Job for listing Amazon SQS queues**

Create a Job to open a connection to access Amazon SQS, then iterate and list the URLs of all Amazon SQS queues in a specified region, finally display the total number of the queues in the region.
Prerequisites: You must create several Amazon SQS queues in an AWS region in order to replicate this scenario. In this example, four queues `talend`, `talend-dev`, `talend-doc` and `talend-qa` have been created in the region `Asia Pacific (Tokyo)` as shown in below figure.

![SQS Queues](image)

Procedure

1. Create a new Job and add a `tSQSConnection` component, a `tSQSQueueList` component, a `tIterateToFlow` component, a `tLogRow` component, and a `tJava` component by typing their names in the design workspace or dropping them from the Palette.
2. Link the `tSQSQueueList` component to the `tIterateToFlow` component using a `Row > Iterate` connection.
3. Link the `tIterateToFlow` component to the `tLogRow` component using a `Row > Main` connection.
4. Link the `tSQSConnection` component to the `tSQSQueueList` component using a `Trigger > OnSubjobOk` connection.
5. Link the `tSQSQueueList` component to the `tJava` component using a `Trigger > OnSubjobOk` connection.
Opening a connection to access Amazon SQS

Configure the **tSQSConnection** component to open a connection to access Amazon SQS.

**Procedure**

1. Double-click the **tSQSConnection** component to open its **Basic settings** view.

2. In the **Access Key** and **Secret Key** fields, specify the authentication information required to access Amazon SQS.
3. Select an AWS region available for Amazon SQS from the **Region** drop-down list. In this example, it is Asia Pacific (Tokyo).

Listing all Amazon SQS queues in an AWS region

Configure the **tSQSQueueList** component, the **tIterateToFlow** component, the **tLogRow** component, and the **tJava** component to list the URLs of all Amazon SQS queues in an AWS region and display the total number of the queues in the region on the console of Talend Studio.

**Procedure**

1. Double-click the **tSQSQueueList** component to open its **Basic settings** view.

2. Specify the connection details required to access Amazon SQS. In this example, select the **Use an existing connection** check box and from the **Component List** drop-down list displayed, select the connection component to reuse its connection details you have already defined.
3. Double-click the **tIterateToFlow** component to open its **Basic settings** view.
4. Click the button next to Edit schema to open the schema dialog box.

5. Click the button to add one String type column CurrentQueueURL that will hold the URLs of the queues to be listed. When done, click OK to close the dialog box.

6. In the Mapping table, set the value for the CurrentQueueURL column. In this example, the value is set to ((String)globalMap.get("tSQSQueueList_1_CURRENT_QUEUE_NAME")), which is the value of the global variable CURRENT_QUEUE_NAME for the tSQSQueueList component.

Note that you can fill the value by pressing Ctrl + Space to access the global variables list and then selecting tSQSQueueList_1_CURRENT_QUEUE_NAME from the list.

7. Double-click the tLogRow component to open its Basic settings view, and then select Table (print values in cells of a table) in the Mode area for better readability of the result.

8. Double-click the tJava component to open its Basic settings view.
9. In the **Code** field, enter the following code to display the total number of the queues in the region.

```java
System.out.println("The number of queues: " + ((Integer)globalMap.get("tSQSQueueList_1_NB_QUEUE"));
```

**Executing the Job to list Amazon SQS queues**

After setting up the Job and configuring the components used in the Job for listing Amazon SQS queues, you can then execute the Job and verify the Job execution result.

**Procedure**

1. Press **Ctrl + S** to save the Job.
2. Press **F6** to execute the Job.

As shown above, the URLs of all queues in the **Asia Pacific (Tokyo)** region and the total number of the queues are displayed on the console.
tSQSQueuePurge

Purges messages in an Amazon SQS (Simple Queue Service) queue.

**tSQSQueuePurge Standard properties**

These properties are used to configure tSQSQueuePurge running in the Standard Job framework.

The Standard tSQSQueuePurge component belongs to the Cloud family.

The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
</table>
| **Access Key** and **Secret Key** | Specify the access keys (the access key ID in the Access Key field and the secret access key in the Secret Key field) required to access the Amazon Web Services. For more information on AWS access keys, see Access keys (access key ID and secret access key).

To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| **Inherit credentials from AWS role** | Select this check box to leverage the instance profile credentials. These credentials can be used on Amazon EC2 instances, and are delivered through the Amazon EC2 metadata service. To use this option, your Job must be running within Amazon EC2 or other services that can leverage IAM Roles for access to resources. For more information, see Using an IAM Role to Grant Permissions to Applications Running on Amazon EC2 Instances. |
| **Assume Role** | Select this check box and specify the values for the following parameters used to create a new assumed role session.

- **Role ARN**: the Amazon Resource Name (ARN) of the role to assume.
- **Role session name**: an identifier for the assumed role session.
- **Session duration (minutes)**: the duration (in minutes) for which we want to have the assumed role session to be active.

For more information on assuming roles, see AssumeRole. |
| **Region** | Specify the AWS region by selecting a region name from the list or entering a region between double quotation marks (for example ‘us-east-1’) in the list. For more |
Queue (Name or URL)  Specify the name or the URL of the queue in which messages will be purged.

Die on error  Select the check box to stop the execution of the Job when an error occurs. Clear the check box to skip any error and continue the Job execution process.

Advanced settings

Config client  Select this check box and in the table displayed specify the client configuration parameters. Click the [+] button below the table to add as many rows as needed, each row for a client configuration parameter, and set the value of the following attributes for each parameter:

- **Client Parameter**: click the cell and select a parameter from the drop-down list.
- **Value**: enter the value for the corresponding parameter.

STS Endpoint  Select this check box and in the field displayed, specify the AWS Security Token Service endpoint where session credentials are retrieved from. This check box is available only when the Assume role check box is selected.

tStatCatcher Statistics  Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

Global variables

**ERROR_MESSAGE**  The error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is selected.

Usage

**Usage rule**  This component can be used as a standalone component of a Job or Subjob.

Related scenario

No scenario is available for this component yet.
tSSH

Establishes a communication with distant server and returns securely sensible information.
Returns data from a remote computer, based on the secure shell command defined.

**tSSH Standard properties**

These properties are used to configure tSSH running in the Standard Job framework.
The Standard tSSH component belongs to the System family.
The component in this framework is generally available.

**Basic settings**

| Schema and Edit Schema | A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either Built-in or stored remotely in the Repository. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
• View schema: choose this option to view the schema only.  
• Change to built-in property: choose this option to change the schema to Built-in for local changes.  
• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the [Repository Content] window.  
Click Sync columns to retrieve the schema from the preceding component in the Job. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Built-in</td>
<td>You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Repository</td>
<td>You have already created the schema and stored it in the Repository. You can reuse it in various projects and job flowcharts. Related topic: see Talend Studio User Guide</td>

</table>
- **to console**: the output is displayed in the console of the Run view.
- **to global variable**: the output is indicated by the corresponding global variable.
- **both to console and global variable**: the output is indicated both of the two means.
- **normal**: the output is a standard ssh output.

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the processing metadata at the Job level as well as at each component level. |

**Global Variables**

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
**STDOUT**: the standard execution output of the remote command. This is an After variable and it returns a string.  
**STDERR**: the error execution output of the remote command. This is an After variable and it returns a string.  
**EXIT_CODE**: the exit code of the remote command. This is an After variable and it returns an integer.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
For further information about variables, see **Talend Studio User Guide**. |

**Usage**

| Usage rule | This component can be used as standalone component. Note that for some sensitive information such as password and username, you can define the context variables in the **Contexts** tab and press **Ctrl + Space** to access them. |
| Connections | Outgoing links (from this component to another):  
**Row**: Main  
**Trigger**: Run if; On Component Ok; On Component Error; On Subjob Ok; On Subjob Error. |
**Scenario: Remote system information display via SSH**

The following use case describes a basic Job that uses SSH command to display the hostname of the distant server being connected to, and the current date on this remote system.

The `tSSH` component is sufficient for this Job. Drop it from the Palette to the design workspace.

Double-click on the `tSSH` component and select the Basic settings view tab.

**Procedure**

1. Type in the name of the **Host** to be accessed through SSH as well as the **Port** number.
2. Fill in the **User** identification name on the remote machine.
3. Select the **Authentication method** on the list. For this use case, the authentication method used is the public key.
4. Thus fill in the corresponding **Private key**.

5. On the **Command** field, type in the following command. For this use case, type in `hostname; date` between double quotes.

6. Select the **Use timeout** check box and set the time before falling in error to 5 seconds.

```
picasso
Wed Sep  26 14:24:15 CEST 2007
Job uniteElisa ended at 16:26 26/09/2007. [exit code=0]
```

**Results**

The remote machine returns the host name and the current date and time as defined on its system.
tStatCatcher

Gathers the Job processing metadata at the Job level and at the component level and transfers the log data to the subsequent component for display or storage.

Based on the pre-defined schema, tStatCatcher gathers the Job processing metadata at the Job level and at the component level when the **tStatCatcher** Statistics check box is selected.

**tStatCatcher Standard properties**

These properties are used to configure tStatCatcher running in the Standard Job framework.

The Standard tStatCatcher component belongs to the Logs & Errors family.

The component in this framework is generally available.

**Basic settings**

| Schema   | A schema is a row description, it defines the fields to be processed and passed on to the next component. In this particular case, the schema is read-only, as this component gathers standard log information including:
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------
| **Moment**: Processing time and date | **Pid**: Process ID
| **Father_pid**: Process ID of the father Job if applicable. If not applicable, Pid is duplicated. | **Root_pid**: Process ID of the root Job if applicable. If not applicable, pid of current Job is duplicated.
| **System_pid**: Thread ID. | **Project**: Project name, which the Job belongs to.
| **Job**: Name of the current Job | **Job_repository_id**: ID of the Job’s .item file stored in the repository.
| **Job_version**: Version of the current Job. | **Context**: Name of the current context
| **Origin**: Name of the component if any | **Message_type**: Begin or End.
| **Message**: Success or Failure. | **Duration**: Time for the execution of a Job or a component with the **tStatCatcher** Statistics check box selected. |
Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see  Talend Studio  User Guide. |

Usage

| Usage rule | This component is the start component of a secondary Job which triggers automatically at the end of the main Job. The processing time is also displayed at the end of the log. |

Scenario: Displaying the statistics log of Job execution

This scenario collects the statistics log for the Job execution and displays it on the Run console. Note that, since the tStatCatcher Statistics check box is not selected for the components, the statistics log applies solely to this specific Job.

Linking the components

Procedure

1. Drop tFixedFlowInput, tFileOutputDelimited, tStatCatcher and tLogRow onto the workspace.
2. Link tFixedFlowInput to tFileOutputDelimited using a Row > Main connection.
3. Link tStatCatcher to tLogRow using a Row > Main connection.
Configuring the components

Procedure

1. Double-click **tFixedFlowInput** to open its **Basic settings** view.

2. Click the **Edit schema** button to open the schema editor.

3. Click the [+ ] button to add three columns, namely **ID_Owners**, **Name_Customer** and **ID_Insurance**, of the Integer and String types respectively.

4. Click **Ok** to validate the setup and close the editor.

5. In the dialog box that appears, click **Yes** to propagate the changes to the subsequent component.

6. Select the **Use Inline Content (delimited file)** option.

7. In the **Content** box, enter `1;Andrew;888`.

8. Double-click **tFileOutputDelimited** to open its **Basic settings** view.
9. In the **File Name** field, enter the full name of the file to save the statistics data.

10. Double-click **tLogRow** to open its **Basic settings** view.

11. Select **Vertical (each row is a key/value list)** for a better display of the results.

**Executing the Job**

**Procedure**

1. Press **Ctrl + S** to save the Job.
2. Press **F6** to run the Job.
As shown above, the statistics log of the Job execution is correctly generated.
tSugarCRMInput

Extracts data from a SugarCRM database based on a query.
tSugarCRMInput connects to a Sugar CRM database module via the relevant webservice.

**tSugarCRMInput Standard properties**

These properties are used to configure tSugarCRMInput running in the Standard Job framework.
The Standard tSugarCRMInput component belongs to the Business and the Cloud families.
The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>SugarCRM Webservice URL</th>
<th>Type in the webservice URL to connect to the SugarCRM DB.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Username and Password</strong></td>
<td>Type in the Webservice user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Module</strong></td>
<td>Select the relevant module from the list</td>
</tr>
<tr>
<td></td>
<td>Note: To use customized tables, select Use custom module from the list. The Custom module package name and Custom module name fields which appear are automatically filled in with the relevant names.</td>
</tr>
<tr>
<td><strong>Schema and Edit Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:</td>
</tr>
<tr>
<td></td>
<td>• View schema: choose this option to view the schema only.</td>
</tr>
<tr>
<td></td>
<td>• Change to built-in property: choose this option to change the schema to Built-in for local changes.</td>
</tr>
<tr>
<td></td>
<td>• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the [Repository Content] window.</td>
</tr>
</tbody>
</table>
In this component the schema is related to the Module selected.

**Query condition**

Type in the query to select the data to be extracted. Example: account_name= 'Talend'.

**Advanced settings**

| **tStat Catcher Statistics** | Select this check box to collect log data at the component level. |

**Global Variables**

| **Global Variables** | **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.  
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
For further information about variables, see **Talend Studio User Guide**. |

**Usage**

| **Usage rule** | Usually used as a Start component. An output component is required. |

**Scenario: Extracting account data from SugarCRM**

This scenario describes a two-component Job which extracts account information from a SugarCRM database and writes it to an Excel output file.

**Setting up the Job**

**Procedure**

1. Drop a **tSugarCRMInput** and a **tFileOutputExcel** component from the **Palette** onto the workspace.
2. Connect the input component to the output component using a **Row > Main** connection.
Configuring the input component

Procedure

1. Double-click tSugarCRMInput to define the component properties in its Basic settings view.

   ![SugarCRM Input Component](image1)

<table>
<thead>
<tr>
<th>Basic settings</th>
<th>Advanced settings</th>
<th>Dynamic settings</th>
<th>View</th>
<th>Documentation</th>
<th>Validation Rules</th>
</tr>
</thead>
<tbody>
<tr>
<td>SugarCRM WebService URL</td>
<td>Username</td>
<td>Password</td>
<td>Module</td>
<td>Schema</td>
<td>Query Condition</td>
</tr>
<tr>
<td>&quot;<a href="http://localhost/sugar/soap.php">http://localhost/sugar/soap.php</a>&quot;</td>
<td>&quot;admin&quot;</td>
<td>&quot;password&quot;</td>
<td>Accounts</td>
<td>Built-In</td>
<td>&quot;billing_address_city='Sunnyvale'&quot;</td>
</tr>
</tbody>
</table>

2. Fill the SugarCRM WebService URL field with the connection information, and the Username and Password fields with the authentication you have.

3. Select the Module from the list of modules offered. In this example, Accounts is selected.

   The Schema is then automatically set according to the module selected. But you can change it and remove the columns that you do not require in the output.

4. In the Query Condition field, type in the query you want to extract from the CRM. In this example: "billing_address_city='Sunnyvale'".

Job execution

Procedure

1. Double-click tFileOutputExcel to define the component properties in its Basic settings view.

   ![File Output Excel Component](image2)

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>File Name</td>
<td>&quot;C:/Output/billing_city.xls&quot;</td>
</tr>
<tr>
<td>Sheet name</td>
<td>&quot;accounts&quot;</td>
</tr>
<tr>
<td>Include header</td>
<td>checked</td>
</tr>
<tr>
<td>Schema Type</td>
<td>Built-In</td>
</tr>
<tr>
<td>Encoding Type</td>
<td>ISO-8859-15</td>
</tr>
</tbody>
</table>

2. Set the destination file name as well as the Sheet name and select the Include header check box.

3. Press CTRL+S to save your Job and press F6 to execute it.
The filtered data is output in the defined spreadsheet of the specified Excel file.
**tSugarCRMOutput**

Writes data into a SugarCRM database.
tSugarCRMOutput writes in a Sugar CRM database module via the relevant webservice.

**tSugarCRMOutput Standard properties**

These properties are used to configure tSugarCRMOutput running in the Standard Job framework. The Standard tSugarCRMOutput component belongs to the Business and the Cloud families. The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>

</tr>
</tbody>
</table>
Click **Sync columns** to retrieve the schema from the previous component connected in the Job.

### Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

### Global Variables

| Global Variables | **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.  
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
For further information about variables, see *Talend Studio User Guide*. |

### Usage

| Usage rule | Used as an output component. An Input component is required. |

### Related scenarios

No scenario is available for the Standard version of this component yet.
tSVNLogInput

Retrieves the information of a specified revision or range of revisions from an SVN repository.

**tSVNLogInput Standard properties**

These properties are used to configure tSVNLogInput running in the Standard Job framework.

The Standard tSVNLogInput component belongs to the Internet family.

The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>URL</strong></td>
<td>Type in the URL to the SVN repository to be accessed.</td>
</tr>
<tr>
<td><strong>Need authentication?</strong></td>
<td>Select this check box if authentication is needed to access the SVN repository.</td>
</tr>
</tbody>
</table>
| **Username and Password** | Enter the username and password to access the SVN repository if authentication is needed.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.  
These two fields appear only when the Need authentication? check box is selected. |
| **From revision**         | Specify a start revision number of the revision range.                     |
| **Only this revision**    | Select this check box if you need to retrieve the information of only the revision specified in the From revision field. |
| **To revision**           | Specify an end revision number of the revision range. Enter 'HEAD' for the latest revision.  
This field disappears when the Only this revision check box is selected. |
| **Schema and Edit schema**| A schema is a row description, it defines the fields to be processed and passed on to the next component.  
The schema of this component is read-only. It describes the properties of the revision information. You can click the [...] button next to Edit schema to view the predefined schema which contains the following fields:  
• revision: the revision number of the log message.  
• author: the author who commits the log message.  
• date: the date when the log message was committed.  
• message: the content of the log message.  
• nb_file_added: the number of added files.  
• nb_file_modified: the number of modified files. |
Advanced settings

### tStatCatcher Statistics

Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

Global Variables

| Global Variables | NB_LINE: the number of rows processed. This is an After variable and it returns an integer.  
ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.  
For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | This component is usually used as a start component in a Job and it needs an output link. |

Connections

| Outgoing links (from this component to another):  
Row: Main, Iterate  
Trigger: On Subjob Ok, On Subjob Error, Run if, On Component Ok, On Component Error |

| Incoming links (from one component to this one):  
Row: Main, Iterate  
Trigger: On Subjob Ok, On Subjob Error, Run if, On Component Ok, On Component Error |

For further information about connections, see Talend Studio User Guide.

---

### Scenario: Retrieving a log message from an SVN repository

This scenario describes a two-component Job that retrieves the information of a specified revision from an SVN repository, and displays the information on the console.
Procedure

1. Create a new Job and add the following two components by typing their names in the design workspace or dropping them from the Palette: a tSVNLogInput component and a tLogRow component.

2. Connect tSVNLogInput to tLogRow using a Row > Main link.

3. Double-click tSVNLogInput to open its Basic settings view.

   ![tSVNLogInput settings](image)

   - URL: "https://talend.com/svndoc/"
   - Need authentication?: select this check box
   - Username: "lena"
   - Password: **********
   - From revision: 17090
   - Only this revision: select this check box

4. In the URL field, enter the URL to the SVN repository to be accessed. In this example, it is https://talend.com/svndoc/. Note that the login credentials provided here is for demonstration only.

5. Select the Need authentication? check box and fill in the Username and Password fields with your authentication information.

6. Specify a revision or revision range. In this example, we want to retrieve the information of revision 17090 only, so enter 17090 in the From revision field and select the Only this revision check box.

7. Double-click tLogRow to open its Basic settings view.

   ![tLogRow settings](image)

   - Schema: Built-In
   - Field Separator: "\n"
   - Mode: Basic
   - Print header: select this box
   - Print component unique name in front of each output row: select this box
   - Print schema column name in front of each value: select this box
   - Use fixed length for values: select this box

8. Define the way you want the output data to be displayed on the console. In this example, enter "\n" in the Field Separator field to display each field of the revision information in a separate line.
9. Select the **Print schema column name in front of each value** check box to show the name of each field of the revision information at the beginning of each line.

10. Press **Ctrl + S** to save the Job and then **F6** to run the Job.

As shown above, the information of the specified revision is displayed on the console.
tSybaseBulkExec

Gains in performance during Insert operations to a Sybase database.

The tSybaseOutputBulk and tSybaseBulkExec components are generally used together as parts of a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tSybaseOutputBulkExec component, detailed in a separate section. The advantage of using two separate components is that the data can be transformed before it is loaded in the database.

tSybaseBulkExec Standard properties

These properties are used to configure tSybaseBulkExec running in the Standard Job framework.

The Standard tSybaseBulkExec component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
<td></td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

**Note:**

When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB Version</td>
<td>Select the version of the Sybase database to be used from the drop-down list.</td>
</tr>
<tr>
<td>Server</td>
<td>Database server IP address</td>

<td>IP address of the database server for the Bcp utility connection.</td>
</tr>
<tr>
<td>Batch size</td>
<td>Number of lines in each processed batch.</td>
</tr>
<tr>
<td>Table</td>
<td>Name of the table to be written. Note that only one table can be written at a time and that the table must exist for the insert operation to succeed.</td>
</tr>
<tr>
<td>Action on table</td>
<td>On the table defined, you can perform one of the following operations:</td>
</tr>
<tr>
<td></td>
<td><strong>None</strong>: No operation is carried out.</td>
</tr>
<tr>
<td></td>
<td><strong>Drop and create table</strong>: The table is removed and created again.</td>
</tr>
<tr>
<td></td>
<td><strong>Create table</strong>: The table does not exist and gets created.</td>
</tr>
<tr>
<td></td>
<td><strong>Create table if not exists</strong>: The table is created if it does not exist.</td>
</tr>
<tr>
<td></td>
<td><strong>Drop table if exists and create</strong>: The table is removed if it already exists and created again.</td>
</tr>
<tr>
<td></td>
<td><strong>Clear table</strong>: The table content is deleted.</td>
</tr>
<tr>
<td><strong>Truncate table</strong>: The table content is deleted. You do not have the possibility to rollback the operation.</td>
<td></td>
</tr>
<tr>
<td>---</td>
<td></td>
</tr>
</tbody>
</table>

### File Name
Name of the file to be loaded.

**Warning:**
This file should be located on the same machine as the database server.

### Schema and Edit Schema
A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

**Built-In:** You create and store the schema locally for this component only. Related topic: see [Talend Studio User Guide](https://help.talend.com).

**Repository:** You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see [Talend Studio User Guide](https://help.talend.com).

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-In** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.

### Advanced settings

| **Use an interface file** | Select this check box to specify an interface file in the field **Interface file**. |
|**Additional JDBC parameters** | Specify additional connection properties in the existing DB connection, to allow specific character set support. E.G.: CHARSET=KANJISJIS_OS to get support of Japanese characters. |
| Action on data | On the data of the table defined, you can perform:  
**Bulk Insert**: Add multiple entries to the table. If duplicates are found, Job stops.  
**Bulk Update**: Make simultaneous changes to multiple entries. |
| Field Terminator | Character, string or regular expression to separate fields.  
**Warning**:  
*With the row/field separators compliant with the Sybase syntax, this component allows for the use of Sybase-orientated characters, such as \x09.* |
| Row Terminator | String (ex: "\n" in Unix) to separate lines. |
| Head row | Number of head lines to be ignored in the beginning of a file. |
| Encoding | Select the encoding from the list, or enter the encoding between double quotes if it does not exist in the list. This field is compulsory for database data handling. |
| Output | Select the type of output for the standard output of the Sybase database:  
to console,  
to global variable. |
| tStataCatcher statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

### Global Variables

| Global Variables |  
**NB_LINE_DATA**: the number of rows read. This is an After variable and it returns an integer.  
**NB_LINE_BAD**: the number of rows rejected. This is an After variable and it returns an integer.  
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.  
For further information about variables, see Talend Studio User Guide. |
Usage

Usage rule
This component is mainly used when no particular transformation is required on the data to be loaded onto the database.

Dynamic settings
Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Limitation
The database server/client must be installed on the same machine where the Studio is installed or where the Job using tSybaseBulkExec is deployed, so that the component functions properly.

As opposed to the Oracle dedicated bulk component, no action on data is possible using this Sybase dedicated component.

This component requires installation of its related jar files.

Related scenarios

For tSybaseBulkExec related topics, see:

- Scenario: Inserting transformed data in MySQL database on page 2537.
- Scenario: Truncating and inserting file data into an Oracle database on page 2752.
tSybaseClose

Closes a transaction committed in the connected database.

tSybaseClose Standard properties

These properties are used to configure tSybaseClose running in the Standard Job framework.

The Standard tSybaseClose component belongs to the Databases family.

The component in this framework is generally available.

Note:

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

| Database | Select a type of database from the list and click Apply. |
|Component list | Select the tSybaseConnection component in the list if more than one connection are planned for the current Job. |

Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

Usage

| Usage rule | This component is to be used along with Sybase components, especially with tSybaseConnection and tSybaseCommit. |
|Dynamic settings | Click the [+ ] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-
Related scenario

This component is to be used with `tSybaseConnection` and `tSybaseRollback` components. It is generally used with a `tSybaseConnection` to close a connection for the ongoing transaction.

For a related scenario `tSybaseClose`, see `tMysqlConnection` on page 2475.
**tSybaseCommit**

Commits in one go, using a unique connection, a global transaction instead of doing that on every row or every batch and thus provides gain in performance.

tSybaseCommit validates the data processed through the Job into the connected DB.

**tSybaseCommit Standard properties**

These properties are used to configure tSybaseCommit running in the Standard Job framework.

The Standard tSybaseCommit component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tSybaseConnection component in the list if more than one connection are planned for the current Job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
<tr>
<td></td>
<td><strong>Warning:</strong> If you want to use a Row &gt; Main connection to link tSybaseCommit to your Job, your data will be committed row by row. In this case, do not select the Close connection check box or your connection will be closed before the end of your first row commit.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStat Catcher Statistics  | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule                | This component is more commonly used with other tSybase components, especially with the tSybaseConnection and tSybaseRollback components. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see **Scenario: Reading data from databases through context-based dynamic connections** on page 2497 and **Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters** on page 489. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide. |

## Related scenario

For **tSybaseCommit** related scenario, see **Scenario: Inserting data in mother/daughter tables** on page 2476.
tSybaseConnection

Opens a connection to the database for a current transaction.

**tSybaseConnection Standard properties**

These properties are used to configure tSybaseConnection running in the Standard Job framework.

The Standard tSybaseConnection component belongs to the Databases and the ELT families.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>

<tr>
<td><strong>Database</strong></td>
<td>The name of the database.</td>
</tr>
<tr>
<td><strong>Username</strong> and <strong>Password</strong></td>
<td>The database user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>The schema of the database.</td>
</tr>
<tr>
<td><strong>Additional JDBC Parameters</strong></td>
<td>Specify additional JDBC parameters for the database connection being created.</td>
</tr>
</tbody>
</table>
### Use or register a shared DB Connection

Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the **Shared DB Connection Name** field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child.

This option is incompatible with the **Use dynamic job** and **Use an independent process to run subjob** options of the **tRunJob** component. Using a shared connection together with a **tRunJob** component with either of these two options enabled will cause your Job to fail.

### Advanced settings

#### Auto Commit

Select this check box to commit any changes to the database automatically upon the transaction.

With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component.

Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component.

#### tStatCatcher Statistics

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Usage

#### Usage rule

This component is more commonly used with other tSybase* components, especially with the **tSybaseCommit** and **tSybaseRollback** components.

### Related scenarios

For a **tSybaseConnection** related scenario, see [Scenario: Inserting data in mother/daughter tables](#) on page 2476.
tSybaseInput

Executes a DB query with a strictly defined order which must correspond to the schema definition. tSybaseInput reads a database and extracts fields based on a query. It passes on the field list to the next component via a Main row link.

tSybaseInput Standard properties

These properties are used to configure tSybaseInput running in the Standard Job framework. The Standard tSybaseInput component belongs to the Databases family. The component in this framework is generally available.

Note:

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Click this icon to open a database connection wizard and store the database connection parameters you set in the component Basic settings view.</td>
<td></td>
</tr>
<tr>
<td>For more information about setting up and storing database connection parameters, see Talend Studio User Guide.</td>
<td></td>
</tr>
</tbody>
</table>

Use an existing connection

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

Note:

When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component.
which creates that very database connection.

2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th>DB Version</th>

<tr>
<td>tStat Catcher Statistics</td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

**Global Variables**

| Global Variables | **NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.  
**QUERY**: the query statement being processed. This is a Flow variable and it returns a string.  
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
For further information about variables, see **Talend Studio User Guide**. |

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component covers all possible SQL queries for Sybase databases.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic settings</td>
<td>Click the [+] button to add a row in the table and fill the <strong>Code</strong> field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.</td>
</tr>
</tbody>
</table>
The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see **Scenario: Reading data from databases through context-based dynamic connections** on page 2497 and **Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters** on page 489. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

| Limitation | This component requires installation of its related jar files. |

**Related scenarios**

For related topics, see:

- **Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters** on page 489.
tSybaseIQBulkExec

Loads data into a Sybase database table from a flat file or other database table.

**tSybaseIQBulkExec Standard properties**

These properties are used to configure tSybaseIQBulkExec running in the Standard Job framework.

The Standard tSybaseIQBulkExec component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property Type</td>
<td>Select the way the connection details will be set.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Built-In:</strong> The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Repository:</strong> The connection details stored centrally in Repository &gt; Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up <strong>Repository Content</strong> dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td></td>
<td>When reusing an existing Sybase 16 (SQL Anywhere) connection created by a tSybaseConnection component and loading data from a file located on the client side, you need to select Sybase 16 (SQL Anywhere) from the <strong>DB Version</strong> drop-down list to display the <strong>Is client file</strong> check box before selecting this check box.</td>
</tr>
</tbody>
</table>

**Note:**

When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component.
which creates that very database connection.

2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

This property is not available when **Sybase IQ 15** is selected from the **DB Version** drop-down list.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>

<tr>
<td></td>
<td>- For Sybase IQ 12 and Sybase IQ 16, the file to be bulk-loaded must be located on the same machine as the Sybase IQ server.</td>
</tr>
<tr>
<td></td>
<td>- For Sybase IQ 15, the file to be bulk-loaded can be located on the client side, however, this means certain setup on the Sybase IQ server. For more information, see <em>Sybase IQ client-side load support enhancements</em>.</td>
</tr>
<tr>
<td></td>
<td>- For Sybase 16 (SQL Anywhere), the file to be bulk-loaded can be located on both the server side and the client side.</td>
</tr>
<tr>
<td></td>
<td>Before loading data into Sybase 16 (SQL Anywhere), SQL Anywhere 17 must be installed. You can download it <a href="#">here</a>. Once the installation is done, you need to check the system variable <em>Path</em> to make sure the installation path of SQL Anywhere 17 has been added to it, and then restart the Studio (in certain case restart the computer) to have the new <em>Path</em> variable take effect.</td>
</tr>
<tr>
<td><strong>Host</strong></td>
<td>The IP address or hostname of the database.</td>
</tr>
<tr>
<td></td>
<td>This property is not available when <strong>Sybase IQ 15</strong> is selected from the <strong>DB Version</strong> drop-down list.</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>The listening port number of the database.</td>
</tr>
<tr>
<td></td>
<td>This property is not available when <strong>Sybase IQ 15</strong> is selected from the <strong>DB Version</strong> drop-down list.</td>
</tr>
<tr>
<td><strong>Data Source</strong></td>
<td>Select the type of the data source to be used and complete the corresponding DSN information in the field alongside. The available types are DSN and FILEDSN.</td>
</tr>
<tr>
<td></td>
<td>When FILEDSN is selected, a [...] button is available next to the <strong>Data Source</strong> field to allow you to browse to the data source file of interest.</td>
</tr>
<tr>
<td></td>
<td>This property is available when <strong>Sybase IQ 15</strong> is selected from the <strong>DB Version</strong> drop-down list.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>The name of the database.</td>
</tr>
<tr>
<td><strong>Sybase Schema</strong></td>
<td>The schema of the database.</td>
</tr>
</tbody>
</table>
| **Username and Password** | The database user authentication data.
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings. |
| **Table** | The name of the table to be written. |
| **Action on table** | On the table defined, you can perform one of the following operations:
- **Default**: No operation is carried out.
- **Drop and create table**: The table is removed and created again.
- **Create table**: The table does not exist and gets created.
- **Create table if does not exist**: The table is created if it does not exist.
- **Drop table if exists and create**: The table is removed if it already exists and created again.
- **Clear table**: The table content is deleted.
- **Truncate table**: The table content is deleted. You do not have the possibility to rollback the operation. |
| **Local filename** | The path to the file to be loaded. |
| **Is client file** | Select this check box if you need to load data from the client side.
This property is available when **Sybase 16 (SQL Anywhere)** is selected from the **DB Version** drop-down list. |
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the **Next Component**. When you create a Spark Job, avoid the reserved word `line` when naming the fields.
- **Built-In**: You create and store the schema locally for this component only. Related topic: see *Talend Studio User Guide*.
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see *Talend Studio User Guide*.

Click **Edit schema** to make changes to the schema. Note that if you make changes, the schema automatically becomes built-in.

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and repository. |
decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.

<table>
<thead>
<tr>
<th><strong>Use Insert-Location</strong></th>

</tr>
</tbody>
</table>

**Advanced settings**

| **Additional JDBC Parameters** | Specify additional JDBC parameters for the database connection being created. |
| **Lines terminated by** | The character or sequence of characters used to separate lines.  
This property is not available when the **Use Insert-Location** check box is selected. |
|-------------------------|--------------------------------------------------------------------------------------------------|
| **Fields terminated by** | The character, string or regular expression used to separate fields.  
With the row/field separators compliant with the Sybase syntax, this component allows the use of Sybase-oriented separators, such as \x09.  
This property is not available when the **Use Insert-Location** or **Use fixed length** check box is selected. |
| **Use enclosed quotes** | Select this check box to use data enclosure characters.  
This property is not available when the **Use Insert-Location** or **Use fixed length** check box is selected. |
| **Use fixed length** | Select this check box to set a fixed width for data lines.  
This property is not available when the **Use Insert-Location** check box is selected. |
| **Include Header** | Select this check box if the file that will be loaded includes header.  
This property is not available when the **Use Insert-Location** check box is selected. |
| **Blank as null** | Select this check box to store the input zero-length varchars as NULLs instead of blanks in the database during the load operation.  
This property is not available when the **Use Insert-Location** or **Use fixed length** check box is selected. |
| **On file error** | Select the action Sybase performs when an error occurs:  
- **Rollback (default)**: rolls back the entire transaction.  
- **Finish**: finishes the insertions already completed and ends the load operation.  
- **Continue**: skips the error and continues the load operation.  
This property is available when **Sybase 16 (SQL Anywhere)** is selected from the **DB Version** drop-down list. |
| **Message log file** | The path to the MESSAGE LOG file that saves the log information about integrity constraint violations, the types of violations, etc. It must be specified together with the **Row log file** property.  
This property is available when **Sybase 16 (SQL Anywhere)** is selected from the **DB Version** drop-down list. |
<p>| <strong>Row log file</strong> | The path to the ROW LOG file that saves the log information about reject data, the timestamps of |</p>
<table>

<td>Select this check box and in the <strong>Packet Size</strong> field displayed specify the TDS packet size in bytes. This property is available only when the <strong>Location Options</strong> check box is selected.</td>
</tr>
<tr>
<td><strong>Quoted Identifier</strong></td>
<td>Select this check box and from the <strong>Status</strong> drop-down list displayed specify the setting of the QUOTED_IDENTIFIER option on the remote server. This property is available only when the <strong>Location Options</strong> check box is selected.</td>
</tr>
<tr>
<td><strong>Set Isolation Level</strong></td>
<td>Select this check box and from the <strong>Isolation Level</strong> drop-down list displayed select the isolation level for the connection to the remote server. This property is available only when the <strong>Location Options</strong> check box is selected.</td>
</tr>
<tr>
<td><strong>Insert Load Options</strong></td>
<td>Select this check box to display the insert load options. For more information about the insert load options, see <a href="http://infocenter.sybase.com/help/index.jsp?topic=%5Ccom.sybase.infocenter.dc00801.1510/html/iqrefso/X315746.htm">http://infocenter.sybase.com/help/index.jsp?topic=\com.sybase.infocenter.dc00801.1510/html/iqrefso/X315746.htm</a>. This property is available only when the <strong>Use Insert-Location</strong> check box is selected.</td>
</tr>
<tr>
<td><strong>Limit Number</strong></td>
<td>Specify the maximum number of rows to be inserted into the Sybase IQ table. This property is available only when the <strong>Insert Load Options</strong> check box is selected.</td>
</tr>
<tr>
<td><strong>Notify Number</strong></td>
<td>Specify that you will be notified with a message each time the number of rows are successfully inserted into the Sybase IQ table.</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Skip Number</td>
<td>Specify the number of rows to be skipped at the beginning of the source table. This property is available only when the <strong>Insert Load Options</strong> check box is selected.</td>
</tr>
<tr>
<td>Start Row ID</td>
<td>Specify the ID of the row in the Sybase IQ table where you want to start the insert. <strong>Note:</strong> Sybase IQ 16 doesn’t support this parameter. This property is available only when the <strong>Insert Load Options</strong> check box is selected.</td>
</tr>
<tr>
<td>Word Skip Number</td>
<td>Enter the number of times the error <em>Words exceeding the maximum permitted word length not supported</em> is ignored when loading data into the Sybase IQ table. This property is available only when the <strong>Insert Select Load Options</strong> check box is selected.</td>
</tr>
</tbody>
</table>
| Ignore Constraint      | Select this check box and in the table displayed you can specify the integrity constraint violation to ignore when loading data into the Sybase IQ table by clicking the [+] button to add as many rows as needed, each row for a constraint violation, and setting the value of the following columns for each constraint violation:  
  - **Constraint Type:** Click the cell and from the drop-down list displayed select the type of the constraint violation to ignore.  
  - **Number:** Enter the maximum number of the constraint violation to ignore before initiating a rollback during a load.  
This property is available only when the **Insert Select Load Options** check box is selected. |
| Log In File            | Select this check box if you want to log the constraint violation information in files. This property is available only when the **Insert Select Load Options** check box is selected.                          |
| Message Log            | Specify the path to the MESSAGE LOG file. This property is available only when the **Log In File** check box is selected.                                                                                      |
| Row Log                | Specify the path to the ROW LOG file.                                                                                                                                                                        |
This property is available only when the Log In File check box is selected.

**Log Delimited By**
Specify the separator between data values in the ROW LOG file.
This property is available only when the Log In File check box is selected.

**Log Filter**
Select this check box and from the Only Log drop-down list displayed select the type of the constraint violation information to be logged.
This property is available only when the Log In File check box is selected.

**tStatCatcher Statistics**
Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Usage

**Dynamic settings**
Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

### Related scenarios

For tSybaseIQBulkExec related topics, see:

- **Scenario: Bulk-loading data to a Sybase IQ 12 database** on page 3820.
- **Scenario: Inserting transformed data in MySQL database** on page 2537.
- **Scenario: Truncating and inserting file data into an Oracle database** on page 2752.
tSybaseIQOutputBulkExec

Gains in performance during Insert operations to a Sybase IQ database.
tSybaseIQOutputBulkExec executes the Insert action on the data provided.

**tSybaseIQOutputBulkExec Standard properties**

These properties are used to configure tSybaseIQOutputBulkExec running in the Standard Job framework.

The Standard tSybaseIQOutputBulkExec component belongs to the Databases family.

The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Property Type</strong></td>
<td>Select the way the connection details will be set.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Built-In</strong>: The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Repository</strong>: The connection details stored centrally in Repository &gt; Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up Repository Content dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>When reusing an existing Sybase 16 (SQL Anywhere) connection created by a tSybaseConnection component and loading data from a file located on the client side, you need to select Sybase 16 (SQL Anywhere) from the DB Version drop-down list to display the Is client file check box before selecting this check box.</td>
</tr>
</tbody>
</table>

**Note:**

When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.

2. In the child level, use a dedicated connection component to read that registered database connection.
For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

This property is not available when **Sybase IQ 15** is selected from the **DB Version** drop-down list.

| **DB Version** | Select the version of the Sybase database to be used from the drop-down list.  
|                | • For Sybase IQ 12 and Sybase IQ 16, the file to be bulk-loaded must be located on the same machine as the Sybase IQ server. 
|                | • For Sybase IQ 15, the file to be bulk-loaded can be located on the client side, however, this means certain setup on the Sybase IQ server. For more information, see [Sybase IQ client-side load support enhancements](#).  
|                | • For Sybase 16 (SQL Anywhere), the file to be bulk-loaded can be located on both the server side and the client side.  
|                | Before loading data into Sybase 16 (SQL Anywhere), SQL Anywhere 17 must be installed. You can download it [here](#). Once the installation is done, you need to check the system variable `Path` to make sure the installation path of SQL Anywhere 17 has been added to it, and then restart the Studio (in certain case restart the computer) to have the new `Path` variable take effect. |
| **Host**       | The IP address or hostname of the database.  
|                | This property is not available when **Sybase IQ 15** is selected from the **DB Version** drop-down list. |

<td>Select this check box to store the input zero-length varchars as NULLs instead of blanks in the database during the load operation.</td>
</tr>
<tr>
<td>On file error</td>
<td>Select the action Sybase performs when an error occurs:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Rollback (default)</strong>: rolls back the entire transaction.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Finish</strong>: finishes the insertions already completed and ends the load operation.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Continue</strong>: skips the error and continues the load operation.</td>
</tr>
<tr>
<td></td>
<td>This property is available when <strong>Sybase 16 (SQL Anywhere)</strong> is selected from the <strong>DB Version</strong> drop-down list.</td>
</tr>
<tr>
<td>Message log file</td>
<td>The path to the MESSAGE LOG file that saves the log information about integrity constraint violations, the types of violations, etc. It must be specified together with the <strong>Row log file</strong> property.</td>
</tr>
</tbody>
</table>
This property is available when Sybase 16 (SQL Anywhere) is selected from the DB Version drop-down list.

**Row log file**
The path to the ROW LOG file that saves the log information about reject data, the timestamps of the start and completion of the load, etc. It must be specified together with the Message log file property.
This property is available when Sybase 16 (SQL Anywhere) is selected from the DB Version drop-down list.

**Encoding**
Select the encoding type from the list or select Custom and define it manually. This field is compulsory for DB data handling.

**tStatCatcher Statistics**
Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

**Usage**

**Dynamic settings**
Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

**Usage rule**
This component is mainly used when no particular transformation is required on the data to be loaded onto the database.

**Scenario: Bulk-loading data to a Sybase IQ 12 database**

This scenario describes a Job that writes data generated by a tRowGenerator component into a file and then bulk-loads the data from the file to a Sybase IQ 12 database.
Adding and linking the components

Procedure

1. Create a new Job and add a tRowGenerator component and a tSybaseIQOutputBulkExec component by typing their names in the design workspace or dropping them from the Palette.
2. Link the tRowGenerator component to the tSybaseIQOutputBulkExec component using a Row > Main connection.

Configuring the components

Procedure

1. Double-click the tRowGenerator component to open its RowGenerator Editor.

2. Click the [+] button to add two columns and set their properties:
   - id, Integer type, using `Numeric.sequence(String,int,int)` from the Functions list to generate sequence numbers.
   - name, String type, using `TalendDataGenerator.getFirstName()` from the Functions list to generate random first names.

3. In the Number of Rows for RowGenerator field, enter the number of rows to be generated. In this example, keep the default value 100.
4. Click OK to close the editor and in the pop-up dialog box click Yes to propagate the schema to the next component.
5. Double-click the tSybaseIQOutputBulkExec component to open its Basic settings view.

6. In the Host, Port, Database, Username and Password fields, enter the information required to access the Sybase IQ 12 database.

7. In the Table field, enter the name of the table into which the data will be written. In this example, it is staff.

8. In the Action on table list, select Create table if not exists.

9. In the Filename field, enter the full path of the file to hold the data.

**Saving and executing the Job**

**Procedure**

1. Press Ctrl+S to save the Job.

2. Press F6 to run the Job.

   Starting job usecase_sybase at 14:50 14/11/2012.

   [statistics] connecting to socket on port 3643
   [statistics] connected
   [statistics] disconnected
   Job usecase_sybase ended at 14:50 14/11/2012. [exit code=0]

3. In the Sybase Central console, open the table staff to check the data:
As shown above, the table is created with data inserted.

**Related scenarios**

For use cases in relation with `tSybaseIQOutputBulkExec`, see the following scenarios:

- **Scenario:** Inserting transformed data in MySQL database on page 2537.
- **Scenario:** Inserting data in bulk in MySQL database on page 2544.
- **Scenario:** Truncating and inserting file data into an Oracle database on page 2752.
tSybaseOutput

Executes the action defined on the table and/or on the data contained in the table, based on the flow incoming from the preceding component in the job.
tSybaseOutput writes, updates, makes changes or suppresses entries in a database.

**tSybaseOutput Standard properties**

These properties are used to configure tSybaseOutput running in the Standard Job framework.
The Standard tSybaseOutput component belongs to the Databases family.
The component in this framework is generally available.

**Note:**
This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.
For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
<td></td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

**Note:**
When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.
For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

Click this icon to open a database connection wizard and store the database connection parameters you set in the component **Basic settings** view.

For more information about setting up and storing database connection parameters, see *Talend Studio User Guide*.

### DB Version
Select the version of the Sybase database to be used from the drop-down list.

### Server
Database server IP address

### Port
Listening port number of DB server.

### Database
Name of the database

### Sybase Schema
Exact name of the Sybase schema.

### Username and Password
DB user authentication data.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

### Table
Name of the table to be written. Note that only one table can be written at a time.

### Action on table
On the table defined, you can perform one of the following operations:

- **Default**: No operation is carried out.
- **Drop and create table**: The table is removed and created again.
- **Create table**: The table does not exist and gets created.
- **Create table if not exists**: The table is created if it does not exist.
- **Drop table if exists and create**: The table is removed if it already exists and created again.
- **Clear table**: The table content is deleted.
- **Truncate table**: The table content is deleted. You do not have the possibility to rollback the operation.

### Turn on identity insert
Select this check box to use your own sequence for the identity value of the inserted records (instead of having the SQL Server pick the next sequential value).

### Action on data
On the data of the table defined, you can perform:

- **Insert**: Add new entries to the table. If duplicates are found, job stops.
- **Update**: Make changes to existing entries.
**Insert or update:** Insert a new record. If the record with the given reference already exists, an update would be made.

**Update or insert:** Update the record with the given reference. If the record does not exist, a new record would be inserted.

**Delete:** Remove entries corresponding to the input flow.

**Warning:**

*It is necessary to specify at least one column as a primary key on which the Update and Delete operations are based. You can do that by clicking Edit Schema and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the Advanced settings view where you can simultaneously define primary keys for the Update and Delete operations. To do that: Select the Use field options check box and then in the Key in update column, select the check boxes next to the column names you want to use as a base for the Update operation. Do the same in the Key in delete column for the Delete operation.*

---

### Schema and Edit schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

### Built-In

You create and store the schema locally for this component only. Related topic: see *Talend Studio User Guide*.

### Repository

You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see *Talend Studio User Guide*.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

### Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema:** choose this option to view the schema only.
- **Change to built-in property:** choose this option to change the schema to Built-in for local changes.
- **Update repository connection:** choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate...
the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **[Repository Content]** window.

<table>
<thead>
<tr>
<th><strong>Die on error</strong></th>
<th>This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a <strong>Row &gt; Rejects</strong> link.</th>
</tr>
</thead>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th><strong>Commit every</strong></th>
<th>Enter the number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and, above all, better performance at execution.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Additional Columns</strong></td>
<td>This option is not offered if you create (with or without drop) the DB table. This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing.</td>
</tr>
<tr>
<td><strong>Name:</strong></td>
<td>Type in the name of the schema column to be altered or inserted as new column</td>
</tr>
<tr>
<td><strong>SQL expression:</strong></td>
<td>Type in the SQL statement to be executed in order to alter or insert the relevant column data.</td>
</tr>
<tr>
<td><strong>Position:</strong></td>
<td>Select <strong>Before</strong>, <strong>Replace</strong> or <strong>After</strong> following the action to be performed on the reference column.</td>
</tr>
<tr>
<td><strong>Reference column:</strong></td>
<td>Type in a column of reference that the <strong>tDBOutput</strong> can use to place or replace the new or altered column.</td>
</tr>
<tr>
<td><strong>Use field options</strong></td>
<td>Select this check box to customize a request, especially when there is double action on data.</td>
</tr>
<tr>
<td><strong>Enable debug mode</strong></td>
<td>Select this check box to display each step during processing entries in a database.</td>
</tr>
<tr>
<td><strong>Use Batch</strong></td>
<td>Select this check box to activate the batch mode for data processing.</td>
</tr>
<tr>
<td><strong>Note:</strong></td>
<td>This check box is available only when you have selected the <strong>Insert</strong>, the <strong>Update</strong> or the <strong>Delete</strong> option in the <strong>Action on data</strong> field.</td>
</tr>
<tr>
<td><strong>Batch Size</strong></td>
<td>Specify the number of records to be processed in each batch. This field appears only when the <strong>Use batch mode</strong> check box is selected.</td>
</tr>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>
### Global Variables

<table>
<thead>
<tr>
<th>Global Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE</strong></td>
<td>the number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_UPDATED</strong></td>
<td>the number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_INSERTED</strong></td>
<td>the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_DELETED</strong></td>
<td>the number of rows deleted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_REJECTED</strong></td>
<td>the number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>QUERY</strong></td>
<td>the query statement processed. This is an After variable and it returns a string.</td>
</tr>
</tbody>
</table>

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

### Usage

#### Usage rule

This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible.

This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in a Sybase database. It also allows you to create a reject flow using a **Row > Rejects** link to filter data in error. For an example of [tMySqlOutput](#) in use, see Scenario: Retrieving data in error with a Reject link on page 2529.

#### Dynamic settings

Click the `[+]` button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario:
Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

| Limitation          | This component requires installation of its related jar files. |

### Related scenarios

For use cases in relation with **tSybaseOutput**, see:

- **Scenario: Inserting a column and altering data using tMysqlOutput** on page 2521.
tSybaseOutputBulk

Prepares the file to be used as parameter in the INSERT query to feed the Sybase database.

The tSybaseOutputBulk and tSybaseBulkExec components are generally used together as parts of a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tSybaseOutputBulkExec component, detailed in a separate section. The advantage of using two separate components is that the data can be transformed before it is loaded in the database.

 Writes a file with columns based on the defined delimiter and the Sybase standards.

**tSybaseOutputBulk Standard properties**

These properties are used to configure tSybaseOutputBulk running in the Standard Job framework.

The Standard tSybaseOutputBulk component belongs to the Databases family.

The component in this framework is generally available.

*Note:*

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see *Dynamic database components* on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td>Judith</td>
<td>- <strong>Built-in</strong>: No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>- <strong>Repository</strong>: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>File Name</td>
<td>Name of the file to be generated.</td>
</tr>
<tr>
<td>Warning</td>
<td>This file is generated on the local machine or a shared folder on the LAN.</td>
</tr>
<tr>
<td>Append</td>
<td>Select this check box to add the new rows at the end of the file.</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <strong>line</strong> when naming the fields.</td>

</tbody>
</table>
### Advanced settings

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Row separator</td>
<td>String (ex: <code>\n</code> on Unix) to distinguish rows.</td>
</tr>
<tr>
<td>Field separator</td>
<td>Character, string or regular expression to separate fields.</td>
</tr>
<tr>
<td>Include header</td>
<td>Select this check box to include the column header in the file.</td>
</tr>
<tr>
<td>Encoding</td>
<td>Select the encoding from the list or select Custom and define it manually.</td>
</tr>
<tr>
<td>tStatCatcher Statistics</td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

### tSybaseOutputBulk

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-In</strong></td>
<td>You create and store the schema locally for this component only. Related topic: see <a href="https://help.talend.com">Talend Studio User Guide</a>.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see <a href="https://help.talend.com">Talend Studio User Guide</a>. When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually. You can find more details about how to verify default values in retrieved schema in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
</tbody>
</table>

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-In** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

---

**Warning:**

*Fully in line with the Java syntax, this component does not allow the use of Sybase-orientated row/field separators, such as `\x09`.*
Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_LINE: the number of rows processed. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td></td>
<td>For further information about variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component requires installation of its related jar files.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>This component is to be used along with tSybaseBulkExec component. Used together they offer gains in performance while feeding a Sybase database.</td>
</tr>
</tbody>
</table>

Component family | Databases/Sybase

Related scenarios

For use cases in relation with tSybaseOutputBulk, see the following scenarios:

- Scenario: Inserting transformed data in MySQL database on page 2537.
- Scenario: Inserting data in bulk in MySQL database on page 2544.
- Scenario: Truncating and inserting file data into an Oracle database on page 2752.
tSybaseOutputBulkExec

Gains in performance during Insert operations to a Sybase database.

The tSybaseOutputBulk and tSybaseBulkExec components are generally used together as parts of a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tSybaseOutputBulkExec component.

tSybaseOutputBulkExec Standard properties

These properties are used to configure tSybaseOutputBulkExec running in the Standard Job framework.

The Standard tSybaseOutputBulkExec component belongs to the Databases family.

The component in this framework is generally available.

Note:

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

Note:

When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th>DB Version</th>
<th>Select the version of the Sybase database to be used from the drop-down list.</th>
</tr>
</thead>
</table>
| Server              | Database server IP address
Currenty, only *localhost, 127.0.0.1 or the exact IP address of the local machine is allowed for proper functioning. In other words, the database server must be installed on the same machine where the Studio is installed or where the Job using tSybaseOutputBulkExec is deployed. |
| Port                | Listening port number of DB server. |
| Database            | Name of the database |
| Username and Password| DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| Bcp utility         | Name of the utility to be used to copy data over to the Sybase server. |
| Batch row number    | Number of lines in each processed batch. |
| Table               | Name of the table to be written. Note that only one table can be written at a time and that the table must exist for the insert operation to succeed. |
| Action on table     | On the table defined, you can perform one of the following operations:
- **None**: No operation is carried out.
- **Drop and create a table**: The table is removed and created again.
- **Create a table**: The table does not exist and gets created.
- **Create a table if not exists**: The table is created if it does not exist.
- **Clear a table**: The table content is deleted. |
| File Name           | Name of the file to be generated and loaded.

> **Warning:**
This file is generated on the machine specified by the URI in the Server field so it should be on the same machine as the database server.
### Append
Select this check box to add the new rows at the end of the records.

### Schema and Edit Schema
A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

<table>
<thead>
<tr>
<th>Built-In</th>
<th>Description</th>
<th>Related topic</th>
</tr>
</thead>
<tbody>
<tr>
<td>You create and store the schema locally for this component only.</td>
<td>Related topic: see Talend Studio User Guide.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Repository</th>
<th>Description</th>
<th>Related topic</th>
</tr>
</thead>
<tbody>
<tr>
<td>You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
<td>Related topic: see Talend Studio User Guide.</td>
<td></td>
</tr>
</tbody>
</table>

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

### Advanced settings

#### Use an interface file
Select this check box to specify an interface file in the field Interface file.

#### Additional JDBC parameters
Specify additional connection properties in the existing DB connection, to allow specific character set support. E.G.: CHARSET=KANJISJIS_OS to get support of Japanese characters.

#### Action on data
On the data of the table defined, you can perform:
- **Bulk Insert**: Add multiple entries to the table. If duplicates are found, job stops.
### Bulk Update

- **Field terminator**: Character, string or regular expression to separate fields.
  - **Warning**: As a combination of `tSybaseOutputBulk` and `tSybaseBulkExec`, this component does not allow the use of Sybase-oriented row/field separators, such as `\x09`. To achieve the desired effect (for example, displaying fields in the tabular form), you need to use `tSybaseOutputBulk` and `tSybaseBulkExec` together to replace `tSybaseOutputBulkExec`, with `\t` used in the former component and `\x09` used in the latter.

- **DB Row terminator**: String (ex: `\n` on Unix) to distinguish rows in the DB.

- **First row NO. of file**: Type in the number of the file row where the action should start at.

- **FILE Row terminator**: Character, string or regular expression to separate fields in a file.

- **Include Head**: Select this checkbox to include the column header.

- **Encoding**: Regarding the source data, select the appropriate encoding from the list or select Custom and define it manually. This field is compulsory for DB data handling.

- **Sybase encoding type**: Select the Sybase-specific encoding type for the data to be processed. This encoding type allows `tSybaseOutputBulk` to properly generate the Sybase Bulk command.

- **Output**: Select the type of output for the standard output of the Sybase database:
  - to console,
  - to global variable.

- **tStatCatcher Statistics**: Select this checkbox to collect log data at the component level.

### Usage

- **Usage rule**: This component is mainly used when no particular transformation is required on the data to be loaded onto the database.

- **Dynamic settings**: Click the `[+]` button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example,
when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

### Limitation

This component requires installation of its related jar files.

The database server/client must be installed on the same machine where the Studio is installed or where the Job using tSybaseOutputBulkExec is deployed, so that the component functions properly.

## Related scenarios

For use cases in relation with tSybaseOutputBulkExec, see the following scenarios:

- Scenario: Inserting transformed data in MySQL database on page 2537.
- Scenario: Inserting data in bulk in MySQL database on page 2544.
- Scenario: Truncating and inserting file data into an Oracle database on page 2752.
tSybaseRollback

 Cancels the transaction committed in the Sybase database.

 **tSybaseRollback Standard properties**

 These properties are used to configure tSybaseRollback running in the Standard Job framework.

 The Standard tSybaseRollback component belongs to the Databases family.

 The component in this framework is generally available.

 ![Note symbol]  

 **Note:**

 This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

 For more information about dynamic database connectors, see [Dynamic database components on page 598](#).

 **Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the <strong>tSybaseConnection</strong> component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

 **Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

 **Usage**

| Usage rule | This component is more commonly used with other tSybase* components, especially with the **tSybaseConnection** and **tSybaseCommit** components. |
| Dynamic settings | Click the [+1] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.  

 Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable. |
Related scenarios

For **tSybaseRollback** related scenario, see Scenario: Rollback from inserting data in mother/daughter tables on page 2480.
tSybaseRow

Acts on the actual DB structure or on the data (although without handling data).

tSybaseRow is the specific component for this database query. It executes the SQL query stated onto the specified database. The row suffix means the component implements a flow in the job design although it doesn’t provide output.

The SQLBuilder tool helps you write easily your SQL statements.

**tSybaseRow Standard properties**

These properties are used to configure tSybaseRow running in the Standard Job framework.

The Standard tSybaseRow component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

**Note:**

When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.

2. In the child level, use a dedicated connection component to read that registered database connection.
<table>
<thead>
<tr>
<th><strong>DB Version</strong></th>
<th>Select the version of the Sybase database to be used from the drop-down list.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Server</strong></td>
<td>Database server IP address</td>

<tbody>
<tr>
<td><strong>Die on error</strong></td>
<td>This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a <strong>Row &gt; Rejects</strong> link.</td>
</tr>
</tbody>
</table>

### Advanced settings

<table>
<thead>
<tr>
<th><strong>Propagate QUERY’s recordset</strong></th>
<th>Select this check box to insert the result of the query into a COLUMN of the current flow. Select this column from the <strong>use column</strong> list.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>i Note:</strong></td>
<td>This option allows the component to have a different schema from that of the preceding component. Moreover, the column that holds the QUERY’s recordset should be set to the type of <strong>Object</strong> and this component is usually followed by <strong>tParseRecordSet</strong>.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Use PreparedStatement</strong></th>
<th>Select this check box if you want to query the database using a PreparedStatement. In the <strong>Set PreparedStatement Parameter</strong> table, define the parameters represented by ‘?’ in the SQL instruction of the <strong>Query</strong> field in the <strong>Basic Settings</strong> tab.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Parameter Index</strong>: Enter the parameter position in the SQL instruction.</td>
<td><strong>Parameter Type</strong>: Enter the parameter type.</td>
</tr>
<tr>
<td><strong>Parameter Value</strong>: Enter the parameter value.</td>
<td><strong>Note:</strong> This option is very useful if you need to execute the same query several times. Performance levels are increased</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Commit every</strong></th>
<th>Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>tStat Catcher Statistics</strong></td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>
## Global Variables

| Global Variables | **QUERY**: the query statement being processed. This is a Flow variable and it returns a string.  
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
For further information about variables, see *Talend Studio User Guide*. |

## Usage

| Usage rule | This component offers the flexibility of the DB query and covers all possible SQL queries. |
| Dynamic settings | Click the [+•] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.  
The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.  
For examples on using dynamic parameters, see *Scenario: Reading data from databases through context-based dynamic connections* on page 2497 and *Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters* on page 489.  
For more information on **Dynamic settings** and context variables, see Talend Studio User Guide. |

## Limitation

| Limitation | This component requires installation of its related jar files. |

## Related scenarios

For **tSybaseRow** related topics, see:
• **Scenario: Combining two flows for selective output** on page 2558.
• **Procedure** on page 625.
• **Scenario: Removing and regenerating a MySQL table index** on page 2552.
tSybaseSCD

Addresses Slowly Changing Dimension needs, reading regularly a source of data and logging the changes into a dedicated SCD table.

tSybaseSCD reflects and tracks changes in a dedicated Sybase SCD table.

**tSybaseSCD Standard properties**

These properties are used to configure tSybaseSCD running in the Standard Job framework.

The Standard tSybaseSCD component belongs to the Business Intelligence and the Databases families.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-in</strong>: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: Select the Repository file where Properties are stored. The following fields are pre-filled in using fetched data.</td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined.

**Note:**

When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.
For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th><strong>DB Version</strong></th>
<th>Select the version of the Sybase database to be used from the drop-down list.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Host</strong></td>
<td>Database server IP address.</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database.</td>
</tr>
</tbody>
</table>
| **Username** and **Password** | DB user authentication data.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings. |
| **Table**      | Name of the table to be written. Note that only one table can be written at a time. |

**Schema and Edit schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **[Repository Content]** window.

**Built-in**: The schema is created and stored locally for this component only. Related topic: see *Talend Studio User Guide*.

**Repository**: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see *Talend Studio User Guide*.

**SCD Editor**

The SCD editor helps to build and configure the data flow for slowly changing dimension outputs.

For more information, see *SCD management methodology* on page 2566.

**Use memory saving Mode**

Select this check box to maximize system performance.
**Die on error**

This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

**Advanced settings**

**Additional JDBC parameters**

Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the **Use an existing connection** check box in the **Basic settings**.

**End date time details**

Specify the time value of the SCD end date time setting in the format of \textit{HH:mm:ss}. The default value for this field is 12:00:00.

This field appears only when SCD Type 2 is used and **Fixed year value** is selected for creating the SCD end date.

**tStatCatcher Statistics**

Select this check box to collect log data at the component level.

**Debug mode**

Select this check box to display each step during processing entries in a database.

**Global Variables**

**Global Variables**

**NB_LINE_UPDATED**: the number of rows updated. This is an After variable and it returns an integer.

**NB_LINE_INSERTED**: the number of rows inserted. This is an After variable and it returns an integer.

**NB_LINE_REJECTED**: the number of rows rejected. This is an After variable and it returns an integer.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press \textbf{Ctrl + Space} to access the variable list and choose the variable to use from it.

For further information about variables, see **Talend Studio User Guide**.

**Usage**

**Usage rule**

This component is used as Output component. It requires an Input component and Row main link as input.
| Dynamic settings | Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on **Dynamic settings and context variables**, see Talend Studio User Guide. |

| Limitation | This component does not support using SCD type 0 together with other SCD types. |

**Related scenarios**

For related topics, see tMysqlSCD on page 2563.
tSybaseSCDELT

Addresses Slowly Changing Dimension needs through SQL queries (server-side processing mode), and logs the changes into a dedicated Sybase SCD table.

tSybaseSCDELT reflects and tracks changes in a dedicated Sybase SCD table.

**tSybaseSCDELT Standard properties**

These properties are used to configure tSybaseSCDELT running in the Standard Job framework.

The Standard tSybaseSCDELT component belongs to the Business Intelligence and the Databases families.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see [Dynamic database components](#) on page 598.

**Basic settings**

<table>
<thead>
<tr>

</tr>
</tbody>
</table>
upon completion and choose this schema metadata again in the [Repository Content] window.

| **Built-in:** | The schema is created and stored locally for this component only. Related topic: see *Talend Studio User Guide*. |
| **Repository:** | The schema already exists and is stored in the Repository, hence can be reused. Related topic: see *Talend Studio User Guide*. |

**Surrogate Key**
Select the surrogate key column from the list.

**Creation**
Select the method to be used for the surrogate key generation.
For more information regarding the creation methods, see *SCD management methodology* on page 2566.

**Source Keys**
Select one or more columns to be used as keys, to ensure the unicity of incoming data.

**Use SCD Type 1 fields**
Use type 1 if tracking changes is not necessary. SCD Type 1 should be used for typos corrections for example. Select the columns of the schema that will be checked for changes.

**Use SCD Type 2 fields**
Use type 2 if changes need to be tracked down. SCD Type 2 should be used to trace updates for example. Select the columns of the schema that will be checked for changes.

**Start date**: Adds a column to your SCD schema to hold the start date value. You can select one of the input schema columns as Start Date in the SCD table.

**End Date**: Adds a column to your SCD schema to hold the end date value for the record. When the record is currently active, the End Date column shows a null value, or you can select Fixed Year value and fill it in with a fictive year to avoid having a null value in the End Date field.

**Log Active Status**: Adds a column to your SCD schema to hold the true or false status value. This column helps to easily spot the active record.

**Log versions**: Adds a column to your SCD schema to hold the version number of the record.

**Advanced settings**

| **Additional JDBC parameters** | Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the *Use an existing connection* check box in the Basic settings. |
| **Debug mode** | Select this check box to display each step during processing entries in a database. |
### tStat Catcher Statistics

Select this check box to collect log data at the component level.

### Global Variables

| Global Variables | Error message: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it. For further information about variables, see *Talend Studio User Guide.* |

### Usage

| Usage rule | This component is used as an output component. It requires an input component and Row main link as input. |

| Dynamic settings | Click the **[+]** button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable. For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on **Dynamic settings** and context variables, see *Talend Studio User Guide.* |

| Limitation | This component requires installation of its related jar files. |
Related Scenario

For related topics, see tMysqlSCD on page 2563 and Tracking data changes using Slowly Changing Dimensions (type 0 through type 3) on page 2569.
tSybaseSP

Calls a Sybase database stored procedure.

**tSybaseSP Standard properties**

These properties are used to configure tSybaseSP running in the Standard Job framework.

The Standard tSybaseSP component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see *Dynamic database components* on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-in</strong>: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

**Use an existing connection**

| Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined. |

**Note:**

When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.

2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*. |
| **DB Version** | Select the version of the Sybase database to be used from the drop-down list. |
| **Host** | Database server IP address |
| **Port** | Listening port number of DB server. |
| **Database** | Name of the database |
| **Username** and **Password** | DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| **Schema** and **Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. |
| **Built-In** | You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide. |
| **Repository** | You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide. |
| **SP Name** | Type in the exact name of the Stored Procedure |
| **Is Function / Return result in** | Select this check box, if a value is to be returned. Select on the list the schema column, the value to be returned is based on. |
| **Timeout Interval** | Maximum waiting time for the results of the stored procedure. |
| **Parameters** | Click the Plus button and select the various Schema Columns that will be required by the procedures. Note |
that the SP schema can hold more columns than there are parameters used in the procedure.

Select the Type of parameter:

**IN**: Input parameter

**OUT**: Output parameter/return value

**IN OUT**: Input parameters is to be returned as value, likely after modification through the procedure (function).

**RECORDSET**: Input parameters is to be returned as a set of values, rather than single value.

**Note:**
Check Scenario: Inserting data in mother/daughter tables on page 2476 if you want to analyze a set of records from a database table or DB query and return single records.

### Advanced settings

<table>
<thead>
<tr>
<th>Additional JDBC Parameters</th>
<th>Fill in additional connection properties for the DB connection you are creating. This option is available when the check box <strong>Use an existing connection</strong> is not selected in the Basic settings.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use Multiple SELECT Procedure</td>
<td>Select this check box to use procedures which contain multiple SELECT statements.</td>
</tr>
<tr>
<td>tStatCatcher Statistics</td>
<td>Select this check box to gather the Job processing metadata at a Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is used as intermediary component. It can be used as start component but only input parameters are thus allowed.</th>
</tr>
</thead>
</table>
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the **Use an existing connection** check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-

- Scenario: Using tMysqlSP to find a State Label using a stored procedure on page 2583.
- Scenario: Checking number format using a stored procedure on page 2809.
- Executing a stored procedure using tMDMsp on page 2190.

Check tMysqlConnection on page 2475 as well if you want to analyze a set of records from a database table or DB query and return single records.
tSystem

Calls other system processing commands, already up and running in a larger Job.

**tSystem Standard properties**

These properties are used to configure tSystem running in the Standard Job framework.

The Standard tSystem component belongs to the System family.

The component in this framework is generally available.

### Basic settings

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use home directory</td>
<td>Select this check box to change the name and path of a dedicated directory.</td>
</tr>
<tr>
<td>Use Single Command</td>
<td>When the required command is very simple, to the degree that, for example, only one parameter is used and without space, select this option to activate its Command field. In this field, enter the simple system command. Note that the syntax is not checked.</td>
</tr>
<tr>
<td></td>
<td><strong>Warning:</strong> In Windows, the MS-DOS commands do not allow you to pass directly from the current folder to the folder containing the file to be launched. To launch a file, you must therefore use an initial command to change the current folder, then a second one to launch the file.</td>
</tr>
<tr>
<td>Use Array Command</td>
<td>Select this option to activate its Command field. In this field, enter the system command in array, one parameter per line. For example, enter the following command with consecutive spaces in array for Linux:</td>
</tr>
<tr>
<td></td>
<td>&quot;cp&quot; &quot;\temp\source.txt&quot; &quot;\temp\copy to/&quot;</td>
</tr>
<tr>
<td>Standard Output and Error Output</td>
<td>Select the type of output for the processed data to be transferred to.</td>
</tr>
<tr>
<td></td>
<td><strong>to console:</strong> data is passed on to be viewed in the Run view.</td>
</tr>
<tr>
<td></td>
<td><strong>to global variable:</strong> data is passed on to an output variable linked to the tSystem component.</td>
</tr>
</tbody>
</table>
### to console and to global variable

Data is passed on to the Run view and to an output variable linked to the tSystem component.

### normal

Data is passed on to the component that comes next.

### Schema and Edit Schema

A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either **Built-in** or stored remotely in the **Repository**.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.

Click **Sync columns** to retrieve the schema from the preceding component in the Job.

### Built-in

You create and store the schema locally for this component only. Related topic: see [Talend Studio User Guide](#).

### Repository

You have already created the schema and stored it in the Repository. You can reuse it in various projects and job flowcharts. Related topic: see [Talend Studio User Guide](#).

### Environment variables

Click the [+ ] button to add as many global variables as needed.

- **name**: Enter the syntax of the new variable.
- **value**: Enter a value for this variable according to the context.

### Advanced settings

### tStatCatcher Statistics

Select this check box to collect log data at the component level.

### Global Variables

### Global Variables

- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

### Usage

#### Usage rule

This component can typically be used for companies which already implemented other applications that they want to integrate into their processing flow through Talend.

#### Connections

**Outgoing links (from this component to another):**
- **Row:** Main.
- **Trigger:** On Subjob Ok; On Subjob Error; Run if.

**Incoming links (from one component to this one):**
- **Row:** Main; Reject; Iterate.
- **Trigger:** On Subjob Ok; On Subjob Error; Run if; On Component Ok; On Component Error; Synchronize; Parallelize.

For further information regarding connections, see Talend Studio User Guide.

### Scenario: Echo 'Hello World!'

This scenario is one single component tSystem to execute a system command and shows the results in the Run view "console".

To replicate this scenario, proceed as follows:
Procedure

1. Drop a tSystem component from the Palette to the design workspace.
2. Double-click tSystem to open its Component view.

3. Select the Use Single Command option to activate its Command field and type in "cmd /c echo Hello World!".
4. In the Standard Output drop-down list, select to both console and global variable.
5. Press F6 to run this Job.

Results

Starting job tSystem_scenario at 17:26 08/10/2009.

[statistics] connecting to socket on port 3961
[statistics] connected
Hello World!
[statistics] disconnected
Job tSystem_scenario ended at 17:26 08/10/2009. [exit code=0]

The Job executes an echo command and shows the output in the Console of the Run view.
tTeradataClose

Closes the transaction committed in the connected DB.

tTeradataClose Standard properties

These properties are used to configure tTeradataClose running in the Standard Job framework.
The Standard tTeradataClose component belongs to the Databases family.
The component in this framework is generally available.

Note:
This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.
For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the t TeradataConnection component in the list if more than one connection are planned for the current Job.</td>
</tr>
</tbody>
</table>

Advanced settings

| tStat Catcher Statistics         | Select this check box to collect log data at the component level. |

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is to be used along with Teradata components, especially with tTeradataConnection and tTeradataCommit.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic settings</td>
<td>Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Scenario: Reading data from databases through context-</td>
</tr>
</tbody>
</table>
Related scenarios

No scenario is available for the Standard version of this component yet.
tTeradataCommit

Commits in one go, using a unique connection, a global transaction instead of doing that on every row or every batch and thus provides gain in performance.

TeradataCommit validates the data processed through the Job into the connected DB.

tTeradataCommit Standard properties

These properties are used to configure tTeradataCommit running in the Standard Job framework.

The Standard tTeradataCommit component belongs to the Databases family.

The component in this framework is generally available.

Note:

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tTeradataConnection component in the list if more than one connection are planned for the current job.</td>
</tr>
</tbody>
</table>
| Close connection | This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task. **Warning:**

If you want to use a Row > Main connection to link tTeradataCommit to your Job, your data will be committed row by row. In this case, do not select the Close connection check box or your connection will be closed before the end of your first row commit. |

Advanced settings

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

Usage

| Usage rule | This component is more commonly used with other tTeradata* components, especially with |
the `tTeradataConnection` and `tTeradataRollback` components.

<table>
<thead>
<tr>
<th>Dynamic settings</th>
</tr>
</thead>
</table>
| **Click the `[+]` button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.**
| **Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.**
| **For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489.**
| **For more information on Dynamic settings and context variables, see Talend Studio User Guide.**

**Related scenario**

For `tTeradataCommit` related scenario, see Scenario: Inserting data in mother/daughter tables on page 2476
**tTeradataConnection**

Opens a connection to the specified database that can then be reused in the subsequent subjob or subjobs.

tTeradataConnection opens a connection to the database for a current transaction.

**tTeradataConnection Standard properties**

These properties are used to configure tTeradataConnection running in the Standard Job framework.

The Standard tTeradataConnection component belongs to the Databases and the ELT families.

The component in this framework is generally available.

**Note:**
This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see [Dynamic database components](#) on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td><strong>Property type</strong></td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in</strong>: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td><strong>Repository</strong>: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
<td></td>
</tr>
<tr>
<td><strong>Host</strong></td>
<td>Database server IP address.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database.</td>
</tr>
<tr>
<td><strong>Username</strong> and <strong>Password</strong></td>
<td>DB user authentication data. To enter the password, click the <code>[...]</code> button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td><strong>Additional JDBC parameters</strong></td>
<td>Specify additional connection properties in the existing DB connection, to allow specific character set support. E.G.: <code>CHARSET=KANJISJIS_OS</code> to get support of Japanese characters. <strong>Note:</strong> You can set the encoding parameters through this field.</td>
</tr>
<tr>
<td><strong>Use or register a shared DB Connection</strong></td>
<td>Select this check box to share your database connection or fetch a database connection shared by a parent or...</td>
</tr>
</tbody>
</table>
child Job, and in the **Shared DB Connection Name** field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child.

This option is incompatible with the **Use dynamic job** and **Use an independent process to run subjob** options of the **tRunJob** component. Using a shared connection together with a **tRunJob** component with either of these two options enabled will cause your Job to fail.

### Advanced settings

#### Query band

Select this check box to use the Teradata Query Banding feature to add metadata to the query to be processed, such as the user running the query. This can help you, for example, identify the origin of this query.

Once selecting the check box, the **Query Band parameters** table is displayed, in which you need to enter the metadata information to be added. This information takes the form of key/value pairs, for example, *DpiID* in the **Key** column and *Finance* in the **Value** column.

This check box actually generates the **SET QUERY_BAND FOR SESSION** statement with the key/value pairs declared in the **Query Band parameters** table. For further information about this statement, see [http://www.info.teradata.com/HTMLPubs/DB_TTU_14_00/index.html#page/SQL_Reference/B035_1144_111A/End_Lo](http://www.info.teradata.com/HTMLPubs/DB_TTU_14_00/index.html#page/SQL_Reference/B035_1144_111A/End_Lo).

#### Auto Commit

Select this check box to commit any changes to the database automatically upon the transaction.

With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component.

Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component.

#### tStatCatcher Statistics

Select this check box to collect log data at the component level.
Usage

Usage rule
This component is more commonly used with other tTeradata™ components, especially with the tTeradataCommit and tTeradataRollback components.

Limitation
Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

Related scenario
For tTeradataConnection related scenario, see tMysqlConnection on page 2475.
**tTeradataFastExport**

Exports data batches from a Teradata table to a customer system or to a smaller database. tTeradataFastExport exports rapidly voluminous data batches from a Teradata table or view.

**tTeradataFastExport Standard properties**

These properties are used to configure tTeradataFastExport running in the Standard Job framework. The Standard tTeradataFastExport component belongs to the Databases family. The component in this framework is generally available.

</table>
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.

| **Use query** | Select this check box to show the **Query** box where you can enter the SQL statement. Available in the **Use Commandline** mode. |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------
| **Query**     | Enter the SQL statement in the **Query** box.                                                                                                                                                     |
| **Log database** | Log database name. Available in the **Use Commandline** mode.                                                                                                                                      |
| **Log table** | Log table name. Available in the **Use Commandline** mode.                                                                                                                                 |
| **Script generated folder** | Browse your directory and select the destination of the file which will be created. Available in the **Use Commandline** mode.                                                                    |
| **Exported file** | Name and path to the file which will be created.                                                                                                                                                  |
| **Field separator** | Character, string or regular expression to separate fields.                                                                                                                                         |
| **Row separator** | String (e.g.: \n on Unix) to separate rows. Available in the **Use Java API** mode.                                                                                                               |
| **Error file** | Browse your directory and select the destination of the file where the error messages will be recorded. Available in the **Use Commandline** mode.                                                   |

### Advanced settings

**Output**

Two options are available in the list:
- **Output error to file**: outputs the error to the file specified in the **Error log** field and continues the processing.
**Output error to console:** outputs the error to the console and ends the processing.
Available in the **Use Commandline** mode.

**tStatCatcher Statistics**
Select this check box to collect log data at the component level.

### Usage

**Usage rule**
This component offers the flexibility benefit of the DB query and covers all possible SQL queries.

**Limitation**
If you have selected the **Use Commandline** mode, you need to install the Teradata client on the machine where there is the Job that involves this component.

### Related scenarios

No scenario is available for the Standard version of this component yet.
tTeradataFastLoad

Executes a database query according to a strict order which must be the same as the one in the schema.

tTeradataFastLoad reads a database and extracts fields using queries. The retrieve list of fields is then transferred to the next component, using a connection flow (Main row).

**tTeradataFastLoad Standard properties**

These properties are used to configure tTeradataFastLoad running in the Standard Job framework. The Standard tTeradataFastLoad component belongs to the Databases family. The component in this framework is generally available.

**Basic settings**

<table>

</tr>
</tbody>
</table>
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.

**Script generated folder**

Browse your directory and select the destination of the file which will be created.

**Load file**

Browse your directory and select the file from which you want to load data.

**Field separator**

Character, string or regular expression to separate fields.

**Error file**

Browse your directory and select the destination of the file where the error messages will be recorded.

### Advanced settings

**Define character set**

Specify the character encoding you need use for your system.

**Check point**

Enter the check point value.

**Error files**

Enter the file name where the error messages are stored. By default, the code `ERRORFILES table_ERR1, table_ERR2` is entered, meaning that the two tables `table_ERR1` and `table_ERR2` are used to record the error messages.

**Return fastload error**

Select this check box to specify the exit code number to indicate the point at which an error message should display in the console.

**ERRLIMIT**

Enter the limit number of errors detected during the loading phase. Processing stops when the limit is reached. The default error limit value is 1000000.

For more information, see *Teradata FastLoad Reference* documentation.
### tStatCatcher Statistics

<table>
<thead>
<tr>
<th>Usage</th>
<th>tStatCatcher Statistics</th>
<th>Select this check box to collect log data at the component level.</th>
</tr>
</thead>
</table>

### Usage

| Usage rule | This component offers the flexibility of the DB query and covers all possible SQL queries. |

## Related scenario

For related topic, see *Scenario: Inserting data into a Teradata database table* on page 3928.
**tTeradataInput**

Executes a DB query with a strictly defined order which must correspond to the schema definition.
tTeradataInput reads a database and extracts fields based on a query. It passes on the field list to the next component via a Main row link.

**tTeradataInput Standard properties**

These properties are used to configure tTeradataInput running in the Standard Job framework.
The Standard tTeradataInput component belongs to the Databases family.
The component in this framework is generally available.

**Note:**
This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

**Note:**
When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.

2. In the child level, use a dedicated connection component to read that registered database connection.
For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

Click this icon to open a database connection wizard and store the database connection parameters you set in the component **Basic settings** view.

For more information about setting up and storing database connection parameters, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th><strong>Host</strong></th>
<th>Database server IP address</th>
</tr>

</table>

Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Global Variables</strong></td>
<td><strong>NB_LINE</strong>: the number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td><strong>QUERY</strong>: the query statement being processed. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td></td>
<td><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
</tbody>
</table>
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component covers all possible SQL queries for Teradata databases.</th>
</tr>
</thead>
</table>

Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

Related scenarios

For related scenarios, see:

- Scenario: Loading data into a Teradata database on page 3913.
- Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489.
tTeradataMultiLoad

Executes a database query according to a strict order which must be the same as the one in the schema.
tTeradataMultiLoad reads a database and extracts fields using queries. The retrieved list of fields is then transferred to the next component, using a connection flow (Main row).

**tTeradataMultiLoad Standard properties**

These properties are used to configure tTeradataMultiLoad running in the Standard Job framework.
The Standard tTeradataMultiLoad component belongs to the Databases family.
The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-in or Repository</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Property type</strong></td>
<td></td>
</tr>
<tr>

<td></td>
</tr>
<tr>
<td><strong>Built-in</strong></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><strong>Execution platform</strong></td>
<td>Select the Operating System type you use.</td>
</tr>
<tr>
<td><strong>Host</strong></td>
<td>Host name or IP address of the database server.</td>
</tr>
<tr>
<td><strong>Database name</strong></td>
<td>Database name.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Table</strong></td>
<td>Name of the table to be written. Note that only one table can be written at a time.</td>
</tr>
<tr>
<td><strong>Schema and Edit Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td><strong>Built-In</strong></td>
<td>Built-In: You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.

<table>
<thead>
<tr>
<th>Script generated folder</th>
<th>Browse your directory and select the destination of the file which will be created.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Action to data</strong></td>
<td>On the data of the table defined, you can perform:</td>

</tr>
<tr>
<td><strong>Error file</strong></td>
<td>Browse your directory and select the destination of the file where the error messages will be recorded.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| Define Log table | This check box is selected to define a log table you want to use in place of the default one that is the database |
table you defined in Basic settings. The syntax required to define the log table is `databasename.logtablename`.

BEGIN LOAD
This field allows you to define your BEGIN LOAD command to initiate or restart a load task. You can specify the number of sessions to use, the error limit, any other parameters needed to execute the task.

For more information, see *Teradata MultiLoad Reference* documentation.

Return mload error
Select this check box to specify the exit code number to indicate the point at which an error message should display in the console.

Define character set
Specify the character encoding you need use for your system.

`tStat Catcher Statistics`
Select this check box to collect log data at the component level.

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th><code>EXIT_VALUE</code>: the process exit code. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><code>ERROR_MESSAGE</code>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press <strong>Ctrl + Space</strong> to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td></td>
<td>For further information about variables, see <em>Talend Studio User Guide</em>.</td>
</tr>
</tbody>
</table>

**Usage**

| Usage rule | This component offers the flexibility of the DB query and covers all possible SQL queries. |

**Related scenario**

For related topic, see *Scenario: Inserting data into a Teradata database table* on page 3928.
tTeradataOutput

Executes the action defined on the table and/or on the data contained in the table, based on the flow incoming from the preceding component in the job.

tTeradataOutput writes, updates, makes changes or suppresses entries in a database.

tTeradataOutput Standard properties

These properties are used to configure tTeradataOutput running in the Standard Job framework.

The Standard tTeradataOutput component belongs to the Databases family.

The component in this framework is generally available.

Note:

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-In or Repository.</td>
</tr>
<tr>
<td>Built-In: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td>Repository: Select the repository file where the properties are stored.</td>
<td></td>
</tr>
</tbody>
</table>

Use an existing connection

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

Note:

When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.

2. In the child level, use a dedicated connection component to read that registered database connection.
For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

Click this icon to open a database connection wizard and store the database connection parameters you set in the component **Basic settings** view.

For more information about setting up and storing database connection parameters, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>Host</th>
<th>Database server IP address</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Name of the database</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>

</tr>
<tr>
<td>- <strong>MULTI SET TABLE</strong></td>
<td>tables allowing duplicate rows.</td>
</tr>
<tr>
<td><strong>Action on data</strong></td>
<td>On the data of the table defined, you can perform:</td>
</tr>
<tr>
<td><strong>Insert</strong></td>
<td>Add new entries to the table. If duplicates are found, job stops.</td>
</tr>
<tr>
<td><strong>Update</strong></td>
<td>Make changes to existing entries.</td>
</tr>
</tbody>
</table>
**Insert or update:** Insert a new record. If the record with the given reference already exists, an update would be made.

**Update or insert:** Update the record with the given reference. If the record does not exist, a new record would be inserted.

**Delete:** Remove entries corresponding to the input flow.

**Warning:**

*It is necessary to specify at least one column as a primary key on which the Update and Delete operations are based. You can do that by clicking **Edit Schema** and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the **Advanced settings** view where you can simultaneously define primary keys for the Update and Delete operations. To do that: Select the **Use field options** check box and then in the **Key in update column**, select the check boxes next to the column names you want to use as a base for the Update operation. Do the same in the **Key in delete column** for the Delete operation.*

### Schema and Edit schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

**Built-In:** You create and store the schema locally for this component only. Related topic: see *Talend Studio User Guide*.

**Repository:** You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see *Talend Studio User Guide*.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema:** choose this option to view the schema only.
- **Change to built-in property:** choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection:** choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate
the changes to the current Job, you can select No upon completion and choose this schema metadata again in the [Repository Content] window.

<table>
<thead>
<tr>
<th>Die on error</th>
<th>This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a Row &gt; Rejects link.</th>
</tr>
</thead>
</table>

### Advanced settings

<table>
<thead>
<tr>
<th>Additional JDBC parameters</th>
<th>Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the Use an existing connection check box in the Basic settings. This is intended to allow specific character set support. E.G.: CHARSET=KANJISJIS_OS to get support of Japanese characters.</th>
</tr>
</thead>
</table>

> **Note:**
> 
> You can press Ctrl+Space to access a list of predefined global variables.

<table>
<thead>
<tr>
<th>Commit every</th>
<th>Enter the number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and, above all, better performance at execution. This option is not available if you have selected the Use an existing connection check box in the Basic settings view.</th>
</tr>
</thead>
</table>

> **Note:**
> 
> If you have selected Drop and create table, Create table, Create table if does not exist or Drop table if exists and create from the Action on table list in the Basic settings view, you need to enter 0 in this field to ensure the validity of the SQL statements. For more information about the validity of the SQL statements in Teradata Database, see teradata.

<table>
<thead>
<tr>
<th>Additional Columns</th>
<th>This option is not offered if you create (with or without drop) the DB table. This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing.</th>
</tr>
</thead>
</table>

**Name:** Type in the name of the schema column to be altered or inserted as new column

**SQL expression:** Type in the SQL statement to be executed in order to alter or insert the relevant column data.

**Position:** Select Before, Replace or After following the action to be performed on the reference column.
**Reference column:** Type in a column of reference that the **tDBOutput** can use to place or replace the new or altered column.

**Query band**

Select this check box to use the Teradata Query Banding feature to add metadata to the query to be processed, such as the user running the query. This can help you, for example, identify the origin of this query.

Once selecting the check box, the **Query Band parameters** table is displayed, in which you need to enter the metadata information to be added. This information takes the form of key/value pairs, for example, **DpID** in the **Key** column and **Finance** in the **Value** column.

This check box actually generates the SET QUERY_BAND FOR SESSION statement with the key/value pairs declared in the **Query Band parameters** table. For further information about this statement, see [http://www.info.teradata.com/HTMLPubs/DB_TTU_14_00/index.html#page/SQL_Reference/B035_1144_111A/End_Logging-Syntax.027.143.html](http://www.info.teradata.com/HTMLPubs/DB_TTU_14_00/index.html#page/SQL_Reference/B035_1144_111A/End_Logging-Syntax.027.143.html).

This check box is not available when you have selected the **Using an existing connection** check box. In this situation, if you need to use the Query Band feature, set it in the **Advanced settings** tab of the Teradata connection component to be used.

**Use field options**

Select this check box to customize a request, especially when there is double action on data.

**Enable debug mode**

Select this check box to display each step during processing entries in a database.

**tStatCatcher Statistics**

Select this check box to collect log data at the component level.

**Use Batch**

Select this check box to activate the batch mode for data processing.

**Batch Size**

Specify the number of records to be processed in each batch.

This field appears only when the **Use batch mode** check box is selected.

**Global Variables**

**Global Variables**

**NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.

**NB_LINE_UPDATED**: the number of rows updated. This is an After variable and it returns an integer.

**NB_LINE_INSERTED**: the number of rows inserted. This is an After variable and it returns an integer.

**NB_LINE_DELETED**: the number of rows deleted. This is an After variable and it returns an integer.
NB_LINE_REJECTED: the number of rows rejected. This is an After variable and it returns an integer.

ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule

This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible.

This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in a Teradata database. It also allows you to create a reject flow using a Row > Rejects link to filter data in error.

Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489.

For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add
all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

**Related scenarios**

For related topics, see:

- **Scenario: Inserting a column and altering data using tMysqlOutput** on page 2521.
**tTeradataRollback**

Cancels the transaction commit in the Teradata database.

**tTeradataRollback Standard properties**

These properties are used to configure tTeradataRollback running in the Standard Job framework.

The Standard tTeradataRollback component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>

<tr>
<td>Close Connection</td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is more commonly used with other tTeradata* components, especially with the **tTeradataConnection** and **tTeradataCommit** components. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable. |
For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenario

For tTeradataRollback related scenario, see Scenario: Rollback from inserting data in mother/daughter tables on page 2480.
tTeradataRow

Acts on the actual DB structure or on the data (although without handling data).
tTeradataRow is the specific component for this database query. It executes the SQL query stated onto the specified database. The row suffix means the component implements a flow in the job design although it doesn’t provide output.
The SQLBuilder tool helps you write easily your SQL statements.

### tTeradataRow Standard properties

These properties are used to configure tTeradataRow running in the Standard Job framework.
The Standard tTeradataRow component belongs to the Databases family.
The component in this framework is generally available.

#### Note:
This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.
For more information about dynamic database connectors, see Dynamic database components on page 598.

#### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td></td>
<td>Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:</td>
</tr>
<tr>
<td></td>
<td>1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.</td>
</tr>
<tr>
<td></td>
<td>2. In the child level, use a dedicated connection component to read that registered database connection.</td>
</tr>
<tr>
<td><strong>Host</strong></td>
<td>Database server IP address</td>
</tr>
<tr>
<td>----------</td>
<td>---------------------------</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Schema and Edit Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td><strong>Built-In</strong></td>
<td>You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

Click **Edit schema** to make changes to the schema. If the current schema is of the Repository type, three options are available:
- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.

<table>
<thead>
<tr>
<th><strong>Query type</strong></th>
<th>Either Built-in or Repository</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-in</strong></td>
<td>Fill in manually the query statement or build it graphically using SQLBuilder</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the relevant query stored in the Repository. The Query field gets accordingly filled in.</td>
</tr>
</tbody>
</table>

| **Query** | Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition. |
| **Commit every** | Number of rows to be completed before committing batches of rows together into the DB. This option |
| **Die on error** | This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a **Row > Rejects** link. |
| **Advanced settings** |  |
| **Additional JDBC parameters** | Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the **Use an existing connection** check box in the **Basic settings**.  
This is intended to allow specific character set support. E.G.: CHARSET=KANJISJIS_OS to get support of Japanese characters. |
| **Propagate QUERY’s recordset** | Select this check box to insert the result of the query into a COLUMN of the current flow. Select this column from the **use column** list.  
**Note:**  
This option allows the component to have a different schema from that of the preceding component. Moreover, the column that holds the QUERY’s recordset should be set to the type of **Object** and this component is usually followed by **tParseRecordSet**. |
| **Use PreparedStatement** | Select this check box if you want to query the database using a PreparedStatement. In the **Set PreparedStatement Parameter** table, define the parameters represented by “?” in the SQL instruction of the **Query** field in the **Basic Settings** tab.  
**Parameter Index**: Enter the parameter position in the SQL instruction.  
**Parameter Type**: Enter the parameter type.  
**Parameter Value**: Enter the parameter value.  
**Note:**  
This option is very useful if you need to execute the same query several times. Performance levels are increased |
| **Commit every** | Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions. |
| **Query band** | Select this check box to use the Teradata Query Banding feature to add metadata to the query to be processed, such as the user running the query. This can help you, for example, identify the origin of this query. |
Once selecting the check box, the **Query Band parameters** table is displayed, in which you need to enter the metadata information to be added. This information takes the form of key/value pairs, for example, **DpID** in the **Key** column and **Finance** in the **Value** column.

This check box actually generates the SET QUERY_BAND FOR SESSION statement with the key/value pairs declared in the **Query Band parameters** table. For further information about this statement, see [http://www.info.teradata.com/HTMLPubs/DB_TTU_14_00/index.html#page/SQL_Reference/B035_1144_111A/End_Logging-Syntax.027.143.html](http://www.info.teradata.com/HTMLPubs/DB_TTU_14_00/index.html#page/SQL_Reference/B035_1144_111A/End_Logging-Syntax.027.143.html).

This check box is not available when you have selected the **Using an existing connection** check box. In this situation, if you need to use the Query Band feature, set it in the **Advanced settings** tab of the Teradata connection component to be used.

<table>
<thead>
<tr>
<th>tStat Catcher Statistics</th>
<th>Select this check box to collect log data at the component level.</th>
</tr>
</thead>
</table>

**Global Variables**

| Global Variables | **QUERY**: the query statement being processed. This is a Flow variable and it returns a string. **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it. For further information about variables, see **Talend Studio User Guide**. |

**Usage**

| Usage rule | This component offers the flexibility of the DB query and covers all possible SQL queries. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, |
when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

**Limitation**

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

### Related scenarios

For related scenarios, see:

- **Scenario: Loading data into a Teradata database** on page 3913.
- **Scenario: Combining two flows for selective output** on page 2558.
- **Procedure** on page 625.
- **Scenario: Removing and regenerating a MySQL table index** on page 2552.
tTeradataSCD

Addresses Slowly Changing Dimension needs, reading regularly a source of data and logging the changes into a dedicated SCD table.

TTeradataSCD reflects and tracks changes in a dedicated Teradata SCD table.

**tTeradataSCD Standard properties**

These properties are used to configure tTeradataSCD running in the Standard Job framework.

The Standard tTeradataSCD component belongs to the Business Intelligence and the Databases families.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td></td>
</tr>
<tr>
<td>Property Type</td>
<td>Either <strong>Built-In</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-In</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the repository file in which the properties are stored. The database connection related fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined.

**Note:**

When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.

2. In the child level, use a dedicated connection component to read that registered database connection.
For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th><strong>Host</strong></th>
<th>Type in the IP address or hostname of the database.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Type in the name of the database you want to use.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>Type in the database user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Table</strong></td>
<td>Type in the name of the table to be written. Note that only one table can be written at a time.</td>
</tr>
</tbody>
</table>
| **Action on table** | On the table defined, you can perform one of the following operations:  
• **None**: No operation is carried out.  
• **Create table**: The table does not exist and gets created.  
• **Create table if not exists**: The table is created if it does not exist. |
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields. |
| **Built-In**: You create and store the schema locally for this component only. Related topic: see *Talend Studio User Guide*. |
| **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see *Talend Studio User Guide*. |
| Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
• **View schema**: choose this option to view the schema only.  
• **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
• **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window. |
### SCD Editor

The SCD editor helps to build and configure the data flow for slowly changing dimension outputs.

For more information, see [SCD management methodology](#) on page 2566.

<table>
<thead>
<tr>
<th><strong>Use memory saving mode</strong></th>
<th>Select this check box to maximize system performance.</th>
</tr>
</thead>
<tbody>

Related scenario

For a similar scenario using MySQL database, see Tracking data changes using Slowly Changing Dimensions (type 0 through type 3) on page 2569.
tTeradataSCDELT

Addresses Slowly Changing Dimension needs through SQL queries (server-side processing mode), and logs the changes into a dedicated Teradata SCD table.
tTeradataSCDELT reflects and tracks changes in a dedicated Teradata SCD table.

**tTeradataSCDELT Standard properties**

These properties are used to configure tTeradataSCDELT running in the Standard Job framework.
The Standard tTeradataSCDELT component belongs to the Business Intelligence and the Databases families.
The component in this framework is generally available.

**Note:**
This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
</table>
| **Property Type** | Either **Built-In** or **Repository**.  
  - **Built-In**: No property data stored centrally.  
  - **Repository**: Select the repository file in which the properties are stored. The database connection fields that follow are completed automatically using the data retrieved. |

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
</table>
| **Note:** | When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:  
  1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.  
  2. In the child level, use a dedicated connection component to read that registered database connection. |
For an example about how to share a database connection across Job levels, see *Talend Studio User Guide.*

<table>
<thead>
<tr>
<th>Host</th>
<th>Enter the IP address or hostname of the database server.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Enter the name of the database you want to use.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>Enter the user authentication data to access the database. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Source table</td>
<td>Enter the name of the input Teradata SCD table.</td>
</tr>
<tr>
<td>Table</td>
<td>Enter the name of the table to be written. Note that only one table can be written at a time.</td>
</tr>
</tbody>
</table>
| Action on table | Select one of the following operations to be performed on the table defined:  
• **None**: No action carried out on the table.  
• **Create table**: A new table gets created.  
• **Drop and create table**: The table is removed and created again.  
• **Create table if not exists**: A table gets created if it does not exist.  
• **Drop table if exists and create**: The table is removed if it already exists and created again.  
• **Clear table**: The table content is deleted. You have the possibility to rollback the operation.  
• **Truncate table**: The table content is deleted. You do not have the possibility to rollback the operation. |
| Create | Select the type of the table to be created:  
• **SET TABLE**: creates a SET table that does not allow duplicate rows to be inserted.  
• **MULTISET TABLE**: creates a MULTISET table that allows duplicate rows to be inserted.  
This list is available only when Create table, Drop and create table, Create table if not exists, or Drop table if exists and create is selected from the Action on table drop-down list. |
| Schema and Edit schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.  
• **Built-In**: The schema is created and stored locally for this component only. Related topic: see *Talend Studio User Guide.* |
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **[Repository Content]** window.

<table>
<thead>
<tr>
<th>Surrogate key</th>
<th>Select the surrogate key column from the list.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Creation</td>
<td>Select the method to be used for the surrogate key generation. For more information about the creation methods, see <a href="#">SCD management methodology</a> on page 2566.</td>
</tr>
<tr>
<td>Source Keys</td>
<td>Select one or more columns to be used as keys, to ensure the unicity of the incoming data.</td>
</tr>
<tr>
<td>Use SCD type 1 fields</td>
<td>Select this check box to use SCD Type 1 if tracking changes is not necessary. SCD Type 1 should be used for typos corrections for example.</td>
</tr>
<tr>
<td>SCD type 1 fields</td>
<td>Click the [+] button to add as many rows as needed, and in each row select an input schema column that will be checked for Type 1 changes. This table is available only when the <strong>Use SCD type 1 fields</strong> check box is selected.</td>
</tr>
<tr>
<td>Use SCD type 2 fields</td>
<td>Select this check box to use SCD Type 2 if changes need to be tracked down. SCD Type 2 should be used to trace updates for example.</td>
</tr>
<tr>
<td>SCD type 2 fields</td>
<td>Click the [+] button to add as many rows as needed, and in each row select an input schema column that will be checked for Type 2 changes. This table is available only when the <strong>Use SCD type 2 fields</strong> check box is selected.</td>
</tr>
<tr>
<td>Start date</td>
<td>Select an input schema column to add it to your SCD schema to hold the start date value for the record. This list is available only when the <strong>Use SCD type 2 fields</strong> check box is selected.</td>
</tr>
</tbody>
</table>
### End date
Select an input schema column to add it to your SCD schema to hold the end date value for the record. When the record is currently active, the End Date column shows a null value, or you can select Fixed year value and fill it in with a fictive year to avoid having a null value in the End Date field.

This list is available only when the **Use SCD type 2 fields** check box is selected.

### Log active status
Select this check box and from the Active field list displayed select an input schema column to add it to your SCD schema to hold the true or false status value, which helps to easily spot the active record.

This check box is available only when the **Use SCD type 2 fields** check box is selected.

### Log versions
Select this check box and from the Version field list displayed select an input schema column to add it to your SCD schema to hold the version number of the record.

This check box is available only when the **Use SCD type 2 fields** check box is selected.

### Advanced settings

| **Additional JDBC Parameters** | Specify additional connection properties for the database connection you are creating.  
This field is not available if the **Use an existing connection** check box is selected. |
|--------------------------------|--------------------------------------------------------------------------------------------------|

<table>
<thead>
<tr>
<th><strong>Source fields value include Null</strong></th>
<th>Select this check box to allow the source columns to have Null values. The source columns here refer to the fields defined in the SCD type 1 fields and SCD type 2 fields tables.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th><strong>tStatCatcher Statistics</strong></th>
<th>Select this check box to gather the Job processing metadata at the Job level as well as at each component level.</th>
</tr>
</thead>
</table>

### Global Variables

| **Global Variables** | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
For further information about variables, see *Talend Studio User Guide*.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is used as an output component and it always needs an incoming link.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic settings</td>
<td>Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

| Limitation | This component requires installation of its related jar files. |

### Related scenario

For related topics, see *tMysqlSCD on page 2563 and Tracking data changes using Slowly Changing Dimensions (type 0 through type 3) on page 2569.*
tTeradataTPTExec

Offers high performance in inserting data from an existing file to a table in a Teradata database.

As the combination of tTeradataFastLoad, tTeradataMultiLoad, tTeradataTPump, and tTeradataFastExport, tTeradataTPTExec loads the data from an existing file to a Teradata database.

**tTeradataTPTExec Standard properties**

These properties are used to configure tTeradataTPTExec running in the Standard Job framework.

The Standard tTeradataTPTExec component belongs to the Databases family.

The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Either Built-In or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Built-In: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The database connection related fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Execution platform</td>
<td>Select the Operating System that will be used to run the Job, either Windows or Unix.</td>
</tr>
<tr>
<td>TDPID</td>
<td>Specify the Teradata director program identifier. It can be either the name or the IP address of the Teradata database system being accessed.</td>
</tr>
<tr>
<td>Database name</td>
<td>Specify the name of the Teradata database.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>Specify the username and the password for the Teradata database authentication. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Note: Avoid using a Teradata database keyword as a Db Column name in the schema. If you have to, be sure to enclose the column name in a pair of &quot;. For example, when the keyword id is used as a database column name, the Db Column should be filled with &quot;id&quot;.</td>
</tr>
</tbody>
</table>
### Consumer Operator

Select a consumer operator from the drop-down list.
- **Load**: writes data into an empty Teradata table using the Teradata FastLoad utility protocol.
- **Inserter**: inserts data into Teradata tables with SQL sessions.
- **Update**: performs Insert, Update, or Delete operations using the Teradata MultiLoad utility protocol.
- **Stream**: loads data continuously into Teradata tables using the Teradata TPump utility.

For more information about Teradata consumer operators, see [http://www.info.teradata.com/HTMLPubs/DB_TTU_14_00/index.html#page/Load_and_UnloadUtilities/B035_2445_071A/2445ch02.109.18.html](http://www.info.teradata.com/HTMLPubs/DB_TTU_14_00/index.html#page/Load_and_UnloadUtilities/B035_2445_071A/2445ch02.109.18.html).

### Action On Data

Select an action to be performed on the data from the drop-down list.
- **Insert**: inserts new records to the table. If duplicates are found, the Job stops.
- **Update**: updates existing records in the table.
- **InsertOrUpdate**: inserts new records or updates existing records based on the given reference key.
- **Delete**: removes records corresponding to the input flow.

**Note:**
You must specify at least one column as the primary key on which the **Update** or **Delete** actions can be performed.
Delete operation is based. You can do that by clicking the `[...]` button next to Edit schema and selecting the check box(es) next to the column(s) you want to set as primary key(s).

This list field appears only when the Update or Stream operator is selected from the Consumer Operator drop-down list.

<table>
<thead>
<tr>
<th>Producer Operator</th>
<th>Select a producer operator from the drop-down list. Currently, only the DataConnector operator is supported. <strong>DataConnector</strong>: accesses files either directly or through an access module, and then writes it to the data stream. For more information about Teradata producer operators, see <a href="http://www.info.teradata.com/HTMLPubs/DB_TTU_13_10/index.html#page/Load_and_UnloadUtilities/B035_2445_020A/2445ch02.04.16.html">http://www.info.teradata.com/HTMLPubs/DB_TTU_13_10/index.html#page/Load_and_UnloadUtilities/B035_2445_020A/2445ch02.04.16.html</a>.</th>

</tbody>
</table>

**Apply TPT consumer operator optional attributes**

Select this check box to define optional attribute(s) for the consumer operator that you have selected.

**Optional attributes**

Click the `[+]` button below the table to add as many rows as needed, each row for an optional attribute, and set the following two parameters for each attribute:

- **Name**: click the cell and select an optional attribute from the drop-down list. The list of optional attributes may vary depending on the consumer operator you have selected. For details about supported optional attributes for each consumer operator, see [Supported optional attributes for each consumer operator on page 3912](http://developer.teradata.com/sites/all/files/documentation/linked_docs/2436020A_TPT-Reference-13.10.pdf).

- **Value**: enter the value for the corresponding optional attribute.

This table appears only when the **Apply TPT consumer operator optional attributes** check box is selected.

**tStatCatcher Statistics**

Select this check box to collect the log data at the component level.

**Global Variables**

**Global Variables**

**EXIT_VALUE**: the process exit code. This is an After variable and it returns an integer.
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see **Talend Studio User Guide**.

## Usage

### Usage rule

Used as a single-component Job or Sub-Job, this component offers high performance in inserting data from an existing file to a table in the Teradata database. For further information about the usage of this component, see http://developer.teradata.com/sites/all/files/documentation/linked_docs/html/online/B035-2436-088A/wwhelp/wwhipml/js/html/wwhelp.htm.

### Limitation

The Teradata client tool with the Teradata Parallel Transporter Base and Teradata Parallel Transporter Stream features needs to be installed on the machine where Jobs using this component are executed.

## Supported optional attributes for each consumer operator

This section lists all supported optional attributes for each consumer operator.

### The Load operator

BufferSize, ErrorLimit, MaxSessions, MinSessions, TenacityHours, TenacitySleep, AccountId, DataEncryption, DateForm, ErrorTable1, ErrorTable2, LogonMech, LogonMechData, NotifyExit, NotifyExitIsDLL, NotifyLevel, NotifyMethod, LogSQL, NotifyString, PauseAcq, PrivateLogName, QueryBandSessInfo, WildcardInsert, WorkingDatabase, TraceLevel.

### The Inserter operator

AccountId, DataEncryption, DateForm, LogonMech, LogonMechData, LogSQL, PrivateLogName, QueryBandSessInfo, ReplicationOverride, TraceLevel, WorkingDatabase.

### The Update operator

PrivateLogName, BufferSize, ErrorLimit, MaxSessions, MinSessions, TenacityHours, TenacitySleep, AccountId, AmpCheck, DataEncryption, DateForm, DeleteTask, DropErrorTable, DropLogTable, DropWorkTable, ErrorTable1, ErrorTable2, LogonMech, LogonMechData, LogSQL, NotifyExit, NotifyExitIsDLL, NotifyLevel, NotifyMethod, NotifyString, PauseAcq, QueryBandSessInfo, QueueErrorTable, WorkingDatabase, WorkTable, TraceLevel.
**The Stream operator**

Buffers, ErrorLimit, MaxSessions, MinSessions, Pack, Rate, Periodicity, TenacityHours, TenacitySleep, AccountId, AppendErrorTable, ArraySupport, DataEncryption, DateForm, DropErrorTable, DropMacro, ErrorTable, LogonMech, LogonMechData, MacroDatabase, OperatorCommandID, NotifyExit, NotifyExitsDLL, NotifyLevel, NotifyMethod, LogSQL, NotifyString, PackMaximum, PrivateLogName, QueryBandSessInfo, QueueErrorTable, ReplicationOverride, Robust, WorkingDatabase, TraceLevel.

**Scenario: Loading data into a Teradata database**

This scenario describes a Job that creates a new Teradata database table, writes data into a delimited file, then loads the data from the file into this table, and finally retrieves the data from the table and displays it on the console.

![](image)

**Dropping and linking the components**

**Procedure**

1. Create a new Job and add the following components by typing their names in the design workspace or dropping them from the Palette: a `tTeradataRow` component, a `tFixedFlowInput` component, a `tFileOutputDelimited` component, a `tTeradataTPTExec` component, a `tTeradataInput` component, and a `tLogRow` component.

2. Connect `tFixedFlowInput` to `tFileOutputDelimited` using a `Row > Main` connection.

3. Do the same to connect `tTeradataInput` to `tLogRow`. 
4. Connect tTeradataRow to tFixedFlowInput using a Trigger > On Subjob Ok connection.
5. Do the same to connect tFixedFlowInput to tTeradataTPTExec and tTeradataTPTExec to tTeradataInput.

Configuring the components

Creating a new Teradata database table

Procedure

1. Double-click tTeradataRow to open its Basic settings view.

![tTeradataRow_1](image)

2. Fill in the Host, Database, Username, and Password fields with your Teradata database connection details.

3. In the Query field, enter the following SQL statement to create a new table named person with three columns id, name, sex.

```sql
CREATE SET TABLE samples.person,
FALLBACK,
NO BEFORE JOURNAL,
NO AFTER JOURNAL
(
    id INTEGER NOT NULL,
    name VARCHAR(50),
    sex VARCHAR(20)
)
UNIQUE PRIMARY INDEX (id)
```

Preparing the source data

Procedure

1. Double-click tFixedFlowInput to open its Basic settings view.
2. Click the [...] button next to Edit schema to open the schema editor.

3. Click the [+] button to add three columns: id of the integer type, name and sex of the string type.

4. Click OK to close the schema editor and accept the propagation prompted by the pop-up dialog box.

5. In the Mode area, select Use Inline Content (delimited file) and enter the input data in the Content field.

   1;Ford;Male
   2;Rose;Female
   3;Sabrina;Female
   4;Teddy;Male
   5;Kate;Male

6. Double-click tFileOutputDelimited to open its Basic settings view.
7. In the **File Name** field, specify the file into which the input data will be written. In this example, it is `E:/person.csv`.

## Loading the source data into an empty table

### Procedure

1. Double-click **tTeradataTPTExec** to open its **Basic settings** view.

2. Fill in the **TDPID**, **Database name**, **Username**, and **Password** fields with your Teradata database connection details.

3. In the **Table** field, enter the name of the table into which the source data will be loaded. In this example, it is `person`.

4. In the **Script generated folder** field, browse to the directory under which the Teradata Parallel Transporter script file will be created during the Job execution. In this example, it is `E:/`.

5. In the **Load file** field, browse to the file that contains the source data. In this example, it is `E:/person.csv`.

6. In the **Error file** field, specify the file in which log messages will be recorded. In this example, it is `E:/error.log`.
7. Click the [...] button next to **Edit schema** to open the schema editor.

![Schema editor screenshot]

Click the [+] button to add three columns: *id* of the integer type, *name* and *sex* of the string type. Note that *id* and *name* in **Db Column** are enclosed in a pair of `\` since they are Teradata database keywords.

Click **OK** to validate these changes and close the schema editor.

8. Click **Advanced settings** to open its view, and then select the **Apply TPT consumer operator optional attributes** check box and click the [+] button below the **Optional attributes** table to add the following attributes needed: *ErrorLimit*, *ErrorTable1*, *QueryBandSessInfo*, and *TraceLevel*.

![Advanced settings screenshot]

**Note:**

For VARCHAR attributes, enter their values between double quotation marks.
Retrieving data from the Teradata database table

Procedure

1. Double-click **tTeradataInput** to open its **Basic settings** view.

2. In the **Table Name** field, enter the name of the table to read data from. In this example, it is `person`.

3. In the **Query** field, enter the following SQL statement to retrieve data from the table `person`.

   ```sql
   SELECT * FROM samples.person ORDER BY id
   ```

4. Click the `[...]` button next to **Edit schema** to open the schema editor.

5. Click the `[+]` button to add three columns: `id` of the integer type, `name` and `sex` of the string type. Note that `id` and `name` in **Db Column** are enclosed in a pair of `\` since they are Teradata database keywords.

6. Click **OK** to close the schema editor and accept the propagation prompted by the pop-up dialog box.

7. Double-click **tLogRow** to open its **Basic settings** view.
8. In the **Mode** area, select the **Table (print values in cells of a table)** option for a better display of the result.

### Saving and executing the Job

**Procedure**

1. Press **Ctrl + S** to save the Job.
2. Press **F6** to execute the Job.

```
Starting job tTeradataTPTExec_Demo at 10:35 28/09/2014.
[statistics] connecting to socket on port 3553
[statistics] connected
<table>
<thead>
<tr>

<tr>
<td>-----</td>
</tr>
<tr>
<td>1</td>
</tr>
<tr>
<td>2</td>
</tr>
<tr>
<td>3</td>
</tr>
<tr>
<td>4</td>
</tr>
<tr>
<td>5</td>
</tr>
</tbody>
</table>
[statistics] disconnected
Job tTeradataTPTExec_Demo ended at 10:35 28/09/2014. [exit code=0]
```

The data written into the specified Teradata database table is displayed on the console.
tTeradataTPTUtility

Writes the incoming data to a file and then loads the data from the file to a Teradata database.

As the combination of tTeradataFastLoad, tTeradataMultiLoad, tTeradataTPump, and tTeradataFastExport, tTeradataTPTUtility writes the incoming data to a file and then loads the data from the file to a Teradata database.

**tTeradataTPTUtility Standard properties**

These properties are used to configure tTeradataTPTUtility running in the Standard Job framework.
The Standard tTeradataTPTUtility component belongs to the Databases family.
The component in this framework is generally available.

**Basic settings Data file**

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Either Built-In or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Built-In</strong>: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: Select the repository file in which the properties are stored. The <strong>Filename</strong> field is completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

**Filename**
Specify the file to save the incoming data.

**Append**
Select this check box to append the incoming data in the file specified in the **Filename** field.

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Either Built-In or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Built-In</strong>: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: Select the repository file in which the properties are stored. The database connection related fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

**Execution platform**
Select the Operating System that will be used to run the Job, either Windows or Unix.

**TDPID**
Specify the Teradata director program identifier. It can be either the name or the IP address of the Teradata database system being accessed.

**Database name**
Specify the name of the Teradata database.

**Username and Password**
Specify the username and the password for the Teradata database authentication.
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter
### Schema and Edit Schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

**Note:**

Avoid using a Teradata database keyword as a **Db Column** name in the schema. If you have to, be sure to enclose the column name in a pair of `\`. For example, when the keyword `id` is used as a database column name, the **Db Column** should be filled with `\id\`.

### Built-In

You create and store the schema locally for this component only. Related topic: see [Talend Studio User Guide](https://www.talend.com/).  

### Repository

You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see [Talend Studio User Guide](https://www.talend.com/).

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **[Repository Content]** window.

### Consumer Operator

Select a consumer operator from the drop-down list.

- **Load**: writes data into an empty Teradata table using the Teradata FastLoad utility protocol.
- **Inserter**: inserts data into Teradata tables with SQL sessions.
- **Update**: performs Insert, Update, or Delete operations using the Teradata MultiLoad utility protocol.
- **Stream**: loads data continuously into Teradata tables using the Teradata TPump utility.

For more information about Teradata consumer operators, see [http://www.info.teradata.com/HTMLPubs/DB_TTU_14_00/index.html#page/Load_and_Unload_Utildies/B035_2445_071A/2445ch02.109.18.html](http://www.info.teradata.com/HTMLPubs/DB_TTU_14_00/index.html#page/Load_and_Unload_Utildies/B035_2445_071A/2445ch02.109.18.html).
### Action On Data

Select an action to be performed on the data from the drop-down list.

- **Insert**: inserts new records to the table. If duplicates are found, the Job stops.
- **Update**: updates existing records in the table.
- **InsertOrUpdate**: inserts new records or updates existing records based on the given reference key.
- **Delete**: removes records corresponding to the input flow.

**Note:**
You must specify at least one column as the primary key on which the **Update** or **Delete** operation is based. You can do that by clicking the [...] button next to **Edit schema** and selecting the check box(es) next to the column(s) you want to set as primary key(s).

This list field appears only when the **Update** or **Stream** operator is selected from the **Consumer Operator** drop-down list.

### Producer Operator

Select a producer operator from the drop-down list. Currently, only the **DataConnector** operator is supported.

**DataConnector**: accesses files either directly or through an access module, and then writes it to the data stream.

### Table

Specify the name of the table to be written into the Teradata database. Note that only one table can be written at a time.

### Script generated folder

Specify the directory under which the Teradata Parallel Transporter script file will be created during the Job execution. This script file will be deleted at the end of the Job execution.

### Error file

Specify the file in which log messages will be recorded.

### Advanced settings

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Row separator</strong></td>
<td>Character, string or regular expression to separate rows.</td>
</tr>
<tr>
<td><strong>Field separator</strong></td>
<td>Character, string or regular expression to separate fields.</td>
</tr>
<tr>
<td><strong>Include header</strong></td>
<td>Select this check box to include the column header to the file.</td>
</tr>
</tbody>
</table>
### Encoding
Select the encoding from the list or select **Custom** and define it manually. This field is compulsory for database data handling.

### Set Script Parameters
Select this check box to define script parameters, which will be used when generating a script during the Job execution. If you do not specify them manually, the system will use their default values.

### Load Operator
Specify the load operator.
This field appears only when the **Set Script Parameters** check box is selected.

### Data Connector
Specify the data connector.
This field appears only when the **Set Script Parameters** check box is selected.

### Job Name
Specify the name of a Teradata Parallel Transporter Job which is defined using the Teradata `tbuilt` command.
This field appears only when the **Set Script Parameters** check box is selected.

### Layout Name (schema)
Specify a schema for the data to be loaded.
This field appears only when the **Set Script Parameters** check box is selected.

### Define Log table
Select this check box to specify a log table so that log messages recorded in the log file will also be written into the log table.

### Return mload error
Select this check box to specify the exit code number to indicate the point at which an error message should display in the console.

### Define character set
Select this check box to specify the character encoding to be used in your system.

### Apply TPT consumer operator optional attributes
Select this check box to define optional attribute(s) for the consumer operator that you have selected.
For more information about optional attributes of each consumer operator, see [Teradata Parallel Transporter Reference](http://developer.teradata.com/sites/all/files/documentation/linked_docs/2436020A_TPT-Reference-13.10.pdf) guide.

### Optional attributes
Click the `[+]` button below the table to add as many rows as needed, each row for an optional attribute, and set the following two parameters for each attribute:

- **Name**: click the cell and select an optional attribute from the drop-down list. The list of optional attributes may vary depending on the consumer.
operator you have selected. For details about supported optional attributes for each consumer operator, see Supported optional attributes for each consumer operator on page 3912.

- **Value**: enter the value for the corresponding optional attribute.

This table appears only when the **Apply TPT consumer operator optional attributes** check box is selected.

### tStatCatcher Statistics

| tStatCatcher Statistics | Select this check box to collect the log data at the component level. |

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>EXIT_VALUE: the process exit code. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Global Variables</td>
<td><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td>Global Variables</td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td>Global Variables</td>
<td>To fill up a field or expression with a variable, press <strong>Ctrl + Space</strong> to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td>Global Variables</td>
<td>For further information about variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

### Usage

| Usage rule | Preceded by an input component, **tTeradataTPTUtility** writes the incoming data to a file and then loads the data from the file to the Teradata Database. High performance is provided during this process. For further information about the usage of this component, see http://developer.teradata.com/sites/all/files/documentation/linked_docs/html/online/B035-2436-088A/wwwhelp/wwwhelp.htm. |

| Limitation | The Teradata client tool with the Teradata Parallel Transporter Base and Teradata Parallel Transporter Stream features needs to be installed on the machine where Jobs using this component are executed. |
Related scenario

For a related scenario, see Scenario: Loading data into a Teradata database on page 3913.
**tTeradataTPump**

Inserts, updates, or deletes data in the Teradata database with the TPump loading utility which allows near-real-time data to be achieved in the data warehouse.

Use this component particularly for environments where batch windows are shrinking and warehouse maintenance overlaps normal working hours.

**tTeradataTPump Standard properties**

These properties are used to configure tTeradataTPump running in the Standard Job framework.

The Standard tTeradataTPump component belongs to the Databases family.

The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-in or Repository</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

**Execution platform**

Select the Operating System type you use.

**Host**

Host name or IP address of the database server.

**Database name**

Database name.

**Username and Password**

DB user authentication data.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

**Table**

Name of the table to be written. Note that only one table can be written at a time.

**Schema and Edit Schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

**Built-In**

You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.

**Repository**

You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.

<table>
<thead>

</tr>
</tbody>
</table>

**Advanced settings**

| **Define Log table**            | This check box is selected to define a log table you want to use in place of the default one that is the database |
BEGIN LOAD

This field allows you to define your BEGIN LOAD command to initiate or restart a TPump task. You can specify the number of sessions to use, the error limit and any other parameters needed to execute the task. The default value is:

SESSIONS 8 PACK 600 ARRAYSUPPORT ON
CHECKPOINT 60 TENACITY 2 ERRLIMIT 1000.

For more information, see Teradata Parallel Data Pump Reference documentation.

Return tpump error

Select this check box to specify the exit code number to indicate the point at which an error message should display in the console.

Define character set

Specify the character encoding you need use for your system.

tStat Catcher Statistics

Select this check box to collect log data at the component level.

Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>EXIT_VALUE: the process exit code. This is an After variable and it returns an integer. ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide.</th>
</tr>
</thead>
</table>

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component offers the flexibility of the DB query and covers all possible SQL queries.</th>
</tr>
</thead>
</table>

Scenario: Inserting data into a Teradata database table

In this scenario, you create a Job using tTeradataTPump to insert customer data into a Teradata database table and specify the exit code to be displayed in the event of an exception error.

Three components are used in this Job:
• **tRowGenerator**: generates rows as required using random customer data taken from a list.
• **tFileOutputDelimited**: outputs the customer data into a delimited file.
• **tTeradataTPump**: inserts the customer data into the Teradata database table in the Tpump mode.

### Dropping components

**Procedure**

1. Drop the required components: **tRowGenerator**, **tFileOutputDelimited** and **tTeradataTPump** from the Palette onto the design workspace.
2. Link **tRowGenerator** to **tFileOutputDelimited** using a Row > Main connection.
3. Link **tRowGenerator** to **tTeradataTPump** using a Trigger > On SubjobOk connection.

### Configuring the components

**Procedure**

1. Double click **tRowGenerator** to open the [tRowGenerator Editor] window.
   
   In the [tRowGenerator Editor] window, define the data to be generated. For this Job, the schema is composed of two columns: *ID* and *Name*.
Enter the **Number of Rows for RowGenerator** to generate.

2. Double click **tFileOutputDelimited** to define its properties in the **Component** view.

3. Next to **File Name**, browse to the output file or enter a name for the output file to be created.

4. Between double quotation marks, enter the delimiters to be used next to **Row Separator** and **Field Separator**.

5. **Click Edit schema** and check that the schema matches the input schema. If need be, **click Sync Columns**.

6. **Double click tTeradataTPump** to open its **Component** view.

   In the **Basic settings** tab of the **Component** view, define the **tTeradataTPump** parameters. I

7. **Enter the Database name**, **User name** and **Password** in accordance with your database authentication information.

8. Specify the **Table** into which you want to insert the customer data. In this scenario, it is called **mytable**.

9. In the **Script generated folder** field, browse to the folder in which you want to store the script files generated.

10. In the **Load file** field, browse to the file which contains the customer data.
10. In the Error file field, browse to the file in which you want to log the error information.

11. In the Action on data field, select Insert.

**Executing the Job**

**Procedure**

1. Press F6 to execute the Job.
2. The Run view console reads as follows:

```
Running job 'tpump'...
Starting job tpump at 17:01 19/07/2010.
[statistics] connecting to socket on port 3740
[statistics] connected
[statistics] disconnected
Job tpump ended at 17:02 19/07/2010. [exit code=0]
```

3. Double-click the tTeradataTPump component to go back to its Component view.

4. On the Advanced settings tab, select the Return tpump error check box and type in the exit code number to indicate the point at which an error message should be displayed in the console. In this example, enter the number 4 and use the default values for the other parameters.

5. Press F6 to run the Job.

6. The Run view console reads as follows:

```
Running job 'tpump'...
Starting job tpump at 17:56 19/07/2010.
[statistics] connecting to socket on port 3549
[statistics] connected
[statistics] disconnected
Exception in component tTeradataTPump_1
java.lang.RuntimeException: TPump returned exit code 12
at bug.tpump_0_1.tpump.tTeradataTPump_1Process(tpump.java:307)
at bug.tpump_0_1.tpump.runJobInOS(tpump.java:504)
at bug.tpump_0_1.tpump.main(tpump.java:378)
Job tpump ended at 17:56 19/07/2010. [exit code=0]
```

An exception error occurs and TPump returned exit code 12 is displayed. If you need to view detailed information about the exception error, you can open the log file stored in the directory you specified in the Error file field in the Basic settings tab of the Component view.
**tUniqRow**

Ensures data quality of input or output flow in a Job.
tUniqRow compares entries and sorts out duplicate entries from the input flow.

**tUniqRow Standard properties**

These properties are used to configure tUniqRow running in the Standard Job framework.
The Standard tUniqRow component belongs to the Data Quality family.
The component in this framework is generally available.

**Basic settings**

| Schema and Edit schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.
Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:
- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the [Repository Content] window.

| Built-In: You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide. |
| Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide. |

| Unique key | In this area, select one or more columns to carry out de duplication on the particular column(s)
- Select the **Key attribute** check box to carry out deduplication on all the columns
- Select the **Case sensitive** check box to differentiate upper case and lower case |
## Advanced settings

<table>
<thead>
<tr>
<th>Only once each duplicated key</th>
<th>Select this check box if you want to have only the first duplicated entry in the column(s) defined as key(s) sent to the output flow for duplicates.</th>
</tr>
</thead>
</table>
| Use of disk (suitable for processing large row set) | Select this check box to enable generating temporary files on the hard disk when processing a large amount of data. This helps to prevent Job execution failure caused by memory overflow. With this check box selected, you need also to define:  
- **Buffer size in memory**: Select the number of rows that can be buffered in the memory before a temporary file is to be generated on the hard disk.  
- **Directory for temp files**: Set the location where the temporary files should be stored.  

**Warning:**  
*Make sure that you specify an existing directory for temporary files; otherwise your Job execution will fail.* |
| Ignore trailing zeros for BigDecimal | Select this check box to ignore trailing zeros for BigDecimal data. |
| tStatCatcher Statistics | Select this check box to gather the job processing metadata at a job level as well as at each component level. |

## Global Variables

| Global Variables | **NB_UNIQUES**: the number of unique rows. This is an After variable and it returns an integer.  
**NB_DUPLICATES**: the number of duplicate rows. This is an After variable and it returns an integer.  
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
For further information about variables, see *Talend Studio User Guide*. |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                  | **NB_UNIQUES**: the number of unique rows. This is an After variable and it returns an integer.  
**NB_DUPLICATES**: the number of duplicate rows. This is an After variable and it returns an integer.  
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
For further information about variables, see *Talend Studio User Guide*. |
**Usage**

| Usage rule | This component handles flow of data therefore it requires input and output, hence is defined as an intermediary step. |

---

**Scenario 1: Deduplicating entries**

In this five-component Job, we will sort entries on an input name list, find out duplicated names, and display the unique names and the duplicated names on the **Run** console.

---

**Setting up the Job**

**Procedure**

1. Drop a **tFileInputDelimited**, a **tSortRow**, a **tUniqRow**, and two **tLogRow** components from the **Palette** to the design workspace, and name the components as shown above.
2. Connect the **tFileInputDelimited** component, the **tSortRow** component, and the **tUniqRow** component using **Row > Main** connections.
3. Connect the **tUniqRow** component and the first **tLogRow** component using a **Main > Uniques** connection.
4. Connect the **tUniqRow** component and the second **tLogRow** component using a **Main > Duplicates** connection.

**Configuring the components**

**Procedure**

1. Double-click the **tFileInputDelimited** component to display its **Basic settings** view.
2. Click the [...] button next to the File Name field to browse to your input file.

3. Define the header and footer rows. In this use case, the first row of the input file is the header row.

4. Click Edit schema to define the schema for this component. In this use case, the input file has five columns: Id, FirstName, LastName, Age, and City. Then click OK to propagate the schema and close the schema editor.

5. Double-click the tSortRow component to display its Basic settings view.

6. To rearrange the entries in the alphabetic order of the names, add two rows in the Criteria table by clicking the plus button, select the FirstName and LastName columns under Schema column, select alpha as the sorting type, and select the sorting order.

7. Double-click the tUniqRow component to display its Basic settings view.
8. In the **Unique key** area, select the columns on which you want deduplication to be carried out. In this use case, you will sort out duplicated names.

9. In the **Basic settings** view of each of the tLogRow components, select the **Table** option to view the Job execution result in table mode.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl+S** to save your Job.
2. Run the Job by pressing **F6** or clicking the **Run** button on the **Run** tab.

The unique names and duplicated names are displayed in different tables on the **Run** console.

---
tUnite

Centralizes data from various and heterogeneous sources.
tUnite merges data from various sources, based on a common schema.
Note that tUnite cannot exist in a data flow loop. For instance, if a data flow goes through several tMap components to generate two flows, they cannot be fed to tUnite.

### tUnite Standard properties

These properties are used to configure tUnite running in the Standard Job framework.
The Standard tUnite component belongs to the Orchestration family.
The component in this framework is generally available.

#### Basic settings

| **Schema and Edit Schema** | A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either Built-in or stored remotely in the Repository. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:
| | • View schema: choose this option to view the schema only.
| | • Change to built-in property: choose this option to change the schema to Built-in for local changes.
| | • Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the [Repository Content] window.
| | Click Sync columns to retrieve the schema from the previous component in the Job.
| Built-in: The schema will be created and stored locally for this component only. Related topic: see Talend Studio User Guide.
| Repository: The schema already exists and is stored in the Repository, hence can be reused in various projects and Job designs. Related topic: see Talend Studio User Guide. |
Advanced settings

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. |
| | NB_LINE: the number of rows processed. This is an After variable and it returns an integer. |
| | A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. |
| | To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. |
| | For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | This component is not startable and requires one or several input components and an output component. |

Connections

| Connections | Outgoing links (from this component to another): 
Row: Main. 
Trigger: Run if; On Component Ok; On Component Error |
| | Incoming links (from one component to this one): 
Row: Main; Reject. |
| | For further information regarding connections, see Talend Studio User Guide. |

Scenario: Iterate on files and merge the content

The following Job iterates on a list of files then merges their content and displays the final 2-column content on the console.
Dropping and linking the components

Procedure

1. Drop the following components onto the design workspace: tFileList, tFileInputDelimited, tUnite and tLogRow.
2. Connect the tFileList to the tFileInputDelimited using an Iterate connection and connect the other component using a row main link.

Configuring the components

Procedure

1. In the tFileList Basic settings view, browse to the directory, where the files to merge are stored.

   The files are pretty basic and contain a list of countries and their respective score.

2. In the Case Sensitive field, select Yes to consider the letter case.
3. Select the tFileInputDelimited component, and display this component’s Basic settings view.
4. Fill in the **File Name/Stream** field by using the **Ctrl+Space bar** combination to access the variable completion list, and selecting `tFileList.CURRENT_FILEPATH` from the global variable list to process all files from the directory defined in the `tFileList`.

5. Click the **Edit Schema** button and set manually the 2-column schema to reflect the input files’ content.

For this example, the 2 columns are **Country** and **Points**. They are both **nullable**. The **Country** column is of **String** type and the **Points** column is of **Integer** type.

6. Click **OK** to validate the setting and accept to propagate the schema throughout the Job.

7. Then select the **tUnite** component and display the **Component view**. Notice that the output schema strictly reflects the input schema and is read-only.

8. In the **Basic settings** view of **tLogRow**, select the **Table** option to display properly the output values.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl+S** to save your Job.

2. Press **F6**, or click **Run** on the **Run** console to execute the Job.

   The console shows the data from the various files, merged into one single table.
tVectorWiseCommit

Commits a global transaction in one go using a single connection instead of doing so on every row or every batch. This provides a gain in performance.
tVectorWiseCommit validates the data processed in a Job into the connected DB.

tVectorWiseCommit Standard properties

These properties are used to configure tVectorWiseCommit running in the Standard Job framework.
The Standard tVectorWiseCommit component belongs to the Databases family.
The component in this framework is generally available.

Note:
This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.
For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tVectorWiseConnection component from the list if more than one connection is planned for the current job.</td>
</tr>
<tr>
<td>Close connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

Warning:
If you want to use a Row > Main connection to link tVectorWiseCommit to your Job, your data will be committed row by row. In this case, do not select the Close connection check box or your connection will be closed before the end of your first row commit.

Advanced settings

| tStatCatcher Statistics         | Select this check box to collect log data at the component level. |

Usage

| Usage rule                     | This component is more commonly used with other tVectorWise* components, especially with the... |
**Dynamic settings**

Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job.

Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

**Related scenario**

For a **tVectorWiseCommit** related scenario, see Scenario: Inserting data in mother/daughter tables on page 2476.
tVectorWiseConnection

Opens a connection to the specified database that can then be reused in the subsequent subjob or subjobs.

**tVectorWiseConnection Standard properties**

These properties are used to configure tVectorWiseConnection running in the Standard Job framework.

The Standard tVectorWiseConnection component belongs to the Databases and the ELT families.

The component in this framework is generally available.

⚠️ **Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th><strong>Database</strong></th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Property type</strong></td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in</strong>: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td><strong>Repository</strong>: Select the repository file where the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
<td></td>
</tr>
<tr>
<td><strong>Server</strong></td>
<td>Database server IP address.</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database.</td>
</tr>
<tr>
<td><strong>Username</strong> and <strong>Password</strong></td>
<td>Authentication information of the database user.</td>
</tr>
<tr>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
<td></td>
</tr>
<tr>
<td><strong>Use or register a shared DB Connection</strong></td>
<td>Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the <strong>Shared DB Connection Name</strong> field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child.</td>
</tr>
</tbody>
</table>
This option is incompatible with the **Use dynamic job** and **Use an independent process to run subjob** options of the **tRunJob** component. Using a shared connection together with a **tRunJob** component with either of these two options enabled will cause your Job to fail.

### Advanced settings

<table>
<thead>
<tr>
<th>Advanced setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Auto Commit</strong></td>
<td>Select this check box to commit any changes to the database automatically upon the transaction. With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component. Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component.</td>
</tr>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

### Usage

<td>This component is more commonly used with other <strong>tVectorWise</strong> components, especially with the <strong>tVectorWiseCommit</strong> and <strong>tVectorWiseRollback</strong> components.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Limitation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Limitation</strong></td>
<td>Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the <strong>Install</strong> button on the <strong>Component</strong> tab view. You can also find out and add all missing JARs easily on the <strong>Modules</strong> tab in the <strong>Integration</strong> perspective of your studio. You can find more details about how to install external modules in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
</tbody>
</table>

### Related scenario

For a **tVectorWiseConnection** related scenario, see **tMysqlConnection** on page 2475.
tVectorWiseInput

Executes a DB query with a strictly defined order which must correspond to the schema definition. tVectorWiseInput reads a database and extracts fields based on a query. It passes on the field list to the next component via a Main row link.

**tVectorWiseInput Standard properties**

These properties are used to configure tVectorWiseInput running in the Standard Job framework. The Standard tVectorWiseInput component belongs to the Databases family. The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>

<td>Enter your DB query, ensuring that the field order matches the order in the schema.</td>
</tr>
</tbody>
</table>
**Guess Query**
Click this button to generate a query that corresponds to your table schema in the Query field.

**Guess schema**
Click this button to retrieve the schema from the table.

### Advanced settings

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Trim all the String/Char columns</td>
<td>Select this check box to remove leading and trailing whitespace from all the String/Char columns.</td>
</tr>
<tr>
<td>Trim column</td>
<td>Define columns from which to remove leading and trailing whitespace.</td>
</tr>
<tr>
<td>tStat Catcher Statistics</td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

### Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NB_LINE</td>
<td>the number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>QUERY</td>
<td>the query statement being processed. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td>ERROR_MESSAGE</td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

<table>
<thead>

</tr>
</thead>
<tbody>
<tr>
<td>Usage rule</td>
<td>This component covers all possible SQL queries for Vertica databases.</td>
</tr>
</tbody>
</table>

| Limitation               | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |
Related scenario

For tVectorWisInput related scenarios, see:

- Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489.
**tVectorWiseOutput**

Executes the action defined on the table and/or on the data contained in the table, based on the flow incoming from the preceding component in the Job.

tVectorWiseOutput writes, updates, makes changes or suppresses entries in a database.

**tVectorWiseOutput Standard properties**

These properties are used to configure tVectorWiseOutput running in the Standard Job framework.

The Standard tVectorWiseOutput component belongs to the Databases family.

The component in this framework is generally available.

<i>Note:</i>

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>

<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><img src="icon" alt="icon" /></td>
<td>Click this icon to open a database connection wizard and store the database connection parameters you set in the component Basic settings view. For more information about setting up and storing database connection parameters, see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

<i>Note:</i>

When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component
which creates that very database connection.

2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th>Host</th>
<th>Database server IP address.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>Listening port number of the DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Table</td>
<td>Name of the table to be written. Note that only one table can be written at a time.</td>
</tr>
</tbody>
</table>
| Action on table | On the table defined, you can perform one of the following operations:  
  * None: No operation is carried out.  
  * Drop and create a table: The table is removed and created again.  
  * Create a table: The table does not exist and gets created.  
  * Create a table if not exists: The table is created if it does not exist.  
  * Drop a table if exists and create: The table is removed if it already exists and created again.  
  * Clear a table: The table content is deleted. |
| Action on data  | On the data of the table defined, you can perform:  
  * Insert: Add new entries to the table. If duplicates are found, job stops.  
  * Update: Make changes to existing entries  
  * Insert or update: Insert a new record. If the record with the given reference already exists, an update would be made.  
  * Update or insert: Update the record with the given reference. If the record does not exist, a new record would be inserted.  
  * Delete: Remove entries corresponding to the input flow.  
  
  **Warning:**  
  * It is necessary to specify at least one column as a primary key on which the Update and Delete operations are based. You can do that by clicking...* |
**Edit Schema** and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the Advanced settings view where you can simultaneously define primary keys for the Update and Delete operations. To do that: Select the Use field options check box and then in the Key in update column, select the check boxes next to the column names you want to use as a base for the Update operation. Do the same in the Key in delete column for the Delete operation.

### Schema and Edit Schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

### Built-In

**Built-In**: You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.

### Repository

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

### Die on error

This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a Row > Rejects link.
## Advanced settings

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Commit every</strong></td>
<td>Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and, above all, better performance at executions.</td>
</tr>
<tr>
<td><strong>Additional Columns</strong></td>
<td>This option is not offered if you create (with or without drop) the DB table. This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing.</td>
</tr>
<tr>
<td></td>
<td><strong>Name:</strong> Type in the name of the schema column to be altered or inserted as new column.</td>
</tr>
<tr>
<td></td>
<td><strong>SQL expression:</strong> Type in the SQL statement to be executed in order to alter or insert the relevant column data.</td>
</tr>
<tr>
<td></td>
<td><strong>Position:</strong> Select Before, Replace or After following the action to be performed on the reference column.</td>
</tr>
<tr>
<td></td>
<td><strong>Reference column:</strong> Type in a column of reference that the tDBOutput can use to place or replace the new or altered column.</td>
</tr>
<tr>
<td><strong>Use field options</strong></td>
<td>Select this check box to customize a request, especially when there is double action on data.</td>
</tr>
<tr>
<td><strong>Enable debug mode</strong></td>
<td>Select this check box to display each step during processing entries in a database.</td>
</tr>
<tr>
<td><strong>Support null in “SQL WHERE” statement</strong></td>
<td>Select this check box if you want to deal with the Null values contained in a DB table.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> Ensure that the Nullable check box is selected for the corresponding columns in the schema.</td>
</tr>
<tr>
<td><strong>Use Batch</strong></td>
<td>Select this check box to activate the batch mode for data processing.</td>
</tr>
<tr>
<td></td>
<td>This option is only supported with Vectorwise version 2.5 and later, and is only available when you select Insert from the Action on data drop-down list in the Basic settings tab.</td>
</tr>
<tr>
<td><strong>Batch Size</strong></td>
<td>Specify the number of records to be processed in each batch.</td>
</tr>
<tr>
<td></td>
<td>This field appears only when the Use batch mode check box is selected.</td>
</tr>
<tr>
<td><strong>tStat Catcher Statistics</strong></td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>
Global Variables

- **NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.
- **NB_LINE_UPDATED**: the number of rows updated. This is an After variable and it returns an integer.
- **NB_LINE_INSERTED**: the number of rows inserted. This is an After variable and it returns an integer.
- **NB_LINE_DELETED**: the number of rows deleted. This is an After variable and it returns an integer.
- **NB_LINE_REJECTED**: the number of rows rejected. This is an After variable and it returns an integer.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

Usage

- **Usage rule**: This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible.

  This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in a Vertica database. It also allows you to create a reject flow using a Row > Rejects link to filter data in error. For an example of *tMySqlOutput* in use, see Scenario: Retrieving data in error with a Reject link on page 2529.

Limitation

- **Limitation**: Due to license incompatibility, one or more JARs required to use this component are not provided.

  You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

Related scenario

For *tVectorWiseOutput* related topics, see:
• **Scenario: Inserting a column and altering data using tMysqlOutput** on page 2521.
tVectorWiseRollback

Cancels transactions committed to the VectorWise database.

**tVectorWiseRollback Standard properties**

These properties are used to configure tVectorWiseRollback running in the Standard Job framework.

The Standard tVectorWiseRollback component belongs to the Databases family.

The component in this framework is generally available.

![Note:](image)

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the <strong>tVectorWiseConnection</strong> component from the list if more than one connection is planned for the current job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is more commonly used with other tVectorWise* components, especially with the **tVectorWiseConnection** and **tVectorWiseCommit** components. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job.  

Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.  

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using **
Related scenario

For a `tVectorWiseRollback` related scenario, see *Scenario: Rollback from inserting data in mother/daughter tables* on page 2480.
tVectorWiseRow

Acts on the actual DB structure or on the data (although without handling data).

tVectorWiseRow is the specific component for this database query. It executes the SQL query stated in the specified database. The row suffix means the component implements a flow in the job design although it doesn’t provide output.

The SQLBuilder tool helps you write your SQL statements easily.

**tVectorWiseRow Standard properties**

These properties are used to configure tVectorWiseRow running in the Standard Job framework.

The Standard tVectorWiseRow component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file where the properties are stored. The fields that follow after are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

**Note:**

When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.

2. In the child level, use a dedicated connection component to read that registered database connection.
For an example about how to share a database connection across Job levels, see [Talend Studio User Guide](#).

<table>
<thead>
<tr>
<th><strong>Host</strong></th>
<th>Database server IP address.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of the DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database.</td>
</tr>
<tr>
<td><strong>Username</strong> and <strong>Password</strong></td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Schema</strong> and <strong>Edit Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td><strong>Built-In</strong>: You create and store the schema locally for this component only. Related topic: see <a href="#">Talend Studio User Guide</a>.</td>
<td></td>
</tr>
<tr>
<td><strong>Repository</strong>: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see <a href="#">Talend Studio User Guide</a>.</td>
<td></td>
</tr>
<tr>
<td><strong>Table Name</strong></td>
<td>Name of the table to be processed.</td>
</tr>
<tr>
<td><strong>Query type</strong></td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in</strong>: Fill in the query statement manually or build it graphically using the SQLBuilder.</td>
<td></td>
</tr>
<tr>
<td><strong>Repository</strong>: Select the relevant query stored in the Repository. The <strong>Query</strong> field is filled in accordingly.</td>
<td></td>
</tr>
<tr>
<td><strong>Guess Query</strong></td>
<td>Click this button to generate a query that corresponds to your table schema in the <strong>Query</strong> field.</td>
</tr>
<tr>
<td>-----------------</td>
<td>--------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>Query</strong></td>
<td>Enter your DB query taking care to sequence the fields properly in order to match the schema definition.</td>
</tr>
<tr>
<td><strong>Die on error</strong></td>
<td>This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a <strong>Row &gt; Rejects</strong> link.</td>
</tr>
</tbody>
</table>

### Advanced settings

| **Propagate QUERY’s recordset** | Select this check box to insert the result of the query into a **COLUMN** of the current flow. Select this column from the **use column** list.  

**Note:**   
This option allows the component to have a different schema from that of the preceding component. Moreover, the column that holds the QUERY’s recordset should be set to the type of **Object** and this component is usually followed by **tParseRecordSet**. |
|-------------------|--------------------------------------------------------------------------------------------------|
| **Use PreparedStatement** | Select this check box if you want to query the database using a PreparedStatement. In the **Set PreparedStatement Parameter** table, define the parameters represented by “?” in the SQL instruction of the **Query** field in the **Basic Settings** tab.  

**Parameter Index:** Enter the parameter position in the SQL instruction.  

**Parameter Type:** Enter the parameter type.  

**Parameter Value:** Enter the parameter value.  

**Note:**  
This option is very useful if you need to execute the same query several times. Performance levels are increased |
| **Commit every** | Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions. |
| **tStat Catcher Statistics** | Select this check box to collect log data at the component level. |

### Global Variables

| **Global Variables** | **QUERY:** the query statement being processed. This is a Flow variable and it returns a string.  

**ERROR_MESSAGE:** the error message generated by the component when an error occurs. This is an After variable. |
|---------------------|--------------------------------------------------------------------------------------------------|
variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component offers the flexibility of the DB query and covers all possible SQL queries.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limitation</td>
<td>Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the <strong>Install</strong> button on the <strong>Component</strong> tab view. You can also find out and add all missing JARs easily on the <strong>Modules</strong> tab in the <strong>Integration</strong> perspective of your studio. You can find more details about how to install external modules in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
</tbody>
</table>

### Related scenario

For related topics, see:

- **Scenario: Combining two flows for selective output** on page 2558
- **Procedure** on page 625.
- **Scenario: Removing and regenerating a MySQL table index** on page 2552.
Load data into a Vertica database table from a local file using the Vertica COPY SQL statement.

For more information about the Vertica COPY SQL statement, see COPY.

The tVerticaOutputBulk component and the tVerticaBulkExec component are generally used together as parts of a two-step process. In the first step, an output file is generated. In the second step, the file is used in a bulk load operation to feed a database. These two steps are fused together in the tVerticaOutputBulkExec component. The advantage of using two separate components is that the data can be transformed before it is loaded into the database.

**tVerticaBulkExec Standard properties**

These properties are used to configure tVerticaBulkExec running in the Standard Job framework.

The Standard tVerticaBulkExec component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
<tr>
<td>Property Type</td>
<td>Select the way the connection details will be set.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-In:</strong> The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository:</strong> The connection details stored centrally in Repository &gt; Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up Repository Content dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in.</td>
</tr>
<tr>
<td>DB Version</td>
<td>Select the version of the database.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:</td>
</tr>
</tbody>
</table>
1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.

2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>Host</th>
<th>The IP address or hostname of the database.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>The listening port number of the database.</td>
</tr>
<tr>
<td>Database</td>
<td>The name of the database.</td>
</tr>
<tr>
<td>Schema</td>
<td>The schema of the database.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>The database user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Table</td>
<td>The name of the table into which data will be written.</td>
</tr>
</tbody>
</table>

**Action on table**
- **Default**: No operation is carried out.
- **Drop and create table**: The table is removed and created again.
- **Create table**: The table does not exist and gets created.
- **Create table if does not exist**: The table is created if it does not exist.
- **Drop table if exist and create**: The table is removed if it already exists and created again.
- **Clear table**: The table content is deleted. You have the possibility to rollback the operation.

**Schema and Edit schema**
- **Built-In**: You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.
When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Click **Edit schema** to make changes to the schema. Note that if you make changes, the schema automatically becomes built-in.

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.

<table>
<thead>
<tr>
<th>Use schema columns for Copy</th>
<th>Select this check box to use the column option in the COPY statement so that you can restrict the load to one or more specified columns in the table. For more information, see the Vertica COPY SQL Statement.</th>
</tr>
</thead>
<tbody>
<tr>
<td>File Name</td>
<td>The path to the file from which data will be loaded. The file should be located on the same machine where the Studio is installed or where the Job using this component is deployed. This property is available only when there is no input flow.</td>
</tr>
<tr>
<td>Compression mode</td>
<td>Select the compression mode for the file from which data will be loaded. This property is available only when you are using Vertica 6.0 and later.</td>
</tr>
</tbody>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th>Additional JDBC Parameters</th>
<th>Specify additional JDBC parameters for the database connection being created. This property is not available when the Use an existing connection check box is selected.</th>

<tr>
<td><strong>Reject not fitted values</strong></td>
<td>Select this check box to reject data rows of type char, varchar, binary, and varbinary if they do not fit the target table. This property is available only when you are using Vertica 6.0 and later.</td>
</tr>
<tr>
<td><strong>Maximum number of rejected records</strong></td>
<td>Select this check box and in the field displayed next to it, specify the maximum number of records that can be rejected before a load fails.</td>
</tr>
</tbody>
</table>
This property is available only when you are using Vertica 6.0 and later.

**Stop and rollback if any row is rejected**
Select this check box to stop and roll back a load without loading any data if any row is rejected.
This property is available only when you are using Vertica 6.0 and later.

**Don't commit**
Select this check box to perform a bulk load transaction without committing the results automatically. This is useful if you want to execute multiple bulk loads in a single transaction.
This property is available only when you are using Vertica 6.0 and later.

**Rejected data file**
Specify the file into which rejected rows will be written.
This property is available only when Bulk insert is selected from the Action on data drop-down list.

**Exception log file**
Specify the file into which the exception log will be written. This log explains why each rejected row was rejected.
This property is available only when Bulk insert is selected from the Action on data drop-down list.

**tStatCatcher Statistics**
Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

**Global Variables**

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACCEPTED_ROW_NUMBER</td>
<td>The number of rows loaded into the database. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>REJECTED_ROW_NUMBER</td>
<td>The number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>ERROR_MESSAGE</td>
<td>The error message generated by the component when an error occurs. This is an After variable and it returns a string.</td>
</tr>
</tbody>
</table>

**Usage**

**Usage rule**
Talend Studio and the Vertica database create very fast and affordable data warehouse and data mart applications. For more information about how to configure Talend Studio to connect to Vertica, see Talend and HP Vertica Tips and Techniques.
You can use this component in either of the following two ways to write data into Vertica.
- It can be used as a Standalone component of a Subjob to write data into Vertica from a file generated by a tVerticaOutputBulk component.
You can link a tFileInputRaw component to it via a Row > Main connection to feed data into Vertica. In this way, the tFileInputRaw component should be in the Stream the file mode and there should be only one column of Object type defined in its schema.

**Dynamic settings**

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

**Related scenarios**

For related topics, see:

- Scenario: Inserting transformed data in MySQL database on page 2537.
- Scenario: Inserting data in bulk in MySQL database on page 2544.
- Scenario: Truncating and inserting file data into an Oracle database on page 2752.
### tVerticaClose

Closes an active connection to a Vertica database.

### tVerticaClose Standard properties

These properties are used to configure tVerticaClose running in the Standard Job framework.

The Standard tVerticaClose component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

#### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component List</td>
<td>Select the component in which the relevant reused connection is configured.</td>
</tr>
</tbody>
</table>

#### Advanced settings

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

#### Usage

**Usage rule**

This component is more commonly used with other tVertica* components, especially with the tVerticaConnection and tVerticaCommit components.

Talend Studio and the Vertica database create very fast and affordable data warehouse and data mart applications. For more information about how to configure Talend Studio to connect to Vertica, see Talend and HP Vertica Tips and Techniques.

**Dynamic settings**

Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.
Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenarios

No scenario is available for the Standard version of this component yet.
tVerticaCommit

Commits in one go a global transaction using a unique connection instead of doing that on every row or every batch and thus provides gain in performance.

### tVerticaCommit Standard properties

These properties are used to configure tVerticaCommit running in the Standard Job framework.

The Standard tVerticaCommit component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component List</td>
<td>Select the component in which the relevant reused connection is configured.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Select this check box to close the database connection once the component has performed its task. Clear this check box to continue to use the selected connection once the component has performed its task. If this component is linked to your Job via a Row &gt; Main connection, your data will be committed row by row. In this case, do not select the Close connection check box or your connection will be closed before the end of the first row commit.</td>
</tr>
</tbody>
</table>

### Advanced settings

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

### Usage

**Usage rule**

This component is more commonly used with other tVertica* components, especially with the tVerticaConnection and tVerticaRollback components.

Talend Studio and the Vertica database create very fast and affordable data warehouse and data mart applications. For more information about how to
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |

**Related scenario**

For tVerticaCommit related scenario, see Scenario: Inserting data in mother/daughter tables on page 2476
tVerticaConnection

Opens a connection to the specified database that can then be reused in the subsequent subjob or subjobs.

**tVerticaConnection Standard properties**

These properties are used to configure tVerticaConnection running in the Standard Job framework. The Standard tVerticaConnection component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see *Dynamic database components* on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Property Type</strong></td>
<td>Select the way the connection details will be set.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Built-In</strong>: The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Repository</strong>: The connection details stored centrally in Repository &gt; Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up Repository Content dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in.</td>
</tr>
<tr>
<td><strong>DB Version</strong></td>
<td>Select the version of the database.</td>
</tr>
<tr>
<td><strong>Host</strong></td>
<td>The IP address or hostname of the database.</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>The listening port number of the database.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>The name of the database.</td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>The schema of the database.</td>
</tr>
<tr>
<td><strong>Username</strong> and <strong>Password</strong></td>
<td>The database user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
</tbody>
</table>
**Additional JDBC Parameters**

Specify additional JDBC parameters for the database connection being created.

**Use or register a shared DB Connection**

Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the **Shared DB Connection Name** field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child.

This option is incompatible with the **Use dynamic job** and **Use an independent process to run subjob** options of the **tRunJob** component. Using a shared connection together with a **tRunJob** component with either of these two options enabled will cause your Job to fail.

**Advanced settings**

**Auto Commit**

Select this check box to commit any changes to the database automatically upon the transaction.

With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component.

Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component.

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

**Usage**

**Usage rule**

This component is more commonly used with other tVertica components, especially with the **tVerticaCommit** and **tVerticaRollback** components.

Talend Studio and the Vertica database create very fast and affordable data warehouse and data mart applications. For more information about how to configure **Talend Studio** to connect to Vertica, see **Talend and HP Vertica Tips and Techniques**.
Related scenario

For `tVerticaConnection` related scenario, see `tMysqlConnection` on page 2475.
tVerticaInput

Retrieves data from a Vertica database table based on a SQL query.

**tVerticaInput Standard properties**

These properties are used to configure tVerticaInput running in the Standard Job framework.

The Standard tVerticaInput component belongs to the Databases family.

The component in this framework is generally available.

Note:

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
</table>
| Property Type | Select the way the connection details will be set.  
| | • **Built-In**: The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.  
| | • **Repository**: The connection details stored centrally in **Repository > Metadata** will be reused by this component. You need to click the [...] button next to it and in the pop-up **Repository Content** dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in. |
| ![icon] | Click the icon to open a database connection wizard and store the database connection parameters you set in the component.  
| | For more information about setting up and storing database connection parameters, see Talend Studio User Guide. |
| DB Version | Select the version of the database. |
| Use an existing connection | Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined.  
| | When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:  
| | 1. In the parent level, register the database connection to be shared in the **Basic settings** view of the |
connection component which creates that very database connection.

2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th>Host</th>

**Global Variables**

| **NB_LINE** | The number of rows processed. This is an After variable and it returns an integer. |
| **QUERY** | The query statement being processed. This is a Flow variable and it returns a string. |
| **ERROR_MESSAGE** | The error message generated by the component when an error occurs. This is an After variable and it returns a string. |

**Usage**

**Usage rule**

This component covers all possible SQL queries for the Vertica database.

Talend Studio and the Vertica database create very fast and affordable data warehouse and data mart applications. For more information about how to configure Talend Studio to connect to Vertica, see Talend and HP Vertica Tips and Techniques.

**Dynamic settings**

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose...
your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

### Related scenarios

For related scenarios, see:

- Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489.
tVerticaOutput

Inserts, updates, deletes, or copies data from an incoming flow into a Vertica database table.

**tVerticaOutput Standard properties**

These properties are used to configure tVerticaOutput running in the Standard Job framework.

The Standard tVerticaOutput component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

</tr>
</tbody>
</table>
connection component which creates that very database connection.

2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>Host</th>
<th>The IP address or hostname of the database.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>The listening port number of the database.</td>
</tr>
<tr>
<td>Database</td>
<td>The name of the database.</td>
</tr>
<tr>
<td>Schema</td>
<td>The schema of the database.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>The database user authentication data.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [..] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Table</td>
<td>The name of the table into which data will be written.</td>
</tr>
<tr>
<td>Action on table</td>
<td>Select an operation to be performed on the table defined.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Default</strong>: No operation is carried out.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Drop and create table</strong>: The table is removed and created again.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Create table</strong>: The table does not exist and gets created.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Create table if does not exist</strong>: The table is created if it does not exist.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Drop table if exist and create</strong>: The table is removed if it already exists and created again.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Clear table</strong>: The table content is deleted. You have the possibility to rollback the operation.</td>
</tr>
<tr>
<td>Use &quot;drop cascade&quot;</td>
<td>Select this check box to remove all objects related to the table which will be dropped.</td>
</tr>
<tr>
<td></td>
<td>This property is available only when a table drop related option is selected from the <strong>Action on table</strong> list.</td>
</tr>
<tr>
<td>Action on data</td>
<td>Select an action to be performed on data of the table defined.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Insert</strong>: Add new entries to the table. If duplicates are found, job stops.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Update</strong>: Make changes to existing entries.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Insert or update</strong>: Insert a new record. If the record with the given reference already exists, an update would be made.</td>
</tr>
</tbody>
</table>
- **Update or insert**: Update the record with the given reference. If the record does not exist, a new record would be inserted.

- **Delete**: Remove entries corresponding to the input flow.

- **Copy**: Read data from a text file and insert tuples of entries into the WOS (Write Optimized Store) or directly into the ROS (Read Optimized Store). This option is ideal for bulk loading. For further information, see Vertica SQL Reference Manual.

It is necessary to specify at least one column as a primary key on which the **Update** and **Delete** operations are based. You can do that by clicking **Edit Schema** and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the **Advanced settings** view where you can simultaneously define primary keys for the **Update** and **Delete** operations. To do that, select the **Use field options** check box and then in the **Update Key** column, select the check boxes next to the column names you want to use as a base for the **Update** operation. Do the same in the **Deletion key** column for the **Delete** operation.

**Schema and Edit schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word **line** when naming the fields.

- **Built-In**: You create and store the schema locally for this component only. Related topic: see **Talend Studio User Guide**.

- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see **Talend Studio User Guide**.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Click **Edit schema** to make changes to the schema. Note that if you make changes, the schema automatically becomes built-in.

- **View schema**: choose this option to view the schema only.

- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.

- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No**.
upon completion and choose this schema metadata again in the [Repository Content] window.

<table>
<thead>
<tr>
<th><strong>Die on error</strong></th>
<th>Select the check box to stop the execution of the Job when an error occurs. Clear the check box to skip any rows on error and complete the process for error-free rows. When errors are skipped, you can collect the rows on error using a Row &gt; Reject connection.</th>
</tr>
</thead>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th><strong>Additional JDBC Parameters</strong></th>
<th>Specify additional JDBC parameters for the database connection being created. This property is not available when the Use an existing connection check box is selected.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Abort on error</strong></td>
<td>Select this check box to stop the Copy operation if any row is rejected and roll back the operation. Thus no data is loaded. This property is available only when COPY is selected from the Action on data drop-down list.</td>
</tr>
<tr>
<td><strong>Maximum rejects</strong></td>
<td>Type in a number to set the REJECTMAX command used by Vertica, which indicates the upper limit on the number of logical records to be rejected before a load fails. If not specified or if value is 0, an unlimited number of rejections are allowed. This property is available only when COPY is selected from the Action on data drop-down list.</td>
</tr>
<tr>
<td><strong>No commit</strong></td>
<td>Select this check box to prevent the current transaction from committing automatically. This property is available only when COPY is selected from the Action on data drop-down list.</td>
</tr>
<tr>
<td><strong>Exception file</strong></td>
<td>Type in the path to, or browse to the file in which messages are written indicating the input line number and the reason for each rejected data record. This property is available only when COPY is selected from the Action on data drop-down list.</td>
</tr>
<tr>
<td><strong>Exception file node</strong></td>
<td>Type in the node of the exception file. If not specified, operations default to the query's initiator node. This property is available only when COPY is selected from the Action on data drop-down list.</td>
</tr>
<tr>
<td><strong>Rejected data file</strong></td>
<td>Type in the path to, or browse to the file in which to write rejected rows. This file can then be edited to resolve problems and reloaded. This property is available only when COPY is selected from the Action on data drop-down list.</td>
</tr>
</tbody>
</table>
| **Rejected data file node** | Type in the node of the rejected data file. If not specified, operations default to the query’s initiator node.  
This property is available only when **COPY** is selected from the **Action on data** drop-down list. |
| **Commit every** | Specify the number of rows to be processed before committing batches of rows together into the database.  
This option ensures transaction quality (but not rollback) and, above all, better performance at executions. |
| **Use batch mode** | Select this check box to activate the batch mode for data processing, and in the **Batch size** field displayed, specify the number of records to be processed in each batch.  
This property is available only when **Insert**, **Update**, **Delete** or **Copy** is selected from the **Action on data** drop-down list. |
| **Additional Columns** | This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing. It is not offered if you create (with or without drop) a database table.  
- **Name**: Type in the name of the schema column to be altered or inserted as new column.  
- **DataType**: Type in the data type for the new column.  
- **SQL expression**: Type in the SQL statement to be executed in order to alter or insert the relevant column data.  
- **Position**: Select **Before**, **Replace** or **After** following the action to be performed on the reference column.  
- **Reference column**: Select a column of reference that the component can use to place or replace the new or altered column. |
| **Use field options** | Select the check box for the corresponding column to customize a request, particularly if multiple actions are being carried out on the data.  
- **Update Key**: Select the check box for the corresponding column based on which the data is updated.  
- **Deletion Key**: Select the check box for the corresponding column based on which the data is deleted.  
- **Updatable**: Select the check box if the data in the corresponding column can be updated.  
- **Insertable**: Select the check box if the data in the corresponding column can be inserted. |
| **Enable debug mode** | Select this check box to display each step during processing entries in a database. |
### Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NB_LINE</td>
<td>The number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>NB_LINE_COPIED</td>
<td>The number of rows copied. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>NB_LINE_DELETED</td>
<td>The number of rows deleted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>NB_LINE_INSERTED</td>
<td>The number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>NB_LINE_REJECTED</td>
<td>The number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>NB_LINE_UPDATED</td>
<td>The number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>ERROR_MESSAGE</td>
<td>The error message generated by the component when an error occurs. This is an After variable and it returns a string.</td>
</tr>
</tbody>
</table>

### Usage

#### Usage rule

This component is usually used as an output component. It allows you to carry out actions on a table or on data of a table in a Vertica database. It also allows you to create a reject flow using a **Row > Rejects** link to filter data in error. For an example of **tMysqlOutput** in use, see **Scenario: Retrieving data in error with a Reject link** on page 2529.

Talend Studio and the Vertica database create very fast and affordable data warehouse and data mart applications. For more information about how to configure **Talend Studio** to connect to Vertica, see **Talend and HP Vertica Tips and Techniques**.

#### Dynamic settings

Click the `[+]` button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple...
connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see **Scenario: Reading data from databases through context-based dynamic connections** on page 2497 and **Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters** on page 489.

For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

---

**Related scenarios**

For **tVerticaOutput** related topics, see:

- **Scenario: Inserting a column and altering data using tMysqlOutput** on page 2521.
tVerticaOutputBulk

Prepares a file to be used by the tVerticaBulkExec component to feed a Vertica database.

The tVerticaOutputBulk component and the tVerticaBulkExec component are generally used together as parts of a two step process. In the first step, an output file is generated. In the second step, the file is used in a bulk load operation to feed a database. These two steps are fused together in the tVerticaOutputBulkExec component. The advantage of using two separate components is that the data can be transformed before it is loaded into the database.

tVerticaOutputBulk Standard properties

These properties are used to configure tVerticaOutputBulk running in the Standard Job framework.

The Standard tVerticaOutputBulk component belongs to the Databases family.

The component in this framework is generally available.

Note:
This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>

</tr>
<tr>
<td>Schema and Edit schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
</tbody>
</table>
- **Built-In**: You create and store the schema locally for this component only. Related topic: see *Talend Studio User Guide*.

- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see *Talend Studio User Guide*.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

Click **Edit schema** to make changes to the schema. Note that if you make changes, the schema automatically becomes built-in.

- **View schema**: choose this option to view the schema only.

- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.

- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **[Repository Content]** window.

### Advanced settings

<table>
<thead>
<tr>
<th><strong>Row Separator</strong></th>
<th>The separator used to identify the end of a row.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Include Header</strong></td>
<td>Select this check box to include the column header to the file.</td>
</tr>
<tr>
<td><strong>Encoding</strong></td>
<td>Select an encoding method from the list, or select <strong>CUSTOM</strong> and define it manually. This field is compulsory for database data handling.</td>
</tr>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to gather the Job processing metadata at the Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

### Global Variables

<table>
<thead>
<tr>
<th><strong>NB_LINE</strong></th>
<th>The number of rows processed. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>ERROR_MESSAGE</strong></td>
<td>The error message generated by the component when an error occurs. This is an After variable and it returns a string.</td>
</tr>
</tbody>
</table>
### Usage

| Usage rule | This component is more commonly used with the **tVerticaBulkExec** component. Used together, they offer gains in performance while feeding a Vertica database. Talend Studio and the Vertica database create very fast and affordable data warehouse and data mart applications. For more information about how to configure *Talend Studio* to connect to Vertica, see *Talend and HP Vertica Tips and Techniques*. |

### Related scenarios

For use cases in relation with **tVerticaOutputBulk**, see the following scenarios:

- **Scenario: Inserting transformed data in MySQL database** on page 2537.
- **Scenario: Inserting data in bulk in MySQL database** on page 2544.
tVerticaOutputBulkExec

Receives data from a preceding component, writes data into a local file, and loads data into a Vertica database from the file using the Vertica COPY SQL statement.

For more information about the Vertica COPY SQL statement, see COPY.

The tVerticaOutputBulk component and the tVerticaBulkExec component are generally used together as parts of a two step process. In the first step, an output file is generated. In the second step, the file is used in a bulk load operation to feed a database. These two steps are fused together in the tVerticaOutputBulkExec component. The advantage of using two separate components is that the data can be transformed before it is loaded into the database.

tVerticaOutputBulkExec Standard properties

These properties are used to configure tVerticaOutputBulkExec running in the Standard Job framework.

The Standard tVerticaOutputBulkExec component belongs to the Databases family.

The component in this framework is generally available.

Note:

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td>Property Type</td>
<td>Select the way the connection details will be set.</td>
</tr>
<tr>
<td></td>
<td>- <em>Built-In</em>: The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.</td>
</tr>
<tr>
<td></td>
<td>- <em>Repository</em>: The connection details stored centrally in <strong>Repository &gt; Metadata</strong> will be reused by this component. You need to click the [...] button next to it and in the pop-up <strong>Repository Content</strong> dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in.</td>
</tr>
<tr>
<td>DB Version</td>
<td>Select the version of the database.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

When a Job contains the parent Job and the child Job, if you need to share an existing connection between the
two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.

2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th>Host</th>
<th>The IP address or hostname of the database.</th>
</tr>
</thead>
<tbody>
<tr>

<td>Select an operation to be performed on the table defined.</td>
</tr>
<tr>
<td>• Default</td>
<td>No operation is carried out.</td>
</tr>
<tr>
<td>• Drop and create table</td>
<td>The table is removed and created again.</td>
</tr>
<tr>
<td>• Create table</td>
<td>The table does not exist and gets created.</td>
</tr>
<tr>
<td>• Create table if does not exist</td>
<td>The table is created if it does not exist.</td>
</tr>
<tr>
<td>• Drop table if exist and create</td>
<td>The table is removed if it already exists and created again.</td>
</tr>
<tr>
<td>• Clear table</td>
<td>The table content is deleted. You have the possibility to rollback the operation.</td>
</tr>
</tbody>
</table>
| Schema and Edit schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the
next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

- **Built-In**: You create and store the schema locally for this component only. Related topic: see *Talend Studio User Guide*.

- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see *Talend Studio User Guide*.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Click **Edit schema** to make changes to the schema. Note that if you make changes, the schema automatically becomes built-in.

- **View schema**: choose this option to view the schema only.

- **Change to built-in property**: choose this option to change the schema to *Built-in* for local changes.

- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the *Repository Content* window.

<table>
<thead>
<tr>
<th>File Name</th>
<th>The path to the file to be generated. This file is generated on the same machine where your Studio is installed or where your Job using this component is deployed.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Append</td>
<td>Select this check box to add new rows at the end of the file.</td>
</tr>
<tr>
<td>Use schema columns for Copy</td>
<td>Select this check box to use the column option in the COPY statement so that you can restrict the load to one or more specified columns in the table. For more information, see the Vertica COPY SQL Statement.</td>
</tr>
</tbody>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th>Additional JDBC Parameters</th>
<th>Specify additional JDBC parameters for the database connection being created. This property is not available when the <strong>Use an existing connection</strong> check box is selected.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stream name</td>
<td>The stream name of a load, which helps identify a particular load.</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------------------</td>
<td>------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>Write to ROS (Read Optimized Store)</strong></td>
<td>Select this check box to store data in a physical storage area, in order to optimize the reading, as the data is compressed and pre-sorted.</td>
</tr>
<tr>
<td><strong>Exit Job if no row was loaded</strong></td>
<td>The Job automatically stops if no row has been loaded.</td>
</tr>
<tr>
<td><strong>Missing columns as null</strong></td>
<td>Select this check box to insert NULL values for the missing columns when there is insufficient data to match the columns specified in the schema. This property is available only when you are using Vertica 6.0 and later.</td>
</tr>
<tr>
<td><strong>Skip Header</strong></td>
<td>Select this check box and in the field displayed next to it, specify the number of records to skip in the file. This property is available only when you are using Vertica 6.0 and later.</td>
</tr>
<tr>
<td><strong>Record terminator</strong></td>
<td>Select this check box and in the field displayed next to it, specify the literal character string used to indicate the end of each record in the file. This property is available only when you are using Vertica 6.0 and later.</td>
</tr>
<tr>
<td><strong>Enclosed by character</strong></td>
<td>Select this check box to set the character within which data is enclosed. This property is available only when you are using Vertica 6.0 and later.</td>
</tr>
<tr>
<td><strong>Field Separator</strong></td>
<td>The character, string or regular expression to separate fields.</td>
</tr>
<tr>
<td><strong>Null String</strong></td>
<td>The string displayed to indicate that the value is null.</td>
</tr>
<tr>
<td><strong>Include Header</strong></td>
<td>Select the check box to include the column header to the file.</td>
</tr>
<tr>
<td><strong>Encoding</strong></td>
<td>Select an encoding method from the list, or select <strong>CUSTOM</strong> and define it manually. This field is compulsory for database data handling.</td>
</tr>
<tr>
<td><strong>Reject not fitted values</strong></td>
<td>Select this check box to reject data rows of type char, varchar, binary, and varbinary if they do not fit the target table. This property is available only when you are using Vertica 6.0 and later.</td>
</tr>
<tr>
<td><strong>Maximum number of rejected records</strong></td>
<td>Select this check box and in the field displayed next to it, specify the maximum number of records that can be rejected before a load fails. This property is available only when you are using Vertica 6.0 and later.</td>
</tr>
</tbody>
</table>
Stop and rollback if any row is rejected

Select this check box to stop and roll back a load without loading any data if any row is rejected.
This property is available only when you are using Vertica 6.0 and later.

Don't commit

Select this check box to perform a bulk load transaction without committing the results automatically. This is useful if you want to execute multiple bulk loads in a single transaction.
This property is available only when you are using Vertica 6.0 and later.

Rejected data file

Specify the file into which rejected rows will be written.
This property is available only when Bulk insert is selected from the Action on data drop-down list.

Exception log file

Specify the file into which the exception log will be written. This log explains why each rejected row was rejected.
This property is available only when Bulk insert is selected from the Action on data drop-down list.

tStatCatcher Statistics

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACCEPTED_ROW_NUMBER</td>
<td>The number of rows loaded into the database. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>REJECTED_ROW_NUMBER</td>
<td>The number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>ERROR_MESSAGE</td>
<td>The error message generated by the component when an error occurs. This is an After variable and it returns a string.</td>
</tr>
</tbody>
</table>

**Usage**

**Usage rule**

This component is mainly used when no particular transformation is required on the data to be loaded into the database.
Talend Studio and the Vertica database create very fast and affordable data warehouse and data mart applications. For more information about how to configure Talend Studio to connect to Vertica, see Talend and HP Vertica Tips and Techniques.

**Related scenarios**

For use cases in relation with **tVerticaOutputBulkExec**, see the following scenarios:
• **Scenario: Inserting transformed data in MySQL database** on page 2537.
• **Scenario: Inserting data in bulk in MySQL database** on page 2544.
tVerticaRollback

Cancels the transaction commit in the Vertica database.

**tVerticaRollback Standard properties**

These properties are used to configure tVerticaRollback running in the Standard Job framework.

The Standard tVerticaRollback component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component List</td>
<td>Select the component in which the relevant reused connection is configured.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Select this check box to close the database connection once the component has performed its task. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Usage**

| Usage rule | This component is more commonly used with other tVertica* components, especially with the tVerticaConnection and tVerticaCommit components. Talend Studio and the Vertica database create very fast and affordable data warehouse and data mart applications. For more information about how to configure Talend Studio to connect to Vertica, see Talend and HP Vertica Tips and Techniques. |
| Dynamic settings | Click the [*] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful |
when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

### Related scenario

For **tVerticaRollback** related scenario, see Scenario: Rollback from inserting data in mother/daughter tables on page 2480.
tVerticaRow

Executes a Vertica SQL statement against a database table.

**tVerticaRow Standard properties**

These properties are used to configure tVerticaRow running in the Standard Job framework.

The Standard tVerticaRow component belongs to the Databases family.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property Type</td>
<td>Select the way the connection details will be set.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Built-In</strong>: The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Repository</strong>: The connection details stored centrally in <strong>Repository &gt; Metadata</strong> will be reused by this component. You need to click the [...] button next to it and in the pop-up <strong>Repository Content</strong> dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in.</td>
</tr>
<tr>
<td>DB Version</td>
<td>Select the version of the database.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td></td>
<td>When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:</td>
</tr>
<tr>
<td></td>
<td>1. In the parent level, register the database connection to be shared in the <strong>Basic settings</strong> view of the connection component which creates that very database connection.</td>
</tr>
<tr>
<td></td>
<td>2. In the child level, use a dedicated connection component to read that registered database connection.</td>
</tr>
</tbody>
</table>
For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th><strong>Host</strong></th>
<th>The IP address or hostname of the database.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Port</strong></td>
<td>The listening port number of the database.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>The name of the database.</td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>The schema of the database.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>The database user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
</tbody>
</table>

**Schema and Edit schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

- **Built-In**: You create and store the schema locally for this component only. Related topic: see *Talend Studio User Guide*.
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see *Talend Studio User Guide*.

Click **Edit schema** to make changes to the schema. Note that if you make changes, the schema automatically becomes built-in.

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the [Repository Content] window.

**Table Name**

The name of the table to be processed.

**Query Type and Query**

Specify the database query statement paying particularly attention to the properly sequence of the fields which must correspond to the schema definition.

- **Built-In**: Fill in the query statement in the Query field manually or click the [...] button next to the Query field to build the statement graphically using the SQLBuilder.
### tVerticaRow

- **Repository**: Select the relevant query stored in the Repository by clicking the [...] button next to it and in the pop-up Repository Content dialog box, select the query to be used, and the **Query** field will be automatically filled in.

### Die on error

Select the check box to stop the execution of the Job when an error occurs.

Clear the check box to skip any rows on error and complete the process for error-free rows.

When errors are skipped, you can collect the rows on error using a **Row > Reject** connection.

### Advanced settings

<table>
<thead>
<tr>
<th>Additional JDBC Parameters</th>
<th>Specify additional JDBC parameters for the database connection being created. This property is not available when the <strong>Use an existing connection</strong> check box is selected.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Propagate QUERY’s recordset</td>
<td>Select this check box to propagate the result of the query to the output flow. From the <strong>use column</strong> list displayed, you need to select a column into which the query result will be inserted. This option allows the component to have a different schema from that of the preceding component. Moreover, the column that holds the query’s recordset should be set to the Object type and this component is usually followed by a <strong>tParseRecordSet</strong> component.</td>
</tr>
<tr>
<td>Use PreparedStatement</td>
<td>Select this check box if you want to query the database using a prepared statement. In the <strong>Set PreparedStatement Parameters</strong> table displayed, specify the value for each parameter represented by a question mark ? in the SQL statement defined in the <strong>Query</strong> field.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Parameter Index</strong>: the position of the parameter in the SQL statement.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Parameter Type</strong>: the data type of the parameter.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Parameter Value</strong>: the value of the parameter. For a related use case of this property, see Scenario: Using PreparedStatement objects to query data on page 2553.</td>
</tr>
<tr>
<td>Commit every</td>
<td>Specify the number of rows to be processed before committing batches of rows together into the database. This option ensures transaction quality (but not rollback) and, above all, better performance at executions.</td>
</tr>
<tr>
<td>tStatCatcher Statistics</td>
<td>Select this check box to gather the Job processing metadata at the Job level as well as at each component level.</td>
</tr>
</tbody>
</table>
Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NB_LINE_DELETED</td>
<td>The number of rows deleted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>NB_LINE_INSERTED</td>
<td>The number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>NB_LINE_UPDATED</td>
<td>The number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>QUERY</td>
<td>The query statement being processed. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td>ERROR_MESSAGE</td>
<td>The error message generated by the component when an error occurs. This is an After variable and it returns a string.</td>
</tr>
</tbody>
</table>

Usage

Usage rule

This component offers the flexibility of the DB query and covers all possible SQL queries.

Talend Studio and the Vertica database create very fast and affordable data warehouse and data mart applications. For more information about how to configure Talend Studio to connect to Vertica, see Talend and HP Vertica Tips and Techniques.

Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenario

For related topics, see:
• **Scenario: Combining two flows for selective output** on page 2558
• **Procedure** on page 625.
• **Scenario: Removing and regenerating a MySQL table index** on page 2552.
tVerticaSCD

Tracks and reflects data changes in a dedicated Vertica SCD table.

**tVerticaSCD Standard properties**

These properties are used to configure tVerticaSCD running in the Standard Job framework.

The Standard tVerticaSCD component belongs to the Business Intelligence and the Databases families.

The component in this framework is generally available.

**Note:**

This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection.

For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property Type</td>
<td>Select the way the connection details will be set.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Built-In</strong>: The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Repository</strong>: The connection details stored centrally in Repository &gt; Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up Repository Content dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in.</td>
</tr>
<tr>
<td>DB Version</td>
<td>Select the version of the database.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.

2. In the child level, use a dedicated connection component to read that registered database connection.
For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>

<tr>
<td>tStatCatcher Statistics</td>
<td>Select this check box to gather the Job processing metadata at the Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

### Global Variables

<table>
<thead>
<tr>
<th>NB_LINE_INSERTED</th>
<th>The number of rows inserted. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td>NB_LINE_UPDATED</td>
<td>The number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>NB_LINE_REJECTED</td>
<td>The number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>ERROR_MESSAGE</td>
<td>The error message generated by the component when an error occurs. This is an After variable and it returns a string.</td>
</tr>
</tbody>
</table>
### Usage

| Usage rule | This component is usually used as an end component of a Job or Subjob and it always needs an input link. Talend Studio and the Vertica database create very fast and affordable data warehouse and data mart applications. For more information about how to configure Talend Studio to connect to Vertica, see Talend and HP Vertica Tips and Techniques. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Scenario: Reading data from databases through context-based dynamic connections on page 2497 and Scenario: Reading data from different MySQL databases using dynamically loaded connection parameters on page 489. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |
| Limitation | This component does not support using SCD type 0 together with other SCD types. |

### Related scenarios

For a similar scenario, see tMysqlSCD on page 2563.
tVtigerCRMInput

Extracts data from a module of a VtigerCRM database.

### tVtigerCRMInput Standard properties

These properties are used to configure tVtigerCRMInput running in the Standard Job framework.

The Standard tVtigerCRMInput component belongs to the Business family.

The component in this framework is generally available.

#### Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vtiger Version</td>
<td>Select the version of the Vtiger Web Services you want to use (either Vtiger 5.0 or Vtiger 5.1)</td>
</tr>
</tbody>
</table>

When the version to be used is Vtiger 5.0:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server Address</td>
<td>Type in the IP address of the VtigerCRM server</td>
</tr>
<tr>
<td>Port</td>
<td>Type in the Port number to access the server</td>
</tr>
<tr>
<td>Vtiger Path</td>
<td>Type in the path to access the VtigerCRM server</td>
</tr>
<tr>
<td>Username and Password</td>
<td>Type in the user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Version</td>
<td>Type in the version of VtigerCRM you are using.</td>
</tr>
<tr>
<td>Module</td>
<td>Select the relevant module in the list</td>
</tr>
<tr>
<td>Method</td>
<td>Select the relevant method in the list. The method specifies the action you can carry out on the VtigerCRM module selected.</td>
</tr>
</tbody>
</table>

### Schema and Edit Schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the
Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the [Repository Content] window.

In this component the schema is related to the Module selected.

When the version to be used to Vtiger 5.1:

<table>
<thead>
<tr>
<th><strong>Endpoint</strong></th>
<th>Type in the URL address of the invoked Web server.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Username</strong></td>
<td>Type in the user name to log in to the vTigerCRM.</td>
</tr>
<tr>
<td><strong>Access key</strong></td>
<td>Type in the access key for the user name.</td>
</tr>
<tr>
<td><strong>Query condition</strong></td>
<td>Type in the query to select the data to be extracted.</td>
</tr>
<tr>
<td><strong>Manual input of SQL query</strong></td>
<td>Manually type in your query in the corresponding field.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| **tStatCatcher Statistics** | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

**Global Variables**

| **Global Variables** | **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer. **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it. For further information about variables, see **Talend Studio User Guide**. |

**Usage**

| **Usage rule** | Usually used as a Start component. An output component is required. |
Related scenarios

No scenario is available for the Standard version of this component yet.
tVtigerCRMOoutput

Writes data into a module of a VtigerCRM database.

**tVtigerCRMOoutput Standard properties**

These properties are used to configure tVtigerCRMOoutput running in the Standard Job framework.
The Standard tVtigerCRMOoutput component belongs to the Business family.
The component in this framework is generally available.

**Basic settings**

Usage

| Usage rule | Used as an output component. An Input component is required. |

Related scenarios

No scenario is available for the Standard version of this component yet.
tWaitForFile

Iterates on a directory and triggers the next component when the defined condition is met.

This component is used to put the component connected with it in waiting state. It then triggers that
component when the defined file operation occurs in the specified directory.

tWaitForFile Standard properties

These properties are used to configure tWaitForFile running in the Standard Job framework.
The Standard tWaitForFile component belongs to the Orchestration family.
The component in this framework is generally available.

Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Time (in seconds) between iterations</td>
<td>Set the time interval in seconds between each two iterations.</td>
</tr>
<tr>
<td>Max. number of iterations (infinite loop if empty)</td>
<td>Set the maximum number of iterations on the specified directory.</td>
</tr>
<tr>
<td>Directory to scan</td>
<td>Specify the directory to iterate on.</td>
</tr>
<tr>
<td>File mask</td>
<td>Type in the file mask to filter the files to be monitored. To monitor a given file, type in the file name.</td>
</tr>
<tr>
<td>Include subdirectories</td>
<td>Select this check box to iterate also on the subdirectories.</td>
</tr>
<tr>
<td>Case sensitive</td>
<td>Select this check box to activate case sensitivity.</td>
</tr>
<tr>
<td>Include present file</td>
<td>Select this check box to include the file in use.</td>
</tr>
<tr>
<td>Trigger action when</td>
<td>Select one of the following trigger conditions:</td>
</tr>
<tr>
<td></td>
<td>a file is created: triggers the next component when a file is created.</td>
</tr>
<tr>
<td></td>
<td>a file is deleted: triggers the next component when a file is removed.</td>
</tr>
<tr>
<td></td>
<td>a file is updated: triggers the next component when a file is modified.</td>
</tr>
<tr>
<td></td>
<td>a file is created or updated or deleted: triggers the next component when a file is created, or removed, or modified.</td>
</tr>
<tr>
<td>Then</td>
<td>Select what to do with the iteration loop after the next component is triggered:</td>
</tr>
<tr>
<td></td>
<td>continue loop: continues iterating until the number of iterations reaches the defined maximum value.</td>
</tr>
<tr>
<td></td>
<td>exit loop: stops iterating immediately.</td>
</tr>
</tbody>
</table>
A schema is a row description, it defines the number of fields that will be processed and passed on to the next component. The schema of this component is **Built-in** and cannot be updated.

**Advanced Settings**

**Wait for file to be released Every (in ms)**

Select this check box so that the next component is triggered only after the file operation is completed.

**Global Variables**

**Global Variables**

- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

- **CURRENT_ITERATION**: the sequence number of the current iteration. This is a Flow variable and it returns an integer.

- **PRESENT_FILE**: the path and name of the present file. This is a Flow variable and it returns a string.

- **DELETED_FILE**: the path and name of the deleted file. This is a Flow variable and it returns a string.

- **CREATED_FILE**: the path and name of the created file. This is a Flow variable and it returns a string.

- **UPDATED_FILE**: the path and name of the updated file. This is a Flow variable and it returns a string.

- **FILENAME**: the name of the file being processed. This is a Flow variable and it returns a string.

- **NOT_UPDATED_FILE**: the path and name of the file that has not been updated. This is a Flow variable and it returns a string.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

**Usage**

**Usage rule**

This component plays the role of triggering the next component based on the defined condition. Therefore this component requires another component to be connected to it via a link.

**Connections**

Outgoing links (from this component to another):
Scenario 1: Waiting for a file to be created and stopping the iteration loop after a message is triggered

This scenario describes a Job that scans a directory and triggers a message showing file creation information on the console when a text file is created in that directory. Immediately after this, the scanning is ended, followed by another message showing the number of iterations finished.

Dropping and linking the components

Procedure
1. Drop three components from the Palette onto the design workspace: one tWaitForFile and two tJava components.
2. Connect tWaitForFile to the first tJava using a Row > Iterate connection.
3. Connect tWaitForFile to the second tJava using a Trigger > On Subjob Ok connection.

Configuring the components

Procedure
1. Double-click tWaitForFile to open its Basic settings view.
2. In the **Directory to scan** field, enter the directory to be scanned.

3. In the **File mask** field, enter "*.txt" to scan only text files.

4. From the **Trigger action when** drop-down list, select **a file is created** to trigger the first **tJava** when a text file is created.

5. From the **Then** drop-down list, select **exit loop** to stop the iteration loop immediately after the first **tJava** is triggered.

6. Double-click the first **tJava** to open its **Basic settings** view.

   ![tJava 1](image)

   In the **code** area, type in the following code:
   ```java
   System.out.println("A file was created at "+TalendDate.getCurrentDate());
   System.out.println("Name of the created file: "+(String)globalMap.get("tWaitForFile_1_CREATED_FILE"));
   ```

7. In the **code** area, type in the following code:
   ```java
   System.out.println("Iteration loop ended at " + TalendDate.getCurrentDate());
   System.out.println("Number of iterations finished: " + ((Integer)globalMap.get("tWaitForFile_1_CURRENT_ITERATION")));
   ```

8. Double-click the second **tJava** to open its **Basic settings** view.

9. In the **code** area, type in the following code:
   ```java
   System.out.println("\r\nIteration loop ended at " + TalendDate.getCurrentDate());
   System.out.println("Number of iterations finished: " + ((Integer)globalMap.get("tWaitForFile_1_CURRENT_ITERATION")));
   ```

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl+S** to save the Job.
2. Press **F6** to execute the Job.
3. Create a text file **exit.txt** in the defined directory.
When a text file is created, a message about file creation is displayed on the Run console. The iteration loop is ended immediately after that, followed by another message showing the time the iteration loop is ended and the number of iterations executed.

**Scenario 2: Waiting for a file to be created and continuing the iteration loop after a message is triggered**

Based on the previous scenario, this scenario describes a Job triggers a message on the console when a text file is created in the directory being scanned, without ending the scanning process immediately. The Job continues scanning the directory until the number of iterations reaches the defined maximum value.

**Procedure**

1. Double-click `tWaitForFile` to open its **Basic settings** view.

2. In the **Time (in seconds) between iterations** field, enter the time interval in seconds between each two iterations. In this example, it is set to 5.

3. In the **Max. number of iterations (infinite loop if empty)** field, enter the maximum number of iterations. In this example, it is set to 10.

4. From the **Then** drop-down list, select **continue loop** to continue the iteration loop after the message is triggered.

5. Press **Ctrl+S** to save the Job.

6. Press **F6** to execute the Job.
7. Create a text file `continue.txt` in the defined directory.

When a text file is created, a message about file creation is displayed on the Run console. The iteration loop is ended until the number of iterations reaches ten, followed by another message showing the time the iteration loop is ended and the number of iterations executed.
tWaitForSocket

Triggers a Job based on a defined condition.

tWaitForSocket component makes a loop on a defined port, to look for data, and triggers a subjob when the condition is met.

**tWaitForSocket Standard properties**

These properties are used to configure tWaitForSocket running in the Standard Job framework.
The Standard tWaitForSocket component belongs to the Orchestration family.
The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>Port</th>
<th>DB server listening port.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>End of line separator</strong></td>
<td>Enter the end of line separator to be used.</td>
</tr>
</tbody>
</table>
| **Then**      | Select the action to be carried out:  
|               | keep on listening  
|               | or  
|               | close socket |
| **Print client/server data** | Select this check box to display the client or server data. |

**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect the log data at a component level. |

**Global Variables**

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  
|                 | **INPUT_DATA**: the data transmitted by the client. This is a Flow variable and it returns a string.  
|                 | A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
|                 | To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
|                 | For further information about variables, see Talend Studio User Guide. |

4017
## Usage

### Usage rule

This is an input, trigger component for the subjob executed depending on the condition set. Hence, it needs to be connected to a subjob via an Iterate link.

### Connections

Outgoing links (from this component to another):

- **Row**: Iterate.
- **Trigger**: On Subjob Ok; On Subjob Error; Run if; On Component Ok; On Component Error.

Incoming links (from one component to this one):

- **Row**: Iterate.
- **Trigger**: On Subjob Ok; On Subjob Error; Run if; On Component Ok; On Component Error; Synchronize; Parallelize.

For further information regarding connections, see Talend Studio User Guide.

## Related scenarios

No scenario is available for the Standard version of this component yet.
tWaitForSqlData

Iterates on a given connection for insertion or deletion of rows and triggers a subjob when a condition linked to SQL data presence is met.

**tWaitForSqlData Standard properties**

These properties are used to configure tWaitForSqlData running in the Standard Job framework.

The Standard tWaitForSqlData component belongs to the Orchestration family.

The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Wait at each iteration (in seconds)</td>
<td>Set the time interval in seconds between each check for the sql data.</td>
</tr>
<tr>
<td>Max. iterations (infinite if empty)</td>
<td>Number of checks for sql data before the Jobs times out.</td>
</tr>
<tr>
<td>Use an existing connection/Component List</td>
<td>A connection needs to be open to allow the loop to check for sql data on the defined DB.</td>
</tr>
</tbody>
</table>

**Note:**

When a Job contains the parent Job and the child Job, Component list presents only the connection components in the same Job level, so if you need to use an existing connection from the other level, you can

From the available database connection component in the level where the current component is, select the **Use or register a shared DB connection** check box. For more information about this check box, see tMysqlConnection on page 2475 for the connection components according to the database you are using.

Otherwise, still in the level of the current component, deactivate the connection components and use **Dynamic settings** of the component to specify the intended connection manually. In this case, make sure the connection name is unique and distinctive all over through the two Job levels. For more information about **Dynamic settings**, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>

</table>

Equal to  Not Equal to  Greater than  Lower than  Greater or equal to  Lower or equal to
**Value**

- **Define the value to take into account.**

**Then**

- **Select the action to be carried out: either stop the iterations when the condition is met (exit loop) or continue the loop until the end of the max iteration number (continue loop).**

---

### Global Variables

**ERROR_MESSAGE:** the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

**CURRENT_ITERATION:** the sequence number of the current iteration. This is a Flow variable and it returns an integer.

**ROW_COUNT:** the number of rows detected in the table. This is a Flow variable and it returns an integer.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

---

### Usage

**Usage rule**

- Although this component requires a Connection component to open the DB access, it plays also the role of the start (or trigger) component of the subjob which gets executed under the condition described. Therefore this component requires a subjob to be connected to via an Iterate link.

---

### Scenario: Waiting for insertion of rows in a table

This scenario describes a Job reading a DB table and waiting for data to be put in this table in order for a subjob to be executed. When the condition of the data insertion in the table is met, then the subjob performs a Select* on the table and simply displays the content of the inserted data onto the standard console.
Drop the following components from the Palette onto the design workspace: tMySqlConnection, tWaitForSqlData, tMysqlInput, tLogRow.

Connect the tMySqlConnection component to the tWaitForSqlData using an OnSubjobOK link, available on the right-click menu.

Then connect the tWaitForSqlData component to the subjob using an Iterate link as no actual data is transferred in this part. Indeed, simply a loop is implemented by the tWaitForSqlData until the condition is met.

On the subjob to be executed if the condition is met, a tMysqlInput is connected to the standard console component, tLogRow. As the connection passes on data, use a Row main link.

Now, set the connection to the table to check at regular intervals. On the Basic Settings view of the tMysqlConnection Component tab, set the DB connection properties.

- Fill out the Host, Port, Database, Username, Password fields to open the connection to the Database table.
- Select the relevant Encoding if needed.
- Then select the tWaitForSqlData component, and on the Basic Setting view of the Component tab, set its properties.
- In the Wait at each iteration field, set the time in seconds you want to wait before the next iteration starts.
- In the Max iterations field, fill out the number of iterations max you want to have before the whole Job is forced to end.
- The tWaitForSqlData component requires a connection to be open in order to loop on the defined number of iteration. Select the relevant connection (if several) in the Component List combo box.
- In the Table to scan field, type in the name of the table in the DB to scan. In this example: test_datatypes.
• In the Trigger action when rowcount is and Value fields, select the condition to be met, for the subjob to be triggered. In this use case, the number of rows in the scanned table should be greater or equal to 1.

• In the Then field, select the action to be carried out when the condition is met before the number of iteration defined is reached. In this use case, as soon as the condition is met, the loop should be ended.

• Then set the subjob to be executed when the condition set is met. In this use case, the subjob simply selects the data from the scanned table and displays it on the console.

• Select the tMySqlInput component, and on the Basic Setting view of the Component tab, set the connection to the table.

  ![Connection Settings](image)

  - Use an existing connection check box selected.
  - Component list: tMysqlConnection_1.
  - Scheme: Repository.
  - Table Name: 'test_datatypes'.
  - Query Type: Built-In.
  - Query: `SELECT * FROM test_datatypes`.

• If the connection is set in the Repository, select the relevant entry on the list. Or alternatively, select the Use an existing connection check box and select the relevant connection component on the list.

• In this use case, the schema corresponding to the table structure is stored in the Repository.

• Fill out the Table Name field with the table the data is extracted from, Test_datatypes.

• Then in the Query field, type in the Select statement to extract the content from the table.

• No particular setting is required in the tLogRow component for this use case.

Then before executing the Job, make sure the table to scan (test_datatypes) is empty, in order for the condition (greater or equal to 1) to be met. Then execute the Job by pressing the F6 key on your keyboard. Before the end of the iterating loop, feed the test_datatypes table with one or more rows in order to meet the condition.

<table>
<thead>

Job tWaitForSql ended at 16:55 06/03/2006. [exit code=0]
tWarn

Triggers a warning often caught by the tLogCatcher component for exhaustive log.

Both tDie and tWarn components are closely related to the tLogCatcher component. They generally make sense when used alongside a tLogCatcher in order for the log data collected to be encapsulated and passed on to the output defined.

This component provides a priority-rated message to the next component. It does not stop your Job in case of error. If you want to kill a Job in case of error, see tDie on page 637.

**tWarn Standard properties**

These properties are used to configure tWarn running in the Standard Job framework.

The Standard tWarn component belongs to the Logs & Errors family.

The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>Warn message</th>
<th>Type in your warning message.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Code</td>
<td>Define the code level.</td>
</tr>
<tr>
<td>Priority</td>
<td>Enter the priority level as an integer.</td>
</tr>
</tbody>
</table>

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>WARN_MESSAGES: the warning message. This is an After variable and it returns a string.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>WARN_CODE: the code level of the warning message. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>WARN_PRIORITY: the priority level of the warning message. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td></td>
<td>For further information about variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>
Usage

| Usage rule | Cannot be used as a start component. If an output component is connected to it, an input component should be preceding it. |

Related scenarios

For use cases in relation with tWarn, see tLogCatcher scenarios:

- Catching messages triggered by a tWarn component on page 1982
- Catching the message triggered by a tDie component on page 1984
tWebService

Calls a method via a Web service in order to retrieve the values of the parameters defined in the component editor.

⚠️ Warning:  
This component requires an Oracle JDK to be functional.

tWebService calls the defined method from the invoked Web service and returns the class as defined, based on the given parameters.

**tWebService Standard properties**

These properties are used to configure tWebService running in the Standard Job framework.

The Standard tWebService component belongs to the Internet family.

The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-in or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Built-in: No property data stored centrally. Enter properties manually.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file where properties are stored. The fields that come after are pre-filled in using the fetched data.</td>
</tr>
</tbody>
</table>

**Service configuration**

Click the three-dot button next to the field to open the component editor.

In this editor, you can:

- select the Web service you want to use,
- configure the input parameters of the Web service,
- configure the output parameters of the Web service.

These parameters will be used to retrieve and output specific data.

**Mapping links display as**

Auto: By default, the links between the input and output schemas and the Web service parameters are in the form of curves.

Curves: Links between the schema and the Web service parameters are in the form of curve.

Lines: Links between the schema and the Web service parameters are in the form of straight lines. This option slightly optimizes performance.

**Connection Time out**

Set a value in seconds for Web service connection timeout.

**Receive Time out**

Set a value in seconds for server answer.
**Input schema**

A schema is a row description. It defines the number of fields that will be processed and passed on to the next component. The schema is either built-in or remote in the Repository. This field is used to process the input schema. The option for this schema may be:

- **Built-in**: No property data stored centrally.
- **Repository**: Select the Repository file where properties are stored. The following fields are pre-filled in using fetched data.

**Edit Schema**

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.

**Sync columns**

This button is available when an input link has been created. Click this button to retrieve the schema from the previous component connected in the Job.

**Output schema**

This field is used to process the output schema. The schema is either built-in or remote in the Repository and is configured the same way as the input schema is.

**Warning:**

*The input schema is not necessarily identical with the output schema.*

**Use NTLM**

Select this check box if you want to use the NTLM authentication protocol.

**Domain**: Name of the client domain,

**Host**: Client IP address.

**Need authentication**

Select this check box and enter a username and a password in the corresponding fields if this is necessary to access the service.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

**Use http proxy**

Select this check box if you are using a proxy server and fill in the necessary information.
| Trust server with SSL | Select this check box to validate the server certificate to the client via an SSL protocol and fill in the corresponding fields:  
**TrustStore file:** enter the path (including filename) to the certificate TrustStore file that contains the list of certificates that the client trusts.  
**TrustStore password:** enter the password used to check the integrity of the TrustStore data. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Die on error</td>
<td>Clear this check box to skip the rows in error and to complete the process for the error free rows.</td>
</tr>
</tbody>
</table>

### Advanced settings

<table>
<thead>
<tr>
<th>Temporary folder (for wsdl2java)</th>
<th>Set or browse to a temporary folder that you configured in order to store the wsdl files.</th>
</tr>
</thead>
<tbody>
<tr>
<td>tStatCatcher Statistics</td>
<td>Select this check box to gather the Job processing metadata at a Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

### Global Variables

| Global Variables |  
**ERROR_MESSAGE:** the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
**NB_LINE:** the number of rows processed. This is an After variable and it returns an integer.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
For further information about variables, see [Talend Studio User Guide](#). |

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component can be used as an input or as an intermediate component. It must be linked to an output component.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limitation</td>
<td>A JDK is required for this component to operate.</td>

</tbody>
</table>
Scenario: Getting country names through a Web service

This scenario describes a three-component Job that uses a Web service to retrieve the country name corresponding to a given country code.

Linking components

Procedure

1. Drop the following components from the Palette onto the design workspace: **tFixedFlowInput**, **tWebService**, and **tLogRow**.

2. Connect the components together using Main Row links.

Configuring the input data

Procedure

1. Double-click **tFixedFlowInput** to open its Basic settings view and define the component properties.

2. Click the three-dot button next to the Edit schema field to open a dialog box where you can define the input schema.

3. In the open dialog box, click the plus button to add a column to the schema.

4. Click in the column and type in a name, CountryCode in this example.

5. Click OK to close the schema definition dialog box. The CountryCode column displays in the Values table in the component Basic settings view.

6. In the Values table, click in the Value column and enter the value of the CountryCode column, cn in this example. This country code will be passed to the tWebService component to retrieve the country name corresponding to it.
Configuring the Web service

Selecting the WSDL

Procedure

1. Double-click tWebService to open the component editor, or select the component in the design workspace and in the Basic settings view, click the three-dot button next to Service configuration.

2. In the WSDL field, enter the Web service address or browse to it, if the WSDL is locally stored, by clicking the [Browse...] button. In this example, the WSDL URL is http://www.webservicex.net/country.asmx?WSDL.

3. Click the refresh button next to the WSDL field to retrieve the WSDL description and display it in the fields that follow.

4. In the Port Name list, select the port you want to use, countrySoap in this example.

5. In the Operation list, select the service you want to use. In this example the selected service is GetCountryByCountryCode(parameters):string.

Configure the input mapping

Procedure

1. Click Next to open a new view in the editor.
2. In the panel to the right of the **Input mapping** view, select **[+] parameters** and then click the plus button on top to display the **[Parameter Tree]** dialog box where you can select any of the listed parameters.

The Web service in this example has only one input parameter, **CountryCode**.

**Note:**

If available, use the **Auto map!** button, located at the bottom left of the interface, to carry out the mapping operation automatically.

You now need to create a connection between the input schema and the input parameter of the defined Web service.

3. In the **Column** list, drag the column in the input schema you want to link to the input parameter of the Web service to the corresponding parameter in the panel to the right.

![Configuring the output mapping](image)

**Configuring the output mapping**

**Procedure**

1. Click **Next** to open a new view in the editor.
In the **Element** list to the left of the view, the output parameter of the web service displays automatically. However, you can add other parameters if you select [+] **parameters** and then click the plus button on top to display the [Parameter Tree] dialog box where you can select any of the parameters listed.

The Web service in this example has only one output parameter: `GetCountryByCountryCodeResult`.

2. In the panel to the right of the view, click the three-dot button next to **Edit Schema** to open a dialog box in which you can define the output schema.

3. In the **Output** list to the right of the dialog box, click the plus button to add a column to the output schema.

4. Click in the column and type in a name, **Result** in this example. This will retrieve the names of the country.

5. Click **OK** to validate your changes and to close the schema definition dialog box.

You now need to create a connection between the output parameter of the defined Web service and the schema of the output component.
6. In the **Element** list to the right of the editor, drag `parameters.GetCountryByCountryCodeResult` to the field that corresponds to the `Result` column to the right of the editor.

![Image of Talend Integration Suite - tWebService_1](image)

![Image of tWebService component](image)

**Note:**

If available, use the **Auto map** button, located at the bottom left of the interface, to carry out the mapping operation automatically.

7. Click **OK** to validate your changes and to close the editor.

8. Click the [...] button to open the [Schema] dialog box, and add a column to the output schema, `Result` in this example. Then click **OK** to validate the schema setting and close the dialog box.

9. Double-click the **tLogRow** component to open its **Basic settings** view, and click **Sync columns** to retrieve the schema from the proceeding component.

### Executing the Job

**Procedure**

Save your Job and press **F6** to execute it.
Results

The country name corresponding to the specified country code is returned from the Web service.
tWebServiceInput

Invokes a Method through a Web service.

This component calls the defined method from the invoked Web service, and returns the class as defined, based on the given parameters.

**tWebServiceInput Standard properties**

These properties are used to configure tWebServiceInput running in the Standard Job framework.

The Standard tWebServiceInput component belongs to the Internet family.

The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either <strong>Built-in</strong> or <strong>Repository</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-in</strong>:</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong>:</td>
<td>Select the Repository file where the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Click this icon...</td>
<td>Click this icon to open a WSDL schema wizard and store your WSDL connection in the <strong>Repository</strong> tree view. For more information about setting up and storing database connection parameters, see <em>Talend Studio User Guide</em>.</td>
</tr>
</tbody>
</table>

**Schema and Edit Schema**

A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either **Built-in** or stored remotely in the **Repository**.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content] window.

**Built-in**: You create the schema and store it locally for the relevant component. Related topic: see *Talend Studio User Guide*. |
<table>
<thead>
<tr>
<th><strong>WSDL</strong></th>
<th>Description of Web service bindings and configuration.</th>
</tr>
</thead>
</table>
| **Need authentication / Username and Password** | Select this check box and:  
- enter a username and a password in the corresponding fields if this is necessary to access the service. Or,  
- select the Windows authentication check box and enter the windows domain in the corresponding field if this is necessary to access the service.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| **Use http proxy** | Select this check box if you are using a proxy server and fill in the necessary information. |
| **Trust server with SSL** | Select this check box to validate the server certificate to the client via an SSL protocol and fill in the corresponding fields:  
**TrustStore file**: enter the path (including filename) to the certificate TrustStore file that contains the list of certificates that the client trusts.  
**TrustStore password**: enter the password used to check the integrity of the TrustStore data. |
| **Time out (second)** | Set a value in seconds for Web service connection time out. |
| **Method Name** | Enter the exact name of the Method to be invoked.  
The Method name MUST match the corresponding method described in the Web Service. The Method name is also case-sensitive. |
| **Parameters** | Enter the parameters expected and the sought values to be returned. Make sure that the parameters entered fully match the names and the case of the parameters described in the method. |
| **Advanced Use** | Select this check box to display the fields dedicated for the advanced use of tWebServiceInput:  
**WSDL2java**: click the three-dot button to generate Talend routines that hold the Java code necessary to connect and query the Web service.  
**Code**: replace the generated model Java code with the code necessary to connect and query the specified Web service using the code in the generated Talend routines. |
**Match Brackets**: select the number of brackets to be used to close the for loop based on the number of open brackets.

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

**Global Variables**

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. |
| | **NB_LINE**: the number of rows processed. This is an After variable and it returns an integer. |
| | A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. |
| | To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. |
| | For further information about variables, see Talend Studio User Guide. |

**Usage**

| Usage rule | This component is generally used as a Start component. It must be linked to an output component. |

**Scenario: Getting country names through a Web service**

This scenario describes a two-component Job which uses a Web service method to obtain the country name corresponding to a given country code and displays the output on the Run console view.

**Procedure**

1. Drop a **tWebServiceInput** component and a **tLogRow** component from the Palette onto the design workspace.
2. Link the two components using a Row > Main connection.
3. Double-click the **tWebServiceInput** component to open its Basic settings view.
4. Click the [...] button next to Edit schema to open the [Schema] dialog box and define the schema for the response from the Web service.

   In this example, the schema is composed of only one column: Result.

5. In the WSDL field, specify the WSDL URL of the Web service to be used, http://www.webservicex.net/country.asmx?WSDL in this example.

6. If you are using a proxy server, select the Use http proxy check box and enter the necessary connection information.

7. In the Method name field, enter the method to be used. Note that the method name is case sensitive.

6. In this example, we use the method GetCountryByCountryCode.

8. In the Parameters area, click the plus [+ ] button to add a row to the table, then enter a country code, fr in this example.

9. Then save your Job and press F6 to execute it.
The country information is returned from the Web service and displayed on the Run view.
tWriteJSONField

Transforms the incoming data into JSON fields and transfers them to a file, a database table, etc.

Configuring a JSON Tree

When configuring a JSON tree, the default type of an element is string. If an element is not of type \textit{string}, you need to add an attribute for the element to set its type.

- For an \textit{integer}, \textit{double}, \textit{float}, or \textit{boolean} element, you need to add an attribute named \texttt{type} and set its static value to \texttt{integer}, \texttt{number}, \texttt{float}, or \texttt{boolean} respectively.

- For an \textit{array} element, you need to add an attribute named \texttt{class} and set its static value to \texttt{array}, and then add a sub-element named \texttt{element} set as a loop.

- For an \textit{object} element, you need to add an attribute named \texttt{class} and set its static value to \texttt{object}.

The following figure shows an example of JSON tree configuration:

![JSON Tree Configuration Example]

\textbf{tWriteJSONField Standard properties}

These properties are used to configure tWriteJSONField running in the Standard Job framework. The Standard tWriteJSONField component belongs to the Processing family. The component in this framework is generally available.
## Basic settings

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Output Column</strong></td>
<td>List of the columns defined in the output schema to hold the JSON field generated.</td>
</tr>
<tr>
<td><strong>Configure JSON Tree</strong></td>
<td>Opens the interface to create the JSON data structure. For more information, see <em>Configuring a JSON Tree</em> on page 4040.</td>
</tr>
</tbody>
</table>
| **Schema and Edit Schema**      | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.  
 Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
  - **View schema**: choose this option to view the schema only.  
  - **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
  - **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window. |
| **Sync columns**                | Click to synchronize the output file schema with the input file schema. The Sync function only displays once the Row connection is linked with the output component. |
| **Group by**                    | Define the aggregation set, the columns you want to use to regroup the data. **Warning**: Make sure that the data to be grouped is in sequential order. |
| **Remove root node**            | Select this check box to remove the root node from the JSON field generated.  |

**Built-In**: You create and store the schema locally for this component only. Related topic: see *Talend Studio User Guide*.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see *Talend Studio User Guide*.
Advanced settings

**Quote all values**
- Select this check box to surround all values including number and boolean values in the generated JSON field with double quotation marks.
- Clear this check box to surround only string values in the generated JSON field with double quotation marks.

**tStatCatcher Statistics**
- Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

Global Variables

**Global Variables**

- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.
- **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.
- A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.
- To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.
- For further information about variables, see *Talend Studio User Guide*.

Usage

**Usage rule**
- Preceded by an input component, this component wraps the incoming data into a JSON field.

Scenario: Writing flat data into JSON fields

In this scenario, flat data is wrapped into JSON fields via **tWriteJSONField**.

Linking the components

**Procedure**

1. Drop the following components from the **Palette** onto the design workspace: **tFixedFlowInput**, **tWriteJSONField** and **tLogRow**.
2. Link **tFixedFlowInput** and **tWriteJSONField** using a **Row > Main** connection.
3. Link **tWriteJSONField** and **tLogRow** using a **Row > Main** connection.
Configuring the components

Procedure

1. Double-click tFixedFlowInput to display its Basic settings view.

2. Click Edit schema to open the schema editor.

   Click the [+] button to add three columns, namely firstname, lastname and dept, with the type of string.
   Click OK to close the editor.

3. Select the Use Inline Content option and enter the data below in the Content box:

   Andrew;Wallace;Doc
   John;Smith;R&D
   Christian;Dior;Sales

4. Click tWriteJSONField to display its Basic settings view.
Select the **Remove root node** option to remove the root node setting from the JSON fields generated.

5. Click **Configure JSON Tree** to open the XML tree editor.

The schema of `tFixedFlowInput` appears in the **Linker source** panel.

6. In the **Linker target** panel, click the default **rootTag** and type in **staff**, which is the root node of the JSON field to be generated.

7. Right-click **staff** and select **Add Sub-element** from the context menu.

8. In the pop-up box, enter the sub-node name, namely **firstname**.
Repeat the steps to add two more sub-nodes, namely `lastname` and `dept`.

9. Right-click `firstname` and select **Set As Loop Element** from the context menu.

10. Drop `firstname` from the **Linker source** panel to its counterpart in the **Linker target** panel.
    In the pop-up dialog box, select **Add linker to target node**.

Click **OK** to close the dialog box.
Repeat the steps to link the two other items.
Click **OK** to close the XML tree editor.

11. Click **Edit schema** to open the schema editor.

12. Click the [+] button in the right panel to add one column, namely `staff`, which will hold the JSON data generated.
    Click **OK** to close the editor.

13. Double-click **tLogRow** to display its **Basic settings** view.
Executing the Job

Procedure

1. Press Ctrl + S to save the Job.
2. Click F6 to execute the Job.

As shown above, the JSON fields have been generated correctly, with the root node settings removed.

Related Scenarios

For related scenarios, see:

- Scenario 1: Retrieving error messages while extracting data from JSON fields on page 949.
- Scenario: Extracting the structure of an XML file and inserting it into the fields of a database table on page 4049.
- Mapping XML data on page 113.
tWriteXMLField

Reads an input XML file and extracts the structure to insert it in defined fields of the output XML file.

**tWriteXMLField Standard properties**

These properties are used to configure tWriteXMLField running in the Standard Job framework.

The Standard tWriteXMLField component belongs to the XML family.

The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th><strong>Output Column</strong></th>
<th>Select the destination field in the output component where you want to write the XML structure.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Configure XML Tree</strong></td>
<td>Opens the interface that supports the creation of the XML structure you want to write in a field. For more information about the interface, see Defining the XML tree on page 111.</td>
</tr>
</tbody>
</table>
| **Schema and Edit Schema** | A schema is a row description, it defines the number of fields that will be processed and passed on to the next component. The schema is either built-in or remote in the Repository. Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
  • **View schema**: choose this option to view the schema only.  
  • **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
  • **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.  

| **Sync columns** | Click to synchronize the output file schema with the input file schema. The Sync function only displays once the Row connection is linked with the input component. |

**Built-in**: You create the schema and store it locally for this component only. Related topic: see Talend Studio User Guide.

**Repository**: You already created the schema and stored it in the Repository, hence can be reused in various projects and job flowcharts. Related topic: see Talend Studio User Guide.

</tbody>
</table>
tStatCatcher Statistics

Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

Global Variables

**Global Variables**

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

**NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

Usage

**Usage rule**

This component can be used as intermediate step in a data flow.

Scenario: Extracting the structure of an XML file and inserting it into the fields of a database table

This three-component scenario allows to read an XML file, extract the XML structure, and finally outputs the structure to the fields of a database table.

Procedure

**Procedure**

1. Drop the following components from the Palette onto the design workspace: **tFileInputXml**, **tWriteXMLField**, and **tMysqlOutput**.

   Connect the three components using **Main links**.

2. Double-click **tFileInputXml** to open its **Basic settings** view and define its properties.
3. If you have already stored the input schema in the Repository tree view, select Repository first from the Property Type list and then from the Schema list to display the [Repository Content] dialog box where you can select the relevant metadata. For more information about storing schema metadata in the Repository tree view, see Talend Studio User Guide.

4. If you have not stored the input schema locally, select Built-in in the Property Type and Schema fields and fill in the fields that follow manually. For more information about tFileInputXML properties, see tFileInputXML on page 1089. If you have selected Built-in, click the three-dot button next to the Edit schema field to open a dialog box where you can manually define the structure of your file.

5. In the Look Xpath query field, enter the node of the structure where the loop is based. In this example, the loop is based on the customer node. Column in the Mapping table will be automatically populated with the defined file content.

In the Xpath query column, enter between inverted commas the node of the XML file that holds the data corresponding to each of the Column fields.

6. In the design workspace, click tWriteXMLField and then in the Component view, click Basic settings to open the relevant view where you can define the component properties.

7. Click the three-dot button next to the Edit schema field to open a dialog box where you can add a line by clicking the plus button.
8. Click in the line and enter the name of the output column where you want to write the XML content, *CustomerDetails* in this example.
Define the type and length in the corresponding fields, *String* and 255 in this example.
Click *Ok* to validate your output schema and close the dialog box.
In the **Basic settings** view and from the **Output Column** list, select the column you already defined where you want to write the XML content.

9. Click the three-dot button next to **Configure Xml Tree** to open the interface that helps to create the XML structure.

10. In the **Link Target** area, click *rootTag* and rename it as *CustomerDetails*.
In the **Linker source** area, drop *CustomerName* and *CustomerAddress* to *CustomerDetails*. A dialog box displays asking what type of operation you want to do.
Select *Create as sub-element of target node* to create a sub-element of the *CustomerDetails node*.
Right-click *CustomerName* and select from the contextual menu **Set As Loop Element**.
Click *OK* to validate the XML structure you defined.

11. Double-click **tMysqlOutput** to open its **Basic settings** view and define its properties.
If you have already stored the schema in the DB Connection node in the Repository tree view, select Repository from the Schema list to display the [Repository Content] dialog box where you can select the relevant metadata.

For more information about storing schema metadata in the Repository tree view, see Talend Studio User Guide.

If you have not stored the schema locally, select Built-in in the Property Type and Schema fields and enter the database connection and data structure information manually. For more information about tMysqlOutput properties, see tMysqlOutput on page 2515.

In the Table field, enter the name of the database table to be created, where you want to write the extracted XML data.

From the Action on table list, select Create table to create the defined table.

From the Action on data list, select Insert to write the data.

Click Sync columns to retrieve the schema from the preceding component. You can click the three-dot button next to Edit schema to view the schema.

Save your Job and click F6 to execute it.

Results

<table>
<thead>
<tr>
<th>CustomerDetails</th>
</tr>
</thead>
</table>

The tWriteXMLField fills every field of the CustomerDetails column with the XML structure of the input file: the XML processing instruction <!--xml version="1.0" encoding="ISO-8859-15"--> , the first node that separates each client <CustomerDetails> and finally customer information <CustomerAddress> and <CustomerName>. 

4052
tXMLMap

Transforms and routes data from single or multiple sources to single or multiple destinations.

� tXMLMap is an advanced component fine-tuned for transforming and routing XML data flow (data of the Document type), especially when processing numerous XML data sources, with or without flat data to be joined.

tXMLMap Standard properties

These properties are used to configure tXMLMap running in the Standard Job framework.

The Standard tXMLMap component belongs to the Processing and the XML families.

The component in this framework is generally available.

Basic settings

<table>
<thead>
<tr>
<th>Map Editor</th>
<th>It allows you to define the tXMLMap routing and transformation properties.</th>
</tr>
</thead>
</table>

Advanced settings

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
<th>Select this check box to gather the Job processing metadata at the Job level as well as at each component level.</th>
</tr>
</thead>
</table>

Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.  

For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | Possible uses are from a simple reorganization of fields to the most complex jobs of data multiplexing or demultiplexing transformation, concatenation, inversion, filtering and so on.  

When needs be, you can define sophisticated outputting strategy for the output XML flows using group element. |
|------------|-------------------------------------------------------------------------------------------------|
aggregate element, empty element and many other features such as All in one. For further information about these features, see Talend Studio User Guide.

It is used as an intermediate component and fits perfectly the process requiring many XML data sources, such as, the ESB request-response processes.

| Limitation          | The limitations to be kept in mind are:
|---------------------|--------------------------------------------------
|                     | - The use of this component supposes minimum Java and XML knowledge in order to fully exploit its functionalities. |
|                     | - This component is a junction step, and for this reason it cannot be a start nor an end component in the Job. |
|                     | - At least one loop element is required for each XML data flow involved. |

The following sections present several generic use cases about how to use the tXMLMap component, while if you need some specific examples using this component along with the ESB components to build data services, see the scenarios for the ESB components:

- Scenario 2: Using tESBConsumer with custom SOAP Headers on page 833
- Scenario: Requesting airport names based on country codes on page 845
- Scenario: Service sending a message without expecting a response on page 860
- Scenario: Returning Hello world response on page 871

**Mapping and transforming XML data**

The following scenario creates a three-component Job that maps and transforms data from an XML source file Customer.xml, and generates an XML output flow which could be reused for various purposes, such as for an ESB request, in the future based on the XML tree structure of the file Customer_State.xml.

These three components are:

- **tFileInputXML**: provides the input data to tXMLMap.
- **tXMLMap**: maps and transforms the received XML data flows into one single XML data flow.
- **tLogRow**: displays the output data.

The content of the XML file Customer.xml is as follows:

```xml
<?xml version="1.0" encoding="ISO-8859-15"?>
<Customers>
    <Customer RegisterTime="2001-01-17 06:26:40.000">
        <Name />
        <id>1</id>
    </Customer>
</Customers>
```
<CustomerName>Griffith Paving and Sealcoatin</CustomerName>
</Name>
<Address>
<br_customer_address>talend@apres91</br_customer_address>
</Address>
<Revenue>
<br_sum>67852</br_sum>
</Revenue>
</Customer>
<Customer RegisterTime="2002-06-07 09:40:00.000">
<Name>
<br_id>2</br_id>
</Name>
<Address>
<br_customer_address>511 Maple Ave. Apt. 1B</br_customer_address>
</Address>
<Revenue>
<br_sum>88792</br_sum>
</Revenue>
</Customer>
<Customer RegisterTime="1987-02-23 17:33:20.000">
<Name>
<br_id>3</br_id>
</Name>
<Address>
<br_customer_address>1859 Green Bay Rd.</br_customer_address>
</Address>
<Revenue>
<br_sum>1225</br_sum>
</Revenue>
</Customer>
<Customer RegisterTime="1992-04-28 23:26:40.000">
<Name>
<br_id>4</br_id>
</Name>
<Address>
<br_customer_address>456 Grossman Ln.</br_customer_address>
</Address>
<Revenue>
<br_sum>64493</br_sum>
</Revenue>
</Customer>
</Customers>

The content of the XML file Customer_State.xml is as follows:

```xml
<?xml version="1.0" encoding="ISO-8859-15"?>
<customers>
  <customer id="1">
    <CustomerName>Griffith Paving and Sealcoatin</CustomerName>
    <CustomerAddress>talend@apres91</CustomerAddress>
    <idState>2</idState>
  </customer>
  <customer id="2">
    <CustomerName>Bill's Dive Shop</CustomerName>
    <CustomerAddress>511 Maple Ave. Apt. 1B</CustomerAddress>
    <idState>3</idState>
  </customer>
  <customer id="3">
    <CustomerName>Glenn Oaks Office Supplies</CustomerName>
    <CustomerAddress>1859 Green Bay Rd.</CustomerAddress>
    <idState>2</idState>
  </customer>
  <customer id="4">
    <CustomerName>DBN Bank</CustomerName>
    <CustomerAddress>456 Grossman Ln.</CustomerAddress>
    <idState>3</idState>
  </customer>
</customers>
```
**Adding and linking the components**

**Procedure**

1. Create a new Job and add a `tFileInputXML` component, a `tXMLMap` component, a `tLogRow` component by typing their names in the design workspace or dropping them from the Palette.

2. Label the `tFileInputXML` component *Customers* to better identify its function.

   **Note:**
   
   A component used in the workspace can be labelled the way you need. For further information about how to label a component, see *Talend Studio User Guide*.

3. Link the `tFileInputXML` component labelled *Customers* to the `tXMLMap` component using a *Row > Main* connection.

4. Link the `tXMLMap` component to the `tLogRow` component using a *Row > *New Output* (Main)* connection. In the pop-up dialog box, enter the name of the output connection, *Customer* in this scenario.

   ![tXMLMap_1Output](image)

**Configuring the input flow**

**Procedure**

1. Double-click the `tFileInputXML` component labelled *Customers* to open its *Basic settings* view.

   ![Customers(tFileInputXML_1)](image)

2. Click the [...] button next to *Edit schema* and in the *Schema* dialog box define the schema by adding one column *Customer* of *Document* type.
Note that the Document data type is essential for making full use of tXMLMap. For further information about this data type, see Talend Studio User Guide.

3. Click OK to validate the changes and close the dialog box. One row is added automatically to the Mapping table.

4. In the File name/Stream field, browse to or type in between double quotation marks the path to the XML source file that provides the customer data. In this scenario, it is E:/Customer.xml.

5. In the Loop XPath query field, type in an XPath expression between double quotation marks to specify the node on which the loop is based. In this scenario, it is /, which means to perform look query from the root.

6. In the XPath query column of the Mapping table, type in the fields to be queried between double quotation marks. In this scenario, it is ., which means all fields under the current node (root) will be extracted.

7. In the Get Nodes column of the Mapping table, select the check box. In order to build the Document type data flow, it is necessary to get the nodes from this component.

**Configuring tXMLMap for transformation**

**Procedure**

1. Double-click the tXMLMap component to open its Map Editor.
Note that the input area is already filled with the default basic XML structure and the top table is the main input table.

2. In the \textit{row1} input table, right-click the \textit{Customer} node and from the contextual menu select \textbf{Import From File}. In the pop-up dialog box, browse to the XML source file to import therefrom the XML tree structure used by the data to be received by \texttt{tXMLMap}. In this scenario, the XML source file is \textit{Customer.xml}, which is the input data to the \texttt{tFileInputXML} component labelled \textit{Customers}.

\begin{itemize}
\item \textbf{Note:}
\begin{itemize}
\item You can also import an XML tree from an XSD file. When importing either an input or an output XML tree structure from an XSD file, you can choose an element as the root of your XML tree. For more information on importing an XML tree structure from an XSD file, see \textit{Talend Studio User Guide}.
\end{itemize}
\end{itemize}

3. In the imported XML tree, right-click the \textit{Customer} node and from the contextual menu select \textbf{As loop element} to set it as the loop element.

4. On the lower part of this map editor, click the \textbf{Schema editor} tab to display the corresponding view. Then on the right side of this view, add one column \textit{Customer_States of Document} type to the \textit{Customer} schema table. The corresponding XML root is added automatically to the \textit{Customer} output table on the top right side which represents the output flow.

5. In the \textit{Customer} output table, right-click the \textit{Customer_States} node and from the contextual menu select \textbf{Import From File}. In the pop-up dialog box, browse to the XML file from which the XML tree structure is imported. In this scenario, it is \textit{Customer_State.xml}. 
6. Right-click the `customer` node and from the contextual menu select **As loop element** to set it as the loop element.

7. In the `row1` input table, click the `id` node and drop it to the **Expression** column in the row of the `@id` node in the `Customer` output table.

Do the same to map `CustomerName` to `CustomerName`, `CustomerAddress` to `CustomerAddress`, and `idState` to `idState` from the input table to the output table.

**Note:**

In some circumstances, you may have to keep empty elements in your output XML tree. If so, you can use **tXMLMap** to manage them. For further information about how to manage empty elements using **tXMLMap**, see *Talend Studio User Guide*.

8. On the top of the `Customer` output table, click the wrench icon and set the value of the **All in one** property to **true** to generate a single XML flow. For further information about the **All in one** feature, see *Talend Studio User Guide*. 
9. Click OK to validate the changes and close the Map Editor.

   Note:
   If you close the Map Editor without having set the required loop elements as described earlier in this scenario, the root element will be automatically set as the loop element.

**Configuring tLogRow to display the customer information**

**Procedure**

1. Double-click the tLogRow component to open its Basic settings view.
2. Click the Sync columns button to retrieve the schema from its preceding component.

**Saving and executing the Job**

**Procedure**

1. Press Ctrl+S to save the Job.
2. Press F6 to execute the Job.

```xml
<customers>
  <customer id="1" CustomerName="Griffith Paving and Sealcoating" CustomerAddress="talex@apress91"/>
  <customer id="2" CustomerName="Bill's Dive Shop" CustomerAddress="511 Maple Ave. Apt 1B"/>
  <customer id="3" CustomerName="Glenn Oaks Office Supplies" CustomerAddress="1859 Green Bay Rd"/>
  <customer id="4" CustomerName="DBN Bank" CustomerAddress="456 Grossman Ln"/>
</customers>
```

As shown above, the transformed customer information is displayed on the console.

**Launching a lookup flow to join complementary data**

Based on the previous scenario, this scenario shows how to use a lookup flow to join data of interest in the XML file `USState.xml` to the main flow. Another tFileInputXML component is added to the Job to load data from the lookup file `USState.xml` to the processing component tXMLMap.
The content of the XML file USState.xml is as follows:

```xml
<?xml version="1.0" encoding="ISO-8859-15"?>
<USStates>
  <States>
    <idState>1</idState>
    <LabelState>Alabama</LabelState>
  </States>
  <States>
    <idState>2</idState>
    <LabelState>Connecticut</LabelState>
  </States>
  <States>
    <idState>3</idState>
    <LabelState>Ohio</LabelState>
  </States>
  <States>
    <idState>4</idState>
    <LabelState>Wyoming</LabelState>
  </States>
  <States>
    <idState>5</idState>
    <LabelState>Hawaii</LabelState>
  </States>
</USStates>
```

Adding and linking another input component

Procedure
1. In your Studio, open the Job used in the previous scenario to display it in the design workspace.
2. Add another tFileInputXML component to the Job by typing its name in the design workspace or dropping it from the Palette. Label the component USStates to better identify its function.
3. Link the tFileInputXML component labelled USStates to the tXMLMap component using a Row > Main connection, and the connection is automatically changed to a lookup flow.

Configuring the input flow for lookup

Procedure
1. Double-click the tFileInputXML component labelled USStates to open its Basic settings view.
2. Click the [...] button next to Edit schema and in the [Schema] dialog box define the schema by adding one column USState of Document type.

3. Click OK to validate the changes and close the dialog box. One row is added automatically to the Mapping table.

4. In the File name/Stream field, browse to or type in between double quotation marks the path to the XML source file that holds the complementary data. In this scenario, it is E:/USState.xml.

5. In the Loop XPath query field, type in an XPath expression between double quotation marks to specify the node on which the loop is based. In this scenario, it is /, which means to perform look query from the root.

6. In the XPath query column of the Mapping table, type in the fields to be queried between double quotation marks. In this scenario, it is ., which means all fields under the current node (root) will be extracted.

7. In the Get Nodes column of the Mapping table, select the check box. This retrieves the XML structure for the Document type data.

Configuring tXMLMap for transformation

Procedure

1. Double-click the tXMLMap component to open its Map Editor.
2. In the row2 input table, right-click the USState node and from the contextual menu select **Import From File**. In the pop-up dialog box, browse to the XML source file to import therefrom the XML tree structure used by the data to be received by **tXMLMap**. In this scenario, the XML source file is **USState.xml**, which is the input data to **tFileInputXML** labelled **USStates**.

3. In the imported XML tree, right-click the States node and from the contextual menu select **As loop element** to set it as the loop element.
4. In the row1 main input table, click the idState node and drop it to the Exp.key column in the row of the idState node in the row2 lookup input table. This creates a join between the two input tables on the idState data, among which the idState node from the main flow provides the lookup key.

5. In the row2 lookup input table, click the LabelState node and drop it on the customer node in the Customer output table. A dialog box pops up.

6. In the pop-up dialog box, select Create as sub-element of target node and click OK. A new LabelState sub-element is added to the output XML tree and mapped with the LabelState node in the lookup input table.
7. Click OK to validate the mappings and close the Map Editor.

Saving and executing the Job

Procedure

1. Press Ctrl+S to save the Job.
2. Press F6 to run the Job.

As shown above, the state names from the lookup file with the state IDs matching those in the main input file are added to the data flow and the combined information is displayed on the console.

Results

A step-by-step tutorial related to this Join topic is available on the Talend Technical Community Site. For further information, see http://talendforge.org/tutorials/tutorial.php?language=english&idTuto=101.
Mapping data using a filter

Based on Launching a lookup flow to join complementary data on page 4060, this scenario presents how to apply filter condition(s) to select the data of interest using tXMLMap.

**Mapping data using a filter**

**Procedure**

1. In your Studio, open the Job used in the previous scenario to display it in the design workspace.

2. Double-click the tXMLMap component to open its Map Editor.

3. On the top of the Customer output table, click the button to open the filter area.
4. Drop the `idState` node in the main input table to the filter area. The XPath `[@1.Customer:/Customers/Customer/Address/idState]` of the `idState` node is added automatically to this filter area. Enter `== 2` after the XPath of the `idState` node, and the complete filter condition becomes `[row1.Customer:/Customers/Customer/Address/idState] == 2`. This means only the customer data with the state id of 2 will be passed to the output flow.

5. Click OK to validate the changes and close the map editor.

6. Press Ctrl + S to save the Job and then F6 to run the Job.

Results

As shown above, the customers *Griffith Paving and Sealcoating* and *Glenn Oaks Office Supplies*, whose state id is 2 are displayed on the console.

Catching the data rejected by lookup and filter

The data rejected by the lookup and filter conditions set in tXMLMap can be caught and outputted by this component itself.
Based on Mapping data using a filter on page 4066, this scenario presents how to catch the data rejected by the lookup and the filter set up in the previous scenarios. Another `tLogRow` component is added to the Job used in the previous scenario to display the rejected data.

**Adding and linking another output component**

**Procedure**

1. In your Studio, open the Job used in the previous scenario to display it in the design workspace.
2. Add another `tLogRow` component to the Job by typing its name in the design workspace or dropping it from the Palette.
3. Link the `tXMLMap` component to the second `tLogRow` using a Row > "New Output" (Main) connection. In the pop-up dialog box, enter the name of the output connection, `Reject` in this example.
Configuring tXMLMap for transformation

Procedure

1. Double-click the tXMLMap component to open its Map Editor. An empty Reject output table that carries the rejected data has been added to the output side to represent the output data flow carrying the rejected data.

2. In the row1 main input table, click the id node and drop it on the Reject output table. A column id is added to the Reject schema table in the Schema editor on the lower part of the map editor.

3. Do the same to drop CustomerName, CustomerAddress, and idState in the row1 main input table and LabelState in the row2 lookup input table on the Reject output table. Another four columns CustomerName, CustomerAddress, idState, and LabelState are added to the Reject schema table in the Schema editor.

   Note:
   In this scenario, the Reject output flow uses the flat data type. However, you can create an XML tree view for this flow similar to the Customer output flow using the Document data type. For further information about how to use the Document type, see Mapping and transforming XML data on page 4054.

4. On the top of the Reject output table, click the button to open the property setting area.
5. Set the value of the **Catch Output Reject** property to **true** to catch the data rejected by the filter set up in the previous scenario for the **Customer** output flow.

6. Set the value of the **Catch Lookup Inner Join Reject** property to **true** to catch the data rejected by the inner join operation.

7. Click **OK** to validate the changes and close the map editor.

### Configuring the output flow

**Procedure**

1. Double-click the second **tLogRow** component to open its **Basic settings** view.

2. Click the **Sync columns** button to retrieve the schema from its preceding component.

3. In the **Mode** area, select **Table (print values in cells of a table)** for better readability of the result.

### Saving and executing the Job

**Procedure**

1. Press **Ctrl+S** to save the Job.

2. Press **F6** to run the Job.

The captured data rejected by the filter and the lookup reads as follows in the **Run** view:

```xml
[statistics] connecting to socket on port 4058
[statistics] connected
<customer><customer id="1"><CustomerName>Griffith Paving and Seals</CustomerName><CustomerAddress>telend@apres91</CustomerAddress><idState>2</idState><LabelState>Connecticut</LabelState><customer><customer id="3"><CustomerName>Glenn Oaks Office Supplies</CustomerName><CustomerAddress>1859 Green Bay Rd</CustomerAddress><idState>2</idState><LabelState>Connecticut</LabelState><customer></customer></customers>
```

<table>
<thead>
<tr>
<th>tLogRow_2</th>
<th>id</th>
<th>CustomerName</th>
<th>CustomerAddress</th>
<th>idState</th>
<th>LabelState</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>[Bill’s Dive Shop]</td>
<td>511 Maple Ave. Apt. 1E</td>
<td>1</td>
<td>Ohio</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>[WBB Bank]</td>
<td>456 Greenman Ln.</td>
<td>3</td>
<td>Ohio</td>
</tr>
</tbody>
</table>

[statistics] disconnected
As shown above, the data whose idState value is 2 is selected by the filter set up in the previous scenario and displayed in the upper part, and the data whose idState value is not 2 is rejected and displayed in the lower part.

**Mapping data using a group element**

Based on Launching a lookup flow to join complementary data on page 4060, this scenario presents how to set up an element as group element in the Map Editor of tXMLMap to group the output data. For more information about how to group the output data using tXMLMap, see Talend Studio User Guide.

The objective of this scenario is to group the customer id and the customer name information according to the states the customers come from. You need to reconstruct the XML tree view of the Customer output table by considering the following factors:

- The elements tagging the customer id and the customer name information should be located under the loop element. Thus they are the sub-elements of the loop element.
- The loop element and its sub-elements should be dependent directly on the group element.
- The element tagging the state information used as the grouping condition should be dependent directly on the group element.
- The group element cannot be the root element.

Based on this analysis, the XML structure of the output data should read as follows. The customers node is the root element, the customer node is set as the group element and the output data is grouped according to the LabelState element.
To put a group element into effect, the XML data to be processed should have been sorted, for example via your XML tools, around the element that will be used as the grouping condition. In this example, the customers possessing the same state id should be put together. The input data in the XML file *Customer.xml* should read as follows:

```xml
<?xml version="1.0" encoding="ISO-8859-15"?>
<Customers>
  <Customer RegisterTime="2001-01-17 06:26:40.000">
    <Name>
      <id>1</id>
      <CustomerName>Griffith Paving and Sealcoatin</CustomerName>
    </Name>
    <Address>
      <CustomerAddress>talend@apres91</CustomerAddress>
      <idState>2</idState>
    </Address>
    <Revenue>
      <Sum1>67852</Sum1>
    </Revenue>
  </Customer>
  <Customer RegisterTime="1987-02-23 17:33:20.000">
    <Name>
      <id>3</id>
      <CustomerName>Glenn Oaks Office Supplies</CustomerName>
    </Name>
    <Address>
      <CustomerAddress>1859 Green Bay Rd.</CustomerAddress>
      <idState>2</idState>
    </Address>
    <Revenue>
      <Sum1>1225</Sum1>
    </Revenue>
  </Customer>
  <Customer RegisterTime="2002-06-07 09:40:00.000">
    <Name>
      <id>2</id>
      <CustomerName>Bill's Dive Shop</CustomerName>
    </Name>
    <Address>
      <CustomerAddress>511 Maple Ave. Apt. 1B</CustomerAddress>
      <idState>3</idState>
    </Address>
    <Revenue>
      <Sum1>88792</Sum1>
    </Revenue>
  </Customer>
  <Customer RegisterTime="1992-04-28 23:26:40.000">
    <Name>
      <id>4</id>
      <CustomerName>DBN Bank</CustomerName>
    </Name>
    <Address>
      <CustomerAddress>456 Grossman Ln.</CustomerAddress>
      <idState>3</idState>
    </Address>
    <Revenue>
      <Sum1>64493</Sum1>
    </Revenue>
  </Customer>
</Customers>
```
**Mapping data using a group element**

**Procedure**

1. In your Studio, open the Job used in Launching a lookup flow to join complementary data on page 4060 to display it in the design workspace, and double-click the tXMLMap component to open its Map Editor.

2. In the XML tree view of the Customer output table, right-click the customer (loop) node and select **Delete** from the contextual menu. Thus all of the elements under the customers root node are removed, then you can reconstruct the XML tree view that can be used to group the output data of interest.

3. Right-click the customers root node and select **Create Sub-Element** from the contextual menu. In the pop-up dialog box, enter the name of the new sub-element. In this example, it is customer.

4. Click **OK** to validate the changes and close the dialog box. A customer node is added under the customers root node in the output table.

5. In the row2 lookup input table, select the LabelState node and drop it onto the customer node in the output table. In the pop-up dialog box, select **Create as sub-element of target node** and click **OK** to close the dialog box. A LabelState node is added under the customer node in the output table.

6. Right-click the customer node in the output table and select **Create Sub-Element** from the contextual menu. In the pop-up dialog box, enter the name of the new sub-element. In this example, it is Name.

7. Click **OK** to validate the changes and close the dialog box. A Name node is added under the customer node in the output table.

8. In the row1 main input table, select the id and CustomerName nodes and drop them onto the Name node in the output table. In the pop-up dialog box, select **Create as sub-element of target node** and click **OK** to close the dialog box. A id node and a CustomerName node are added under the Name node in the output table.

9. In the output table, right-click the Name node and from the contextual menu select **As loop element** to set it as the loop element, then right-click the customer node and from the contextual menu select **As group element** to group the output data according to the LabelState element.
10. Click OK to validate the changes and close the map editor.
11. Press Ctrl+S to save the Job and then F6 to run the Job.

Results
As shown above, the id element and the CustomerName element contained in the loop are grouped according to the LabelState element. The group element customer tags the start and the end of each group.

Classifying the output data with aggregate element

Based on the previous scenarios, this scenario presents how to set up an element as aggregate element in the Map Editor of tXMLMap to classify the output data into separate XML flows. For more information about how to aggregate the output data using tXMLMap, see Talend Studio User Guide.

The objective of this scenario is to classify the customer id and the customer name information using an aggregate element in accordance with the states they come from and then to send these classes separately in different XML flows to the next component.

To put an aggregate element into effect, the XML data to be processed should have been sorted, for example via your XML tools, around the element that will be used as the aggregating condition. In
this example, the customers possessing the same state id should be put together. The input data in the XML file Customer.xml should be same as the input data in.

Classifying the output data with aggregate element

Procedure

1. In your Studio, open the Job used in, and double-click the tXMLMap component to open its Map Editor.
2. Right-click the customer element in the output table and select Remove group element from the contextual menu.
3. On the top of the output table, click the wrench icon and set the value of the All in one property to false.
4. Right-click the LabelState element and select As aggregate element from the contextual menu. The LabelState element tags the state information of each customer and the customer information will be classified according to the state information.

To make the aggregate element available, ensure that the value of the All in one property is set to false. For further information about the All in one feature, see Talend Studio User Guide.

5. Click OK to validate the changes and close the Map Editor.
6. Press Ctrl+S to save the Job and then F6 to run the Job.
Results

As shown above, tXMLMap outputs two separate XML flows, each of which carries the information of one state and the customers from that state.

Restructuring products data using multiple loop elements

The following scenario creates a four-component Job that restructures the products data from an XML source file ProductsIn.xml using multiple loop elements.

These four components are:

- **tFileInputXML**: reads the source products data and passes it to the tXMLMap component.
- **tXMLMap**: transforms the input flow to the expected structure streamlined.
- **tLogRow**: presents the execution result on the console.
- **tFileOutputXML**: writes the output flow into an XML file.

The content of the source XML file ProductsIn.xml is as follows:

```xml
<?xml version="1.0" encoding="ISO-8859-15"?>
<products category="1" name="laptop">
  <!-- Summary -->
  <summary>
    <company>DELL, HP</company>
    <sales unit="Dollars">12345678910.12345</sales>
    <model>business</model>
  </summary>
  <!-- Loop1 manufacture -->
  <manufacture id="manu_1" date="2012-10-30">
    <name>DELL</name>
  </manufacture>
  <manufacture id="manu_2" date="2012-10-28">
    <name>HP</name>
  </manufacture>
  <!-- Loop2 types -->
  <types model="business1">
    <type>DELL123</type>
    <manufacture_id>manu_1</manufacture_id>
  </types>
</products>
```
The objective of this scenario is to restructure the products data to streamline the presentation of the products information to serve the manufacturing operations. The expected output data is as follows. The root element is changed to manufacturers, the sales information is consolidated into the sale element, and the manufacturer element is reduced to one single level.

```xml
<?xml version="1.0" encoding="ISO-8859-15"?>
<manufacturers category="1" name="laptop">
  <sales unit="Dollars">
    <sale sales_type="DELL123">12345.0</sale>
    <sale sales_type="HP123">12345.123</sale>
  </sales>
  <manufacturer id="manu_1" date="03-04-0036" name="DELL"/>
  <manufacturer id="manu_2" date="04-04-0034" name="HP"/>
  <types>
    <type>DELL123</type>
    <manufacturer_id>manu_1</manufacturer_id>
  </types>
  <types>
    <type>DELL123</type>
    <manufacturer_id>manu_2</manufacturer_id>
  </types>
  <types>
    <type>HP123</type>
    <manufacturer_id>manu_1</manufacturer_id>
  </types>
  <types>
    <type>HP123</type>
    <manufacturer_id>manu_2</manufacturer_id>
  </types>
</manufacturers>
```

### Adding and linking the components

**Procedure**

1. Create a new Job and add a tFileInputXML component, a tXMLMap component, a tLogRow component, and a tFileOutputXML component by typing their names in the design workspace or dropping them from the Palette.

2. Link the tFileInputXML component to the tXMLMap component using a Row > Main connection.

3. Link the tXMLMap component to the tLogRow component using a Row > “New Output” (Main) connection. In the pop-up dialog box, enter the name of the output connection, outDoc in this example.

4. Link the tLogRow component to the tFileOutputXML component using a Row > Main connection.
Configuring the input flow

Procedure

1. Double-click the tFileInputXML component to open its Basic settings view.

2. Click the [...] button next to Edit schema and in the [Schema] dialog box define the schema by adding one column doc of Document type.

3. Click OK to validate the changes and close the dialog box. One row is added automatically to the Mapping table.

4. In the File name/Stream field, browse to or type in between double quotation marks the path to the XML source file that provides the products data. In this scenario, it is E:/ProductsIn.xml.

5. In the Loop XPath query field, type in an XPath expression between double quotation marks to specify the node on which the loop is based. In this scenario, it is /, which means to perform look query from the root.

6. In the XPath query column of the Mapping table, type in the fields to be queried between double quotation marks. In this scenario, it is ., which means all fields under the current node (root) will be extracted.

7. In the Get Nodes column of the Mapping table, select the check box.
Configuring tXMLMap with multiple loops

Procedure

1. Double-click the tXMLMap component to open its Map Editor.

![Image of tXMLMap Map Editor]

Note that the input area is already filled with the default basic XML structure and the top table is the main input table.

2. In the row1 input table, right-click the doc node and from the contextual menu select Import From File. In the pop-up dialog box, browse to the XML source file to import therefrom the XML structure used by the data to be received by tXMLMap. In this scenario, the XML source file is ProductsIn.xml, which contains the input data to tFileInputXML.

![Image of XML tree with doc node]

3. In the imported XML tree, right-click the manufacturer node and from the contextual menu select As loop element to set it as the loop element. Then do the same to set the types node and the sale node as loop elements respectively.
4. On the lower part of the map editor, click the **Schema editor** tab to display the corresponding view. Then on the right side of this view, add one column `outDoc` of **Document** type to the schema table. The corresponding XML root is added automatically to the output table on the top right side which represents the output flow.

5. In the `outDoc` output table, import the XML data structure to be used from the XML file that contains the expected output data and provides the expected XML structure. Right-click the `sale` node in the output table and select **As loop element** from the contextual menu. Then do the same to set the `manufacturer` node and the `types` node as loop elements respectively.
6. In the row1 input table, click the @category node and drop it to the Expression field of the @category node in the outDoc output table.

Do the same to map other nodes from the input table to the output table:

- the @name node to the @name node,
- the @unit node under the summary node to the @unit node,
- the @id node to the @id node and to the manufacturer_id node respectively,
- the @date node to the @date node,
• the name node to the @name node,
• the type node to the type node,
• the @type node to the @sales_type node, and
• the income node to the sale (loop) node.

7. On the top of the outDoc output table, click the wrench icon and set the value of the All in one property to true to generate a single XML flow. For further information about the All in one feature, see Talend Studio User Guide.

8. Click the [...] button next to the manufacturer loop element and in the pop-up [Configure source loops] dialog box click the [+] button to add one source loop manufacturer. Do the same to add one source loop sale for the sale loop element.

9. Click the [...] button next to the types loop element and in the pop-up [Configure source loops] dialog box add two source loops types and manufacturer. Make sure the sequence number of the types source loop is 0 so that the relative part of the output flow will be sorted based on the values of the type element.

Note:
When a loop element receives mappings from more than one loop element of the input flow, it allows you to set the sequence of the input loops. For example, the types loop element of the output flow in this scenario is mapped with the @id node which belongs to
the manufacturer loop element and the type node which belongs to the types loop element of the input flow. The output flow will be sorted according to the primary types loop.

10. Click OK to validate the mappings and close the **Map Editor**.

### Configuring the output flow

#### Procedure

1. Double-click the tLogRow component to open its **Basic settings** view.
2. Click the **Sync columns** button to retrieve the schema from its preceding component and accept the propagation prompted by the pop-up dialog box.
3. Double-click the tFileOutputXML component to open its **Basic settings** view.

![tFileOutputXML_1](image)

4. In the **File Name** field, browse to or enter the path to the file in which the output data will be written. In this scenario, it is *E:/ProductsOut.xml*.
5. Select the **Incoming record is a document** check box.

### Saving and executing the Job

#### Procedure

1. Press **Ctrl+S** to save the Job.
2. Press **F6** to execute the Job.
As shown above, the input products data is restructured as expected and the output data is displayed on the console and written into the XML file `ProductsOut.xml`.

```xml
<?xml version="1.0" encoding="ISO-8859-15"?>
<manufacturers category="1" name="laptop">
  <sale sales_type="DELL123">12345.0</sale>
  <sale sales_type="HP123">12345.123</sale>
  <manufacturer id="manu_1" date="03-04-0036" name="DELL"/>
  <manufacturer id="manu_2" name="HP"/>
</manufacturers>
```
**tXMLRPCInput**

Invokes a Method through a Web service and for the described purpose.

This component calls the defined method from the invoked RPC service, and returns the class as defined, based on the given parameters.

**tXMLRPCInput Standard properties**

These properties are used to configure tXMLRPCInput running in the Standard Job framework.

The Standard tXMLRPCInput component belongs to the Internet family.

The component in this framework is generally available.

**Basic settings**

| Schema and Edit Schema | A schema is a row description, it defines the number of fields that will be processed and passed on to the next component. The schema is either Built-in or remote in the Repository. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
  * View schema: choose this option to view the schema only.  
  * Change to built-in property: choose this option to change the schema to Built-in for local changes.  
  * Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the [Repository Content] window.  
In the RPC context, the schema corresponds to the output parameters. If two parameters are meant to be returned, then the schema should contain two columns. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Server URL</td>
<td>URL of the RPC service to be accessed</td>
</tr>
<tr>
<td>Need authentication / Username and Password</td>
<td>Select this check box and fill in a username and password if required to access the service.</td>
</tr>
<tr>
<td>Method Name</td>
<td>Enter the exact name of the Method to be invoked. The Method name MUST match the corresponding method described in the RPC Service. The Method name is also case-sensitive.</td>
</tr>
<tr>
<td>Return class</td>
<td>Select the type of data to be returned by the method. Make sure it fully matches the one defined in the method.</td>
</tr>
</tbody>
</table>
Parameters

Enter the parameters expected by the method as input parameters.

Global Variables

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

**NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

Usage

| Usage rule | This component is generally used as a Start component. It requires to be linked to an output component. |

Scenario: Guessing the State name from an XMLRPC

This scenario describes a two-component Job aiming at using a RPC method and displaying the output on the console view.

- Drop the **tXMLRPCInput** and a **tLogRow** components from the **Palette** to the design workspac.
- Set the **tXMLRPCInput** basic settings.
• Define the **Schema type** as **Built-in** for this use case.

• Set a single-column schema as the expected output for the called method is only one parameter: `StateName`.

• Then set the **Server url**. For this demo, use: `http://phpxmlrpc.sourceforge.net/server.php`

• No authentication details are required in this use case.

• The **Method** to be called is: `examples.getStateName`

• The **Return class** is not compulsory for this method but might be strictly required for another. Leave the default setting for this use case.

• Then set the input **Parameters** required by the method called. The **Name** field is not used in the code but the value should follow the syntax expected by the method. In this example, the Name used is **State Nr** and the value randomly chosen is **42**.

• The class has not much impact using this demo method but could have with another method, so leave the default setting.

• On the **tLogRow** component **Component** view, check the box: **Print schema column name in front of each value**.

• Then save the Job and press **F6** to execute it.

```
StateName: South Dakota
Job xmlrpc ended at 16:25 21/09/2007. [exit code=0]
```

*South Dakota* is the state name found using the `getStateName` RPC method and corresponds the 42nd State of the United States as defined as input parameter.
tXSDValidator

Helps at controlling data and structure quality of the file or flow to be processed.

tXSDValidator validates an input XML file or an input XML flow against an XSD file and sends the validation log to the defined output.

**tXSDValidator Standard properties**

These properties are used to configure tXSDValidator running in the Standard Job framework. The Standard tXSDValidator component belongs to the XML family.
The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
</table>
| **Mode**           | Select the validation mode from the drop-down list.  
  - **File Mode**: to validate an input file.  
  - **Flow Mode**: to validate an input flow. |
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields to be processed and passed on to the next component.  
  Note that when **File Mode** is selected from the **Mode** list, the schema of this component is read-only and it contains standard information regarding the file validation. |
| **XSD file**       | Specify the path to the XSD reference file. The HTTP URL is also supported, for example, `http://localhost:8080/book.xsd`.  
  This field is available only when **File Mode** is selected from the **Mode** drop-down list. |
| **XML file**       | Specify the path to the XML file to be validated.  
  This field is available only when **File Mode** is selected from the **Mode** drop-down list. |
| **If XML is valid, display** | Type in the message to be displayed on the console if the XML file is valid.  
  This field is available only when **File Mode** is selected from the **Mode** drop-down list. |
| **If XML is invalid, display** | Type in the message to be displayed on the console if the XML file is invalid.  
  This field is available only when **File Mode** is selected from the **Mode** drop-down list. |
| **Print to console** | Select this check box to display the validation message on the console. |
This check box is available only when **File Mode** is selected from the **Mode** drop-down list.

### Allocate

Click the [+] button to add as many rows as needed, and in each row set the value of the following columns:

- **Input Column**: click the cell and select a column to be validated.
- **XSD File**: enter the path to the corresponding XSD reference file.

This table is available only when **Flow Mode** is selected from the **Mode** drop-down list.

### Advanced settings

#### Enable Features

Click the [+] button to add as many rows as needed, and in each row enter the feature to be enabled on the underlying parser between double quotation marks, for example, "http://apache.org/xml/features/honour-all-schemaLocations".

For more information about the features, see [https://xerces.apache.org/xerces2-j/features.html](https://xerces.apache.org/xerces2-j/features.html).

#### Encoding

Enter the encoding type between double quotation marks.

#### tStatCatcher Statistics

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

**Global Variables**

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

**DIFFERENCE**: the result of the validation. This is a Flow variable and it returns a string.

**VALID**: the validation result. This is a Flow variable and it returns a boolean.

**XSD_ERROR_MESSAGE**: the xsd error message generated by the component. This is a Flow variable and it returns a string.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.
Usage

| Usage rule | When **File Mode** is selected, this component can be used as a standalone component but it is usually linked to an output component to gather the log data. |

**Scenario: Validating data flows against an XSD file**

This scenario describes a Job that validates an XML column in the input file *ShipOrder.csv* against the XSD reference file *ShipOrder.xsd* and then outputs valid rows into the delimited file *ShipOrder_Valid.csv* and invalid rows and error messages into the delimited file *ShipOrder_Invalid.csv*. For a similar use case that validates an XML file, see Validating XML files on page 663.

The content of the input file *ShipOrder.csv* that includes the XML column *ShipOrder* to be validated is as follows:

```
ID;ShipOrder
000001;<shiporder orderid="000001"><orderperson>George Bush</orderperson><shipto>John Adams</shipto><item><title>Empire Burlesque</title><note>Special Edition</note><quantity>1</quantity><price>10.90</price></item></shiporder>
000002;<shiporder orderid="000002"><orderperson>Judy Liu</orderperson><shipto>Jack Liu</shipto><item><title>Hide Your Heart</title><quantity>1</quantity><price>9.90</price></item></shiporder>
000003;<shiporder><orderperson>Peter Qian</orderperson><shipto>Thomas Wang</shipto><item><title>The Power of Habit</title><quantity>1</quantity><price>8.99</price></item></shiporder>
```

The content of the XSD reference file *ShipOrder.xsd* is as follows:

```
<?xml version="1.0" encoding="ISO-8859-1" ?>
<xs:schema xmlns:xs="http://www.w3.org/2001/XMLSchema">
  <xs:element name="shiporder">
    <xs:complexType>
      <xs:sequence>
        <xs:element name="orderperson" type="xs:string"/>
        <xs:element name="shipto">
          <xs:complexType>
            <xs:sequence>
              <xs:element name="name" type="xs:string"/>
              <xs:element name="address" type="xs:string"/>
            </xs:sequence>
          </xs:complexType>
        </xs:element>
      </xs:sequence>
    </xs:complexType>
  </xs:element>
</xs:schema>
```
Adding and linking components

Procedure
1. Create a new Job and add a tFileInputDelimited component, a tXSDValidator component, and two tFileOutputDelimited components by typing their names in the design workspace or dropping them from the Palette.

2. Double-click the tXSDValidator component to open its Basic settings view and select Flow Mode from the Mode drop-down list.

3. Link the tFileInputDelimited component to the tXSDValidator component using a Row > Main connection.

4. Link the tXSDValidator component to the first tFileOutputDelimited component using a Row > Main connection to output valid rows.

5. Link the tXSDValidator component to the second tFileOutputDelimited component using a Row > Rejects connection to output invalid rows.

Configuring the components

Procedure
1. Double-click the tFileInputDelimited component to open its Basic settings view on the Component tab.

2. In the File name/Stream field, specify the path to the input file. In this example, it is E:/ShipOrder.csv.
In the **Header** field, enter 1 to skip the first header row of the input file.

Click the [...] button next to **Edit schema** and define the schema by adding two columns **ID** and **ShipOrder** of **String** type.

3. Double-click the **tXSDValidator** component to open its **Basic settings** view on the **Component** tab.

4. Click the **Sync columns** button to retrieve the schema from the preceding **tFileInputDelimited** component, and in the pop-up dialog box, click **Yes** to propagate the schema to the two **tFileOutputDelimited** components.

Add a row in the **Allocate** table by clicking the [+] button. Then click the **Input Column** cell and select the XML column **ShipOrder** to be validated from the drop-down list. And in the **XSD File** cell, enter the path to the XSD reference file, *E:/ShipOrder.xsd* in this example.

5. Double-click the first **tFileOutputDelimited** component to open its **Basic settings** view on the **Component** tab.
6. In the File Name field, specify the path to the output file that will store valid rows. In this example, it is E:/ShipOrder_Valid.csv. Select the Include Header check box to include column headers in the output file.

7. Double-click the second tFileOutputDelimited component to open its Basic settings view on the Component tab.

8. Click the [...] button next to Edit schema to view its schema.

You can see an extra column errorMessage that holds the error information for invalid rows is added automatically into the schema in addition to the two propagated columns.

9. In the File Name field, specify the path to the output file that will store invalid rows and error messages. In this example, it is E:/ShipOrder_Invalid.csv. Select the Include Header check box to include column headers in the output file.

Saving and executing the Job

Procedure

1. Press Ctrl+S to save the Job.
2. Press F6 to run the Job.
As shown above, the output file *ShipOrder_Valid.csv* contains two valid rows, and the output file *ShipOrder_Invalid.csv* contains one invalid row that doesn’t define the *orderid* attribute and the error message.
tXSLT

Helps to transform data structure to another structure.
This component refers to an XSL stylesheet, to transform an XML source file into a defined output file.

**tXSLT Standard properties**

These properties are used to configure tXSLT running in the Standard Job framework.
The Standard tXSLT component belongs to the XML family.
The component in this framework is generally available.

**Basic settings**

<table>
<thead>
<tr>
<th>XML file</th>
<th>File path to the XML file to be validated.</th>
</tr>
</thead>
<tbody>
<tr>
<td>XSL file</td>
<td>File path to the reference XSL transformation file.</td>
</tr>
<tr>
<td>Output file</td>
<td>File path to the output file. If the file does not exist, it will be created. The output file can be any structured or unstructured file such as html, xml, txt or even pdf or edifact depending on your xsl.</td>
</tr>
</tbody>
</table>

**Parameters**

Click the plus button to add new lines in the Parameters list and define the transformation parameters of the XSLT file. Click in each line and enter the key in the name list and its associated value in the value list.

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the processing metadata at the Job level as well as at each component level. |

**Global Variables**

- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

- **OUTPUT_FILEPATH**: the output file path. This is a Flow variable and it returns a string.

- **OUTPUT_FILENAME**: the output file name. This is a Flow variable and it returns a string.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.
For further information about variables, see Talend Studio User Guide.

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component can be used as standalone component.</th>
</tr>
</thead>
</table>

Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

Scenario: Transforming XML to html using an XSL stylesheet

This scenario describes a two-component Job that converts xml data into an html document using an xsl stylesheet. It as well defines a transformation parameter of the xsl stylesheet to change the background color of the header of the created html document.

Procedure

Procedure

1. Drop the tXSLT and tMsBox components from the Palette to the design workspace.

2. Double-click tXSLT to open its Basic settings view where you can define the component properties.
3. In the **XML file** field, set the path or browse to the xml file to be transformed. In this example, the xml file holds a list of MP3 song titles and related information including artist names, company etc.

4. In the **XSL file** field in the **Basic settings** view, set the path or browse to the relevant xsl file.

5. In the **Output file** field, set the path or browse to the output html file.

In this example, we want to convert the xml data into an html file holding a table heading followed by a table listing artists' names next to song titles.
6. In the Parameters area of the Basic settings view, click the plus button to add a line where you can define the name and value of the transformation parameter of the xsl file. In this example, the name of the transformation parameter we want to use is bgcolor and the value is green.

7. Double-click the tMsgBox to display its Basic settings view and define its display properties as needed.

8. Save the Job and press F6 to execute it. The message box displays confirming that the output html file is created and stored in the defined path.
9. Click **OK** to close the message box.

**Results**

You can now open the output html file to check the transformation of the xml data and that of the background color of the table heading.
