tAS400Input Standard properties............................................................................................................................245
Handling data with AS/400....................................................................................................................................... 247
Related scenarios...........................................................................................................................................................251

tAS400LastInsertId..................................................................................................................................................252
  tAS400LastInsertId Standard properties............................................................................................................... 252
  Related scenario.............................................................................................................................................................253

tAS400Output............................................................................................................................................................254
  tAS400Output Standard properties.........................................................................................................................254
  Related scenarios...........................................................................................................................................................258

tAS400Rollback..........................................................................................................................................................259
  tAS400Rollback Standard properties..................................................................................................................... 259
  Related scenarios...........................................................................................................................................................260

tAS400Row...............................................................................................................................................................261
  tAS400Row Standard properties..............................................................................................................................261
  Related scenarios...........................................................................................................................................................264

tAssert......................................................................................................................................................................265
  tAssert Standard properties....................................................................................................................................... 265
  Viewing product orders status (on a daily basis) against a benchmark number............................................266
  Setting up the assertive condition for a Job execution..................................................................................269

tAssertCatcher..........................................................................................................................................................275
  tAssertCatcher Standard properties........................................................................................................................275
  Related scenarios...........................................................................................................................................................276

tAzureStorageConnection..........................................................................................................................................277
  tAzureStorageConnection Standard properties.................................................................................................. 277
  Related scenario.............................................................................................................................................................278

tAzureStorageContainerCreate.................................................................................................................................279
  tAzureStorageContainerCreate Standard properties............................................................................................279
  Creating a container in Azure Storage..................................................................................................................280

tAzureStorageContainerDelete..................................................................................................................................285
  tAzureStorageContainerDelete Standard properties..........................................................................................285
  Related scenarios...........................................................................................................................................................286

tAzureStorageContainerExist..................................................................................................................................287
  tAzureStorageContainerExist Standard properties..........................................................................................287
  Related scenario.............................................................................................................................................................288

tAzureStorageContainerList......................................................................................................................................289
tBoxDelete ................................................................................................................................................................. 393
  tBoxDelete Standard properties.................................................................................................................................. 393
  Related scenarios............................................................................................................................................................ 394

tBoxGet ........................................................................................................................................................................ 395
  tBoxGet Standard properties......................................................................................................................................... 395
  Related scenario............................................................................................................................................................. 396

tBoxList .......................................................................................................................................................................... 397
  tBoxList Standard properties.......................................................................................................................................... 397
  Related scenarios............................................................................................................................................................. 398

tBoxPut ............................................................................................................................................................................. 399
  tBoxPut Standard properties............................................................................................................................................. 399
  Uploading and downloading files from Box.................................................................................................................. 401

  tBufferInput ................................................................................................................................................................. 404
  tBufferInput Standard properties.................................................................................................................................. 404
  Retrieving bufferized data............................................................................................................................................... 405

  tBufferOutput ............................................................................................................................................................... 407
  tBufferOutput Standard properties.................................................................................................................................. 407
  Buffering data.................................................................................................................................................................. 408
  Buffering data to be used as a source system................................................................................................................ 410
  Buffering output data on the webapp server.................................................................................................................. 411
  Calling a Job with context variables from a browser................................................................................................... 414
  Calling a Job exported as Webservice in another Job................................................................................................... 416

  tCassandraBulkExec ...................................................................................................................................................... 419
  tCassandraBulkExec Standard properties.................................................................................................................. 419
  Related scenarios............................................................................................................................................................ 420

  tCassandraClose .............................................................................................................................................................. 421
  tCassandraClose Standard properties........................................................................................................................ 421
  Related Scenario............................................................................................................................................................. 421

  tCassandraConnection .................................................................................................................................................... 422
  tCassandraConnection Standard properties................................................................................................................ 422
  Related scenario............................................................................................................................................................. 423

  tCassandraInput ............................................................................................................................................................. 424
  Mapping tables between Cassandra type and Talend data type.................................................................................. 424
  tCassandraInput Standard properties........................................................................................................................ 425
  Handling data with Cassandra.......................................................................................................................................... 429
Related scenarios.................................................................572

**tDB2Output**............................................................................573
  tDB2Output Standard properties...............................................573
  Related scenarios...............................................................578

**tDB2Rollback**........................................................................579
  tDB2Rollback Standard properties............................................579
  Related scenarios...............................................................580

**tDB2Row**................................................................................581
  tDB2Row Standard properties................................................581
  Related scenarios...............................................................584

**tDB2SCD**..............................................................................585
  tDB2SCD Standard properties................................................585
  Related scenarios...............................................................588

**tDB2SCDELT**.......................................................................589
  tDB2SCDELT Standard properties...........................................589
  Related scenario.....................................................................592

**tDB2SP**................................................................................594
  tDB2SP Standard properties..................................................594
  Related scenarios...............................................................596

Dynamic database components.............................................598

**tDBBulkExec**......................................................................599
  tDBBulkExec Standard properties..........................................599

**tDBClose**............................................................................600
  tDBClose Standard properties................................................600

**tDBCOLUMNList**..................................................................601
  tDBCOLUMNList Standard properties.......................................601

**tDBCOLUMNCommit**...........................................................602
  tDBCOLUMNCommit Standard properties.................................602

**tDBCOLUMNConnection**......................................................603
  tDBCOLUMNConnection Standard properties............................603

**tDBInput**.............................................................................604
  tDBInput Standard properties................................................604
Resetting a DB auto-increment

tDynamoDBInput.......................................................................................................665
  tDynamoDBInput Standard properties.................................................................665
  Related scenarios...............................................................................................668

tDynamoDBOutput..................................................................................................669
  tDynamoDBOutput Standard properties...............................................................669
  Related scenarios...............................................................................................671

tEDIFACTtoXML......................................................................................................672
  tEDIFACTtoXML Standard properties.................................................................672
  Reading an EDIFACT message file and saving it to XML.................................673

tELTGreenplumInput...............................................................................................676
  tELTGreenplumInput Standard properties..........................................................676
  Related scenarios...............................................................................................677

tELTGreenplumMap.................................................................................................678
  tELTGreenplumMap Standard properties............................................................678
  Mapping data using a simple implicit join.........................................................680
  Related scenarios...............................................................................................687

tELTGreenplumOutput..............................................................................................688
  tELTGreenplumOutput Standard properties.......................................................688
  Related scenarios...............................................................................................690

tELTHiveInput.........................................................................................................691
  tELTHiveInput Standard properties....................................................................691
  Related scenarios...............................................................................................692

tELTHiveMap..........................................................................................................693
  tELTHiveMap Standard properties......................................................................693
  Joining table columns and writing them into Hive............................................704
  Related scenarios...............................................................................................711

tELTHiveOutput......................................................................................................712
  tELTHiveOutput Standard properties.................................................................712
  Related scenarios...............................................................................................714

tELTInput...............................................................................................................715
  tELTInput Standard properties..........................................................................715
  Related scenarios...............................................................................................716

tELTMap.................................................................................................................717
  tELTMap Standard properties.............................................................................717
  Aggregating Snowflake data using context variables as table and connection names........719
Related scenarios...........................................................................................................................................................760

tELTOracleMap..............................................................................................................................................................761
tELTOracleMap Standard properties................................................................................................................................761
Updating Oracle DB entries...........................................................................................................................................763
Related scenario.............................................................................................................................................................766

tELTOracleOutput............................................................................................................................................................767
tELTOracleOutput Standard properties........................................................................................................................767
Using the Oracle MERGE function to update and add data simultaneously...............................................................769

tELTPostgresqlInput......................................................................................................................................................774
tELTPostgresqlInput Standard properties....................................................................................................................774
Related scenarios.............................................................................................................................................................775

tELTPostgresqlMap.........................................................................................................................................................776
tELTPostgresqlMap Standard properties.......................................................................................................................776
Related scenarios.............................................................................................................................................................778

tELTPostgresqlOutput.......................................................................................................................................................779
tELTPostgresqlOutput Standard properties....................................................................................................................779
Related scenarios.............................................................................................................................................................781

tELTSybaseInput.................................................................................................................................................................782
tELTSybaseInput Standard properties...........................................................................................................................782
Related scenarios.............................................................................................................................................................783

tELTSybaseMap.................................................................................................................................................................784
tELTSybaseMap Standard properties...............................................................................................................................784
Related scenarios.............................................................................................................................................................786

tELTSybaseOutput...............................................................................................................................................................787
tELTSybaseOutput Standard properties...........................................................................................................................787
Related scenarios.............................................................................................................................................................789

tELTTeradataInput...............................................................................................................................................................790
tELTTeradataInput Standard properties...........................................................................................................................790
Related scenarios.............................................................................................................................................................791

tELTTeradataMap...............................................................................................................................................................792
tELTTeradataMap Standard properties...........................................................................................................................792
Mapping data using a subquery......................................................................................................................................794
Related scenarios.............................................................................................................................................................802

tELTTeradataOutput............................................................................................................................................................803
tELTTeradataOutput Standard properties.......................................................................................................................803

Checking for the presence of a file and creating it if it does not exist.................................................... 989

tFileFetch...................................................................................................................................................... 993
tFileFetch Standard properties............................................................................................................................993
Fetching data through HTTP..................................................................................................................................996
Reusing stored cookie to fetch files through HTTP.................................................................................................998
Related scenario.................................................................................................................................................. 1002

tFileInputARFF................................................................................................................................................... 1003
tFileInputARFF Standard properties.....................................................................................................................1003
Displaying the content of a ARFF file........................................................................................................................1004

tFileInputDelimited............................................................................................................................................. 1008
tFileInputDelimited Standard properties............................................................................................................1008
Reading data from a Delimited file and display the output....................................................................................1011
Reading data from a remote file in streaming mode.............................................................................................1013

tFileInputExcel.................................................................................................................................................. 1017
tFileInputExcel Standard properties.................................................................................................................... 1017
Related scenarios................................................................................................................................................ 1020

tFileInputFullRow............................................................................................................................................. 1021
tFileInputFullRow Standard properties.............................................................................................................1021
Reading full rows in a delimited file..................................................................................................................1022

tFileInputJSON.................................................................................................................................................. 1025
tFileInputJSON Standard properties...................................................................................................................1025
Extracting JSON data from a file using JSONPath without setting a loop node.................................................1027
Extracting JSON data from a file using JSONPath................................................................................................1030
Extracting JSON data from a file using XPath....................................................................................................1032
Extracting JSON data from a URL.......................................................................................................................1033

tFileInputLDIF................................................................................................................................................... 1038
tFileInputLDIF Standard properties.....................................................................................................................1038
Related scenario.................................................................................................................................................. 1040

tFileInputMail.................................................................................................................................................. 1041
tFileInputMail Standard properties.................................................................................................................... 1041
Extracting key fields from an email....................................................................................................................1043

tFileInputMSDelimited....................................................................................................................................... 1045
tFileInputMSDelimited Standard properties.......................................................................................................1045
The Multi Schema Editor.....................................................................................................................................1046
Reading a multi structure delimited file................................................................................................................1047

tFileInputMSPositional................................................................................................................................. 1054
tFileTouch.................................................................1159
  tFileTouch Standard properties.................................1159
  Related scenarios......................................................1160

Related scenarios.........................................................1160

Related scenarios.........................................................1162

Related Scenario.........................................................1164

Filtering a list of names using simple conditions.............1166
Filtering a list of names through different logical operations.1170

Related scenarios.........................................................1173

Related scenario.........................................................1175

Related scenarios.........................................................1177

Related scenarios.........................................................1180

Related scenarios.........................................................1185

Related scenario.........................................................1187

Related scenarios.........................................................1191
tFixedFlowInput......................................................................................................1192
  tFixedFlowInput Standard properties..................................................................................................................1192
  Related scenarios........................................................................................................................................................ 1193

FlowMeter.............................................................................................................. 1194
  tFlowMeter Standard properties............................................................................................................................1194
  Related scenario.......................................................................................................................................................... 1195

FlowMeterCatcher.................................................................................................1196
  tFlowMeterCatcher Standard properties.............................................................................................................1196
  Catching flow metrics from a Job..........................................................................................................................1197

FlowToIterate........................................................................................................ 1201
  tFlowToIterate Standard properties.....................................................................................................................1201
  Transforming data flow to a list...........................................................................................................................1202

Foreach................................................................................................................... 1206
  tForeach Standard properties.................................................................................................................................1206
  Iterating on a list and retrieving the values....................................................................................................1206

FTPClose.................................................................................................................1209
  tFTPClose Standard properties.............................................................................................................................. 1209
  Related scenarios........................................................................................................................................................ 1209

FTPConnection...................................................................................................... 1210
  tFTPConnection Standard properties...................................................................................................................1210
  Related scenarios........................................................................................................................................................ 1212

FTPDelete...............................................................................................................1213
  tFTPDelete Standard properties............................................................................................................................ 1213
  Related scenario.......................................................................................................................................................... 1216

FTPFileExist........................................................................................................... 1217
  tFTPFileExist Standard properties........................................................................................................................ 1217
  Related scenario.......................................................................................................................................................... 1219

FTPFileList............................................................................................................. 1220
  tFTPFileList Standard properties...........................................................................................................................1220
  Listing and getting files/folders on an FTP directory...................................................................................1222

FTPFileProperties................................................................................................1228
  tFTPFileProperties Standard properties..............................................................................................................1228
  Related scenario........................................................................................................................................................ 1230

FTPGet....................................................................................................................1231
tGSCopy Standard properties..................................................................................................................................1359
Related scenario..................................................................................................................................................1360

tGSDelete..........................................................................................................................................................1361
tGSDelete Standard properties..............................................................................................................................1361
Related scenario..................................................................................................................................................1362

tGSGet...............................................................................................................................................................1363
tGSGet Standard properties..................................................................................................................................1363
Related scenarios..................................................................................................................................................1365

tGSLList............................................................................................................................................................1366
tGSLList Standard properties...............................................................................................................................1366
Related scenario..................................................................................................................................................1367

tGSPut.................................................................................................................................................................1368
tGSPut Standard properties..................................................................................................................................1368
Managing files with Google Cloud Storage.......................................................................................................1369

Managing files with Google Cloud Storage......................................................................................................1369

Reading data from the cache memory for high-speed data access.....................................................................1378
Clearing the memory before loading data to it in case an iterator exists in the same subJob.........................1382

Related scenarios..................................................................................................................................................1388

tHBaseClose......................................................................................................................................................1389
tHBaseClose Standard properties..........................................................................................................................1389
Related scenario..................................................................................................................................................1390

tHBaseConnection..............................................................................................................................................1391
tHBaseConnection Standard properties................................................................................................................1391
Related scenario..................................................................................................................................................1395

HBase filters..........................................................................................................................................................1396
tHBaseInput Standard properties..........................................................................................................................1397
Exchanging customer data with HBase..................................................................................................................1402

tHBaseOutput......................................................................................................................................................1410
tHBaseOutput Standard properties..........................................................................................................................1410
Related scenario..................................................................................................................................................1415

tHCatalogInput....................................................................................................................................................1416
Related scenarios ........................................................................................................................................................ 1758

\textbf{tIngresRow}....................................................................................................................................................... 1759
\begin{itemize}
  \item tIngresRow Standard properties ......................................................................................................................... 1759
  \item Related scenarios ................................................................................................................................................. 1762
\end{itemize}

\textbf{tIngresSCD}....................................................................................................................................................... 1763
\begin{itemize}
  \item tIngresSCD Standard properties ........................................................................................................................... 1763
  \item Related scenario .................................................................................................................................................... 1765
\end{itemize}

\textbf{tInterbaseClose}............................................................................................................................................... 1766
\begin{itemize}
  \item tInterbaseClose Standard properties .................................................................................................................. 1766
  \item Related scenarios .................................................................................................................................................. 1767
\end{itemize}

\textbf{tInterbaseCommit}.............................................................................................................................................. 1768
\begin{itemize}
  \item tInterbaseCommit Standard properties ................................................................................................................ 1768
  \item Related scenario ..................................................................................................................................................... 1769
\end{itemize}

\textbf{tInterbaseConnection}....................................................................................................................................... 1770
\begin{itemize}
  \item tInterbaseConnection Standard properties ......................................................................................................... 1770
  \item Related scenarios .................................................................................................................................................. 1771
\end{itemize}

\textbf{tInterbaseInput}............................................................................................................................................... 1772
\begin{itemize}
  \item tInterbaseInput Standard properties ................................................................................................................... 1772
  \item Related scenarios .................................................................................................................................................. 1775
\end{itemize}

\textbf{tInterbaseOutput}.............................................................................................................................................. 1776
\begin{itemize}
  \item tInterbaseOutput Standard properties ................................................................................................................ 1776
  \item Related scenarios .................................................................................................................................................. 1781
\end{itemize}

\textbf{tInterbaseRollback}........................................................................................................................................... 1782
\begin{itemize}
  \item tInterbaseRollback Standard properties ............................................................................................................... 1782
  \item Related scenarios .................................................................................................................................................. 1783
\end{itemize}

\textbf{tInterbaseRow}................................................................................................................................................... 1784
\begin{itemize}
  \item tInterbaseRow Standard properties ....................................................................................................................... 1784
  \item Related scenarios .................................................................................................................................................. 1787
\end{itemize}

\textbf{tIntervalMatch}................................................................................................................................................. 1788
\begin{itemize}
  \item tIntervalMatch Standard properties ...................................................................................................................... 1788
  \item Identifying server locations based on their IP addresses ..................................................................................... 1789
\end{itemize}

\textbf{tIterateToFlow}................................................................................................................................................ 1793

tAccessBulkExec

Offers gains in performance when carrying out Insert operations in an Access database.

The tAccessOutputBulk and tAccessBulkExec components are generally used together to output data to a delimited file and then to perform various actions on the file in an Access database, in a two step process. These two steps are fused together in the tAccessOutputBulkExec component, detailed in a separate section. The advantage of using a two step process is that it makes it possible to carry out transformations on the data before loading it in the database.

This component executes an Insert action on the data provided.

**tAccessBulkExec Standard properties**

These properties are used to configure tAccessBulkExec running in the Standard Job framework.

The Standard tAccessBulkExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
<table>

</table>
| **Action on table** | On the table defined, you can perform one of the following operations:  
- **None**: No operation is carried out.  
- **Drop and create table**: The table is removed and created again.  
- **Create table**: The table does not exist and gets created.  
- **Create table if not exists**: The table is created if it does not exist.  
- **Drop table if exists and create**: The table is removed if it already exists and created again.  
- **Clear table**: The table content is deleted. |
| **Table** | Name of the table to be written. Note that only one table can be written at a time and that the table must exist already for the insert operation to succeed. |
| **Local filename** | Browse to the delimited file to be loaded into your database. |
| **Action on data** | On the data of the table defined, you can perform:  
- **Insert**: Add new entries to the table. |
| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.  
- **Built-in**: The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide.  
- **Repository**: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide. |
|  | Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
- **View schema**: choose this option to view the schema only.  
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon... |

</table>

Related scenarios

For use cases in relation with tAccessBulkExec, see the following scenarios:

- Inserting transformed data in MySQL database on page 2493
- Inserting data in bulk in MySQL database on page 2500
tAccessClose

Closes an active connection to the Access database so as to release occupied resources.

tAccessClose Standard properties

These properties are used to configure tAccessClose running in the Standard Job framework.

The Standard tAccessClose component belongs to the Databases family.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

<td></td>
</tr>
</tbody>
</table>

**Related scenarios**

No scenario is available for the Standard version of this component yet.
**tAccessCommit**

Commits in one go a global transaction instead of doing that on every row or every batch, and provides gain in performance, using a unique connection.

tAccessCommit validates the data processed through the Job into the connected database.

**tAccessCommit Standard properties**

These properties are used to configure tAccessCommit running in the Standard Job framework.

The Standard tAccessCommit component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the <strong>tAccessConnection</strong> component in the list if more than one connection are planned for the current Job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Warning:**
If you want to use a **Row > Main** connection to link tAccessCommit to your Job, your data will be committed row by row. In this case, do not select the **Close connection** check box or your connection will be closed before the end of your first row commit.

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is more commonly used with other tAccess* components, especially with the **tAccessConnection** and **tAccessRollback** components. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to acces |
s database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

**Limitation**

| If you are using an ODBC driver, you need to work with Java 7, and make sure that your JVM and ODBC versions match up: both 64-bit or 32-bit. |

**Related scenario**

For **tAccessCommit** related scenario, see Inserting data in mother/daughter tables on page 2437
**tAccessConnection**

Opens a connection to the specified database that can then be reused in the subsequent subjob or subjobs.

*tAccessConnection* opens a connection to the database for a current transaction.

**tAccessConnection Standard properties**

These properties are used to configure *tAccessConnection* running in the Standard Job framework.

The Standard *tAccessConnection* component belongs to the Databases and the ELT families.

The component in this framework is available in all *Talend products*.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
</tbody>
</table>

**Built-in:** No property data stored centrally.

**Repository:** Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.

**DB Version**

Access 2003 or later versions.

**Database**

Name of the database.

**Username and Password**

DB user authentication data.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

**Use or register a shared DB Connection**

Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the **Shared DB Connection Name** field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child.

This option is incompatible with the **Use dynamic job** and **Use an independent process to run subjob** options of the *tRunJob* component. Using a shared connection together with a *tRunJob* component with either of these two options enabled will cause your Job to fail.
Inserting data in parent/child tables

The following Job is dedicated to advanced database users, who want to carry out multiple table insertions using a parent table Table1 to generate two child tables: Name and Birthday.

- In Access 2007, create an Access database named Database1.
- Once the Access database is created, create a table named Table1 with two column headings: Name and Birthday.

Back into the Integration perspective of Talend Studio, the Job requires twelve components including tAccessConnection, tAccessCommit, tAccessInput, tAccessOutput and tAccessClose.
• Drop the following components from the Palette to the design workspace: **tFileList**, **tFileInputDelimited**, **tMap**, **tAccessOutput (two)**, **tAccessInput (two)**, **tAccessCommit**, **tAccessClose** and **tLogRow (x2)**.

• Connect the **tFileList** component to the input file component using an Iterate link. Thus, the name of the file to be processed will be dynamically filled in from the **tFileList** directory using a global variable.

• Connect the **tFileInputDelimited** component to the **tMap** component and dispatch the flow between the two output Access components. Use a Row link for each of these connections representing the main data flow.

• Set the **tFileList** component properties, such as the directory where files will be fetched from.

• Add a **tAccessConnection** component and connect it to the starter component of this Job. In this example, the **tFileList** component uses an OnComponentOk link to define the execution order.

• In the **tAccessConnection** Component view, set the connection details manually or fetch them from the Repository if you centrally store them as a Metadata DB connection entry. For more information about Metadata, see **Talend Studio User Guide**.

• In the **tFileInputDelimited** component’s Basic settings view, press Ctrl+Space bar to access the variable list. Set the File Name field to the global variable: **tFileList_1.CURRENT_FILEPATH**. For more information about using variables, see **Talend Studio User Guide**.

• Set the rest of the fields as usual, defining the row and field separators according to your file structure.

• Then set the schema manually through the Edit schema dialog box or select the schema from the Repository. Make sure the data type is correctly set, in accordance with the nature of the data processed.

• In the **tMap** Output area, add two output tables, one called **Name** for the **Name** table, the second called **Birthday**, for the **Birthday** table. For more information about the **tMap** component, see **Talend Studio User Guide**.

• Drag the **Name** column from the **Input** area, and drop it to the **Name** table.

• Drag the **Birthday** column from the **Input** area, and drop it to the **Birthday** table.
Then connect the output row links to distribute the flow correctly to the relevant DB output components.

In each of the **tAccessOutput** components’ **Basic settings** view, select the **Use an existing connection** check box to retrieve the **tAccessConnection** details.

- Set the **Table** name making sure it corresponds to the correct table, in this example either **Name** or **Birthday**.
- There is no action on the table as they are already created.
- Select **Insert** as **Action on data** for both output components.
- Click on **Sync columns** to retrieve the schema set in the **tMap**.
- Then connect the first **tAccessOutput** component to the first **tAccessInput** component using an **OnComponentOk** link.
- In each of the **tAccessInput** components’ **Basic settings** view, select the **Use an existing connection** check box to retrieve the distributed data flow. Then set the schema manually through **Edit schema** dialog box.
- Then set the **Table Name** accordingly. In **tAccessInput_1**, this will be **Name**.
- Click on the **Guess Query**.
- Connect each **tAccessInput** component to **tLogRow** component with a **Row > Main** link. In each of the **tLogRow** components’ **basic settings** view, select **Table** in the **Mode** field.
- Add the **tAccessCommit** component below the **tFileList** component in the design workspace and connect them together using an **OnComponentOk** link in order to terminate the Job with the trans action commit.
- In the **basic settings** view of **tAccessCommit** component and from the **Component list**, select the connection to be used, **tAccessConnection_1** in this scenario.
- Save your Job and press **F6** to execute it.
The parent table *Table1* is reused to generate the *Name* table and *Birthday* table.

```plaintext

| 03-03-2023|

[statistics] disconnected
Job Access ended at 18:02 28/12/2010. [exit code=0]
```
**tAccessInput**

Reads a database and extracts fields based on a query.

tAccessInput executes a DB query with a strictly defined statement which must correspond to the schema definition. Then it passes on the field list to the next component via a **Row > Main** connection.

**tAccessInput Standard properties**

These properties are used to configure tAccessInput running in the Standard Job framework.

The Standard tAccessInput component belongs to the Databases family.

The component in this framework is available in all **Talend products**.

---

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
</tbody>
</table>

**Built-in:** No property data stored centrally.

**Repository:** Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.

Click this icon to open a database connection wizard and store the database connection parameters you set in the component **Basic settings** view.

For more information about setting up and storing database connection parameters, see the section describing how to set up a DB connection of **Talend Studio User Guide**.

| Use an existing connection | Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined. |
Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>DB Version</th>
<th>Select the version of Access that you are using.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Name of the database.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>

If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.</td>
<td></td>
</tr>
<tr>
<td>Query type and Query</td>
<td>Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.</td>
</tr>
</tbody>
</table>
**Advanced settings**

**Additional JDBC parameters**
Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the **Use an existing connection** check box in the **Basic** settings.

**tStat Catcher Statistics**
Select this check box to collect log data at the component level.

**Trim all the String/Char columns**
Select this check box to remove leading and trailing whitespace from all the String/Char columns.

**Trim column**
Remove leading and trailing whitespace from defined columns.

**Global Variables**

**Global Variables**

**NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.

**QUERY**: the query statement being processed. This is a Flow variable and it returns a string.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

**Usage**

**Usage rule**
This component offers the flexibility benefit of the DB query and covers all possible SQL queries.

**Dynamic settings**
Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.
For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

**Limitation**

If you are using an ODBC driver, you need to work with Java 7, and make sure that your JVM and ODBC versions match up: both 64-bit or 32-bit.

When working with Java 8, this component supports only the General collation mode of Access.

## Related scenarios

For related topics, see:

Related topic in description of tContextLoad on page 490.
tAccessOutput

Writes, updates, makes changes or suppresses entries in a database.

tAccessOutput executes the action defined on the table and/or on the data contained in the table, based on the flow incoming from the preceding component in the Job.

**tAccessOutput Standard properties**

These properties are used to configure tAccessOutput running in the Standard Job framework.

The Standard tAccessOutput component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>

<td><strong>Built-in:</strong> No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository:</strong> Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td></td>
<td>Click this icon to open a database connection wizard and store the database connection parameters you set in the component Basic settings view.</td>
</tr>
<tr>
<td></td>
<td>For more information about setting up and storing database connection parameters, see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th><strong>DB Version</strong></th>
<th>Select the version of Access that you are using.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td><strong>Table</strong></td>
<td>Name of the table to be written. Note that only one table can be written at a time</td>
</tr>
</tbody>
</table>
| **Action on table** | On the table defined, you can perform one of the following operations:  
  **None:** No operation is carried out.  
  **Drop and create table:** The table is removed and created again.  
  **Create table:** The table does not exist and gets created.  
  **Create table if not exists:** The table is created if it does not exist.  
  **Drop table if exists and create:** The table is removed if it already exists and created again.  
  **Clear table:** The table content is deleted. |
| **Action on data** | On the data of the table defined, you can perform:  
  **Insert:** Add new entries to the table. If duplicates are found, Job stops.  
  **Update:** Make changes to existing entries.  
  **Insert or update:** Insert a new record. If the record with the given reference already exists, an update would be made.  
  **Update or insert:** Update the record with the given reference. If the record does not exist, a new record would be inserted.  
  **Delete:** Remove entries corresponding to the input flow. |
### Warning:
You must specify at least one column as a primary key on which the Update and Delete operations are based. You can do that by clicking Edit Schema and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the Advanced settings view where you can simultaneously define primary keys for the update and delete operations. To do that: Select the Use field options check box and then in the Key in update column, select the check boxes next to the column name on which you want to base the update operation. Do the same in the Key in delete column for the deletion operation.

### Schema and Edit schema
A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

**Built-In:** You create and store the schema locally for this component only.

**Repository:** You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema:** choose this option to view the schema only.
- **Change to built-in property:** choose this option to change the schema to Built-in for local changes.
- **Update repository connection:** choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

### Die on error
This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a Row > Rejects link.

### Advanced settings

#### Additional JDBC parameters
Specify additional connection properties for the DB connection you are creating. This option is not available if
you have selected the **Use an existing connection** check box in the **Basic** settings.

**Note:**
You can press **Ctrl+Space** to access a list of predefined global variables.

<table>
<thead>
<tr>
<th>Commit every</th>
<th>Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and, above all, better performance at executions.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Additional Columns</td>
<td>This option is not offered if you create (with or without drop) the DB table. This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing.</td>
</tr>
</tbody>
</table>

**Name:** Type in the name of the schema column to be altered or inserted as new column.

**SQL expression:** Type in the SQL statement to be executed in order to alter or insert the relevant column data.

**Position:** Select **Before, Replace** or **After** following the action to be performed on the reference column.

**Reference column:** Type in a column of reference that the tDBOutput can use to place or replace the new or altered column.

<table>
<thead>
<tr>
<th>tStat Catcher Statistics</th>

<tr>
<th>Global Variables</th>
<th><strong>NB_LINE:</strong> the number of rows processed. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>NB_LINE_UPDATED:</strong> the number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td><strong>NB_LINE_INSERTED:</strong> the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
</tbody>
</table>
**Usage**

**Usage rule**
This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible.

This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in an Access database. It also allows you to create a reject flow using a Row > Rejects link to filter data in error. For an example of *tMysqlOutput* in use, see Retrieving data in error with a Reject link on page 2485.

**Dynamic settings**
Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

**Limitation**
If you are using an ODBC driver, you need to work with Java 7, and make sure that your JVM and ODBC versions match up: both 64-bit or 32-bit.

When working with Java 8, this component supports only the General collation mode of Access.

<table>
<thead>
<tr>
<th><strong>tAccessOutput</strong></th>
<th><strong>NB_LINE_DELETED</strong>: the number of rows deleted. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE_REJECTED</strong>: the number of rows rejected. This is an After variable and it returns an integer.</td>
<td></td>
</tr>
<tr>
<td><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
<td></td>
</tr>
<tr>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
<td></td>
</tr>
<tr>
<td>To fill up a field or expression with a variable, press <strong>Ctrl + Space</strong> to access the variable list and choose the variable to use from it.</td>
<td></td>
</tr>
<tr>
<td>For further information about variables, see Talend Studio User Guide.</td>
<td></td>
</tr>
</tbody>
</table>
Related scenarios

For related topics, see:

- Inserting a column and altering data using tMysqlOutput on page 2477.
tAccessOutputBulk

Prepares the file which contains the data used to feed the Access database.

The tAccessOutputBulk and tAccessBulkExec components are generally used together to output data to a delimited file and then to perform various actions on the file in an Access database, in a two step process. These two steps are fused together in the tAccessOutputBulkExec component, detailed in a separate section. The advantage of using a two step process is that it makes it possible to carry out transformations on the data before loading it in the database.

tAccessOutputBulk writes a delimited file.

**tAccessOutputBulk Standard properties**

These properties are used to configure tAccessOutputBulk running in the Standard Job framework.

The Standard tAccessOutputBulk component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Property type</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td><strong>Property type</strong></td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in</strong>: No property data stored centrally.&lt;br&gt;<strong>Repository</strong>: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
<td></td>
</tr>
<tr>
<td><strong>File Name</strong></td>
<td>Name and path to the file to be created and/or the variable to be used. For further information about how to define and use a variable in a Job, see Talend Studio User Guide.</td>
</tr>
<tr>
<td><strong>Create directory if not exists</strong></td>
<td>Select this check box to create the as yet non-existent file directory that specified in the <strong>File name</strong> field.</td>
</tr>
<tr>
<td><strong>Append</strong></td>
<td>Select this check box to add any new rows to the end of the file.</td>
</tr>
<tr>
<td><strong>Schema and Edit schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <strong>line</strong> when naming the fields.</td>
</tr>
<tr>
<td><strong>Built-In</strong>: You create and store the schema locally for this component only.</td>
<td></td>
</tr>
</tbody>
</table>
Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

### Advanced settings

<table>
<thead>
<tr>

<tr>
<td>Limitation</td>
<td>If you are using an ODBC driver, you need to work with Java 7, and make sure that your JVM and ODBC versions match up: both 64-bit or 32-bit. When working with Java 8, this component supports only the General collation mode of Access.</td>
</tr>
</tbody>
</table>

Related scenarios

For use cases in relation with tAccessOutputBulk, see the following scenarios:

- Inserting transformed data in MySQL database on page 2493
- Inserting data in bulk in MySQL database on page 2500
**tAccessOutputBulkExec**

Executes an Insert action on the data provided, in an Access database.

The tAccessOutputBulk and tAccessBulkExec components are generally used together to output data to a delimited file and then to perform various actions on the file in an Access database, in a two step process. These two steps are fused together in tAccessOutputBulkExec.

As a dedicated component, tAccessOutputBulkExec improves performance during Insert operations in an Access database.

**tAccessOutputBulkExec Standard properties**

These properties are used to configure tAccessOutputBulkExec running in the Standard Job framework.

The Standard tAccessOutputBulkExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>

<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

| Use an existing connection | Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined. |

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
<table>

<tr>
<td><strong>Action on data</strong></td>
<td>On the data of the table defined, you can perform: <strong>Insert</strong>: Add new entries to the table.</td>
</tr>
<tr>
<td><strong>Schema and Edit schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. <strong>Built-In</strong>: You create and store the schema locally for this component only. <strong>Repository</strong>: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually. You can find more details about how to verify default values in retrieved schema in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
</tbody>
</table>
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

### Create directory if not exists

Select this check box to create the as yet non existent file directory specified in the **File name** field.

### Append

Select this check box to append new rows to the end of the file.

### Advanced settings

#### Additional JDBC parameters

Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the **Use an existing connection** check box in the **Basic** settings.

**Note:**

You can press **Ctrl+Space** to access a list of predefined global variables.

#### Include header

Select this check box to include the column header to the file.

#### Encoding

Select the encoding from the list or select **Custom** and define it manually. This field is compulsory for DB data handling.

#### tStatCatcher Statistics

Select this check box to collect the log data at the component level.

### Usage

#### Usage rule

This component is mainly used when no particular transformation is required on the data to be loaded in the database.

#### Dynamic settings

Click the [+ ] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.
The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

| Limitation | If you are using an ODBC driver, make sure that your JVM and ODBC versions match up: both 64-bit or 32-bit. |

## Related scenarios

For use cases in relation with **tAccessOutputBulkExec**, see the following scenarios:

- Inserting data in bulk in MySQL database on page 2500
- Inserting transformed data in MySQL database on page 2493
tAccessRollback

Cancels the transaction commit in the connected database and avoids to commit part of a transaction involuntarily.

### tAccessRollback Standard properties

These properties are used to configure tAccessRollback running in the Standard Job framework.

The Standard tAccessRollback component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

#### Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

#### Usage

| Usage rule | This component is more commonly used with other tAccess* components, especially with the tAccessConnection and tAccessCommit components. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection |
parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

| Limitation | If you are using an ODBC driver, you need to work with Java 7, and make sure that your JVM and ODBC versions match up: both 64-bit or 32-bit. |

**Related scenarios**

No scenario is available for the Standard version of this component yet.
tAccessRow

Executes the SQL query stated onto the specified database.

Depending on the nature of the query and the database, tAccessRow acts on the actual DB structure or on the data (although without handling data). The SQLBuilder tool helps you write easily your SQL statements. tAccessRow is the specific component for this database query. The row suffix means the component implements a flow in the job design although it does not provide output.

**tAccessRow Standard properties**

These properties are used to configure tAccessRow running in the Standard Job framework.

The Standard tAccessRow component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

<thead>
<tr>
<th>Usage rule</th>
<th>This component offers the flexibility of the DB query and covers all possible SQL queries.</th>
</tr>
</thead>
</table>

**Dynamic settings**

Click the [+ ] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

**Limitation**

If you are using an ODBC driver, you need to work with Java 7, and make sure that your JVM and ODBC versions match up: both 64-bit or 32-bit.

When working with Java 8, this component supports only the General collation mode of Access.

Related scenarios

For related topics, see:

- Procedure on page 625
- Removing and regenerating a MySQL table index on page 2508.
tAddCRCRow

Provides a unique ID which helps improving the quality of processed data. CRC stands for Cyclical Redundancy Checking.

tAddCRCRow calculates a surrogate key based on one or several columns and adds it to the defined schema.

**tAddCRCRow Standard properties**

These properties are used to configure tAddCRCRow running in the Standard Job framework.

The Standard tAddCRCRow component belongs to the Data Quality family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Schema and Edit Schema</th>
<th>A schema is a row description. It defines the number of fields to be processed and passed on to the next component. The schema is either <strong>Built-in</strong> or stored remotely in the Repository. In this component, a new CRC column is automatically added.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-in:</strong> The schema will be created and stored locally for this component only. Related topic: see Talend Studio User Guide.</td>
<td></td>
</tr>
<tr>
<td><strong>Repository:</strong> The schema already exists and is stored in the Repository, hence can be reused in various projects and Job designs. Related topic: see Talend Studio User Guide.</td>
<td></td>
</tr>
</tbody>
</table>

| Implication | Select the check box facing the relevant columns to be used for the surrogate key checksum. |

**Advanced Settings**

| CRC type | Select a CRC type in the list. The longer the CRC, the least overlap you will have. |

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Global Variables**

| Global Variables | **NB_LINE:** the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer. **ERROR_MESSAGE:** the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. |
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

### Usage

<table>

<td>Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
</tbody>
</table>

### Adding a surrogate key to a file

This scenario describes a Job adding a surrogate key to a delimited file schema.

![Diagram](image)

**Setting up the Job**

**Procedure**

1. Drop the following components: tFileInputDelimited, tAddCRCRow and tLogRow.
2. Connect them using a Main row connection.

**Configuring the input component**

**Procedure**

1. In the tFileInputDelimited Component view, set the File Name path and all related properties in case these are not stored in the Repository.
2. Create the schema through the Edit Schema button, if the schema is not stored already in the Repository. Remember to set the data type column and for more information on the Date pattern to be filled in, visit [http://docs.oracle.com/javase/6/docs/api/index.html](http://docs.oracle.com/javase/6/docs/api/index.html).

## Configuring the tAddCRCRow component

### Procedure

1. In the tAddCRCRow Component view, select the check boxes of the input flow columns to be used to calculate the CRC.

   - **CRC Type**: CRC32

   Notice that a CRC column (read-only) has been added at the end of the schema.

2. Select CRC32 as CRC Type to get a longer surrogate key.

3. In the Basic settings view of tLogRow, select the Print values in cells of a table option to display the output data in a table on the Console.

### Job execution

Then save your Job and press F6 to execute it.
An additional CRC Column has been added to the schema calculated on all previously selected columns (in this case all columns of the schema).
tAddLocationFromIP

Replaces IP addresses with geographical locations.

tAddLocationFromIP geolocates visitors through their IP addresses: this component identifies visitors’ geographical locations (country, region, city, latitude, longitude, ZIP code, etc.) using an IP address lookup database file.

**tAddLocationFromIP Standard properties**

These properties are used to configure tAddLocationFromIP running in the Standard Job framework.

The Standard tAddLocationFromIP component belongs to the Misc family.

The component in this framework is available in all Talend products.

**Basic settings**

</tbody>
</table>
**Usage**

**Usage rule**
This component is an intermediary step in the data flow allowing to replace IP with geolocation information. It can not be a start component as it requires an input flow. It also requires an output component.

**Limitation**
Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

- geoip.jar

**Identifying a real-world geographic location of an IP**

The following scenario creates a three-component Job that associates an IP with a geographical location. It obtains a site visitor’s geographical location based on its IP.

**Dropping and linking components**

**Procedure**

1. Drop the following components from the Palette onto the design workspace: `tFixedFlowInput`, `tAddLocationFromIP`, and `tLogRow`.
2. Connect the three components using Row Main links.
Configuring the components

Procedure

1. In the design workspace, select tFixedFlowInput, and click the Component tab to define the basic settings for tFixedFlowInput.

2. Click the [...] button next to Edit Schema to define the structure of the data you want to use as input. In this scenario, the schema is made of one column that holds an IP address.

3. Click OK to close the dialog box, and accept propagating the changes when prompted by the system. The defined column is displayed in the Values panel of the Basic settings view.

4. In the Number of rows field, enter the number of rows to be generated, and click in the Value cell and set the value for the IP address.

5. In the design workspace, select tAddLocationFromIP and click the Component tab to define the basic settings for tAddLocationFromIP.

6. Click the Sync columns button to synchronize the schema with the input schema set with tFixedFlowInput.

7. Browse to the GeoIP.dat file to set its path in the Database filepath field.
8. In the **Input parameters** panel, set your input parameters as needed. In this scenario, the input column is the *ip* column defined earlier that holds an IP address.

9. In the **Location type** panel, set location type as needed. In this scenario, we want to display the country name.

10. In the design workspace, select **tLogRow** and click the **Component** tab and define the basic settings for **tLogRow** as needed. In this scenario, we want to display values in cells of a table.

### Saving and executing the Job

**Procedure**

1. Press **Ctrl+S** to save your Job.

2. Press **F6** or click **Run** in the **Run** tab to execute the Job.

```plaintext
Starting job add_location at 11:00 06/08/2008.
<table>
<thead>
<tr>
<th>tLogRow_1</th>
</tr>
</thead>
<tbody>
<tr>
<td>ip</td>
</tr>
<tr>
<td>location</td>
</tr>
<tr>
<td>88.131.8.250</td>
</tr>
</tbody>
</table>
```

`Job add_location ended at 11:00 06/08/2008. [exit code=0]`

### Results

One row is generated to display the country name that is associated with the set IP address.
**tAdvancedFileOutputXML**

Writes an XML file with separated data values according to an XML tree structure.

tAdvancedFileOutputXML outputs data to an XML type of file and offers an interface to deal with loop and group by elements if needed.

**tAdvancedFileOutputXML Standard properties**

These properties are used to configure tAdvancedFileOutputXML running in the Standard Job framework.

The Standard tAdvancedFileOutputXML component belongs to the File and the XML families.

The component in this framework is available in all *Talend products*.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-in or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Built-in</strong>: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: Select the Repository file where Properties are stored. The following fields are pre-filled in using fetched data.</td>
</tr>
</tbody>
</table>

**Use Output Stream**

Select this check box process the data flow of interest. Once you have selected it, the *Output Stream* field displays and you can type in the data flow of interest.

The data flow to be processed must be added to the flow in order for this component to fetch these data via the corresponding representative variable.

This variable could be already pre-defined in your Studio or provided by the context or the components you are using along with this component; otherwise, you could define it manually and use it according to the design of your Job, for example, using *tJava* or *tJavaFlex*.

In order to avoid the inconvenience of hand writing, you could select the variable of interest from the auto-completion list (Ctrl+Space) to fill the current field on condition that this variable has been properly defined.

For further information about how to use a stream, see **Reading data from a remote file in streaming mode** on page 1013.

**File name**

Name or path to the output file and/or the variable to be used.

This field becomes unavailable once you have selected the **Use Output Stream** check box.

For further information about how to define and use a variable in a Job, see *Talend Studio User Guide*.

**Configure XML tree**

Opens the dedicated interface to help you set the XML mapping. For details about the interface, see **Defining the XML tree** on page 127.
**Schema and Edit Schema**

A schema is a row description, it defines the number of fields that will be processed and passed on to the next component. The schema is either built-in or remote in the Repository.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Built-in**: The schema will be created and stored locally for this component only. Related topic: see *Talend Studio User Guide*.

**Repository**: The schema already exists and is stored in the Repository, hence can be reused in various projects and job designs. Related topic: see *Talend Studio User Guide*.

**Sync columns**

Click to synchronize the output file schema with the input file schema. The Sync function only displays once the Row connection is linked with the Output component.

**Append the source xml file**

Select this check box to add the new lines at the end of your source XML file.

**Generate compact file**

Select this check box to generate a file that does not have any empty space or line separators. All elements then are presented in a unique line and this will reduce considerably file size.

**Include DTD or XSL**

Select this check box to add the DOCTYPE declaration, indicating the root element, the access path and the DTD file, or to add the processing instruction, indicating the type of stylesheet used (such as XSL types), along with the access path and file name.

**Advanced settings**

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Split output in several files</td>
<td>If the XML file output is big, you can split the file every certain number of rows.</td>
</tr>
<tr>
<td>Trim data</td>
<td>This check box is activated when you are using the dom4j generation mode. Select this check box to trim the leading or trailing whitespace from the value of a XML element.</td>

<td>This option allows you to use dom4j to process the XML files of high complexity.</td>
</tr>
<tr>
<td>• Fast with low memory consumption</td>
<td>Once you select Append the source xml file in the Basic settings view, this field disappears because in this situation, your generation mode is set automatically as dom4j.</td>
</tr>
<tr>
<td>Encoding</td>
<td>Select the encoding from the list or select Custom and define it manually. This field is compulsory for DB data handling.</td>
</tr>
<tr>
<td>Don’t generate empty file</td>
<td>Select the check box to avoid the generation of an empty file.</td>
</tr>
<tr>
<td>tStatCatcher Statistics</td>
<td>Select the check box to collect the log data at a Job level as well as at each component level.</td>
</tr>
</tbody>
</table>
Global Variables

ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

NB_LINE: the number of rows processed. This is an After variable and it returns an integer.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule
Use this component to write an XML file with data passed on from other components using a Row link.

Defining the XML tree

Double-click on the tAdvancedFileOutputXML component to open the dedicated interface or click on the three-dot button on the Basic settings vertical tab of the Component Settings tab.
To the left of the mapping interface, under **Schema List**, all of the columns retrieved from the incoming data flow are listed (only if an input flow is connected to the `tAdvancedFileOutputXML` component).

To the right of the interface, define the XML structure you want to obtain as output.

You can easily import the XML structure or create it manually, then map the input schema columns onto each corresponding element of the XML tree.

### Importing the XML tree

The easiest and most common way to fill out the XML tree panel, is to import a well-formed XML file.

**Procedure**

1. Rename the **root tag** that displays by default on the XML tree panel, by clicking on it once.
2. Right-click on the root tag to display the contextual menu.
3. On the menu, select **Import XML tree**.
4. Browse to the file to import and click **OK**.
   - You can import an XML tree from files in XML, XSD and DTD formats.
   - When importing an XML tree structure from an XSD file, you can choose an element as the root of your XML tree.

   The **XML Tree** column is hence automatically filled out with the correct elements.
5. If you need to add or remove an element or sub-elements, right-click the relevant element of the tree to display the contextual menu.
6. Select **Delete** to remove the selection from the tree or select the relevant option among: **Add sub-element**, **Add attribute**, **Add namespace** to enrich the tree.

### Creating the XML tree manually

If you don’t have any XML structure defined as yet, you can create it manually.

**Procedure**

1. Rename the **root tag** that displays by default on the XML tree panel, by clicking on it once.
2. Right-click on the root tag to display the contextual menu.
3. On the menu, select Add sub-element to create the first element of the structure.
4. If you need to add an attribute or a child element to any element or remove any element, right-click the left of the corresponding element name to display the contextual menu.
5. Right-click to the left of the element name to display the contextual menu.
6. On the menu, select the relevant option among: **Add sub-element**, **Add attribute**, **Add namespace** or **Delete**.

### Mapping XML data

Once your XML tree is ready, you can map each input column with the relevant XML tree element or sub-element to fill out the **Related Column**.
Procedure
1. Click on one of the Schema column name.
2. Drag it onto the relevant sub-element to the right.
3. Release to implement the actual mapping.
4. If you need to disconnect any mapping on any element of the XML tree, select the element and right-click to the left of the element name to display the contextual menu.
5. Select Disconnect linker.

Defining the node status

Defining the XML tree and mapping the data is not sufficient. You also need to define the loop element and if required the group element.

Define a loop element

The loop element allows you to define the iterating object. Generally the Loop element is also the row generator.

About this task
To define an element as loop element:

Procedure
1. Select the relevant element on the XML tree.
2. Right-click to the left of the element name to display the contextual menu.
3. Select Set as Loop Element.

Results
The Node Status column shows the newly added status.
There can only be one loop element at a time.

Define a group element

The group element is optional, it represents a constant element where the groupby operation can be performed. A group element can be defined only if a loop element was defined before.

About this task
When using a group element, the rows should sorted, in order to be able to group by the selected node.

To define an element as group element:

Procedure
1. Select the relevant element on the XML tree.
2. Right-click to the left of the element name to display the contextual menu.
3. Select Set as Group Element.
## Results

The **Node Status** column shows the newly added status and any group status required are automatically defined, if needed.

Click **OK** once the mapping is complete to validate the definition and continue the job configuration where needed.

## Creating an XML file using a loop

The following scenario describes the creation of an XML file from a sorted flat file gathering a video collection.

![Diagram of data flow](image)

### Configuring the source file

**Procedure**

1. Drop a **tFileInputDelimited** and a **tAdvancedFileOutputXML** from the **Palette** onto the design workspace.
2. Alternatively, if you configured a description for the input delimited file in the **Metadata** area of the **Repository**, then you can directly drag & drop the metadata entry onto the editor, to set up automatically the input flow.
3. Right-click on the input component and drag a row main link towards the **tAdvancedFileOutputXML** component to implement a connection.
4. Select the **tFileInputDelimited** component and display the **Component settings** tab located in the tab system at the bottom of the Studio.

<table>
<thead>
<tr>
<th>Basic settings</th>
<th>Property Type</th>
<th>Repository</th>
<th>DELIM:video2</th>
<th>DELIM:video2 - metadata</th>
</tr>
</thead>
<tbody>
<tr>
<td>Advanced settings</td>
<td>File name/Stream</td>
<td>D:\Input\video\videocollection.txt</td>
<td>*</td>
<td></td>
</tr>
<tr>
<td>Dynamic settings</td>
<td>Row Separator</td>
<td>&quot;</td>
<td>Field Separator</td>
<td>;</td>
</tr>
</tbody>
</table>

5. Select the **Property type**, according to whether you stored the file description in the Repository or not. If you dragged & dropped the component directly from the Metadata, no changes to the settings should be needed.

If you didn’t setup the file description in the **Repository**, then select **Built-in** and manually fill out the fields displayed on the **Basic settings** vertical tab.

The input file contains the following type of columns separated by semi-colons: *id, name, category, year, language, director and cast*. 

---

130
In this simple use case, the **Cast** field gathers different values and the id increments when changing movie.

6. If needed, define the **tFileDelimitedInput** schema according to the file structure.

7. Once you checked that the schema of the input file meets your expectation, click on **OK** to validate.

**Configuring the XML output and mapping**

**Procedure**

1. Then select the **tAdvancedFileOutputXML** component and click on the **Component settings** tab to configure the basic settings as well as the mapping. Note that a double-click on the component will open directly the mapping interface.
2. In the **File Name** field, browse to the file to be written if it exists or type in the path and file name that needs to be created for the output. By default, the schema (file description) is automatically propagated from the input flow. But you can edit it if you need.

3. Then click on the three-dot button or double-click on the **tAdvancedFileOutputXML** component on the design workspace to open the dedicated mapping editor. To the left of the interface, are listed the columns from the input file description.

4. To the right of the interface, set the XML tree panel to reflect the expected XML structure output. You can create the structure node by node. For more information about the manual creation of an XML tree, see **Defining the XML tree** on page 127. In this example, an XML template is used to populate the XML tree automatically.

5. Right-click on the **root tag** displaying by default and select **Import XML tree** at the end of the contextual menu options.

6. Browse to the XML file to be imported and click **OK** to validate the import operation.

**Note:**

You can import an XML tree from files in XML, XSD and DTD formats.

7. Then drag & drop each column name from the **Schema List** to the matching (or relevant) **XML tree** elements as described in Mapping XML data on page 128. The mapping is shown as blue links between the left and right panels.
Finally, define the node status where the loop should take place. In this use case, the `Cast` being the changing element on which the iteration should operate, this element will be the loop element.

Right-click on the `Cast` element on the XML tree, and select **Set as loop element**.

8. To group by movie, this use case needs also a group element to be defined.
   Right-click on the `Movie` parent node of the XML tree, and select **Set as group element**.
   The newly defined node status show on the corresponding element lines.

9. Click **OK** to validate the configuration.
10. Press **F6** to execute the Job.
The output XML file shows the structure as defined.
**tAggregateRow**

Receives a flow and aggregates it based on one or more columns.

For each output line, are provided the aggregation key and the relevant result of set operations (min, max, sum...).

tAggregateRow helps to provide a set of metrics based on values or calculations.

**tAggregateRow Standard properties**

These properties are used to configure tAggregateRow running in the Standard Job framework.

The Standard tAggregateRow component belongs to the Processing family.

The component in this framework is available in all Talend products.

### Basic settings

| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word **line** when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:
| | • View schema: choose this option to view the schema only.
| | • Change to built-in property: choose this option to change the schema to Built-in for local changes.
| | • Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.
| Built-In: You create and store the schema locally for this component only.
| Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.
| Group by | Define the aggregation sets, the values of which will be used for calculations.
| Output Column: Select the column label in the list offered based on the schema structure you defined. You can add as many output columns as you wish to make more precise aggregations.
<p>| Ex: Select Country to calculate an average of values for each country of a list or select Country and Region if you want to compare one country’s regions with another country’s regions. |</p>
<table>
<thead>
<tr>
<th><strong>Input Column</strong></th>
<th>Match the input column label with your output columns, in case the output label of the aggregation set needs to be different.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th><strong>Operations</strong></th>
<th>Select the type of operation along with the value to use for the calculation and the output field.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th><strong>Output Column</strong></th>
<th>Select the destination field in the list.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th><strong>Function</strong></th>
<th>Select the operator among:</th>
</tr>
</thead>
<tbody>
<tr>
<td>count</td>
<td>calculates the number of rows</td>
</tr>
<tr>
<td>min</td>
<td>selects the minimum value</td>
</tr>
<tr>
<td>max</td>
<td>selects the maximum value</td>
</tr>
<tr>
<td>avg</td>
<td>calculates the average</td>
</tr>
<tr>
<td>sum</td>
<td>calculates the sum</td>
</tr>
<tr>
<td>first</td>
<td>returns the first value</td>
</tr>
<tr>
<td>last</td>
<td>returns the last value</td>
</tr>
<tr>
<td>list</td>
<td>lists values of an aggregation by multiple keys.</td>
</tr>
<tr>
<td>list (object)</td>
<td>lists Java values of an aggregation by multiple keys</td>
</tr>

<td>counts the number of the distinct rows</td>
</tr>
<tr>
<td>standard deviation</td>
<td>calculates the variability</td>
</tr>
<tr>
<td>union (geometry)</td>
<td>makes the union of a set of Geometry objects</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Input column</strong></th>
<th>Select the input column from which the values are taken to be aggregated.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th><strong>Ignore null values</strong></th>
<th>Select the check boxes corresponding to the names of the columns for which you want the NULL value to be ignored.</th>
</tr>
</thead>
</table>

### Advanced settings

<table>
<thead>
<tr>
<th><strong>Delimiter (only for list operation)</strong></th>
<th>Enter the delimiter you want to use to separate the different operations.</th>
</tr>
</thead>
</table>

| **Use financial precision, this is the max precision for “sum” and “avg” operations, checked option heaps more memory and slower than unchecked.** | Select this check box to use a financial precision. This is a max precision but consumes more memory and slows the processing. |

**Warning:**

*We advise you to use the BigDecimal type for the output in order to obtain precise results.*

<table>
<thead>
<tr>
<th><strong>Check type overflow (slower)</strong></th>
<th>Checks the type of data to ensure that the Job doesn’t crash.</th>
</tr>
</thead>
</table>

| **Check ULP (Unit in the Last Place), ensure that a value will be incremented or decremented correctly, only float and double types. (slower)** | Select this check box to ensure the most precise results possible for the Float and Double types. |

<table>
<thead>
<tr>
<th><strong>tStatCatcher Statistics</strong></th>
<th>Check this box to collect the log data at component level. Note that this check box is not available in the Map/Reduce version of the component.</th>
</tr>
</thead>
</table>

136
Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | This component handles flow of data therefore it requires input and output, hence is defined as an intermediary step. Usually the use of tAggregateRow is combined with the tSortRow component. |

Aggregating values and sorting data

This example shows you how to use Talend components to aggregate the students' comprehensive scores and then sort the aggregated scores based on the student names.

Creating a Job for aggregating and sorting data

Create a Job to aggregate the students' comprehensive scores using the tAggregateRow component, then sort the aggregated data using the tSortRow component, finally display the aggregated and sorted data on the console.

Procedure

1. Create a new Job and add a tFixedFlowInput component, a tAggregateRow component, a tSortRow component, and a tLogRow component by typing their names in the design workspace or dropping them from the Palette.
2. Link the tFixedFlowInput component to the tAggregateRow component using a Row > Main connection.
3. Do the same to link the tAggregateRow component to the tSortRow component, and the tSortRow component to the tLogRow component.
Configuring the Job for aggregating and sorting data

Configure the Job to aggregate the students’ comprehensive scores using the tAggregateRow component and then sort the aggregated data using the tSortRow component.

Procedure

1. Double-click the tFixedFlowInput component to open its Basic settings view.

2. Click the button next to Edit schema to open the schema dialog box and define the schema by adding two columns, name of String type and score of Double type. When done, click OK to save the changes and close the schema dialog box.

3. In the Mode area, select Use Inline Content (delimited file) and in the Content field displayed, enter the following input data:

```
Peter;92
James;93
Thomas;91
Peter;94
James;96
Thomas;95
Peter;96
James;92
Thomas;98
Peter;95
James;96
Thomas;93
Peter;98
James;97
Thomas;95
```

4. Double-click the tAggregateRow component to open its Basic settings view.

5. Click the button next to Edit schema to open the schema dialog box and define the schema by adding five columns, name of String type, and sum, average, max, and min of Double type.
When done, click **OK** to save the changes and close the schema dialog box.

6. Add one row in the **Group by** table by clicking the + button below it, and select *name* from both the **Output column** and **Input column position** column fields to group the input data by the *name* column.

7. Add four rows in the **Operations** table and define the operations to be carried out. In this example, the operations are *sum*, *average*, *max*, and *min*. Then select *score* from all four **Input column position** column fields to aggregate the input data based on it.

8. Double-click the **tSortRow** component to open its **Basic settings** view.

9. Add one row in the **Criteria** table and specify the column based on which the sort operation is performed. In this example, it is the *name* column. Then select *alpha* from the **sort num or alpha?** column field and *asc* from the **Order asc or desc?** column field to sort the aggregated data in ascending alphabetical order.

10. Double-click the **tLogRow** component to open its **Basic settings** view, and then select **Table (print values in cells of a table)** in the **Mode** area for better readability of the result.

---

### Executing the Job to aggregate and sort data

After setting up the Job and configuring the components used in the Job for aggregating and sorting data, you can then execute the Job and verify the Job execution result.

**Procedure**

1. Press **Ctrl + S** to save the Job.
2. Press **F6** to execute the Job.
Results
As shown above, the students' comprehensive scores are aggregated and then sorted in ascending alphabetical order based on the student names.
tAggregateSortedRow

Aggregates the sorted input data for output column based on a set of operations. Each output column is configured with many rows as required, the operations to be carried out and the input column from which the data will be taken for better data aggregation.

**tAggregateSortedRow Standard properties**

These properties are used to configure `tAggregateSortedRow` running in the Standard Job framework. The Standard `tAggregateSortedRow` component belongs to the Processing family.

The component in this framework is available in all Talend products.

**Basic settings**

| **Schema and Edit Schema** | A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either **Built-in** or stored remotely in the **Repository**.  
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
• **View schema**: choose this option to view the schema only.  
• **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
• **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.  
Click **Sync columns** to retrieve the schema from the previous component connected in the Job. |
| **Built-in**: The schema will be created and stored locally for this component only. Related topic: see Talend Studio User Guide. |
| **Repository**: The schema already exists and is stored in the Repository, hence can be reused in various projects and Job flowcharts. Related topic: see Talend Studio User Guide. |
| **Input rows count** | Specify the number of rows that are sent to the **tAggregateSortedRow** component.  
**Note:**  
If you specified a **Limit** for the number of rows to be processed in the input component, you will have to use that same limit in the **Input rows count** field. |
<table>
<thead>
<tr>
<th><strong>Group by</strong></th>
<th>Define the aggregation sets, the values of which will be used for calculations.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Output Column</strong>: Select the column label in the list offered based on the schema structure you defined. You can add as many output columns as you wish to make more precise aggregations. Ex: Select Country to calculate an average of values for each country of a list or select Country and Region if you want to compare one country’s regions with another country’ regions.</td>
<td></td>
</tr>
<tr>
<td><strong>Input Column</strong>: Match the input column label with your output columns, in case the output label of the aggregation set needs to be different.</td>
<td></td>
</tr>
<tr>
<td><strong>Operations</strong></td>
<td>Select the type of operation along with the value to use for the calculation and the output field.</td>
</tr>
<tr>
<td><strong>Output Column</strong>: Select the destination field in the list.</td>
<td></td>
</tr>
<tr>
<td><strong>Function</strong>: Select the operator among: • count: calculates the number of rows • min: selects the minimum value • max: selects the maximum value • avg: calculates the average • sum: calculates the sum • first: returns the first value • last: returns the last value • list: lists values of an aggregation by multiple keys. • list (object): lists Java values of an aggregation by multiple keys • count (distinct): counts the number of the distinct rows • standard deviation: calculates the variability • union (geometry): makes the union of a set of Geometry objects</td>
<td></td>
</tr>
<tr>
<td><strong>Input column</strong>: Select the input column from which the values are taken to be aggregated.</td>
<td></td>
</tr>
<tr>
<td><strong>Ignore null values</strong>: Select the check boxes corresponding to the names of the columns for which you want the NULL value to be ignored.</td>
<td></td>
</tr>
</tbody>
</table>

**Advanced settings**

| **tStatCatcher Statistics** | Check this box to collect the log data at component level. |

**Global Variables**

| **Global Variables** | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. |
**Usage**

| Usage rule | This component handles flow of data therefore it requires input and output, hence is defined as an intermediary step. |

**Sorting and aggregating the input data**

This scenario describes a Job that sorts the entries of the input data based on two columns and displays the sorted data on the console, then aggregates the sorted data based on one column and displays the aggregated data on the console.

**Adding and linking components**

**Procedure**

1. Create a new Job and add the following components by typing their names in the design workspace or dropping them from the Palette: a `tFixedFlowInput` component, a `tSortRow` component, a `tAggregateSortedRow` component, and two `tLogRow` components.

2. Link `tFixedFlowInput` to `tSortRow` using a `Row > Main` connection.

3. Do the same to link `tSortRow` to the first `tLogRow`, link the first `tLogRow` to `tAggregateSortedRow`, and link `tAggregateSortedRow` to the second `tLogRow`.

**Configuring the components**

**Sorting the input data**

**Procedure**

1. Double-click `tFixedFlowInput` to open its Basic settings view.
2. Click the [...] button next to Edit schema and in the pop-up window define the schema by adding four columns: Id and Age of Integer type, and Name and Team of String type.

Click OK to close the schema editor and accept the propagation prompted by the pop-up dialog box.

3. In the Mode area, select Use Inline Content(delimited file), and then in the Content field displayed, enter the input data to be sorted and aggregated. In this example, the input data is as follows:

1;Thomas;28;Component Team
2;Harry;32;Doc Team
3;John;26;Component Team
4;Nicolas;27;QA Team
5;George;24;Component Team
6;Peter;30;Doc Team
7;Teddy;23;QA Team
8;James;26;Component Team

4. Double-click tSortRow to open its Basic settings view.
5. Click the [+] button below the Criteria table to add as many rows as required and then specify the sorting criteria in the table. In this example, two rows are added, and the input entries will be sorted based on the column Team and then the column Age, both in ascending order.

6. Double-click the first LogRow to open its Basic settings view.

7. In the Mode area, select Table (print values in cells of a table) for better readability of the sorting result.

**Aggregating the sorted data**

**Procedure**

1. Double-click AggregateSortedRow to open its Basic settings view.
2. Click the [...] button next to **Edit schema** and in the pop-up window define the schema by adding five columns: *AggTeam* of String type, *AggCount*, *MinAge*, *MaxAge*, and *AvgAge* of Integer type.

![Schema of tAggregateSortedRow](image1)

Click **OK** to close the schema editor and accept the propagation prompted by the pop-up dialog box.

3. In the **Input rows count** field, enter the exact number of rows of the input data. In this example, it is 8.

4. Click the [+ ] button below the **Group by** table to add as many rows as required and specify the aggregation set in the table. In this example, the data will be aggregated based on the input column *Team*.

5. Click the [+ ] button below the **Operations** table to add as many rows as required and specify the operation to be carried out and the corresponding input column from which the data will be taken for each output column. In this example, we want to calculate the number of the input entries, the minimum age, the maximum age, and the average age for each team.

6. Double-click the second tLogRow to open its **Basic settings** view.

![tLogRow2 Basic settings](image2)

7. In the **Mode** area, select **Table (print values in cells of a table)** for better readability of the sorting result.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl + S** to save the Job.

2. Execute the Job by pressing **F6** or clicking **Run** on the **Run** tab.
As shown above, the input entries are sorted based on the column `Team` and then the column `Age`, both in ascending order, and the sorted entries are then aggregated based on the column `Team`. 
tAmazonAuroraClose

Closes an active connection to an Amazon Aurora database instance to release the occupied resources.

**tAmazonAuroraClose Standard properties**

These properties are used to configure tAmazonAuroraClose running in the Standard Job framework. The Standard tAmazonAuroraClose component belongs to the Cloud and the Databases families. The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component List</td>
<td>Select the tAmazonAuroraConnection component that opens the connection you need to close from the list.</td>
</tr>
</tbody>
</table>

### Advanced settings

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

### Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

### Usage

| Usage rule | This component is more commonly used with other Amazon Aurora components, especially with the tAmazonAuroraConnection and tAmazonAuroraCommit components. |
Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenario

For a related scenario, see Handling data with Amazon Aurora on page 158.
tAmazonAuroraCommit

Commits in one go a global transaction instead of doing that on every row or every batch, and provides gain in performance, using a unique connection.

tAmazonAuroraCommit validates the data processed through the Job into the connected Amazon Aurora database.

**tAmazonAuroraCommit Standard properties**

These properties are used to configure tAmazonAuroraCommit running in the Standard Job framework. The Standard tAmazonAuroraCommit component belongs to the Cloud and the Databases families. The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component List</td>
<td>Select the tAmazonAuroraConnection component for which you want the commit action to be performed.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default and it allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection after the component has performed its task.</td>
</tr>
</tbody>
</table>

**Warning:**

If you want to use a Row > Main connection to link tAmazonAuroraCommit to your Job, your data will be committed row by row. In this case, do not select the Close Connection check box or your connection will be closed before the end of your first row commit.

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global Variables**

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. |
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

### Usage

| Usage rule | This component is more commonly used with other Amazon Aurora components, especially with the tAmazonAuroraConnection and tAmazonAuroraRollback components. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |

### Related scenario

For a related scenario, see Handling data with Amazon Aurora on page 158.
tAmazonAuroraConnection

Opens a connection to an Amazon Aurora database instance that can then be reused by other Amazon Aurora components.

**tAmazonAuroraConnection Standard properties**

These properties are used to configure tAmazonAuroraConnection running in the Standard Job framework.

The Standard tAmazonAuroraConnection component belongs to the Cloud and the Databases families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td>Property Type</td>
<td>Either <strong>Built-In</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td>Built-In:</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository:</td>
<td>Select the repository file in which the properties are stored. The database connection fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Host</td>
<td>Type in the IP address or hostname of the Amazon Aurora database.</td>
</tr>
<tr>
<td>Port</td>
<td>Type in the listening port number of the Amazon Aurora database.</td>
</tr>
<tr>
<td>Database</td>
<td>Type in the name of the database you want to use.</td>
</tr>
<tr>
<td>Additional JDBC parameters</td>
<td>Specify additional connection properties for the database connection you are creating.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>Type in the database user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td>Use or register a shared DB Connection</td>
<td>Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the <strong>Shared DB Connection Name</strong> field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child.</td>
</tr>
<tr>
<td>tAmazonAuroraConnection</td>
<td>This option is incompatible with the <strong>Use dynamic job</strong> and <strong>Use an independent process to run subjob</strong> options of the tRunJob component. Using a shared connection together with a tRunJob component with either of these two options enabled will cause your Job to fail. This check box is not available when the <strong>Specify a data source alias</strong> check box is selected.</td>
</tr>
<tr>
<td>-------------------------</td>
<td>------------------------------------------------------------------------------------------------ -------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>Specify a data source alias</strong></td>
<td>Select this check box and specify the alias of a data source created on the Talend Runtime side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in Talend Runtime. This check box disappears when the <strong>Use or register a shared DB Connection</strong> check box is selected.</td>
</tr>
<tr>
<td><strong>Data source alias</strong></td>
<td>Type in the alias of the data source created on the Talend Runtime side. This field appears only when the <strong>Specify a data source alias</strong> check box is selected.</td>
</tr>
</tbody>
</table>

### Advanced settings

| **Auto Commit** | Select this check box to commit any changes to the database automatically upon the transaction. With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component. Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component. |
|-----------------|------------------------------------------------------------------------------------------------ -------------------------------------------------------------------------------------------------------------------|
| **tStatCatcher Statistics** | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

### Global Variables

| **Global Variables** | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it. |
|----------------------|------------------------------------------------------------------------------------------------ -------------------------------------------------------------------------------------------------------------------|
For further information about variables, see *Talend Studio User Guide*.

### Usage

| Usage rule | This component is more commonly used with other Amazon Aurora components, especially with the `tAmazonAuroraCommit` and `tAmazonAuroraRollback` components. |

### Related scenario

For a related scenario, see *Handling data with Amazon Aurora* on page 158.
tAmazonAuroraInput

Reads an Amazon Aurora database and extracts fields based on a query.

tAmazonAuroraInput executes a database query with a strictly defined order which must correspond to the schema definition. Then it passes on the field list to the next component via a Row > Main link.

**tAmazonAuroraInput Standard properties**

These properties are used to configure tAmazonAuroraInput running in the Standard Job framework.

The Standard tAmazonAuroraInput component belongs to the Cloud and the Databases families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
<tr>
<td><strong>Property Type</strong></td>
<td>Either Built-In or Repository.</td>
</tr>
<tr>
<td><strong>Built-In</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the repository file in which the properties are stored. The database connection fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><strong>Use an existing connection</strong></td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td><strong>Host</strong></td>
<td>Type in the IP address or hostname of the Amazon Aurora database.</td>
</tr>
</tbody>
</table>

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

Handling data with Amazon Aurora

This scenario describes a Job that writes the user information into Amazon Aurora, and then reads the information in Amazon Aurora and displays it on the console.
The scenario requires the following seven components:

- **tAmazonAuroraConnection**: opens a connection to Amazon Aurora.
- **tFixedFlowInput**: defines the user information data structure, and sends the data to the next component.
- **tAmazonAuroraOutput**: writes the data it receives from the preceding component into Amazon Aurora.
- **tAmazonAuroraCommit**: commits in one go the data processed to Amazon Aurora.
- **tAmazonAuroraInput**: reads the data from Amazon Aurora.
- **tLogRow**: displays the data it receives from the preceding component on the console.
- **tAmazonAuroraClose**: closes the connection to Amazon Aurora.
Adding and linking the components

Procedure

1. Create a new Job and add seven components listed previously by typing their names in the design workspace or dropping them from the Palette.
2. Connect `tFixedFlowInput` to `tAmazonAuroraOutput` using a Row > Main connection.
3. Do the same to connect `tAmazonAuroraInput` to `tLogRow`.
4. Connect `tAmazonAuroraConnection` to `tFixedFlowInput` using a Trigger > OnSubjobOk connection.
5. Do the same to connect `tFixedFlowInput` to `tAmazonAuroraCommit`, `tAmazonAuroraCommit` to `tAmazonAuroraInput`, and `tAmazonAuroraInput` to `tAmazonAuroraClose`.

Configuring the components

Opening a connection to Amazon Aurora

Procedure

1. Double-click `tAmazonAuroraConnection` to open its Basic settings view.

2. In the Host, Port, Database, Username and Password fields, enter the information required for the connection to Amazon Aurora.

Writing the data into Amazon Aurora

Procedure

1. Double-click `tFixedFlowInput` to open its Basic settings view.
2. Click the [...] button next to **Edit schema** and in the pop-up window define the schema by adding three columns: *id* of Integer type, and *name* and *city* of String type.

![Schema of tFixedFlowInput_1](image)

Click **OK** to validate the changes and accept the propagation prompted by the pop-up dialog box.

3. In the **Mode** area, select **Use Inline Content (delimited file)** and enter the following user information in the **Content** field.

```
1;George;Bismarck
2;Abraham;Boise
3;Taylor;Nashville
4;William;Jefferson City
5;Alexander;Jackson
6;James;Boise
7;Gerald;Little Rock
8;Tony;Richmond
9;Thomas;Springfield
10;Andre;Nashville
```

4. Double-click **tAmazonAuroraOutput** to open its **Basic settings** view.
5. Select the **Use an existing connection** check box and in the **Component List** that appears, select the connection component you have configured.

6. In the **Table** field, enter or browse to the table into which you want to write the data. In this example, it is `TalendUser`.

7. Select **Drop table if exists and create** from the **Action on table** drop-down list, and select **Insert** from the **Action on data** drop-down list.

8. Double-click `tAmazonAuroraCommit` to open its **Basic settings** view.

9. Clear the **Close Connection** check box if it is selected.

**Retrieving the data from Amazon Aurora**

**Procedure**

1. Double-click `tAmazonAuroraInput` to open its **Basic settings** view.

2. Select the **Use an existing connection** check box and in the **Component List** that appears, select the connection component you have configured.
3. Click the [...] button next to Edit schema and in the pop-up window define the schema by adding three columns: id of Integer type, and name and city of String type. The data structure is same as the structure you have defined for tFixedFlowInput.

4. In the Table Name field, enter or browse to the table into which you write the data. In this example, it is TalendUser.

5. Click the Guess Query button to generate the query. The Query field will be filled with the automatically generated query.

6. Double-click tLogRow to open its Basic settings view.

7. In the Mode area, select Table (print values in cells of a table) for better readability of the result.

Closing the connection to Amazon Aurora

Procedure

1. Double-click tAmazonAuroraClose to open its Basic settings view.

2. In the Component List, select the connection component you have configured.

Saving and executing the Job

Procedure

1. Press Ctrl + S to save the Job.
2. Press F6 or click Run on the Run tab to run the Job.
As shown above, the user information is written into Amazon Aurora, and then the data is retrieved from Amazon Aurora and displayed on the console.

<table>
<thead>

tAmazonAuroraOutput

Writes, updates, makes changes or suppresses entries in an Amazon Aurora database.

tAmazonAuroraOutput executes the action defined on the table and/or on the data contained in the table, based on the flow incoming from the preceding component in the Job.

**tAmazonAuroraOutput Standard properties**

These properties are used to configure tAmazonAuroraOutput running in the Standard Job framework.
The Standard tAmazonAuroraOutput component belongs to the Cloud and the Databases families.
The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
<tr>
<td>Property Type</td>
<td>Either Built-In or Repository.</td>
</tr>
<tr>
<td>Built-In</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The database connection fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td>Host</td>
<td>Type in the IP address or hostname of the Amazon Aurora database.</td>
</tr>
</tbody>
</table>

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
<table>
<thead>
<tr>
<th>Port</th>
<th>Type in the listening port number of the Amazon Aurora database.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Type in the name of the database you want to use.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>Type in the database user authentication data.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Table</td>
<td>Type in the name of the table to be written. Note that only one table can be written at a time.</td>
</tr>
<tr>
<td>Action on table</td>
<td>On the table defined, you can perform one of the following operations:</td>
</tr>
<tr>
<td></td>
<td>• None: No operation is carried out.</td>
</tr>
<tr>
<td></td>
<td>• Drop and create table: The table is removed and created again.</td>
</tr>
<tr>
<td></td>
<td>• Create table: The table does not exist and gets created.</td>
</tr>
<tr>
<td></td>
<td>• Create table if not exists: The table is created if it does not exist.</td>
</tr>
<tr>
<td></td>
<td>• Drop table if exists and create: The table is removed if it already exists and created again.</td>
</tr>
<tr>
<td></td>
<td>• Clear table: The table content is deleted.</td>
</tr>
<tr>
<td></td>
<td>• Truncate table: The table content is quickly deleted. However, you will not be able to rollback the operation.</td>
</tr>
<tr>
<td>Action on data</td>
<td>On the data of the table defined, you can perform one of the following operations:</td>
</tr>
<tr>
<td></td>
<td>• Insert: Add new entries to the table. If duplicates are found, the job stops.</td>
</tr>
<tr>
<td></td>
<td>• Update: Make changes to existing entries.</td>
</tr>
<tr>
<td></td>
<td>• Insert or update: Insert a new record. If the record with the given reference already exists, an update would be made.</td>
</tr>
<tr>
<td></td>
<td>• Update or insert: Update the record with the given reference. If the record does not exist, a new record would be inserted.</td>
</tr>
<tr>
<td></td>
<td>• Delete: Remove entries corresponding to the input flow.</td>
</tr>
<tr>
<td></td>
<td>• Replace: Add new entries to the table. If an old row in the table has the same value as a new row for a PRIMARY KEY or a UNIQUE index, the old row is deleted before the new row is inserted.</td>
</tr>
<tr>
<td></td>
<td>• Insert or update on duplicate key or unique index: Add entries if the inserted value does not exist or update entries if the inserted value already exists and there is a risk of violating a unique index or primary key.</td>
</tr>
<tr>
<td></td>
<td>• Insert Ignore: Add only new rows to prevent duplicate key errors.</td>
</tr>
</tbody>
</table>
### Warning:

You must specify at least one column as a primary key on which the **Update** and **Delete** operations are based. You can do that by clicking **Edit schema** and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the **Advanced settings** view where you can simultaneously define primary keys for the update and delete operations. To do that: Select the **Use field options** check box and then in the **Key in update** column, select the check boxes next to the column name on which you want to base the update operation. Do the same in the **Key in delete** column for the deletion operation.

### Schema and Edit schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

**Built-In:** You create and store the schema locally for this component only.

**Repository:** You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema:** choose this option to view the schema only.
- **Change to built-in property:** choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection:** choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

### Specify a data source alias

Select this check box and specify the alias of a data source created on the **Talend Runtime** side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your **Job** in **Talend Runtime**.

This check box disappears when the **Use an existing connection** check box is selected.

### Data source alias

Type in the alias of the data source created on the **Talend Runtime** side.
**Die on error**

This check box is selected by default. Clear the check box to skip the row in error and complete the process for error-free rows. If needed, you can retrieve the rows in error via a Row > Rejects link.

### Advanced settings

<table>
<thead>
<tr>
<th><strong>Additional JDBC parameters</strong></th>
<th>Specify additional connection properties for the database connection you are creating. This field disappears when the Use an existing connection check box in the Basic settings view is selected.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Note:</strong></td>
<td>You can press Ctrl+Space to access a list of predefined global variables.</td>
</tr>
<tr>
<td><strong>Extend Insert</strong></td>
<td>Select this check box to carry out a bulk insert of a defined set of lines instead of inserting lines one by one. The gain in system performance is considerable. This check box appears only when the Insert option is selected from the Action on data list in the Basic settings view.</td>
</tr>
<tr>
<td><strong>Note:</strong></td>
<td>This option is not compatible with the Reject link. You should therefore clear the check box if you are using a Row &gt; Rejects link with this component.</td>
</tr>
<tr>
<td><strong>Number of rows per insert</strong></td>
<td>Enter the number of rows to be inserted per operation. Note that the higher the value specified, the lower performance levels shall be due to the increase in memory demands. This field appears only when the Extend Insert check box is selected.</td>
</tr>
<tr>
<td><strong>Use Batch</strong></td>
<td>Select this check box to activate the batch mode for data processing. This check box is available only when the Update or Delete option is selected from the Action on data list in the Basic settings view.</td>
</tr>
<tr>
<td><strong>Batch Size</strong></td>
<td>Specify the number of records to be processed in each batch. This field appears only when the Use batch mode check box is selected.</td>
</tr>
<tr>
<td><strong>Commit every</strong></td>
<td>Enter the number of rows to be included in a batch before it is committed to the database. This option ensures transaction quality (but not rollback) and, above all, a higher performance level.</td>
</tr>
<tr>
<td><strong>Additional columns</strong></td>
<td>This option allows you to call SQL functions to perform actions on columns, provided that these are not insert, update or delete actions, or actions that require pre-</td>
</tr>
</tbody>
</table>
processing. This option is not available if you have just created the database table (even if you delete it beforehand). Click the [+] button under the table to add column(s), and set the following parameters for each column.

- **Name**: Type in the name of the schema column to be altered or inserted.
- **SQL expression**: Type in the SQL statement to be executed in order to alter or insert the data in the corresponding column.
- **Position**: Select Before, After or Replace depending on the action to be performed on the reference column.
- **Reference column**: Type in a reference column that `tAmazonAuroraOutput` can use to locate or replace the new column or the column to be modified.

### Use field options

Select the check box for the corresponding column to customize a request, particularly if multiple actions are being carried out on the data.

- **Key in update**: Select the check box for the corresponding column based on which the data is updated.
- **Key in delete**: Select the check box for the corresponding column based on which the data is deleted.
- **Updatable**: Select the check box if the data in the corresponding column can be updated.
- **Insertable**: Select the check box if the data in the corresponding column can be inserted.

### Use Hint Options

Select this check box to configure the hint(s) which can help you optimize a query’s execution.

### Hint Options

Click the [+] button under the table to add hint(s) and set the following parameters for each hint. This table appears only when the **Use Hint Options** check box is selected.

- **HINT**: Specify the hint you need, using the syntax `/*+`.
- **POSITION**: Specify where you put the hint in an SQL statement.
- **SQL STMT**: Select an SQL statement INSERT, UPDATE, or DELETE you need to use.

### Enable debug mode

Select this check box to display each step involved in the process of writing data in the database.

### Use duplicate key update mode insert

Select this check box to activate the ON DUPLICATE KEY UPDATE mode, and then click the [+] button under the table displayed to add column(s) to be updated and specify the update action to be performed on the corresponding column.

- **Column**: Enter the name of the column to be updated.
- **Value**: Enter the action to be performed on the column.

This check box is available only when the Insert option is selected from the **Action on data** list in the Basic settings view.
**Global Variables**

**Global Variables**

- **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.
- **NB_LINE_UPDATED**: the number of rows updated. This is an After variable and it returns an integer.
- **NB_LINE_INSERTED**: the number of rows inserted. This is an After variable and it returns an integer.
- **NB_LINE_DELETED**: the number of rows deleted. This is an After variable and it returns an integer.
- **NB_LINE_REJECTED**: the number of rows rejected. This is an After variable and it returns an integer.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

**Usage**

**Usage rule**

This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in an Amazon Aurora database. It also allows you to create a reject flow using a Row > Rejects link to filter data in error. For a similar scenario, see .

**Dynamic settings**

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different...
Related scenario

For a related scenario, see Handling data with Amazon Aurora on page 158.
tAmazonAuroraRollback

Rolls back any changes made in the Amazon Aurora database to prevent partial transaction commit if an error occurs.

**tAmazonAuroraRollback Standard properties**

These properties are used to configure tAmazonAuroraRollback running in the Standard Job framework.

The Standard tAmazonAuroraRollback component belongs to the Cloud and the Databases families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component List</td>
<td>Select the <strong>tAmazonAuroraConnection</strong> component for which you want the rollback action to be performed.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default and it allows you to close the database connection once the rollback is done. Clear this check box to continue to use the selected connection after the component has performed its task.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics   | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global Variables**

**ERROR_MESSAGE:** the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see **Talend Studio User Guide**.
## Usage

| Usage rule | This component is more commonly used with other Amazon Aurora components, especially with the \texttt{tAmazonAuroraConnection} and \texttt{tAmazonAuroraCommit} components. |
| Dynamic settings | Click the [+\texttt{}] button to add a row in the table and fill the \texttt{Code} field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the \texttt{Component List} box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |

## Related Scenario

No scenario is available for the Standard version of this component yet.
tAmazonEMRListInstances

Lists the details about the instance groups in a cluster on Amazon EMR (Elastic MapReduce).

**tAmazonEMRListInstances Standard properties**

These properties are used to configure tAmazonEMRListInstances running in the Standard Job framework.

The Standard tAmazonEMRListInstances component belongs to the Cloud family.

The component in this framework is available in all Talend products.

### Basic settings

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Access key and Secret key</strong></td>
<td>Specify the access keys (the access key ID in the Access Key field and the secret access key in the Secret Key field) required to access the Amazon Web Services. For more information on AWS access keys, see Access keys (access key ID and secret access key). To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Inherit credentials from AWS role</strong></td>
<td>Select this check box to leverage the instance profile credentials. These credentials can be used on Amazon EC2 instances, and are delivered through the Amazon EC2 metadata service. To use this option, your Job must be running within Amazon EC2 or other services that can leverage IAM Roles for access to resources. For more information, see Using an IAM Role to Grant Permissions to Applications Running on Amazon EC2 Instances.</td>
</tr>
<tr>
<td><strong>Assume role</strong></td>
<td>If you temporarily need some access permissions associated to an AWS IAM role that is not granted to your user account, select this check box to assume that role. Then specify the values for the following parameters to create a new assumed role session.</td>
</tr>
<tr>
<td><strong>Region</strong></td>
<td>Specify the AWS region by selecting a region name from the list or entering a region between double quotation marks (for example &quot;us-east-1&quot;). For more information about how to specify the AWS region, see Choose an AWS Region.</td>
</tr>
<tr>
<td><strong>Filter master and core instances</strong></td>
<td>Select this check box to ignore the master and core instance groups and list only the task instance groups.</td>
</tr>
<tr>
<td><strong>Cluster id</strong></td>
<td>Enter the ID of the cluster for which you want to list the instance groups.</td>
</tr>
</tbody>
</table>

### Advanced settings

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>STS Endpoint</strong></td>
<td>Select this check box and in the field displayed, specify the AWS Security Token Service endpoint, for example,</td>
</tr>
</tbody>
</table>
tAmazonEMRListInstances

sts.amazonaws.com, where session credentials are retrieved from.
This check box is available only when the Assume role check box is selected.

tStatCatcher Statistics
Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

Global Variables

Global Variables

CURRENT_GROUP_ID: the ID of the current instance group. This is an After variable and it returns a string.
CURRENT_GROUP_NAME: the name of the current instance group. This is an After variable and it returns a string.
ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule
tAmazonEMRListInstances is usually used as a start component of a Job or subjob.

Related scenario

No scenario is available for the Standard version of this component yet.
**tAmazonEMRManage**

Launches or terminates a cluster on Amazon EMR (Elastic MapReduce).

**tAmazonEMRManage Standard properties**

These properties are used to configure tAmazonEMRManage running in the Standard Job framework.

The Standard tAmazonEMRManage component belongs to the Cloud family.

The component in this framework is available in all Talend products.

**Basic settings**

| **Access key and Secret key** | Specify the access keys (the access key ID in the Access Key field and the secret access key in the Secret Key field) required to access the Amazon Web Services. For more information on AWS access keys, see Access keys (access key ID and secret access key).

To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
|---|---|

<table>
<thead>
<tr>
<th><strong>Inherit credentials from AWS role</strong></th>
<th>Select this check box to leverage the instance profile credentials. These credentials can be used on Amazon EC2 instances, and are delivered through the Amazon EC2 metadata service. <tr>
<td></td>
<td>• <strong>Applications</strong>: click the [+] button below the table to add as many rows as needed, each row for an application, and specify the application by clicking the right side of the cell and selecting the application from the drop-down list displayed, or just entering the application name in the cell if it is not in the list.</td>
</tr>
<tr>
<td><strong>Subnet id</strong></td>
<td>Specify the identifier of the Amazon VPC (Virtual Private Cloud) subnet where you want the job flow to launch.</td>
</tr>
<tr>
<td><strong>Availability Zone</strong></td>
<td>Specify the availability zone for your cluster’s EC2 instances.</td>
</tr>
<tr>
<td><strong>Master security group</strong></td>
<td>Specify the security group for the master instance.</td>
</tr>
<tr>
<td><strong>Additional master security groups</strong></td>
<td>Specify additional security groups for the master instance and separate them with a comma, for example, gname1, gname2, gname3.</td>
</tr>
<tr>
<td><strong>Slave security group</strong></td>
<td>Specify the security group for the slave instances.</td>
</tr>
<tr>
<td><strong>Additional slave security groups</strong></td>
<td>Specify additional security groups for the slave instances and separate them with a comma, for example, gname1, gname2, gname3.</td>
</tr>
<tr>
<td><strong>Service Access Security Group</strong></td>
<td>Specify the identifier of the Amazon EC2 security group for the Amazon EMR service to access clusters in VPC private subnet. For how to create a private subnet to enable service access security group on Amazon EMR, see Scenario 2: VPC with Public and Private Subnets (NAT).</td>
</tr>
<tr>
<td><strong>Actions</strong></td>
<td>Specify the bootstrap actions associated with the cluster, by clicking the [+] button below the table to add as many rows as needed, each row for a bootstrap action, and setting the following parameters for each action:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Name</strong>: enter the name of the bootstrap action.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Script location</strong>: specify the location of the script run by the bootstrap action, for example, s3://ap-northeast-1.elasticmapreduce/bootstrap-actions/run-if.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Arguments</strong>: enter the list of command line arguments (separated by commas) passed to the bootstrap action script, for example, “arg0”, “arg1”, “arg2”.</td>
</tr>
</tbody>
</table>
For more information about the bootstrap actions, see BootstrapActionConfig.

### Steps

Specify the job flow step(s) to be invoked on the cluster after its launch, by clicking the [+] button below the table to add as many rows as needed, each row for a step, and setting the following parameters for each step:

- **Name**: enter the name of the job flow step.
- **Action on Failure**: click the cell and from the drop-down list select the action to take if the job flow step fails.
- **Main Class**: enter the name of the main class in the specified Java file. If not specified, the JAR file should specify a Main-Class in its manifest file.
- **Jar**: enter the path to the JAR file run during the step, for example, 's3://inputjar/test.jar'.
- **Args**: enter the list of command line arguments (separated by commas) passed to the JAR file's main function when executed, for example, "arg0","arg1","arg2".

For more information about the job flow steps, see StepConfig.

### Keep alive after steps complete

Select this check box to keep the job flow alive after completing all steps.

### Wait for steps to complete

Select this check box to let your Job wait until the job flow steps are completed.

This check box is available only when the Wait for cluster ready check box is selected.

### Properties

Specify the classification and property information supplied to the configuration object of the EMR cluster to be created, by clicking the [+] button below the table to add as many rows as needed, each row for a property, and setting the following parameters:

- **Classification**: specify the classification of the configuration.
- **Key**: enter the key of the property.
- **Value**: enter the value of the property.

### tStatCatcher Statistics

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLUSTER_FINAL_ID</td>
<td>The ID of the cluster. This is an After variable and it returns a string.</td>
</tr>
<tr>
<td>CLUSTER_FINAL_NAME</td>
<td>The name of the cluster. This is an After variable and it returns a string.</td>
</tr>
<tr>
<td>ERROR_MESSAGE</td>
<td>The error message generated by the component when an error occurs. This is an After variable and it returns a string.</td>
</tr>
</tbody>
</table>
### Usage

| Usage rule | tAmazonEMRManage is usually used as a standalone component. |

### Managing an Amazon EMR cluster

Here's an example of using Talend components to manage an Amazon EMR cluster.

#### Creating an Amazon EMR cluster management Job

Create a Job to start a new Amazon EMR cluster, then resize the cluster, and finally list the ID and name information of the instance groups in the cluster.

#### Procedure

1. Create a new Job and add a `tAmazonEMRManage` component, a `tAmazonEMRResize` component, a `tAmazonEMRListInstances` component, and a `tJava` component by typing their names in the design workspace or dropping them from the Palette.
2. Link the `tAmazonEMRManage` component to the `tAmazonEMRResize` component using a `Trigger > OnSubjobOk` connection.
3. Link the `tAmazonEMRResize` component to the `tAmazonEMRListInstances` component using a `Trigger > OnSubjobOk` connection.
4. Link the `tAmazonEMRListInstances` component to the `tJava` component using a `Row > Iterate` connection.

#### Starting a new Amazon EMR cluster

Configure the `tAmazonEMRManage` component to start a new Amazon EMR cluster.

#### Procedure

1. Double-click the `tAmazonEMRManage` component to open its Basic settings view.
2. In the **Access Key** and **Secret Key** fields, enter the authentication credentials required to access Amazon S3.

3. From the **Action** list, select **Start** to start a cluster.

4. Select the AWS region from the **Region** drop-down list. In this example, it is **Asia Pacific (Tokyo)**.

5. In the **Cluster name** field, enter the name of the cluster to be started. In this example, it is **talend-doc-emr-cluster**.

6. From the **Cluster version** and **Application** drop-down list, select the version of the cluster and the application to be installed on the cluster.

7. Select the **Enable log** check box and in the field displayed, specify the path to a folder in an S3 bucket where you want Amazon EMR to write the log data. In this example, it is **s3://talend-doc-emr-bucket**.

**Resizing the Amazon EMR cluster by adding a new task instance group**

Configure the **tAmazonEMRResize** component to resize a running Amazon EMR cluster by adding a new task instance group.

**Procedure**

1. Double-click the **tAmazonEMRResize** component to open its **Basic settings** view.
2. In the **Access Key** and **Secret Key** fields, enter the authentication credentials required to access Amazon S3.

3. From the **Action** drop-down list, select **Add task instance group** to resize the cluster by adding a new task instance group.

4. In the **Cluster id** field, enter the ID of the cluster to be resized. In this example, the returned value of the global variable `CLUSTER_FINAL_ID` of the previous `tAmazonEMRManage` component is used. Note that you can retrieve the global variable by pressing `Ctrl + Space` and selecting the relevant global variable from the list.

5. In the **Group name** field, enter the name of the task instance group to be added in the cluster. In this example, it is `talend-doc-instance-group`.

6. In the **Instance count** field, specify the number of the instances to be created.

7. From the **Task instance type** drop-down list, select the type of the instances to be created.

**Listing the instance groups in the Amazon EMR cluster**

Configure the `tAmazonEMRListInstances` component and the `tJava` component to retrieve and display the ID and name information of all instance groups in a running cluster.

**Procedure**

1. Double-click the `tAmazonEMRListInstances` component to open its **Basic settings** view.

2. In the **Access Key** and **Secret Key** fields, enter the authentication credentials required to access Amazon S3.

3. Select the AWS region from the **Region** drop-down list. In this example, it is `Asia Pacific (Tokyo)`.

4. Clear the **Filter master and core instances** check box to list all instance groups, including the Master, Core, and Task type instance groups.

5. In the **Cluster id** field, enter the ID of the cluster for which to list the instance groups. In this example, the returned value of the global variable `CLUSTER_FINAL_ID` of the previous `tAmazonEMRManage` component is used.

6. Double-click the `tJava` component to open its **Basic settings** view.
7. In the **Code** field, enter the following code to print the ID and Name information of each instance group in the cluster.

```java
System.out.println("\n\n===== Instance Group =====");
System.out.println("Instance Group ID:    " + (String)globalMap.get("tAmazonEMRListInstances_1_CURRENT_GROUP_ID");
System.out.println("Instance Group Name:  " + (String)globalMap.get("tAmazonEMRListInstances_1_CURRENT_GROUP_NAME");
```

### Executing the Job to manage the Amazon EMR cluster

After setting up the Job and configuring the components used in the Job for managing Amazon EMR cluster, you can then execute the Job and verify the Job execution result.

**Procedure**

1. Press **Ctrl + S** to save the Job and then **F6** to execute the Job.

```
Starting job DOCT7011_AmazonEMRXCC on 16:50 24/08/2016.
[statistics] connecting to socket on port 3912
[statistics] connected
Waiting for cluster to become available.

------- Instance Group ------
Instance Group ID:    ag-3DFY11W2EZVY
Instance Group Name:  master

------- Instance Group ------
Instance Group ID:    ag-178B2U9C14XA2
Instance Group Name:  talend-doc-instance-group

------- Instance Group ------
Instance Group ID:    ag-3HLDU2ZP9CD33
Instance Group Name:  slave
[statistics] disconnected
```

Job DOCT7011_AmazonEMRXCC ended at 17:00 24/08/2016. [exit code=0]

As shown above, the Job starts and resizes the Amazon EMR cluster, and then lists all instance groups in the cluster.

2. View the cluster details on the Amazon EMR Cluster List page to validate the Job execution result.
tAmazonEMRResize

Adds or resizes a task instance group in a cluster on Amazon EMR (Elastic MapReduce).

**tAmazonEMRResize Standard properties**

These properties are used to configure tAmazonEMRResize running in the Standard Job framework.
The Standard tAmazonEMRResize component belongs to the Cloud family.
The component in this framework is available in all Talend products.

### Basic settings

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
</table>
| **Access key and Secret key** | Specify the access keys (the access key ID in the **Access Key** field and the secret access key in the **Secret Key** field) required to access the Amazon Web Services. For more information on AWS access keys, see [Access keys (access key ID and secret access key)](#).  
To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings. |
| **Inherit credentials from AWS role** | Select this check box to leverage the instance profile credentials. These credentials can be used on Amazon EC2 instances, and are delivered through the Amazon EC2 metadata service. To use this option, your Job must be running within Amazon EC2 or other services that can leverage IAM Roles for access to resources. For more information, see [Using an IAM Role to Grant Permissions to Applications Running on Amazon EC2 Instances](#). |
| **Assume role** | If you temporarily need some access permissions associated to an AWS IAM role that is not granted to your user account, select this check box to assume that role. Then specify the values for the following parameters to create a new assumed role session. |
| **Action** | Select an action to be performed from the drop-down list.  
- **Add task instance group**: add a task instance group in a cluster.  
- **Resize task instance group**: resize a task instance group in a cluster. |
| **Region** | Specify the AWS region by selecting a region name from the list or entering a region between double quotation marks (for example "us-east-1"). For more information about how to specify the AWS region, see [Choose an AWS Region](#). |
| **Cluster id** | Enter the ID of the cluster to be resized. |
| **Group name** | Enter the name of the task instance group to be added.  
This field is available only when **Add task instance group** is selected from the **Action** drop-down list. |
| **Group id** | Enter the ID of the task instance group to be resized. This field is available only when **Resize task instance group** is selected from the **Action** drop-down list. |
| **Instance count** | Enter the number of instances for the task instance group. |
| **Task instance type** | Select an instance type for all instances in the task instance group to be added from the drop-down list. This list is available only when **Add task instance group** is selected from the **Action** drop-down list. |
| **Request spot** | Select this check box to launch Spot instances, and in the **Bid price($)** field displayed, enter the maximum hourly rate (in dollars) you are willing to pay per instance. This check box is available only when **Add task instance group** is selected from the **Action** drop-down list. |

### Advanced settings

| **STS Endpoint** | Select this check box and in the field displayed, specify the AWS Security Token Service endpoint, for example, `sts.amazonaws.com`, where session credentials are retrieved from. This check box is available only when the **Assume role** check box is selected. |
| **tStatCatcher Statistics** | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

### Global Variables

| **Global Variables** | **TASK_GROUP_ID**: the ID of the task instance group. This is an After variable and it returns a string.  
**TASK_GROUP_NAME**: the name of the task instance group. This is an After variable and it returns a string.  
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
For further information about variables, see **Talend Studio User Guide**. |

### Usage

| **Usage rule** | **tAmazonEMRResize** is usually used as a standalone component. |
Related scenario

No scenario is available for the Standard version of this component yet.
**tAmazonMysqlClose**

Closes the transaction committed in the connected DB.

**tAmazonMysqlClose Standard properties**

These properties are used to configure tAmazonMysqlClose running in the Standard Job framework.

The Standard tAmazonMysqlClose component belongs to the Cloud and the Databases families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tAmazonMysqlConnection component in the list if more than one connection are planned for the current Job.</td>
</tr>
</tbody>
</table>

### Advanced settings

- **tStatCatcher Statistics**
  - Select this check box to collect log data at the component level.

### Global Variables

**ERROR_MESSAGE:** the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

### Usage

- **Usage rule**
  - This component is to be used along with AmazonMysql components, especially with tAmazonMysqlConnection and tAmazonMysqlCommit.

- **Dynamic settings**
  - Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database.
connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenarios

No scenario is available for the Standard version of this component yet.
tAmazonMysqlCommit

Commits in one go a global transaction instead of doing that on every row or every batch, and provides gain in performance, using a unique connection.
tAmazonMysqlCommit validates the data processed through the Job into the connected database.

**tAmazonMysqlCommit Standard properties**

These properties are used to configure tAmazonMysqlCommit running in the Standard Job framework. The Standard tAmazonMysqlCommit component belongs to the Cloud and the Databases families. The component in this framework is available in all Talend products.

---

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

---

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tAmazonMysqlConnection component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Warning:** If you want to use a Row > Main connection to link tAmazonMysqlCommit to your Job, your data will be committed row by row. In this case, do not select the Close connection check box or your connection will be closed before the end of your first row commit.

### Advanced settings

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

### Global Variables

**Global Variables**

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. |
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is more commonly used with other tAmazonMysql* components, especially with the tAmazonMysqlConnection and tAmazonMysqlRollback components.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic settings</td>
<td>Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

### Related scenario

For **tAmazonMysqlCommit** related scenario, see Inserting data in mother/daughter tables on page 2437.
tAmazonMysqlConnection

Opens a connection to the specified database that can then be reused in the subsequent subjob or subjobs.

`tAmazonMysqlConnection` opens a connection to the database for a current transaction.

**tAmazonMysqlConnection Standard properties**

These properties are used to configure `tAmazonMysqlConnection` running in the Standard Job framework.

The `Standard tAmazonMysqlConnection` component belongs to the Cloud and the Databases families. The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td><strong>Property type</strong></td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><strong>DB Version</strong></td>
<td>MySQL 5 is available.</td>
</tr>
<tr>
<td><strong>Host</strong></td>
<td>Database server IP address.</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database.</td>
</tr>
<tr>
<td><strong>Additional JDBC parameters</strong></td>
<td>Specify additional connection properties for the DB connection you are creating.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Use or register a shared DB Connection</strong></td>
<td>Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the Shared DB Connection Name field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database</td>
</tr>
</tbody>
</table>
connection components from different Job levels that can be either parent or child.

This option is incompatible with the Use dynamic job and Use an independent process to run subjob options of the tRunJob component. Using a shared connection together with a tRunJob component with either of these two options enabled will cause your Job to fail.

### Advanced settings

| **Auto Commit** | Select this check box to commit any changes to the database automatically upon the transaction.
With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component.

Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component. |

| **tStatCatcher Statistics** | Select this check box to collect log data at the component level. |

### Global Variables

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.
For further information about variables, see Talend Studio User Guide. |

### Usage

| Usage rule | This component is more commonly used with other tAmazonMysql* components, especially with the tAmazonMysqlCommit and tAmazonMysqlRollback components. |
Related scenario

For a related scenario using this component, see Inserting data in mother/daughter tables on page 2437
**tAmazonMysqlInput**

Reads a database and extracts fields based on a query.

tAmazonMysqlInput executes a DB query with a strictly defined order which must correspond to the schema definition. Then it passes on the field list to the next component via a Row > Main link.

**tAmazonMysqlInput Standard properties**

These properties are used to configure tAmazonMysqlInput running in the Standard Job framework.

The Standard tAmazonMysqlInput component belongs to the Cloud and the Databases families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>DB Version</td>
<td>MySQL 5 is available.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<p>| Host | Database server IP address. |</p>
<table>

For more information on Dynamic settings and context variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

**Related scenarios**

For related scenarios, see tMysqlInput on page 2448.
tAmazonMysqlOutput

Writes, updates, makes changes or suppresses entries in a database.

tAmazonMysqlOutput executes the action defined on the table and/or on the data contained in the table, based on the flow incoming from the preceding component in the Job.

**tAmazonMysqlOutput Standard properties**

These properties are used to configure tAmazonMysqlOutput running in the Standard Job framework. The Standard tAmazonMysqlOutput component belongs to the Cloud and the Databases families.
The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>DB Version</td>
<td>MySQL 5 is available.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:
1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
<table>
<thead>
<tr>
<th><strong>Port</strong></th>
<th>Listening port number of DB server.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database.</td>
</tr>
</tbody>
</table>
| **Username and Password** | DB user authentication data.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| **Table**         | Name of the table to be written. Note that only one table can be written at a time |
| **Action on table** | On the table defined, you can perform one of the following operations:  
**None**: No operation is carried out.  
**Drop and create table**: The table is removed and created again.  
**Create table**: The table does not exist and gets created.  
**Create table if not exists**: The table is created if it does not exist.  
**Drop table if exists and create**: The table is removed if it already exists and created again.  
**Clear table**: The table content is deleted.  
**Truncate table**: The table content is quickly deleted. However, you will not be able to rollback the operation. |
| **Action on data** | On the data of the table defined, you can perform:  
**Insert**: Add new entries to the table. If duplicates are found, the job stops.  
**Update**: Make changes to existing entries.  
**Insert or update**: Insert a new record. If the record with the given reference already exists, an update would be made.  
**Update or insert**: Update the record with the given reference. If the record does not exist, a new record would be inserted.  
**Delete**: Remove entries corresponding to the input flow.  
**Replace**: Add new entries to the table. If an old row in the table has the same value as a new row for a PRIMARY KEY or a UNIQUE index, the old row is deleted before the new row is inserted.  
**Insert or update on duplicate key or unique index**: Add entries if the inserted value does not exist or update entries if the inserted value already exists and there is a risk of violating a unique index or primary key.  
**Insert Ignore**: Add only new rows to prevent duplicate key errors. |
Warning:
You must specify at least one column as a primary key on which the Update and Delete operations are based. You can do that by clicking Edit Schema and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the Advanced settings view where you can simultaneously define primary keys for the update and delete operations. To do that: Select the Use field options check box and then in the Key in update column, select the check boxes next to the column name on which you want to base the update operation. Do the same in the Key in delete column for the deletion operation.

<table>
<thead>
<tr>
<th>Schema and Edit schema</th>
<th>A schema is a row description, i.e. it defines the number of fields to be processed and passed on to the next component. The schema is either Built-in or stored remotely in the Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Built-In:</td>
<td>You create and store the schema locally for this component only.</td>
</tr>
<tr>
<td>Repository:</td>
<td>You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually. You can find more details about how to verify default values in retrieved schema in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
<tr>
<td>Die on error</td>
<td>This check box is selected by default. Clear the check box to skip the row in error and complete the process for error-free rows. If needed, you can retrieve the rows in error via a Row &gt; Rejects link.</td>
</tr>
</tbody>
</table>

Advanced settings

<table>
<thead>
<tr>
<th>Additional JDBC parameters</th>
<th>Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the Use an existing connection check box in the Basic settings.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Note:</td>
<td>You can press Ctrl+Space to access a list of predefined global variables.</td>
</tr>
<tr>
<td>Extend Insert</td>
<td>Select this check box to carry out a bulk insert of a defined set of lines instead of inserting lines one by one. The gain in system performance is considerable. Number of rows per insert: enter the number of rows to be inserted per operation. Note that the higher the value specified, the lower performance levels shall be due to the increase in memory demands.</td>
</tr>
</tbody>
</table>
### Use Batch
Select this check box to activate the batch mode for data processing.

**Note:**
This check box is available only when you have selected, the Update or the Delete option in the Action on data field.

### Batch Size
Specify the number of records to be processed in each batch.

This field appears only when the Use batch mode check box is selected.

### Commit every
Number of rows to be included in the batch before it is committed to the DB. This option ensures transaction quality (but not rollback) and, above all, a higher performance level.

### Additional Columns
This option is not available if you have just created the DB table (even if you delete it beforehand). This option allows you to call SQL functions to perform actions on columns, provided that these are not insert, update or delete actions, or actions that require pre-processing.

| Name: | Type in the name of the schema column to be altered or inserted. |
| SQL expression: | Type in the SQL statement to be executed in order to alter or insert the data in the corresponding column. |
| Position: | Select Before, Replace or After, depending on the action to be performed on the reference column. |
| Reference column: | Type in a reference column that tAmazonMysqlOutput can use to locate or replace the new column, or the column to be modified. |

### Use field options
Select this check box to customize a request, particularly if multiple actions are being carried out on the data.

### Use Hint Options
Select this check box to activate the hint configuration area which helps you optimize a query's execution. In this area, parameters are:
### Enable debug mode
Select this check box to display each step involved in the process of writing data in the database.

### Use duplicate key update mode insert
Updates the values of the columns specified, in the event of duplicate primary keys:

**Column**: Between double quotation marks, enter the name of the column to be updated.

**Value**: Enter the action you want to carry out on the column.

**Note**: To use this option you must first of all select the **Insert** mode in the **Action on data** list found in the **Basic Settings** view.

### tStatCatcher Statistics
Select this check box to collect log data at the component level.

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE</strong></td>
<td>the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_UPDATED</strong></td>
<td>the number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_INSERTED</strong></td>
<td>the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_DELETED</strong></td>
<td>the number of rows deleted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_REJECTED</strong></td>
<td>the number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>QUERY</strong></td>
<td>the query statement processed. This is an After variable and it returns a string.</td>
</tr>
<tr>
<td><strong>ERROR_MESSAGE</strong></td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).
### Usage

| Usage rule | This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible. This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in a MySQL database. It also allows you to create a reject flow using a Row > Rejects link to filter data in error. For an example of tAmazonMysqlOutput in use, see . |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |

### Related scenarios

For related scenarios, see tMysqlSCD on page 2519.
**tAmazonMysqlRollback**

Cancels the transaction commit in the connected database and avoids to commit part of a transaction involuntarily.

**tAmazonMysqlRollback Standard properties**

These properties are used to configure tAmazonMysqlRollback running in the Standard Job framework.

The Standard tAmazonMysqlRollback component belongs to the Cloud and the Databases families.

The component in this framework is available in all *Talend products*.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see *Dynamic database components on page 598*.  

### Basic settings

<table>
<thead>
<tr>
<th><strong>Database</strong></th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Component list</strong></td>
<td>Select the <code>tAmazonMysqlConnection</code> component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td><strong>Close Connection</strong></td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

### Advanced settings

| **tStatCatcher Statistics** | Select this check box to collect log data at the component level. |

### Global Variables

**Global Variables**

| **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. |
| **Die on error** check box | A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. |
| **To fill up a field or expression with a variable, press Ctrl + Space** to access the variable list and choose the variable to use from it. |
| **For further information about variables, see *Talend Studio User Guide*** |
Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is more commonly used with other tAmazonMysql* components, especially with the tAmazonMysqlConnection and tAmazonMysqlCommit components.</th>
</tr>
</thead>
</table>
| Dynamic settings | Click the [+ ] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |

Related scenario

For a related scenario, see Rollback from inserting data in mother/daughter tables on page 2440.
tAmazonMysqlRow

Executes the SQL query stated onto the specified database.

Depending on the nature of the query and the database, tAmazonMysqlRow acts on the actual DB structure or on the data (although without handling data). The SQLBuilder tool helps you write easily your SQL statements. tAmazonMysqlRow is the specific component for this database query. The row suffix means the component implements a flow in the job design although it does not provide output.

**tAmazonMysqlRow Standard properties**

These properties are used to configure tAmazonMysqlRow running in the Standard Job framework.
The Standard tAmazonMysqlRow component belongs to the Cloud and the Databases families.
The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-in</strong>: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>DB Version</td>
<td>MySQL 5 is available.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
<table>
<thead>
<tr>
<th><strong>Host</strong></th>
<th>Database server IP address</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>

</tbody>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th><strong>Additional JDBC parameters</strong></th>
<th>Specify additional connection properties for the DB connection you are creating. This option is not available if</th>
</tr>
</thead>
</table>
you have selected the **Use an existing connection** check box in the **Basic settings**.

### Propagate QUERY’s recordset

Select this check box to insert the result of the query in a COLUMN of the current flow. Select this column from the **use column** list.

**Note:**
This option allows the component to have a different schema from that of the preceding component. Moreover, the column that holds the QUERY’s recordset should be set to the type of Object and this component is usually followed by **tParseRecordSet**.

### Use PreparedStatement

Select this check box if you want to query the database using a PreparedStatement. In the **Set PreparedStatement Parameter** table, define the parameters represented by “?” in the SQL instruction of the **Query** field in the **Basic Settings** tab.

- **Parameter Index**: Enter the parameter position in the SQL instruction.
- **Parameter Type**: Enter the parameter type.
- **Parameter Value**: Enter the parameter value.

**Note:**
This option is very useful if you need to execute the same query several times. Performance levels are increased.

### Commit every

Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions.

### tStatCatcher Statistics

Select this check box to collect log data at the component level.

### Global Variables

**Global Variables**

**QUERY**: the query statement being processed. This is a Flow variable and it returns a string.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*. 
Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component offers the flexibility of the DB query and covers all possible SQL queries.</th>
</tr>
</thead>
</table>

| Dynamic settings | Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide. |

Related scenario

For a related scenario, see:

- Combining two flows for selective output on page 2514
tAmazonOracleClose

Closes the transaction committed in the connected database.

tAmazonOracleClose Standard properties

These properties are used to configure tAmazonOracleClose running in the Standard Job framework.
The Standard tAmazonOracleClose component belongs to the Cloud and the Databases families.
The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related
to database settings vary depending on your database type selection. For more information about
dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tAmazonOracleConnection component in the list if more than one connection are planned for the current Job.</td>
</tr>
</tbody>
</table>

Advanced settings

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

Global Variables

| Global Variables | ERROR MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | This component is to be used along with AmazonOracle components, especially with tAmazonOracleConnection and tAmazonOracleCommit. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database |
connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenario

This component is to be used with tAmazonOracleConnection and tAmazonOracleRollback components. It is generally used with a tAmazonOracleConnection to close a connection for the ongoing transaction.

For a related scenario, see tMysqlConnection on page 2436.
**tAmazonOracleCommit**

Commits in one go a global transaction instead of doing that on every row or every batch, and provides gain in performance, using a unique connection. tAmazonOracleCommit validates the data processed through the Job into the connected database.

**tAmazonOracleCommit Standard properties**

These properties are used to configure tAmazonOracleCommit running in the Standard Job framework. The Standard tAmazonOracleCommit component belongs to the Cloud and the Databases families. The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tAmazonOracleConnection component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Warning:** If you want to use a Row > Main connection to link tAmazonOracleCommit to your Job, your data will be committed row by row. In this case, do not select the Close connection check box or your connection will be closed before the end of your first row commit.

### Advanced settings

**tStatCatcher Statistics**

Select this check box to collect log data at the component level.

### Global Variables

**Global Variables**

**ERROR_MESSAGE:** the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

</tr>
</tbody>
</table>

### Related scenario

For tAmazonOracleCommit related scenario, see Inserting data in mother/daughter tables on page 2437
tAmazonOracleConnection

Opens a connection to the specified database that can then be reused in the subsequent subjob or subjobs.
tAmazonOracleConnection opens a connection to the database for a current transaction.

**tAmazonOracleConnection Standard properties**

These properties are used to configure tAmazonOracleConnection running in the Standard Job framework.

The Standard tAmazonOracleConnection component belongs to the Cloud and the Databases families.
The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Connection type</td>
<td>Drop-down list of available drivers:</td>
</tr>
<tr>
<td>Oracle SID</td>
<td>Select this connection type to uniquely identify a particular database on a system.</td>
</tr>
<tr>
<td>DB Version</td>
<td>Oracle 11-5 is available.</td>
</tr>
<tr>
<td>Use tns file</td>
<td>Select this check box to use the metadata of a context included in a tns file.</td>
</tr>
<tr>
<td>TNS File</td>
<td>Enter the path to the tns file manually or browse to the file by clicking the three-dot button next to the field.</td>
</tr>
<tr>
<td>Select a DB Connection in Tns File</td>
<td>Click the three-dot button to display all the contexts held in the tns file and select the desired one.</td>
</tr>
<tr>
<td>Host</td>
<td>Database server IP address.</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database.</td>
</tr>
<tr>
<td>-----------</td>
<td>----------------------</td>
</tr>
<tr>
<td>Schema</td>
<td>Name of the schema.</td>
</tr>
</tbody>
</table>
| Username and Password | DB user authentication data.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| Additional JDBC parameters | Specify additional connection properties for the DB connection you are creating.  
**Note:**  
You can set the encoding parameters through this field. |
| Use or register a shared DB Connection | Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the Shared DB Connection Name field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child.  
This option is incompatible with the Use dynamic job and Use an independent process to run subjob options of the tRunJob component. Using a shared connection together with a tRunJob component with either of these two options enabled will cause your Job to fail. |

### Advanced settings

| Auto Commit | Select this check box to commit any changes to the database automatically upon the transaction.  
With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component.  
Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component. |
| tStatCatcher Statistics | Select this check box to gather the job processing metadata at a Job level as well as at each component level. |

### Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable |
and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

| Usage rule | This component is more commonly used with other tAmazonOracle* components, especially with the tAmazonOracleCommit and tAmazonOracleRollback components. |

### Related scenario

For **tAmazonOracleConnection** related scenario, see **tMysqlConnection** on page 2436
tAmazonOracleInput

Reads a database and extracts fields based on a query.

tAmazonOracleInput executes a DB query with a strictly defined order which must correspond to the schema definition. Then it passes on the field list to the next component via a Row > Main link.

**tAmazonOracleInput Standard properties**

These properties are used to configure tAmazonOracleInput running in the Standard Job framework.

The Standard tAmazonOracleInput component belongs to the Cloud and the Databases families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-in:</strong> No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository:</strong> Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Connection type</td>
<td>Drop-down list of available drivers:</td>
</tr>
<tr>
<td></td>
<td><strong>Oracle SID:</strong> Select this connection type to uniquely identify a particular database on a system.</td>
</tr>
<tr>
<td>DB Version</td>
<td>Select the Oracle version in use.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th><strong>Host</strong></th>
<th>Database server IP address.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database.</td>
</tr>
<tr>
<td><strong>Oracle schema</strong></td>
<td>Oracle schema name.</td>
</tr>
</tbody>
</table>
| **Username and Password** | DB user authentication data.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| **Schema and Edit Schema** | A schema is a row description, i.e. it defines the number of fields to be processed and passed on to the next component. The schema is either **Built-in** or stored remotely in the **Repository**.  
- **Built-in**: The schema is created and stored locally for this component only. Related topic: see *Talend Studio User Guide*.  
- **Repository**: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see *Talend Studio User Guide*. |
| **Table name** | Database table name. |
| **Query type and Query** | Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition. |

**Advanced settings**

<p>| <strong>tStatCatcher Statistics</strong> | Select this check box to collect log data at the component level. |
| <strong>Use cursor</strong> | When selected, helps to decide the row set to work with at a time and thus optimize performance. |</p>
<table>
<thead>
<tr>
<th>Trim all the String/Char columns</th>
<th>Select this check box to remove leading and trailing whitespace from all the String/Char columns.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Trim column</td>
<td>Remove leading and trailing whitespace from defined columns.</td>
</tr>
</tbody>
</table>

Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_LINE: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>

Limitation

| Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the |
Related scenarios

For related scenarios, see:

- Reading data from different MySQL databases using dynamically loaded connection parameters on page 491.
**tAmazonOracleOutput**

Writes, updates, makes changes or suppresses entries in a database.

tAmazonOracleOutput executes the action defined on the table and/or on the data contained in the table, based on the flow incoming from the preceding component in the Job.

**tAmazonOracleOutput Standard properties**

These properties are used to configure tAmazonOracleOutput running in the Standard Job framework.
The Standard tAmazonOracleOutput component belongs to the Cloud and the Databases families.
The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

**Connection type**

Drop-down list of available drivers:

**Oracle SID:** Select this connection type to uniquely identify a particular database on a system.
<table>
<thead>
<tr>
<th><strong>DB Version</strong></th>
<th>Select the Oracle version in use.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Host</strong></td>
<td>Database server IP address.</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data.</td>
</tr>
<tr>
<td><strong>Oracle schema</strong></td>
<td>Name of the Oracle schema.</td>
</tr>
<tr>
<td><strong>Table</strong></td>
<td>Name of the table to be written. Note that only one table can be written at a time.</td>
</tr>
<tr>
<td><strong>Action on table</strong></td>
<td>On the table defined, you can perform one of the following operations:&lt;br&gt;- <strong>None</strong>: No operation is carried out.&lt;br&gt;- <strong>Drop and create a table</strong>: The table is removed and created again.&lt;br&gt;- <strong>Create a table</strong>: The table does not exist and gets created.&lt;br&gt;- <strong>Create a table if not exists</strong>: The table is created if it does not exist.&lt;br&gt;- <strong>Drop a table if exists and create</strong>: The table is removed if it already exists and created again.&lt;br&gt;- <strong>Clear a table</strong>: The table content is deleted.</td>
</tr>
</tbody>
</table>

**Warning:**<br>If you select the Use an existing connection check box and select an option other than None from the Action on table list, a commit statement will be generated automatically before the data update/insert/delete operation.

| **Action on data** | On the data of the table defined, you can perform:<br>- **Insert**: Add new entries to the table. If duplicates are found, job stops.<br>- **Update**: Make changes to existing entries<br>- **Insert or update**: Insert a new record. If the record with the given reference already exists, an update would be made.<br>- **Update or insert**: Update the record with the given reference. If the record does not exist, a new record would be inserted.<br>- **Delete**: Remove entries corresponding to the input flow. |
### Warning:

It is necessary to specify at least one column as a primary key on which the Update and Delete operations are based. You can do that by clicking Edit Schema and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the Advanced settings view where you can simultaneously define primary keys for the Update and Delete operations. To do that: Select the Use field options check box and then in the Key in update column, select the check boxes next to the column names you want to use as a base for the Update operation. Do the same in the Key in delete column for the Delete operation.

### Schema and Edit schema

A schema is a row description, i.e. it defines the number of fields to be processed and passed on to the next component. The schema is either **Built-in** or stored remotely in the **Repository**.

- **Built-In**: You create and store the schema locally for this component only.

- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

  When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

  You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

### Die on error

This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a Row > Rejects link.

### Advanced settings

<table>
<thead>
<tr>
<th><strong>Advanced settings</strong></th>
<th><strong>Description</strong></th>

<tr>
<td><strong>Position:</strong></td>
<td>Select <strong>Before</strong>, <strong>Replace</strong> or <strong>After</strong> following the action to be performed on the reference column.</td>
</tr>
<tr>
<td><strong>Reference column:</strong></td>
<td>Type in a column of reference that the tDBOutput can use to place or replace the new or altered column.</td>
</tr>
<tr>
<td><strong>Use field options</strong></td>
<td>Select this check box to customize a request, especially when there is double action on data.</td>
</tr>
<tr>
<td><strong>Use Hint Options</strong></td>
<td>Select this check box to activate the hint configuration area which helps you optimize a query's execution. In this area, parameters are:</td>
</tr>
<tr>
<td></td>
<td>- <strong>HINT</strong>: specify the hint you need, using the syntax /*+/ */.</td>
</tr>
<tr>
<td></td>
<td>- <strong>POSITION</strong>: specify where you put the hint in a SQL statement.</td>
</tr>
<tr>
<td></td>
<td>- <strong>SQL STMT</strong>: select the SQL statement you need to use.</td>
</tr>
<tr>
<td><strong>Convert columns and table to uppercase</strong></td>
<td>Select this check box to set the names of columns and table in upper case.</td>
</tr>
<tr>
<td><strong>Enable debug mode</strong></td>
<td>Select this check box to display each step during processing entries in a database.</td>
</tr>
<tr>
<td><strong>Use Batch</strong></td>
<td>Select this check box to activate the batch mode for data processing.</td>
</tr>
<tr>
<td><strong>Batch Size</strong></td>
<td>Specify the number of records to be processed in each batch. This field appears only when the <strong>Use batch mode</strong> check box is selected.</td>
</tr>
<tr>
<td><strong>Support null in &quot;SQL WHERE&quot; statement</strong></td>
<td>Select this check box to validate null in &quot;SQL WHERE&quot; statement.</td>
</tr>
</tbody>
</table>

**Global Variables**

| **Global Variables** | **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer. |
**Usage**

| Usage rule | This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible. This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in an Oracle database. It also allows you to create a reject flow using a Row > Rejects link to filter data in error. For such an example, see Retrieving data in error with a Reject link on page 2485. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access databases having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |
Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

Related scenarios

For tAmazonOracleOutput related topics, see:

- Inserting a column and altering data using tMysqlOutput on page 2477.
tAmazonOracleRollback

Cancels the transaction commit in the connected database and avoids to commit part of a transaction involuntarily.

tAmazonOracleRollback Standard properties

These properties are used to configure tAmazonOracleRollback running in the Standard Job framework.

The Standard tAmazonOracleRollback component belongs to the Cloud and the Databases families.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tAmazonOracleConnection component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

Advanced settings

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

For further information about variables, see Talend Studio User Guide.
**Usage**

**Usage rule**

This component is more commonly used with other tAmazonOracle* components, especially with the tAmazonOracleConnection and tAmazonOracleCommit components.

**Dynamic settings**

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

**Related scenario**

For tAmazonOracleRollback related scenario, see tMysqlRollback on page 2502.
tAmazonOracleRow

Executes the SQL query stated onto the specified database.

Depending on the nature of the query and the database, tAmazonOracleRow acts on the actual DB structure or on the data (although without handling data). The SQLBuilder tool helps you write easily your SQL statements. tAmazonOracleRow is the specific component for this database query. The row suffix means the component implements a flow in the job design although it does not provide output.

tAmazonOracleRow Standard properties

These properties are used to configure tAmazonOracleRow running in the Standard Job framework.

The Standard tAmazonOracleRow component belongs to the Cloud and the Databases families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined.

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<p>| Connection type | Drop-down list of available drivers.                                       |</p>
<table>
<thead>
<tr>
<th><strong>Host</strong></th>
<th>Database server IP address</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database</td>
</tr>
</tbody>
</table>
| **Username and Password** | DB user authentication data.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| **Schema and Edit Schema** | A schema is a row description, i.e. it defines the number of fields to be processed and passed on to the next component. The schema is either Built-in or stored remotely in the Repository.  
**Built-in:** The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide.  
**Repository:** The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide. |
| **Query type**    | Either Built-in or Repository.  
**Built-in:** Fill in manually the query statement or build it graphically using SQLBuilder  
**Repository:** Select the relevant query stored in the Repository. The Query field gets accordingly filled in. |
| **Query**         | Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition. |
| **Use NB_LINE_**  | This option allows you feed the variable with the number of rows inserted/updated/deleted to the next component or subjob. This field only applies if the query entered in Query field is a INSERT, UPDATE or DELETE query.  
- **NONE:** does not feed the variable.  
- **INSERTED:** feeds the variable with the number of rows inserted.  
- **UPDATED:** feeds the variable with the number of rows updated.  
- **DELETED:** feeds the variable with the number of rows deleted. |
| **Die on error**  | This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a Row > Rejects link. |
## Advanced settings

| Propagate QUERY’s recordset | Select this check box to insert the result of the query into a COLUMN of the current flow. Select this column from the *use column* list.

**Note:**
This option allows the component to have a different schema from that of the preceding component. Moreover, the column that holds the QUERY’s recordset should be set to the type of *Object* and this component is usually followed by *tParseRecordSet*. |
|---|---|
| Use PreparedStatement | Select this check box if you want to query the database using a PreparedStatement. In the *Set PreparedStatement Parameter* table, define the parameters represented by "?" in the SQL instruction of the *Query* field in the *Basic Settings* tab.

**Parameter Index**: Enter the parameter position in the SQL instruction.

**Parameter Type**: Enter the parameter type.

**Parameter Value**: Enter the parameter value.

**Note:**
This option is very useful if you need to execute the same query several times. Performance levels are increased. |
| Commit every | Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions. |
| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

## Global Variables

| Global Variables | *QUERY*: the query statement being processed. This is a Flow variable and it returns a string.  
*NB_LINE_UPDATED*: the number of rows updated. This is an After variable and it returns an integer.  
*NB_LINE_INSERTED*: the number of rows inserted. This is an After variable and it returns an integer.  
*NB_LINE_DELETED*: the number of rows deleted. This is an After variable and it returns an integer.  
*ERROR_MESSAGE*: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the *Die on error* check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. |

---

---
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component offers the flexibility of the DB query and covers all possible SQL queries.</th>
</tr>
</thead>
</table>

**Dynamic settings**

Click the \[+\] button to add a row in the table and fill the *Code* field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The *Dynamic settings* table is available only when the *Use an existing connection* check box is selected in the *Basic settings* view. Once a dynamic parameter is defined, the *Component List* box in the *Basic settings* view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on *Dynamic settings* and context variables, see Talend Studio User Guide.

Related scenarios

For related topics, see:

- Combining two flows for selective output on page 2514
- Procedure on page 625.
- Removing and regenerating a MySQL table index on page 2508.
tAmazonRedshiftManage

Manages Amazon Redshift clusters and snapshots.
tAmazonRedshiftManage manages the work of creating a new Amazon Redshift cluster, creating a snapshot of an Amazon Redshift cluster, resizing an existing Amazon Redshift cluster, and deleting an existing cluster or snapshot.

**tAmazonRedshiftManage Standard properties**

These properties are used to configure tAmazonRedshiftManage running in the Standard Job framework.
The Standard tAmazonRedshiftManage component belongs to the Cloud and the Databases families.
The component in this framework is available in all Talend products.

**Basic settings**

| Access Key and Secret Key | Specify the access keys (the access key ID in the Access Key field and the secret access key in the Secret Key field) required to access the Amazon Web Services. For more information on AWS access keys, see Access keys (access key ID and secret access key).

To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Inherit credentials from AWS role</td>
<td>Select this check box to leverage the instance profile credentials. These credentials can be used on Amazon EC2 instances, and are delivered through the Amazon EC2 metadata service. To use this option, your Job must be running within Amazon EC2 or other services that can leverage IAM Roles for access to resources. For more information, see Using an IAM Role to Grant Permissions to Applications Running on Amazon EC2 Instances.</td>
</tr>
<tr>
<td>Assume role</td>
<td>If you temporarily need some access permissions associated to an AWS IAM role that is not granted to your user account, select this check box to assume that role. Then specify the values for the following parameters to create a new assumed role session.</td>
</tr>
</tbody>
</table>
| Action | Select an action to be performed from the list.

- **Create cluster**: create a new Amazon Redshift cluster.
- **Delete cluster**: delete a previously provisioned Amazon Redshift cluster.
- **Resize cluster**: resize an existing Amazon Redshift cluster.
- **Restore from snapshot**: create a new Amazon Redshift cluster from a snapshot.
- **Delete snapshot**: delete the specified manual snapshot. |
| Region | Specify the AWS region by selecting a region name from the list or entering a region between double quotation marks. |
(e.g. "us-east-1") in the list. For more information about the supported AWS regions where you can provision an Amazon Redshift cluster, see Regions and Endpoints.

<table>
<thead>
<tr>
<th>Create snapshot</th>
<th>Select this check box to create a final snapshot of the Amazon Redshift cluster before it is deleted. This check box is available only when <strong>Delete cluster</strong> is selected from the <strong>Action</strong> list.</th>
</tr>
</thead>
</table>
| Snapshot id     | Enter the identifier of the snapshot. This field is available when:  
|                 | • **Delete cluster** is selected from the **Action** list and the **Create snapshot** check box is selected.  
|                 | • **Restore from snapshot** or **Delete snapshot** is selected from the **Action** list. |
| Cluster id      | Enter the ID of the cluster. This field is available when **Create cluster**, **Delete cluster**, **Resize cluster**, or **Restore from snapshot** is selected from the **Action** list. |
| Database        | Enter the name of the first database to be created when the cluster is created. This field is available only when **Create cluster** is selected from the **Action** list. |
| Port            | Enter the port number on which the cluster accepts connections. This field is available when **Create cluster** or **Restore from snapshot** is selected from the **Action** list. |
| Master username and Master password | The user name and the password associated with the master user account for the cluster to be created. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings. The two fields are available only when **Create cluster** is selected from the **Action** list. |
| Node type       | Select the node type for the cluster. This list is available when **Create cluster**, **Resize cluster**, or **Restore from snapshot** is selected from the **Action** list. |
| Node count      | Enter the number of compute nodes in the cluster. This field is available only when **Create cluster** or **Resize cluster** is selected from the **Action** list. |

**Advanced settings**

| STS Endpoint | Select this check box and in the field displayed, specify the AWS Security Token Service endpoint, for example, sts.amazonaws.com, where session credentials are retrieved from. |
| **Wait for cluster ready** | Select this check box to let your Job wait until the launch of the cluster is completed. This check box is available when Create cluster or Restore from snapshot is selected from the Action list. |
| **Original cluster id of snapshot** | Enter the name of the cluster the source snapshot was created from. This field is available when Restore from snapshot or Delete snapshot is selected from the Action list. |
| **Parameter group name** | Enter the name of the parameter group to be associated with the cluster. This field is available when Create cluster or Restore from snapshot is selected from the Action list. |
| **Subnet group name** | Enter the name of the subnet group where you want the cluster to be restored. This field is available when Create cluster or Restore from snapshot is selected from the Action list. |
| **Publicly accessible** | Select this check box so that the cluster can be accessed from a public network. This check box is available when Create cluster or Restore from snapshot is selected from the Action list. |
| **Set public ip address** | Select this check box and in the field displayed enter the Elastic IP (EIP) address for the cluster. This check box is available only when the Publicly accessible check box is selected. |
| **Availability zone** | Enter the EC2 Availability Zone in which you want Amazon Redshift to provision the cluster. This field is available when Create cluster or Restore from snapshot is selected from the Action list. |
| **VPC security group ids** | Enter Virtual Private Cloud (VPC) security groups to be associated with the cluster and separate them with a comma, for example, gname1, gname2, gname3. This field is available when Create cluster or Restore from snapshot is selected from the Action list. |
| **tStatCatcher Statistics** | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global Variables**

| **Global Variables** | **CLUSTER_FINAL_ID**: the ID of the cluster. This is an After variable and it returns a string. **ENDPOINT**: the endpoint address of the cluster. This is an After variable and it returns a string. **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the |
Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

### Usage

| Usage rule | tAmazonRedshiftManage is usually used as a standalone component. |

### Related scenario

No scenario is available for the Standard version of this component yet.
tApacheLogInput

Reads the access-log file for an Apache HTTP server.

To effectively manage the Apache HTTP Server, it is necessary to get feedback about the activity and performance of the server as well as any problems that may be occurring.

**tApacheLogInput Standard properties**

These properties are used to configure tApacheLogInput running in the Standard Job framework.

The Standard tApacheLogInput component belongs to the File family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-in or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file where the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><strong>Schema and Edit Schema</strong></td>
<td>A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either Built-in or stored remotely in the Repository.</td>
</tr>
<tr>
<td></td>
<td>In the context of tApacheLogInput usage, the schema is read-only.</td>
</tr>
<tr>
<td><strong>Built-in</strong></td>
<td>You can create the schema and store it locally for this component. Related topic: see Talend Studio User Guide.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>You have already created and stored the schema in the Repository. You can reuse it in various projects and Job flowcharts. Related topic: see Talend Studio User Guide.</td>
</tr>
<tr>
<td><strong>File Name</strong></td>
<td>Name of the file and/or the variable to be processed. For further information about how to define and use a variable in a Job, see Talend Studio User Guide.</td>
</tr>
<tr>
<td><strong>Die on error</strong></td>
<td>Select this check box to stop the execution of the Job when an error occurs. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can collect the rows on error using a Row &gt; Reject link.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| Encoding | Select the encoding type from the list or select Custom and define it manually. This field is compulsory for DB data handling. |
Global Variables

- **NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

**Usage rule**

- **tApacheLogInput** can be used with other components or as a standalone component. It allows you to create a data flow using a **Row > Main** connection, or to create a reject flow to filter specified data using a **Row > Reject** connection. For an example of how to use these two links, see Procedure on page 968.

Reading an Apache access-log file

The following scenario creates a two-component Job, which aims at reading the access-log file for an Apache HTTP server and displaying the output in the Run log console.

**Procedure**

1. Drop a **tApacheLogInput** component and a **tLogRow** component from the Palette onto the design workspace.
2. Right-click on the **tApacheLogInput** component and connect it to the **tLogRow** component using a **Main Row** link.
3. In the design workspace, select **tApacheLogInput**.
4. Click the **Component** tab to define the basic settings for **tApacheLogInput**.

![tApacheLogInput_1](image)

- **Basic settings**
  - Property Type: Built-in
  - Schema: Built-in
  - File Name: C:/tests/log.txt
  - Die on error: unchecked

5. If desired, click the **Edit schema** button to see the read-only columns.

6. In the **File Name** field, enter the file path or browse to the access-log file you want to read.

7. In the design workspace, select **tLogRow** and click the **Component** tab to define its basic settings. For more information, see **tLogRow** on page 1956

8. Press **F6** to execute the Job.

```
Starting job apach at 12:11 01/09/2008
194.84.172.4 - - [27/May/2007:03:06:12] +0200 "GET /forum/index.php HTTP/1.0|200|15024|http://www.talendforge.org/forum/index.php|Mozilla/4.0 (compatible; MSIE 6.0; Windows NT 5.1; .NET CLR 1.1.4322)
194.84.172.4 - - [27/May/2007:03:06:12] +0200 "GET /forum/login.php HTTP/1.0|200|17445|http://www.talendforge.org/login.php|Mozilla/4.0 (compatible; MSIE 6.0; Windows NT 5.1) Opera 7.54 [en]
```

Results

The log lines of the defined file are displayed on the console.
tAS400Close

Closes the transaction committed in the connected database.

**tAS400Close Standard properties**

These properties are used to configure tAS400Close running in the Standard Job framework.

The Standard tAS400Close component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the <strong>tAS400Connection</strong> component in the list if more than one connection are planned for the current Job.</td>
</tr>
</tbody>
</table>

### Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

### Usage

| Usage rule | This component is to be used along with AS/400 components, especially with **tAS400Connection** and **tAS400Commit**. |
| Dynamic settings | Click the **[+]** button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide. |
Related scenario

No scenario is available for the Standard version of this component yet.
tAS400Commit

Commits in one go a global transaction instead of doing that on every row or every batch, and provides gain in performance, using a unique connection.

tAS400Commit validates the data processed through the Job into the connected database.

**tAS400Commit Standard properties**

These properties are used to configure tAS400Commit running in the Standard Job framework.

The Standard tAS400Commit component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tAS400Connection component in the list if more than one connection are planned for the current Job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Warning:**

If you want to use a Row > Main connection to link tAS400Commit to your Job, your data will be committed row by row. In this case, do not select the Close connection check box or your connection will be closed before the end of your first row commit.

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is more commonly used with other tAS400* components, especially with the tAS400Connection and tAS400Rollback components. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to acces |
s database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

**Related scenario**

For a similar scenario using other database, see Inserting data in mother/daughter tables on page 2437.
tAS400Connection

Opens a connection to the specified database that can then be reused in the subsequent subjob or subjobs.

**tAS400Connection Standard properties**

These properties are used to configure tAS400Connection running in the Standard Job framework.

The Standard tAS400Connection component belongs to the Databases and the ELT families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-in</strong>: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>DB Version</td>
<td>Select the AS/400 version in use</td>
</tr>
<tr>
<td>Host</td>
<td>Database server IP address</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td>Use or register a shared DB Connection</td>
<td>Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the <strong>Shared DB Connection Name</strong> field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child.</td>
</tr>
<tr>
<td></td>
<td>This option is incompatible with the <strong>Use dynamic job</strong> and <strong>Use an independent process to run subjob</strong> options of the <strong>tRunJob</strong> component. Using a shared connection together</td>
</tr>
</tbody>
</table>
with a \texttt{tRunJob} component with either of these two options enabled will cause your Job to fail.

### Advanced settings

<table>
<thead>
<tr>
<th>Additional JDBC parameters</th>
<th>Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the \textit{Use an existing connection} check box in the \textit{Basic settings}.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Auto Commit</strong></td>
<td>Select this check box to commit any changes to the database automatically upon the transaction. With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component. Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component.</td>
</tr>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to gather the job processing metadata at a Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

### Usage

| Usage rule | This component is more commonly used with other tAS400* components, especially with the \texttt{tAS400Commit} and \texttt{tAS400Rollback} components. |

### Related scenario

For similar scenarios using other database, see \texttt{tMysqlConnection} on page 2436.
**tAS400Input**

Reads a database and extracts fields based on a query.

tAS400Input executes a DB query with a strictly defined order which must correspond to the schema definition. Then it passes on the field list to the next component via a **Row > Main** link.

**tAS400Input Standard properties**

These properties are used to configure tAS400Input running in the Standard Job framework.

The Standard tAS400Input component belongs to the Databases family.

The component in this framework is available in all **Talend products**.

---

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

---

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see **Talend Studio User Guide**.

<table>
<thead>

</tbody>
</table>

**Handling data with AS/400**

This scenario describes a Job that writes the user information into AS/400, and then reads the information in AS/400 and displays it on the console.
Adding and linking the components

Procedure

1. Create a new Job and add a tFixedFlowInput component, a tAS400Output component, a tAS400Input component, and a tLogRow component by typing their names in the design workspace or dropping them from the Palette.
2. Connect tFixedFlowInput to tAS400Output using a Row > Main connection.
3. Do the same to connect tAS400Input to tLogRow.
4. Connect tFixedFlowInput to tAS400Input using a Trigger > OnSubjobOk connection.

Configuring the components

Writing the data into AS/400

Procedure

1. Double-click tFixedFlowInput to open its Basic settings view.

2. Click the [...] button next to Edit schema and in the Schema dialog box define the schema by adding three columns: id of Integer type, and name and city of String type.
Click **OK** to close the **Schema** dialog box and accept the propagation prompted by the pop-up dialog box.

3. In the **Mode** area, select **Use Inline Content (delimited file)** and enter the following user information in the **Content** field.

   1;George;Bismarck  
   2;Abraham;Boise  
   3;Taylor;Nashville  
   4;William;Jefferson City  
   5;Alexander;Jackson  
   6;James;Boise  
   7;Gerald;Little Rock  
   8;Tony;Richmond  
   9;Thomas;Springfield  
   10;Andre;Nashville

4. Double-click **tAS400Output** to open its **Basic settings** view.

5. In the **Host**, **Database**, **Username** and **Password** fields, enter the information required for the connection to AS/400.

6. In the **Table** field, specify the table into which you want to write the data. In this example, it is `doct1018`.

7. Select **Drop table if exists and create** from the **Action on table** drop-down list, and select **Insert** from the **Action on data** drop-down list.
Retrieving the data from AS/400

Procedure

1. Double-click **tAS400Input** to open its **Basic settings** view.

![tAS400Input Basic settings](image)

2. In the **Host**, **Database**, **Username** and **Password** fields, enter the information required for the connection to AS/400.

3. Click the [...] button next to **Edit schema** and in the **Schema** dialog box define the schema by adding three columns: `id` of Integer type, and `name` and `city` of String type. The data structure is same as the structure you have defined for **tFixedFlowInput**.

4. In the **Table Name** field, enter or browse to the table into which you write the data. In this example, it is `doct1018`.

5. In the **Query** field, enter the SQL query sentence to be used to retrieve the user data from AS/400. In this example, it is `SELECT * FROM doct1018`.

6. Double-click **tLogRow** to open its **Basic settings** view.

![tLogRow Basic settings](image)

7. In the **Mode** area, select **Table (print values in cells of a table)** for better readability of the result.

Saving and executing the Job

Procedure

1. Press **Ctrl + S** to save the Job.
2. Press **F6** or click **Run** on the **Run** tab to run the Job.

```plaintext

```

[statistics] disconnected

As shown above, the user information is written into AS/400, and then the data is retrieved from AS/400 and displayed on the console.

**Related scenarios**

For similar scenarios using other databases, see:

Related topic in `ContextLoad`, see **Reading data from different MySQL databases using dynamically loaded connection parameters** on page 491.
tAS400LastInsertId

Obtains the primary key value of the record that was last inserted in an AS/400 table.
tAS400LastInsertId fetches the last inserted ID from a selected AS/400 Connection.

**tAS400LastInsertId Standard properties**

These properties are used to configure tAS400LastInsertId running in the Standard Job framework.
The Standard tAS400LastInsertId component belongs to the Databases family.
The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related
to database settings vary depending on your database type selection. For more information about
dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

Usage

| Usage rule | This component is to be used as an intermediary component. |

Dynamic settings

Click the \([+]\) button to add a row in the table and fill the \(\text{Code}\) field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the \text{Component List} box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see \text{Reading data from databases through context-based dynamic connections} on page 2457 and \text{Reading data from different MySQL databases using dynamically loaded connection parameters} on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenario

For a similar scenario using other database, see \text{Getting the ID for the last inserted record with tMysqlLastInsertId} on page 2466.
tAS400Output

Writes, updates, makes changes or suppresses entries in a database.
tAS400Output executes the action defined on the table and/or on the data contained in the table, based on the flow incoming from the preceding component in the Job.

tAS400Output Standard properties

These properties are used to configure tAS400Output running in the Standard Job framework.
The Standard tAS400Output component belongs to the Databases family.
The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
<td></td>
</tr>
<tr>
<td>Click this icon to open a database connection wizard and store the database connection parameters you set in the component Basic settings view.</td>
<td></td>
</tr>
<tr>
<td>For more information about setting up and storing database connection parameters, see Talend Studio User Guide.</td>
<td></td>
</tr>
<tr>
<td>DB Version</td>
<td>Select the AS/400 version in use</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>Host</th>
<th>Database server IP address</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Table</td>
<td>Name of the table to be written. Note that only one table can be written at a time</td>
</tr>
<tr>
<td>Action on table</td>
<td>On the table defined, you can perform one of the following operations:</td>
</tr>
<tr>
<td></td>
<td>None: No operation is carried out.</td>
</tr>
<tr>
<td></td>
<td>Drop and create a table: The table is removed and created again.</td>
</tr>
<tr>
<td></td>
<td>Create a table: The table does not exist and gets created.</td>
</tr>
<tr>
<td></td>
<td>Create a table if not exists: The table is created if it does not exist.</td>
</tr>
<tr>
<td></td>
<td>Drop a table if exists and create: The table is removed if it already exists and created again.</td>
</tr>
<tr>
<td></td>
<td>Clear a table: The table content is deleted.</td>
</tr>
<tr>
<td>Action on data</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td>Schema and Edit schema</td>
<td>Built-In: You create and store the schema locally for this component only.</td>
</tr>
<tr>
<td></td>
<td>Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
</tr>
</tbody>
</table>
When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the jobs upon completion. If you just want to propagate the changes to the current job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Die on error**

This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a **Row > Rejects** link.

### Advanced settings

| **Use commit control** | Select this check box to have access to the **Commit every** field where you can define the commit operation.  
**Commit every**: Enter the number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and, above all, better performance at execution. |
|-----------------------|--------------------------------------------------------------------------------------------------|

**Additional JDBC parameters**

Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the **Use an existing connection** check box in the **Basic settings**.

**Note:**

You can press Ctrl+Space to access a list of predefined global variables.

| **Additional Columns** | This option is not offered if you create (with or without drop) the DB table. This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing.  
**Name**: Type in the name of the schema column to be altered or inserted as new column  
**SQL expression**: Type in the SQL statement to be executed in order to alter or insert the relevant column data. |
|------------------------|--------------------------------------------------------------------------------------------------|
Position: Select Before, Replace or After following the action to be performed on the reference column.

Reference column: Type in a column of reference that the tDBOutput can use to place or replace the new or altered column.

Use field options
Select this check box to customize a request, especially when there is double action on data.

Enable debug mode
Select this check box to display each step during processing entries in a database.

Use Batch
Select this check box to activate the batch mode for data processing.

Note:
This check box is available only when you have selected the Insert, Update or Delete option in the Action on data field.

Batch Size
Specify the number of records to be processed in each batch.
This field appears only when the Use batch mode check box is selected.

tStat Catcher Statistics
Select this check box to collect log data at the component level.

Usage

Usage rule
This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible.

This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in an AS/400 database. It also allows you to create a reject flow using a Row > Rejects link to filter data in error.
For an example of tMySqlOutput in use, see Retrieving data in error with a Reject link on page 2485.

Dynamic settings
Click the [+ ] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different...
Related scenarios

For related scenario, see Handling data with AS/400 on page 247.

For similar scenarios using other databases, see:

- Inserting a column and altering data using tMysqlOutput on page 2477.
tAS400Rollback

Cancels the transaction commit in the connected database and avoids to commit part of a transaction involuntarily.

**tAS400Rollback Standard properties**

These properties are used to configure tAS400Rollback running in the Standard Job framework.

The Standard tAS400Rollback component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tAS400Connection component in the list if more than one connection are planned for the current Job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is more commonly used with other tAS400* components, especially with the tAS400Connection and tAS400Commit components. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connections |
Related scenarios

For a similar scenario using other database, see Rollback from inserting data in mother/daughter tables on page 2440.
tAS400Row

Executes the SQL query stated onto the specified database.

Depending on the nature of the query and the database, tAS400Row acts on the actual DB structure or on the data (although without handling data). The SQLBuilder tool helps you write easily your SQL statements. tAS400Row is the specific component for this database query. The row suffix means the component implements a flow in the job design although it does not provide output.

**tAS400Row Standard properties**

These properties are used to configure tAS400Row running in the Standard Job framework.

The Standard tAS400Row component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th><strong>Database</strong></th>

## Usage

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Dynamic settings</strong></td>
<td>Click the <code>[+]</code> button to add a row in the table and fill the <strong>Code</strong> field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.</td>
</tr>
</tbody>
</table>
The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

### Related scenarios

For similar scenarios using other databases, see:

- **Combining two flows for selective output** on page 2514.
- **Procedure** on page 625.
- **Removing and regenerating a MySQL table index** on page 2508.
tAssert

Generates the boolean evaluation on the concern for the Job execution status and provides the Job status messages to tAssertCatcher.

The status includes:
- **Ok**: the Job execution succeeds.
- **Fail**: the Job execution fails.

The tested Job’s result does not match the expectation or an execution error occurred at runtime.

The tAssert component works alongside tAssertCatcher to evaluate the status of a Job execution. It concludes with the boolean result based on an assertive statement related to the execution and feed the result to tAssertCatcher for proper Job status presentation.

**tAssert Standard properties**

These properties are used to configure tAssert running in the Standard Job framework.

The Standard tAssert component belongs to the Logs & Errors family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Description</th>
<th>Type in your descriptive message to help identify the assertion of a tAssert.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Expression</td>
<td>Type in the assertive statement you base the evaluation on.</td>
</tr>
</tbody>
</table>

**Global Variables**

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

**Usage**

| Usage rule | This component follows the action the assertive condition is directly related to. It can be the intermediate or end component of the main Job, or the start, intermediate or end component of the secondary Job. |
### Viewing product orders status (on a daily basis) against a benchmark number

This scenario allows you to insert the orders information into a database table and to evaluate the orders status (every day once scheduled to run) by using `tAssert` to compare the orders against a fixed number and `tAssertCatcher` to indicate the results. In this case, Ok is returned if the number of orders is greater than 20 and Failed is returned if the number of orders is less than 20.

In practice, this Job can be scheduled to run every day for the daily orders report and `tFixedFlowInput` as well as `tLogRow` are replaced by input and output components in the `Database/File` families.

### Linking the components

**Procedure**

1. Drop `tFixedFlowInput`, `tMysqlOutput`, `tAssert`, `tAssertCatcher`, and `tLogRow` onto the workspace.
2. Rename `tFixedFlowInput` as `orders`, `tAssert` as `orders >=20`, `tAssertCatcher` as `catch comparison result` and `tLogRow` as `ok or failed`.
3. Link `tFixedFlowInput` to `tMysqlOutput` using a Row > Main connection.
4. Link `tFixedFlowInput` to `tAssert` using the Trigger > On Subjob OK connection.
5. Link `tAssertCatcher` to `tLogRow` using a Row > Main connection.

### Configuring the components

**Procedure**

1. Double-click `tFixedFlowInput` to open its Basic settings view.
Select **Use Inline Content (delimited file)** in the **Mode** area.

In the **Content** field, enter the data to write to the Mysql database, for example:

```
AS2152;Washington Berry Juice;2013-02-19 11:14:15;3.6
AS2152;Washington Berry Juice;2013-02-19 12:14:15;3.6
AS2152;Washington Berry Juice;2013-02-19 13:14:15;3.6
AS2152;Washington Berry Juice;2013-02-19 14:14:15;3.6
AS2152;Washington Berry Juice;2013-02-19 12:14:15;3.6
AS2152;Washington Berry Juice;2013-02-19 12:14:15;3.6
AS2152;Washington Berry Juice;2013-02-19 12:14:15;3.6
AS2152;Washington Berry Juice;2013-02-19 12:14:15;3.6
AS2152;Washington Berry Juice;2013-02-19 12:14:15;3.6
AS2152;Washington Berry Juice;2013-02-19 12:14:15;3.6
AS2152;Washington Berry Juice;2013-02-19 12:14:15;3.6
AS2152;Washington Berry Juice;2013-02-19 12:14:15;3.6
AS2152;Washington Berry Juice;2013-02-19 12:14:15;3.6
```

Note that the orders listed are just for illustration of how **tAssert** functions and the number here is less than 20.

2. Click the **Edit schema** button to open the schema editor.
3. Click the [+] button to add four columns, namely `product_id`, `product_name`, `date` and `price`, of the String, Date, Float types respectively.
   Click OK to validate the setup and close the editor.

4. Double-click `tMysqlOutput` to display the **Basic settings** view.

5. In the Host, Port, Database, Username and Password fields, enter the connection details and the authentication credentials.

6. In the Table field, enter the name of the table, for example `order`.

7. In the Action on table list, select the option **Drop table if exists and create**.

8. In the Action on data list, select the option **Insert**.

9. Double-click `tAssert` to display the **Basic settings** view.
10. In the description field, enter the descriptive information for the purpose of tAssert in this case.

11. In the expression field, enter the expression allowing you to compare the data to a fixed number:

$$((\text{Integer})\text{globalMap.get("tMysqlOutput_1_NB_LINE_INSERTED"))} \geq 20$$

12. Double-click tLogRow to display the Basic settings view.

13. In the Mode area, select Table (print values in cells of a table) for a better display.

**Executing the Job**

**Procedure**

1. Press Ctrl + S to save the Job.
2. Press F6 to run the Job.

As shown above, the orders status indicates Failed as the number of orders is less than 20.

**Setting up the assertive condition for a Job execution**

This scenario describes how to set up an assertive condition in tAssert in order to evaluate that a Job execution succeeds or not. Moreover, you can also find out how the two different evaluation results display and the way to read them. Apart from tAssert, the scenario uses the following components as well:

- **tFileInputDelimited** and **tFileOutputDelimited**. The two components compose the main Job of which the execution status is evaluated. For the detailed information on the two components, see tFileInputDelimited on page 1008 and tFileOutputDelimited on page 1106.

- **tFileCompare**. It realizes the comparison between the output file of the main Job and a standard reference file. The comparative result is evaluated by tAssert against the assertive condition set
up in its settings. For more detailed information on `tFileCompare`, see `tFileCompare` on page 977.

- **tAssertCatcher**. It captures the evaluation generated by `tAssert`. For more information on `tAssertCatcher`, see `tAssertCatcher` on page 275.
- **tLogRow**. It allows you to read the captured evaluation. For more information on `tLogRow`, see `tLogRow` on page 1956.

First proceed as follows to design the main Job:

- Prepare a delimited `.csv` file as the source file read by your main Job.
- Edit two rows in the delimited file. The contents you edit are not important, so feel free to simplify them.
- Name it `source.csv`.
- In `Talend Studio`, create a new job `JobAssertion`.
- Place `tFileInputDelimited` and `tFileOutputDelimited` on the workspace.
- Connect them with a `Row Main` link to create the main Job.

- Double-click `tFileInputDelimited` to open its `Component` view.
- In the `File Name` field of the `Component` view, fill in the path or browse to `source.csv`.

- Still in the `Component` view, set `Property Type` to `Built-In` and click next to `Edit schema` to define the data to pass on to `tFileOutputDelimited`. In the scenario, define the data presented in `source.csv` you created.

For more information about schema types, see `Talend Studio User Guide`.

- Define the other parameters in the corresponding fields according to `source.csv` you created.
- Double-click `tFileOutputDelimited` to open its `Component` view.
- In the `File Name` field of the `Component` view, fill in or browse to specify the path to the output file, leaving the other fields as they are by default.
Press F6 to execute the main Job. It reads source.csv, pass the data to tFileOutputDelimited and output an delimited file, out.csv.

Then continue to edit the Job to see how tAssert evaluates the execution status of the main Job.

- Rename out.csv as reference.csv. This file is used as the expected result the main Job should output.
- Place tFileCompare, tAssert and tLogRow on the workspace.
- Connect them with Row Main link.
- Connect tFileInputDelimited to tFileCompare with OnSubjobOk link.

- Double-click tFileCompare to open its Component view.
- In the Component view, fill in the corresponding file paths in the File to compare field and the Reference file field, leaving the other fields as default.
For more information on the `tFileCompare` component, see `tFileCompare` on page 977.

- Then click `tAssert` and click the `Component` tab on the lower side of the workspace.

In the `Component` view, edit the assertion `row2.differ==0` in the `expression` field and the descriptive message of the assertion in `description` field.

In the `expression` field, `row2` is the data flow transmitting from `tFileCompare` to `tAssert`, `differ` is one of the columns of the `tFileCompare` schema and presents whether the compared files are identical, and `0` means no difference is detected between the `out.csv` and `reference.csv` by `tFileCompare`. Hence when the compared files are identical, the assertive condition is thus fulfilled, `tAssert` concludes that the main Job succeeds; otherwise, it concludes failure.

**Note:**
The `differ` column is in the read-only `tFileCompare` schema. For more information on its schema, see `tFileCompare` on page 977.

- Press F6 to execute the Job.
- Check the result presented in the `Run` view

```
Starting job JobAssertion at 14:00 29/01/2010.
[statistics] connecting to socket on port 3788
[statistics] connected
[Job JobAssertion] Files are identical
<table>
<thead>
<tr>
<th>tLogRow_1</th>
</tr>
</thead>
<tbody>
<tr>
<td>file</td>
</tr>
<tr>
<td>------------</td>
</tr>
<tr>
<td>C:\out.csv</td>
</tr>
<tr>
<td>------------</td>
</tr>
</tbody>
</table>
[statistics] disconnected
Job JobAssertion ended at 14:00 29/01/2010. [exit code=0]
```

The console shows the comparison result of `tFileCompare`: Files are identical. But you find nowhere the evaluation result of `tAssert`.

So you need `tAssertCatcher` to capture the evaluation.

- Place `tAssertCatcher` and `tLogRow` on the workspace.
- Connect them with `Row Main` link.
• Use the default configuration in the **Component** view of **tAssertCatcher**.

- Press **F6** to execute the Job.
- Check the result presented in the **Run** view. You will see the Job status information is added in:

```
2010-01-29 15:37:33|fAvAzH|TASSERT|JobAssertion|java|tAssert_1|Ok|--|
The output file should be identical with the reference file.
```

The console indicates that the execution status of Job **JobAssertion** is **Ok**. In addition to the evaluation, you can still see other descriptive information about **JobAssertion** including the descriptive message you have edited in the **Basic settings** of **tAssert**.
Then you will perform operations to make the main Job fail to generate the expected file. To do so, proceed as follows in the same Job you have executed:

- Delete a row in `reference.csv`.
- Press F6 to execute the Job again.
- Check the result presented in Run view.

The console shows that the execution status of the main Job is Failed. The detailed explanation for this status is closely behind it, reading Test logically failed.

You can thus get a basic idea about your present Job status: it fails to generate the expected file because of a logical failure. This logical failure could come from a logical mistake during the Job design.

The status and its explanatory information are presented respectively in the status and the substatus columns of the tAssertCatcher schema. For more information on the columns, see tAssertCatcher on page 275.
tAssertCatcher

Generates a data flow consolidating the status information of a job execution and transfer the data into defined output files.

Based on its pre-defined schema, tAssertCatcher fetches the execution status information from repository, Job execution and tAssert.

**tAssertCatcher Standard properties**

These properties are used to configure tAssertCatcher running in the Standard Job framework.

The Standard tAssertCatcher component belongs to the Logs & Errors family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Schema and Edit schema</th>
<th>A schema is a row description, it defines the fields to be processed and passed on to the next component. In this particular case, the schema is read-only, as this component gathers standard log information including:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Moment</strong>: Processing time and date.</td>
</tr>
<tr>
<td></td>
<td><strong>Pid</strong>: Process ID.</td>
</tr>
<tr>
<td></td>
<td><strong>Project</strong>: Project which the job belongs to.</td>
</tr>
<tr>
<td></td>
<td><strong>Job</strong>: Job name.</td>
</tr>
<tr>
<td></td>
<td><strong>Language</strong>: Language used by the Job (Java)</td>
</tr>
<tr>
<td></td>
<td><strong>Origin</strong>: Status evaluation origin. The origin may be different tAssert components.</td>
</tr>
<tr>
<td></td>
<td><strong>Status</strong>: Evaluation fetched from tAssert. They may be - Ok: if the assertive statement of tAssert is evaluated as true at runtime. - Failed: if the assertive statement of tAssert is evaluated as false or an execution error occurs at runtime. The tested Job’s result does not match the expectation or an execution error occurred at runtime.</td>
</tr>
<tr>
<td></td>
<td><strong>Substatus</strong>: Detailed explanation for failed execution. The explanation can be: - Test logically failed: the investigated Job does not produce the expected result. - Execution error: an execution error occurred at runtime.</td>
</tr>
<tr>
<td></td>
<td><strong>Description</strong>: Descriptive message typed in Basic settings of tAssert (when Catch tAssert is selected) and/or the message of the exception captured (when Catch Java Exception is selected).</td>
</tr>
</tbody>
</table>
Exception: The Exception object thrown by the Job, namely the original exception.
Available when Get original exception is selected.

<table>
<thead>
<tr>
<th>Catch Java Exception</th>
<th>This check box allows to capture Java exception errors and show the message in the Description column (Get original exception not selected) or in the Exception column (Get original exception selected) column, once checked.</th>
</tr>
</thead>
</table>
| Get original exception | This check box allows to show the original exception object in the Exception column, once checked.
Available when Catch Java Exception is selected. |
| Catch tAssert | This check box allows to capture the evaluations of tAssert. |

Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.
For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | This component is the start component of a secondary Job which fetches the execution status information from several sources. It generates a data flow to transfer the information to the component which proceeds. |
| Limitation | This component must be used with tAssert together. |

Related scenarios

For using case in relation with tAssertCatcher, see tAssert scenario:

- Setting up the assertive condition for a Job execution on page 269
tAzureStorageConnection

Uses authentication and the protocol information to create a connection to the Microsoft Azure Storage system that can then be reused by other Azure Storage components.

tAzureStorageConnection Standard properties

These properties are used to configure tAzureStorageConnection running in the Standard Job framework.

The Standard tAzureStorageConnection component belongs to the Cloud family.

The component in this framework is available in all Talend products.

Basic settings

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Select the way the connection details will be set.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• Built-in: The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.</td>
</tr>
<tr>
<td></td>
<td>• Repository: The connection details stored centrally in Repository &gt; Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up Repository Content dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in.</td>
</tr>
</tbody>
</table>

Account Name

Enter the name of the storage account you need to access. A storage account name can be found in the Storage accounts dashboard of the Microsoft Azure Storage system to be used. Ensure that the administrator of the system has granted you the appropriate access permissions to this storage account.

Account Key

Enter the key associated with the storage account you need to access. Two keys are available for each account and by default, either of them can be used for this access.

Protocol

Select the protocol for this connection to be created.

Use Azure Shared Access Signature

Select this check box to use a shared access signature (SAS) to access the storage resources without need for the account key. For more information, see Using Shared Access Signatures (SAS).

In the Azure Shared Access Signature field displayed, enter your account SAS URL between double quotation marks. You can get the SAS URL for each allowed service on Microsoft Azure portal after generating SAS. The SAS URL format is `https://<$storagename>.$service>.core.windows.net/<$sastoken>`, where `$storagename` is the storage account name, `$service` is the allowed service name (blob, file, queue or table), and `$sastoken` is the SAS token value. For more information, see Constructing the Account SAS URL.
Note that the SAS has valid period, you can set the start time at which the SAS becomes valid and the expiry time after which the SAS is no longer valid when generating it, and you need to make sure your SAS is still valid when running your Job.

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global Variables**

| ERROR_MESSAGE | The error message generated by the component when an error occurs. This is an After variable and it returns a string. |

**Usage**

| Usage rule | This component is generally used with other Azure Storage components. Knowledge about Microsoft Azure Storage is required. |

**Related scenario**

For related scenarios, see:

- [Retrieving files from a Azure Storage container](#) on page 297
- [Creating a container in Azure Storage](#) on page 280
- [Handling data with Microsoft Azure Table storage](#) on page 307
**tAzureStorageContainerCreate**

Creates a new storage container used to hold Azure blobs (Binary Large Object) for a given Azure storage account.

**tAzureStorageContainerCreate Standard properties**

These properties are used to configure tAzureStorageContainerCreate running in the Standard Job framework.

The Standard tAzureStorageContainerCreate component belongs to the Cloud family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Select the way the connection details will be set.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Built-In</strong>: The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: The connection details stored centrally in Repository &gt; Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up Repository Content dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in.</td>
</tr>
</tbody>
</table>

This property is not available when other connection component is selected from the Connection Component drop-down list.

<table>
<thead>
<tr>
<th>Connection Component</th>
<th>Select the component whose connection details will be used to set up the connection to Azure storage from the drop-down list.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Account Name</td>
<td>Enter the name of the storage account you need to access. A storage account name can be found in the Storage accounts dashboard of the Microsoft Azure Storage system to be used. Ensure that the administrator of the system has granted you the appropriate access permissions to this storage account.</td>

When errors are skipped, you can collect the rows on error using a <strong>Row &gt; Reject</strong> link.</strong></td>
</tr>
</tbody>
</table>

### Advanced settings

| **tStatCatcher Statistics** | **Select this check box to gather the Job processing metadata at the Job level as well as at each component level.** |

### Global Variables

| **CONTAINER** | **The name of the blob container. This is an After variable and it returns a string.** |
| **ERROR_MESSAGE** | **The error message generated by the component when an error occurs. This is an After variable and it returns a string.** |

### Usage

| **Usage rule** | **This component can be used as a standalone component of a Job or Subjob.** |
| **Prerequisites** | **Knowledge about Microsoft Azure Storage is required.** |

**Creating a container in Azure Storage**

In this scenario, a four-component Job uses Azure Storage components to create a container in a given Azure Storage system and check whether this container is successfully created.
Before replicating this scenario, you must have appropriate rights and permissions to read and write files in the Azure storage account to be used. For further information, see Microsoft’s documentation for Azure Storage: [http://azure.microsoft.com/en-us/documentation/services/storage/](http://azure.microsoft.com/en-us/documentation/services/storage/).

**Linking the components**

**Procedure**

1. In the **Integration** perspective of the Studio, create an empty Job, named `azureTalend` for example, from the **Job Designs** node in the **Repository** tree view.
2. Drop `tAzureStorageConnection`, `tAzureStorageContainerCreate`, `tAzureStorageContainerExist` and `tJava` onto the workspace.
3. Connect them using the **Trigger > OnSubjobOk** link.

**Connecting to an Azure storage account**

**Procedure**

1. Double-click `tAzureStorageConnection` to open its **Component** view.

   ![tAzureStorageConnection 1](image)

   **Basic settings**
   - **Property Type**: Built-In
   - **Account Name**: `talendstorage`
   - **Account Key**: `**************`
   - **Protocol**: HTTPS

2. In the **Account name** field, enter the name of the storage account to be connected to. In this example, it is `talendstorage`, an account that has been created for demonstration purposes.
3. In the **Account key** field, paste the primary or the secondary key associated with the storage account to be used. These keys can be found in the Manage Access Key dashboard in the Azure Storage system to be connected to.
4. From the **Protocol** list, select the protocol for the endpoint of the storage account to be used. In this example, it is HTTPS.
Creating a container

Procedure

1. Double-click \texttt{tAzureStorageContainerCreate} to open its Component view.

   \begin{itemize}
     \item Select the component whose connection details will be used to set up the Azure storage connection. In this example, it is \texttt{tAzureStorageConnection_1}.
     \item In the Container name field, enter the name of the container you need to create. If a container using the same name exists, that container will be overwritten at runtime.
     \item From the Access control list, select the access restriction level for the container to be created. In this example, select \texttt{Private}.
   \end{itemize}

Verifying the creation

Procedure

1. Double-click \texttt{tAzureStorageContainerExist} to open its Component view.

   \begin{itemize}
     \item Select the component whose connection details will be used to set up the Azure storage connection. In this example, it is \texttt{tAzureStorageConnection_1}.
     \item In the Container name field, enter the name of the container you need to check whether it exists.
     \item Double-click \texttt{Java} to open its Component view.
   \end{itemize}

   \begin{itemize}
     \item In the Code field, enter \texttt{System.out.println();}
     \item In the Outline panel, which, by default, is found to the left side of the Component view, expand the \texttt{tAzureStorageContainerExist} node.
   \end{itemize}
7. From the **Outline** panel, drop the **CONTAINER_EXSIT** global variable into the parentheses in the code in the **Component** view in order to make the code read: `System.out.println(((Boolean)globalMap.get("tAzureStorageContainerExist_1_CONTAINER_EXIST"));`

**Executing the Job**

**Procedure**

1. Press **F6** to run this Job.
2. Check the execution result on the **Run** console.

You can read that the Job returns true as the verification result, that is to say, the talendcontainer container has been created in the storage account being used.

3. Double-check the result in the web console of the Azure storage account.
You can read as well that the `talendcontainer` container has been created.
tAzureStorageContainerDelete

Automates the removal of a given blob container from the space of a specific storage account.

**tAzureStorageContainerDelete Standard properties**

These properties are used to configure tAzureStorageContainerDelete running in the Standard Job framework.

The Standard tAzureStorageContainerDelete component belongs to the Cloud family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Select the way the connection details will be set.</th>
</tr>
</thead>
<tbody>
<tr>
<td>• <strong>Built-In</strong></td>
<td>The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.</td>
</tr>
<tr>
<td>• <strong>Repository</strong></td>
<td>The connection details stored centrally in Repository &gt; Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up Repository Content dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in. This property is not available when other connection component is selected from the Connection Component drop-down list.</td>
</tr>
</tbody>
</table>

| Connection Component | Select the component whose connection details will be used to set up the connection to Azure storage from the drop-down list. |

| Account Name | Enter the name of the storage account you need to access. A storage account name can be found in the Storage accounts dashboard of the Microsoft Azure Storage system to be used. Ensure that the administrator of the system has granted you the appropriate access permissions to this storage account. |

| Account Key | Enter the key associated with the storage account you need to access. Two keys are available for each account and by default, either of them can be used for this access. |

| Protocol | Select the protocol for this connection to be created. |

| Use Azure Shared Access Signature | Select this check box to use a shared access signature (SAS) to access the storage resources without need for the account key. For more information, see Using Shared Access Signatures (SAS). In the **Azure Shared Access Signature** field displayed, enter your account SAS URL between double quotation marks. You can get the SAS URL for each allowed service on Microsoft Azure portal after generating SAS. The SAS URL format is https://<$storagename>./<
$service>.core.windows.net/<$sastoken>,
where <$storagename> is the storage account name, <$service> is the allowed service name (blob, file, queue or table), and <$sastoken> is the SAS token value. For more information, see Constructing the Account SAS URI.

Note that the SAS has valid period, you can set the start time at which the SAS becomes valid and the expiry time after which the SAS is no longer valid when generating it, and you need to make sure your SAS is still valid when running your Job.

Container name
Enter the name of the blob container to be removed.

Die on error
Select the check box to stop the execution of the Job when an error occurs.
Clear the check box to skip any rows on error and complete the process for error-free rows. When errors are skipped, you can collect the rows on error using a Row > Reject link.

Advanced settings

Global Variables

Usage
This component can be used as a standalone component of a Job or Subjob.

Prerequisites
Knowledge about Microsoft Azure Storage is required.

Related scenarios
No scenario is available for the Standard version of this component yet.
tAzureStorageContainerExist

Automates the verification of whether a given blob container exists or not within a storage account.

**tAzureStorageContainerExist Standard properties**

These properties are used to configure tAzureStorageContainerExist running in the Standard Job framework.

The Standard tAzureStorageContainerExist component belongs to the Cloud family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Select the way the connection details will be set.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• <strong>Built-In</strong>: The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Repository</strong>: The connection details stored centrally in Repository &gt; Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up Repository Content dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in.</td>
</tr>
<tr>
<td></td>
<td>This property is not available when other connection component is selected from the Connection Component drop-down list.</td>
</tr>
</tbody>
</table>

| Connection Component | Select the component whose connection details will be used to set up the connection to Azure storage from the drop-down list. |

| Account Name | Enter the name of the storage account you need to access. A storage account name can be found in the Storage accounts dashboard of the Microsoft Azure Storage system to be used. Ensure that the administrator of the system has granted you the appropriate access permissions to this storage account. |

| Account Key | Enter the key associated with the storage account you need to access. Two keys are available for each account and by default, either of them can be used for this access. |

| Protocol | Select the protocol for this connection to be created. |

| Use Azure Shared Access Signature | Select this check box to use a shared access signature (SAS) to access the storage resources without need for the account key. For more information, see [Using Shared Access Signatures (SAS)](https://)\. |

In the **Azure Shared Access Signature** field displayed, enter your account SAS URL between double quotation marks. You can get the SAS URL for each allowed service on Microsoft Azure portal after generating SAS. The SAS URL format is \https://<$storagename>\.<
$service>.core.windows.net/<$sastoken>
where <$storagename> is the storage account name,
<$service> is the allowed service name (blob, file, queue or table), and <$sastoken> is the SAS token value. For more information, see Constructing the Account SAS URI.

Note that the SAS has valid period, you can set the start time at which the SAS becomes valid and the expiry time after which the SAS is no longer valid when generating it, and you need to make sure your SAS is still valid when running your Job.

**Container name**
Enter the name of the blob container you need to verify whether it exists.

**Die on error**
Select the check box to stop the execution of the Job when an error occurs.
Clear the check box to skip any rows on error and complete the process for error-free rows. When errors are skipped, you can collect the rows on error using a Row > Reject link.

**Advanced settings**
- **tStatCatcher Statistics**
Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

**Global Variables**
- **CONTAINER**
The name of the blob container. This is an After variable and it returns a string.
- **CONTAINER_EXIST**
The result of whether the given container exists or not. This is an After variable and it returns a boolean.
- **ERROR_MESSAGE**
The error message generated by the component when an error occurs. This is an After variable and it returns a string.

**Usage**
- **Usage rule**
This component can be used as a standalone component of a Job or Subjob.
- **Prerequisites**
Knowledge about Microsoft Azure Storage is required.

**Related scenario**
For a related scenario, see Creating a container in Azure Storage on page 280
tAzureStorageContainerList

Lists all containers in a given Azure storage account.

tAzureStorageContainerList Standard properties

These properties are used to configure tAzureStorageContainerList running in the Standard Job framework.

The Standard tAzureStorageContainerList component belongs to the Cloud family.

The component in this framework is available in all Talend products.

where <$storagename> is the storage account name, <$service> is the allowed service name (blob, file, queue or table), and <$sastoken> is the SAS token value. For more information, see Constructing the Account SAS URI.

Note that the SAS has valid period, you can set the start time at which the SAS becomes valid and the expiry time after which the SAS is no longer valid when generating it, and you need to make sure your SAS is still valid when running your Job.

Schema and Edit schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

- **Built-In**: You create and store the schema locally for this component only.
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

The schema of this component is predefined with a single column ContainerName of String type, which indicates the name of each container to be listed.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

Die on error

Select the check box to stop the execution of the Job when an error occurs.

Advanced settings

tStatCatcher Statistics

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

Related scenarios

No scenario is available for the Standard version of this component yet.
tAzureStorageGet

Retrieves blobs from a given container for an Azure storage account according to the specified filters applied on the virtual hierarchy of the blobs and then write selected blobs in a local folder.

tAzureStorageGet Standard properties

These properties are used to configure tAzureStorageGet running in the Standard Job framework.
The Standard tAzureStorageGet component belongs to the Cloud family.
The component in this framework is available in all Talend products.

Basic settings

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Select the way the connection details will be set.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• <strong>Built-In</strong>: The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Repository</strong>: The connection details stored centrally in Repository &gt; Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up Repository Content dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in.</td>
</tr>
<tr>
<td></td>
<td>This property is not available when other connection component is selected from the Connection Component drop-down list.</td>
</tr>
</tbody>
</table>

<table>
<thead>

<tr>
<th>Use Azure Shared Access Signature</th>
<th>Select this check box to use a shared access signature (SAS) to access the storage resources without need for the account key. For more information, see Using Shared Access Signatures (SAS).</th>
</tr>
</thead>
</table>
|                                  | In the **Azure Shared Access Signature** field displayed, enter your account SAS URL between double quotation marks. You can get the SAS URL for each allowed service on Microsoft Azure portal after generating SAS. The SAS URL format is `https://<$storagename>..<
$service>.core.windows.net/$sastoken>, where <$storagename> is the storage account name, <$service> is the allowed service name (blob, file, queue or table), and <$sastoken> is the SAS token value. For more information, see Constructing the Account SAS URI.

Note that the SAS has valid period, you can set the start time at which the SAS becomes valid and the expiry time after which the SAS is no longer valid when generating it, and you need to make sure your SAS is still valid when running your Job.

<table>
<thead>
<tr>
<th>Container</th>
<th>Enter the name of the container you need to retrieve blobs from.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Local folder</td>
<td>Enter the path, or browse to the folder in which you need to store the retrieved blobs.</td>
</tr>
<tr>
<td>Blobs</td>
<td>Complete this table to select the blobs to be retrieved. The parameters to be provided are:</td>
</tr>
<tr>
<td></td>
<td>• Prefix: enter the common prefix of the names of the blobs you need to retrieve. This prefix allows you to filter the blobs which have the specified prefix in their names in the given container.</td>
</tr>
<tr>
<td></td>
<td>A blob name contains the virtual hierarchy of the blob itself. This hierarchy is a virtual path to that blob and is relative to the container where that blob is stored. For example, in a container named photos, the name of a photo blob might be 2014/US/Oakland/Talend.jpg.</td>
</tr>
<tr>
<td></td>
<td>For this reason, when you define a prefix, you are actually designating a directory level as the blob filter, for example, 2014/ or 2014/US/.</td>
</tr>
<tr>

<td>If you want to select the blobs stored directly beneath the container level, that is to say, the blobs without virtual path in their names, remove quotation marks and enter null.</td>
</tr>
<tr>
<td></td>
<td>• Include sub-directories: select this check box to retrieve all of the sub-folders and the blobs in those folders beneath the designated directory level in the Blob prefix column. If you leave this check box clear, tAzureStorageGet returns only the blobs directly beneath that directory level.</td>
</tr>
<tr>
<td></td>
<td>• Create parent directories: select this check box to replicate the virtual directory of the retrieved blobs in the local folder.</td>
</tr>
<tr>
<td></td>
<td>Note that if you leave this check box clear, there must be the same directory in the local folder as the retrieved blobs have in the container; otherwise, those blobs cannot be retrieved.</td>
</tr>
<tr>
<td>Die on error</td>
<td>Select the check box to stop the execution of the Job when an error occurs. Clear the check box to skip any rows on error and complete the process for error-free rows. When errors are skipped, you can collect the rows on error using a Row &gt; Reject link.</td>
</tr>
</tbody>
</table>
Advanced settings

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

Global Variables

| CONTAINER | The name of the blob container. This is an After variable and it returns a string. |
| LOCAL_FOLDER | The local directory used in this component. This is an After variable and it returns a string. |
| ERROR_MESSAGE | The error message generated by the component when an error occurs. This is an After variable and it returns a string. |

Usage

| Usage rule | This component can be used as a standalone component of a Job or Subjob. |
| Prerequisites | Knowledge about Microsoft Azure Storage is required. |

Retrieving files from a Azure Storage container

In this scenario, a five-component Job uses Azure Storage components to write files in a given Azure Storage system and then retrieve selected files (blobs in terms of Azure Storage) from that system.

Before replicating this scenario, you must have appropriate rights and permissions to read and write files in the Azure storage account to be used. For further information, see Microsoft’s documentation for Azure Storage: http://azure.microsoft.com/en-us/documentation/services/storage/.
The *talendcontainer* container used in this scenario was created using **tAzureStorageContainerCreate** in the scenario **Creating a container in Azure Storage** on page 280.

**Linking the components**

**Procedure**

1. In the **Integration** perspective of the Studio, create an empty Job, named `azureTalend` for example, from the **Job Designs** node in the **Repository** tree view.
2. Drop **tAzureStoragePut**, **tAzureStorageList**, **tJava** and **tAzureStorageGet** onto the workspace.
3. Connect the Azure Storage components using the **Trigger > OnSubjobOk** link while connect **tAzureStorageList** to **tJava** using the **Row > Iterate** link.

**Connecting to an Azure storage account**

**Procedure**

1. Double-click **tAzureStorageConnection** to open its **Component** view.

   ![tAzureStorageConnection](image)

   2. In the **Account name** field, enter the name of the storage account to be connected to. In this example, it is `talendstorage`, an account that has been created for demonstration purposes.
   3. In the **Account key** field, paste the primary or the secondary key associated with the storage account to be used. These keys can be found in the Manage Access Key dashboard in the Azure Storage system to be connected to.
   4. From the **Protocol** list, select the protocol for the endpoint of the storage account to be used. In this example, it is HTTPS.

**Writing files in Azure Storage**

**Procedure**

1. Double-click **tAzureStoragePut** to open its **Component** view.

   ![tAzureStoragePut](image)
2. Select the component whose connection details will be used to set up the Azure storage connection. In this example, it is tAzureStorageConnection_1.

3. In the Container name field, enter the name of the container you need to write files in. In this example, it is talendcontainer, a container created in the scenario Creating a container in Azure Storage on page 280.

4. In the Local folder field, enter the path, or browse, to the directory where the files to be used are stored. In this scenario, they are some pictures showing technical process and stored locally in E:/photos. Therefore, put E:/photos; this allows tAzureStoragePut to upload all the files of this folder and its sub-folders into the talendcontainer container.

   For demonstration purposes, the example photos are organized as follows in the E:/photos folder.

   • Directly beneath the E:/photos level:

      components-use_case_triakinput_1.png
      components-use_case_triakinput_2.png
      components-use_case_triakinput_3.png
      components-use_case_triakinput_4.png

   • In the E:/photos/mongodb/step1 directory:

      components-use_case_tmongodbbulkload_1.png
      components-use_case_tmongoddbulkload_2.png
      components-use_case_tmongoddbulkload_3.png
      components-use_case_tmongoddbulkload_4.png

   • In the E:/photos/mongodb/step2 directory:

      components-use_case_tmongoddbulkload_5.png
      components-use_case_tmongoddbulkload_6.png
      components-use_case_tmongoddbulkload_7.png
      components-use_case_tmongoddbulkload_8.png

5. In the Azure Storage folder field, enter the directory where you want to write files. This directory will be created in the container to be used if it does not exist. In this example, enter photos.

Verifying the file transfer

Configuring tAzureStorageList

Procedure

1. Double-click tAzureStorageList to open its Component view.
2. Select the component whose connection details will be used to set up the Azure storage connection. In this example, it is `tAzureStorageConnection_1`.

3. In the **Container name** field, enter the name of the container in which you need to check whether the given files exist. In this scenario, it is `talendcontainer`.

4. Under the **Blob filter** table, click the `[+]` button to add one row in the table.

5. In the **Prefix** column, enter the common prefix of the names of the files (blobs) to be checked. This prefix represents a virtual directory level you designate as the starting point down from which files (blobs) are checked. In this example, it is `photos/`.

6. In the **Include sub-directories** column, select the check box in the newly added row. This allows `tAzureStorageList` to check all the files at any hierarchical level beneath the designated starting point.

**Configuring tJava**

**Procedure**

1. Double-click **tJava** to open its Component view.

2. In the **Code** field, enter `System.out.println();`

3. In the **Outline** panel, which, by default, is found to the left side of the Component view, expand the **tAzureStorageList** node.
4. From the Outline panel, drop the CONTAINER_BLOB global variable into the parentheses in the code in the Component view so as to make the code read: System.out.println(((Boolean)globalMap.get("tAzureStorageList_1_CURRENT_BLOB")));

Retrieving selected files

Procedure

1. Double-click tAzureStorageGet to open its Component view.

2. Select the component whose connection details will be used to set up the Azure storage connection. In this example, it is tAzureStorageConnection_1.

3. In the Container name field, enter the name of the container from which you need to retrieve files. In this scenario, it is talendcontainer.

4. In the Local folder field, enter the path, or browse, to the directory where you want to put the retrieved files. In this example, it is E:/screenshots.

5. Under the Blob table, click the [+] button to add one row in the table.

6. In the Prefix column, enter the common name prefix of the files (blobs) to be retrieved. In this example, it is photos/mongodb/.

7. In the Include sub-directories column, select the check box in the newly added row. This allows tAzureStorageGet to retrieve all the files (blobs) beneath the photos/mongodb/ level.

8. In the Create parent directories column, select the check box in the newly added row to create the same directory in the specified local folder as the retrieved blobs have in the container.
Note that having this same directory is necessary for successfully retrieving blobs. If you leave this check box clear, then you need to create the same directory yourself in the target local folder.

**Executing the Job**

**Procedure**

1. Press **F6** to run this Job.
2. Check the execution result on the Run console.

You can read that the Job returns the list of the blobs with the photos prefix in the container.

3. Double-check the result in the web console of the Azure storage account.

4. Check the retrieved files in the specified local folder.
You can see the blobs with the `photos/mongodb/` prefix have been retrieved and their prefix transformed to directories.
**tAzureStorageInputTable**

Retrieves a set of entities that satisfy the specified filter criteria from an Azure storage table.

**tAzureStorageInputTable Standard properties**

These properties are used to configure tAzureStorageInputTable running in the Standard Job framework.

The Standard tAzureStorageInputTable component belongs to the Cloud family.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property Type</td>
<td>Select the way the connection details will be set.</td>

<td>Use Azure Shared Access Signature</td>
<td>Select this check box to use a shared access signature (SAS) to access the storage resources without need for the account key. For more information, see Using Shared Access Signatures (SAS).</td>
</tr>
<tr>
<td></td>
<td>In the Azure Shared Access Signature field displayed, enter your account SAS URL between double quotation marks. You can get the SAS URL for each allowed service on Microsoft Azure portal after generating SAS. The</td>
</tr>
</tbody>
</table>
The SAS URL format is `https://<$storagename>.$service.core.windows.net/<$sastoken>`, where `<$storagename>` is the storage account name, `<$service>` is the allowed service name (blob, file, queue or table), and `<$sastoken>` is the SAS token value. For more information, see Constructing the Account SAS URI.

Note that the SAS has a valid period, you can set the start time at which the SAS becomes valid and the expiry time after which the SAS is no longer valid when generating it, and you need to make sure your SAS is still valid when running your Job.

### Table name
Specify the name of the table from which the entities will be retrieved.

### Schema and Edit schema
A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

- **Built-In**: You create and store the schema locally for this component only.
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

The schema of this component is predefined with the following columns that describe the three system properties of each entity:

- **PartitionKey**: the partition key for the partition that the entity belongs to.
- **RowKey**: the row key for the entity within the partition.

`PartitionKey` and `RowKey` are string type values that uniquely identify every entity in a table, and the user must include them in every insert, update, and delete operation.

- **Timestamp**: the time that the entity was last modified. This DateTime value is maintained by the Azure server and it cannot be modified by the user.

For more information about these system properties, see Understanding the Table Service Data Model.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No upon completion** and choose this schema metadata again in the **Repository Content** window.

**Use filter expression**
Select this check box and complete the **Filter expressions** table displayed to specify the conditions used to filter the entities to be retrieved by clicking the `[*]` button to add as
many rows as needed, each row for a condition, and setting
the value for the following parameters for each condition.

- **Column**: specify the name of the property on which you
  want to apply for the condition.
- **Function**: click the cell and select the comparison
  operator you want to use from the drop-down list.
- **Value**: specify the value used to compare the property
to.
- **Predicate**: select the predicate used to combine the
  conditions.
- **Field type**: click the cell and select the type of the
column from the drop-down list.

The generated filter expression will be displayed in the
read-only **Effective filter** field.

For more information about the filter expressions, see
*Querying Tables and Entities*.

### Die on error

| Die on error | Select the check box to stop the execution of the Job when an error occurs. |

### Advanced settings

#### Name mappings

<table>
<thead>
<tr>
<th>Name mappings</th>
<th>Complete this table to map the column name of the component schema with the property name of the Azure table entity if they are different.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>- <strong>Schema column name</strong>: enter the column name of the component schema between double quotation marks.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Entity property name</strong>: enter the property name of the Azure table entity between double quotation marks.</td>
</tr>
</tbody>
</table>

For example, if there are three schema columns CompanyID, EmployeeID, and EmployeeName that are used to feed the values for the PartitionKey, RowKey, and Name entity properties respectively, since the PartitionKey and RowKey columns have already been added to the schema automatically and you do not need to specify the mapping relationship for them, you only need to add one row and set the value of the **Schema column name** cell with "EmployeeName" and the value of the **Entity property name** cell with "Name" to specify the mapping relationship for the EmployeeName column when retrieving data from the Azure table.

#### tStatCatcher Statistics

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

### Global variables

<table>
<thead>
<tr>
<th>Global variables</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE</strong></td>
<td>The number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>ERROR_MESSAGE</strong></td>
<td>The error message generated by the component when an error occurs. This is an After variable and it returns a string.</td>
</tr>
</tbody>
</table>
Usage

| Usage rule | This component is usually used as a start component of a Job or Subjob and it always needs an output link. |

Handling data with Microsoft Azure Table storage

Here is an example of using Talend components to connect to a Microsoft Azure storage account that gives you access to Azure storage table service, write some employee data into an Azure storage table, and then retrieve the employee data from the table and display it on the console.

The employee data used in this example is as follows:

```
#Id;Name;Site;Job;Date;Salary
12000;Gerald Roosevelt;Beijing;Software Developer;2008-01-01;15000.01
12001;Benjamin Harrison;Paris;Software Developer;2008-11-22;13000.11
12002;Bob Clinton;Beijing;Software Tester;2008-05-12;12000.22
12003;James Quincy;Paris;Technical Writer;2009-03-10;12000.33
12004;Gerald Harrison;Beijing;Software Tester;2009-06-20;12500.44
12005;Harry Madison;Paris;Software Developer;2009-10-15;14000.55
12006;Helen Roosevelt;Beijing;Software Tester;2009-03-25;13500.66
12007;Mary Clinton;Beijing;Software Developer;2010-02-20;16000.77
12008;Cathey Quincy;Paris;Software Developer;2010-07-15;14000.88
12009;John Smith;Beijing;Technical Writer;2011-02-10;12500.99
```

Creating a Job for handling data with Azure Table storage

Create a Job to connect to an Azure storage account, write some employee data into an Azure storage table, and then retrieve that information from the table and display it on the console.
Procedure

1. Create a new Job and add a `tAzureStorageConnection` component, a `tFixedFlowInput` component, a `tAzureStorageOutputTable` component, a `tAzureStorageInputTable` component, and a `tLogRow` component by typing their names in the design workspace or dropping them from the Palette.

2. Link the `tFixedFlowInput` component to the `tAzureStorageOutputTable` component using a Row > Main connection.

3. Do the same to link the `tAzureStorageInputTable` component to the `tLogRow` component.

4. Link the `tAzureStorageConnection` component to the `tFixedFlowInput` component using a Trigger > OnSubjobOk connection.

5. Do the same to link the `tFixedFlowInput` component to the `tAzureStorageInputTable` component.

Connecting to an Azure Storage account

Configure the `tAzureStorageConnection` component to open the connection to an Azure Storage account.

Before you begin

The Azure Storage account, which allows you to access the Azure Table storage service and store the provided employee data, has already been created. For more information about how to create an Azure Storage account, see About Azure storage accounts.

Procedure

1. Double-click the `tAzureStorageConnection` component to open its Basic settings view on the Component tab.

2. In the Account Name field, specify the name of the storage account you need to access.

3. In the Account Key field, specify the key associated with the storage account you need to access.

Writing data into an Azure Storage table

Configure the `tFixedFlowInput` component and the `tAzureStorageOutputTable` component to write the employee data into an Azure Storage table.

Procedure

1. Double-click the `tFixedFlowInput` component to open its Basic settings view on the Component tab.
2. Click next to Edit schema to open the schema dialog box and define the schema by adding six columns: Id, Name, Site, and Job of String type, Date of Date type, and Salary of Double type. Then click OK to save the changes and accept the propagation prompted by the pop-up dialog box.

3. In the Mode area, select Use Inline Content(delimited file) and in the Content field displayed, enter the employee data that will be written into the Azure Storage table.

4. Double-click the tAzureStorageOutputTable component to open its Basic settings view on the Component tab
5. From the connection component drop-down list, select the component whose connection details will be used to set up the connection to the Azure Storage service, tAzureStorageConnection_1 in this example.

6. In the **Table name** field, enter the name of the table into which the employee data will be written, `employee` in this example.

7. From the **Action on table** drop-down list, select the operation to be performed on the specified table, `Drop table if exist and create` in this example.

8. Click **Advanced settings** to open its view.

9. Click under the **Name mappings** table to add three rows and map the schema column name with the property name of each entity in the Azure table. In this example,

   - the **Site** column is used to feed the value of the **PartitionKey** system property, in the first row you need to set the **Schema column name** cell with the value "Site" and the **Entity property name** cell with the value "PartitionKey".
   - the **Id** column is used to feed the value of the **RowKey** system property, in the second row you need to set the **Schema column name** cell with the value "Id" and the **Entity property name** cell with the value "RowKey".
   - the **Name** column is used to feed the value of the **EmployeeName** property, in the third row you need to set the **Schema column name** cell with the value "Name" and the **Entity property name** cell with the value "EmployeeName".

**Retrieving data from the Azure Storage table**

Configure the `tAzureStorageInputTable` component and the `tLogRow` component to retrieve the employee data from the Azure Storage table.

**Procedure**

1. Double-click the `tAzureStorageInputTable` component to open its **Basic settings** view.
2. From the connection component drop-down list, select the component whose connection details will be used to set up the connection to the Azure Storage service, tAzureStorageConnection_1 in this example.

3. In the Table name field, enter the name of the table from which the employee data will be retrieved, employee in this example.

4. Click next to Edit schema to open the schema dialog box.

Note that the schema has already been predefined with two read-only columns RowKey and PartitionKey of String type, and another column Timestamp of Date type. The RowKey and PartitionKey columns correspond to the Id and Site columns of the tAzureStorageO utputTable schema.

5. Define the schema by adding another four columns that hold other employee data, Name and Job of String type, Date of Date type, and Salary of Double type. Then click OK to save the changes and accept the propagation prompted by the pop-up dialog box.

6. Click Advanced settings to open its view.
7. Click under the **Name mappings** table to add one row and set the **Schema column name** cell with the value "Name" and the **Entity property name** cell with the value "EmployeeName" to map the schema column name with the property name of each entity in the Azure table.

   Note that for the **tAzureStorageInputTable** component, the **PartitionKey** and **RowKey** columns have already been added automatically to the schema and you do not need to specify the mapping relationship for them.

8. Double-click the **tLogRow** component to open its **Basic settings** view and in the **Mode** area, select **Table (print values in cells of a table)** for a better display of the result.

### Executing the Job to handle data with Azure Table storage

After setting up the Job and configuring the components used in the Job for handling data with Azure Table storage, you can then execute the Job and verify the Job execution result.

**Procedure**

1. Press **Ctrl + S** to save the Job.
2. Press **F6** to execute the Job.

   As shown above, the Job is executed successfully and the employee data is displayed on the console, with the timestamp value that indicates when each entity was inserted.

3. Double-check the employee data that has been written into the Azure Storage table `employee` using Microsoft Azure Storage Explorer if you want.

Activities:
tAzureStorageList

Lists blobs in a given container according to the specified blob filters.

**tAzureStorageList Standard properties**

These properties are used to configure tAzureStorageList running in the Standard Job framework.

The Standard tAzureStorageList component belongs to the Cloud family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property Type</td>
<td>Select the way the connection details will be set.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Built-In</strong>: The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Repository</strong>: The connection details stored centrally in Repository &gt; Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up Repository Content dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in.</td>
</tr>
<tr>
<td></td>
<td>This property is not available when other connection component is selected from the Connection Component drop-down list.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Connection Component</th>
<th>Select the component whose connection details will be used to set up the connection to Azure storage from the drop-down list.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Account Name</td>
<td>Enter the name of the storage account you need to access. A storage account name can be found in the Storage accounts dashboard of the Microsoft Azure Storage system to be used. Ensure that the administrator of the system has granted you the appropriate access permissions to this storage account.</td>
</tr>
<tr>
<td>Account Key</td>
<td>Enter the key associated with the storage account you need to access. Two keys are available for each account and by default, either of them can be used for this access.</td>
</tr>
<tr>
<td>Protocol</td>
<td>Select the protocol for this connection to be created.</td>
</tr>
<tr>
<td>Use Azure Shared Access Signature</td>
<td>Select this check box to use a shared access signature (SAS) to access the storage resources without need for the account key. For more information, see Using Shared Access Signatures (SAS).</td>
</tr>
</tbody>
</table>

In the Azure Shared Access Signature field displayed, enter your account SAS URL between double quotation marks. You can get the SAS URL for each allowed service on Microsoft Azure portal after generating SAS. The SAS URL format is `https://<$storagename>.$service.core.windows.net/<$sastoken>`, where `$<storagename>` is the storage account name, `<service>` is the service name.
$service>$ is the allowed service name (blob, file, queue or table), and <$sastoken> is the SAS token value. For more information, see Constructing the Account SAS URI.

Note that the SAS has valid period, you can set the start time at which the SAS becomes valid and the expiry time after which the SAS is no longer valid when generating it, and you need to make sure your SAS is still valid when running your Job.

<table>
<thead>
<tr>
<th>Container name</th>
<th>Enter the name of the container from which you need to select blobs to be listed.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Blob filter</td>
<td>Complete this table to select the blobs to be listed. The parameters to be provided are:</td>
</tr>
<tr>
<td>⋅ Prefix: enter the common prefix of the names of the blobs you need to list. This prefix allows you to filter the blobs which have the specified prefix in their names in the given container.</td>
<td></td>
</tr>
<tr>
<td>A blob name contains the virtual hierarchy of the blob itself. This hierarchy is a virtual path to that blob and is relative to the container where that blob is stored. For example, in a container named photos, the name of a photo blob might be 2014/US/Oakland/Talend.jpg.</td>
<td></td>
</tr>
<tr>
<td>For this reason, when you define a prefix, you are actually designating a directory level as the blob filter, for example, 2014/ or 2014/US/.</td>
<td></td>
</tr>
<tr>
<td>If you want to select the blobs stored directly beneath the container level, that is to say, the blobs without virtual path in their names, remove quotation marks and enter null.</td>
<td></td>
</tr>
<tr>
<td>⋅ Include sub-directories: select this check box to select all of the sub-folders and the blobs in those folders beneath the designated directory level. If you leave this check box clear, tAzureStorageList returns only the blobs, if any, directly beneath that directory level.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Schema and Edit schema</th>
<th>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</th>
</tr>
</thead>
<tbody>
<tr>
<td>⋅ Built-In: You create and store the schema locally for this component only.</td>
<td></td>
</tr>
<tr>
<td>⋅ Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
<td></td>
</tr>
<tr>
<td>The schema of this component is predefined with a single column BlobName of String type, which indicates the name of each blob to be listed.</td>
<td></td>
</tr>
<tr>
<td>Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:</td>
<td></td>
</tr>
<tr>
<td>⋅ View schema: choose this option to view the schema only.</td>
<td></td>
</tr>
<tr>
<td>⋅ Change to built-in property: choose this option to change the schema to Built-in for local changes.</td>
<td></td>
</tr>
<tr>
<td>⋅ Update repository connection: choose this option to change the schema stored in the repository and...</td>
<td></td>
</tr>
</tbody>
</table>
decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

| Die on error | Select the check box to stop the execution of the Job when an error occurs.
Clear the check box to skip any rows on error and complete the process for error-free rows. When errors are skipped, you can collect the rows on error using a Row > Reject link. |

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global Variables**

| CONTAINER | The name of the blob container. This is an After variable and it returns a string. |
| CURRENT_BLOB | The blob name being processed by this component. This is an After variable and it returns a string. |
| NB_LINE | The number of rows processed. This is an After variable and it returns an integer. |
| ERROR_MESSAGE | The error message generated by the component when an error occurs. This is an After variable and it returns a string. |

**Usage**

| Usage rule | This component can be used as a standalone component of a Job or Subjob. |
| Prerequisites | Knowledge about Microsoft Azure Storage is required. |

**Related scenario**

For a related scenario, see Retrieving files from a Azure Storage container on page 297
tAzureStorageOutputTable

Performs the defined action on a given Azure storage table and inserts, replaces, merges or deletes entities in the table based on the incoming data from the preceding component.

tAzureStorageOutputTable Standard properties

These properties are used to configure tAzureStorageOutputTable running in the Standard Job framework.

The Standard tAzureStorageOutputTable component belongs to the Cloud family.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

Basic settings

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property Type</td>
<td>Select the way the connection details will be set.</td>
</tr>
<tr>

<td>• Built-In: The connection details will be set locally for this component.</td>
</tr>
<tr>
<td></td>
<td>You need to specify the values for all related connection properties manually.</td>
</tr>
<tr>
<td></td>
<td>• Repository: The connection details stored centrally in Repository &gt; Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up Repository Content dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in.</td>
</tr>
<tr>
<td></td>
<td>This property is not available when other connection component is selected from the Connection Component drop-down list.</td>
</tr>
</tbody>
</table>

| Connection Component   | Select the component whose connection details will be used to set up the connection to Azure storage from the drop-down list. |

| Account Name           | Enter the name of the storage account you need to access. A storage account name can be found in the Storage accounts dashboard of the Microsoft Azure Storage system to be used. Ensure that the administrator of the system has granted you the appropriate access permissions to this storage account. |

| Account Key            | Enter the key associated with the storage account you need to access. Two keys are available for each account and by default, either of them can be used for this access. |

| Protocol               | Select the protocol for this connection to be created.                      |

| Use Azure Shared Access Signature | Select this check box to use a shared access signature (SAS) to access the storage resources without need for the account key. For more information, see Using Shared Access Signatures (SAS). |
|                             | In the Azure Shared Access Signature field displayed, enter your account SAS URL between double quotation marks. You can get the SAS URL for each allowed service.
on Microsoft Azure portal after generating SAS. The SAS URL format is `https://<$storagename>.<$service>.core.windows.net/<$sastoken>`, where `<$storagename>` is the storage account name, `<$service>` is the allowed service name (blob, file, queue or table), and `<$sastoken>` is the SAS token value. For more information, see [Constructing the Account SAS URI](#).

Note that the SAS has valid period, you can set the start time at which the SAS becomes valid and the expiry time after which the SAS is no longer valid when generating it, and you need to make sure your SAS is still valid when running your Job.

<table>
<thead>
<tr>
<th>Table name</th>
<th>Specify the name of the table into which the entities will be written.</th>
</tr>
</thead>
</table>
| Schema and Edit schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.  
  • **Built-In**: You create and store the schema locally for this component only.  
  • **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.  
  Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
  • **View schema**: choose this option to view the schema only.  
  • **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
  • **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window. |
| Partition Key | Select the schema column that holds the partition key value from the drop-down list. |
| Row Key | Select the schema column that holds the row key value from the drop-down list. |
| Action on data | Select an action to be performed on data of the table defined.  
  • **Insert**: insert a new entity into the table.  
  • **Insert or replace**: replace an existing entity or insert a new entity if it does not exist. When replace an entity, any properties from the previous entity will be removed if the new entity does not define them.  
  • **Insert or merge**: merge an existing entity or insert a new entity if it does not exist. When merge an entity, any properties from the previous entity will be retained if the new entity does not define or include them. |
- **Merge**: update an existing entity without removing the property value of the previous entity if the new entity does not define its value.
- **Replace**: update an existing entity and remove the property value of the previous entity if the new entity does not define its value.
- **Delete**: delete an existing entity.

For performance reasons, the incoming data is processed in parallel and in random order. Therefore, it is not recommended to perform any order-sensitive data operation (for example, insert or replace) if there are duplicated rows in your data.

### Action on table

Select an operation to be performed on the table defined.

- **Default**: No operation is carried out.
- **Drop and create table**: The table is removed and created again.
- **Create table**: The table does not exist and gets created.
- **Create table if does not exist**: The table is created if it does not exist.
- **Drop table if exist and create**: The table is removed if it already exists and created again.

### Process in batch

Select this check box to process the input entities in batch.

Note that the entities to be processed in batch should belong to the same partition group, which means, they should have the same partition key value.

### Die on error

Select the check box to stop the execution of the Job when an error occurs.

### Advanced settings

#### Name mappings

Complete this table to map the column name of the component schema with the property name of the Azure table entity if they are different.

- **Schema column name**: enter the column name of the component schema between double quotation marks.
- **Entity property name**: enter the property name of the Azure table entity between double quotation marks.

For example, if there are three schema columns CompanyID, EmployeeID, and EmployeeName that are used to feed the values for the PartitionKey, RowKey, and Name entity properties respectively, then you need to add the following rows for the mapping when writing data into the Azure table.

- the **Schema column name** cell with the value "CompanyID" and the **Entity property name** cell with the value "PartitionKey".
- the **Schema column name** cell with the value "EmployeeID" and the **Entity property name** cell with the value "RowKey".
- the **Schema column name** cell with the value "EmployeeName" and the **Entity property name** cell with the value "Name".
**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NB_LINE</td>
<td>The number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>NB_SUCCESS</td>
<td>The number of rows successfully processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>NB_REJECT</td>
<td>The number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>ERROR_MESSAGE</td>
<td>The error message generated by the component when an error occurs. This is an After variable and it returns a string.</td>
</tr>
</tbody>
</table>

### Usage

**Usage rule**

This component is usually used as an end component of a Job or Subjob and it always needs an input link.

### Related scenario

For a related scenario, see Handling data with Microsoft Azure Table storage on page 307.
# tAzureStoragePut

Uploads local files into a given container for an Azure storage account.

## tAzureStoragePut Standard properties

These properties are used to configure tAzureStoragePut running in the Standard Job framework. The Standard tAzureStoragePut component belongs to the Cloud family. The component in this framework is available in all Talend products.

### Basic settings

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Description</th>

**Usage**

| Usage rule | This component can be used as a standalone component of a Job or Subjob. |

**Related scenario**

No scenario is available for this component yet.
# tAzureStorageQueueInput

Retrieves one or more messages from the front of an Azure queue.

## tAzureStorageQueueInput Standard properties

These properties are used to configure tAzureStorageQueueInput running in the Standard Job framework.

The Standard tAzureStorageQueueInput component belongs to the Cloud family.

The component in this framework is available in all Talend products.

### Basic settings

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Select the way the connection details will be set.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• <strong>Built-In</strong>: The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Repository</strong>: The connection details stored centrally in Repository &gt; Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up Repository Content dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in.</td>
</tr>
</tbody>
</table>

This property is not available when other connection component is selected from the Connection Component drop-down list.

<table>
<thead>
<tr>
<th>Connection Component</th>
<th>Select the component whose connection details will be used to set up the connection to Azure storage from the drop-down list.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Account Name</strong>: Enter the name of the storage account you need to access. A storage account name can be found in the Storage accounts dashboard of the Microsoft Azure Storage system to be used. Ensure that the administrator of the system has granted you the appropriate access permissions to this storage account.</td>
</tr>
<tr>
<td></td>
<td><strong>Account Key</strong>: Enter the key associated with the storage account you need to access. Two keys are available for each account and by default, either of them can be used for this access.</td>
</tr>
<tr>
<td></td>
<td><strong>Protocol</strong>: Select the protocol for this connection to be created.</td>
</tr>
<tr>
<td></td>
<td><strong>Use Azure Shared Access Signature</strong>: Select this check box to use a shared access signature (SAS) to access the storage resources without need for the account key. For more information, see Using Shared Access Signatures (SAS).</td>
</tr>
</tbody>
</table>

In the **Azure Shared Access Signature** field displayed, enter your account SAS URL between double quotation marks. You can get the SAS URL for each allowed service on Microsoft Azure portal after generating SAS. The SAS URL format is `https://<$storagename>...`
$service>.core.windows.net/$sastoken$, where <$storagename> is the storage account name, <$service> is the allowed service name (blob, file, queue or table), and <$sastoken> is the SAS token value. For more information, see Constructing the Account SAS URI.

Note that the SAS has valid period, you can set the start time at which the SAS becomes valid and the expiry time after which the SAS is no longer valid when generating it, and you need to make sure your SAS is still valid when running your Job.

<table>
<thead>
<tr>
<th>Queue name</th>
<th>Specify the name of the Azure queue from which the messages will be retrieved.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Schema and Edit schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td></td>
<td>• Built-In: You create and store the schema locally for this component only.</td>
</tr>
<tr>
<td></td>
<td>• Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
</tr>
<tr>
<td></td>
<td>The schema of this component is predefined with the following columns:</td>
</tr>
<tr>
<td></td>
<td>• MessageId: the id of the message.</td>
</tr>
<tr>
<td></td>
<td>• MessageContent: the body of the message.</td>
</tr>
<tr>
<td></td>
<td>• InsertionTime: the time when the message was added to the queue.</td>
</tr>
<tr>
<td></td>
<td>• ExpirationTime: the time when the message will be expired.</td>
</tr>
<tr>
<td></td>
<td>• NextVisibleTime: the time when the message becomes visible next time.</td>
</tr>
<tr>
<td></td>
<td>• DequeueCount: the number of times that the message has been dequeued. This value is incremented each time the message is dequeued, but it will not be incremented when the message is peeked.</td>
</tr>
<tr>
<td></td>
<td>• PopReceipt: the pop receipt value that is required to delete the message.</td>
</tr>
<tr>
<td></td>
<td>Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:</td>
</tr>
<tr>
<td></td>
<td>• View schema: choose this option to view the schema only.</td>
</tr>
<tr>
<td></td>
<td>• Change to built-in property: choose this option to change the schema to Built-in for local changes.</td>
</tr>
<tr>
<td></td>
<td>• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.</td>
</tr>
<tr>
<td>Number of messages</td>
<td>Enter the number of messages to be retrieved from the specified queue at a time, up to a maximum of 32.</td>
</tr>
</tbody>
</table>
**Peer messages**

Select this check box to retrieve messages without removing them from the queue and altering the visibility of them. The messages will remain available to other consumers.

**Delete the message while streaming**

Select this check box to delete the messages while retrieving them from the queue.

**Die on error**

Select the check box to stop the execution of the Job when an error occurs.

### Advanced settings

**Visibility timeout in seconds**

Enter the visibility timeout value (in seconds) relative to the server time. This timeout value is added to the time at which the message is retrieved to determine its `NextVisibleTime` value. The message will not be visible to other consumers for this time interval after it has been retrieved.

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

**NB_LINE**

The number of rows processed. This is an After variable and it returns an integer.

**QUEUE_NAME**

The name of the Azure queue. This is an After variable and it returns a string.

**ERROR_MESSAGE**

The error message generated by the component when an error occurs. This is an After variable and it returns a string.

### Usage

**Usage rule**

This component is usually used as a start component of a Job or Subjob and it always needs an output link.

### Related scenario

No scenario is available for this component yet.
tAzureStorageQueueInputLoop

Runs an endless loop to retrieve messages from the front of an Azure queue.

**tAzureStorageQueueInputLoop Standard properties**

These properties are used to configure tAzureStorageQueueInputLoop running in the Standard Job framework.

The Standard tAzureStorageQueueInputLoop component belongs to the Cloud family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Select the way the connection details will be set.</th>
</tr>
</thead>
<tbody>

</tbody>
</table>
|                               | In the Azure Shared Access Signature field displayed, enter your account SAS URL between double quotation marks. You can get the SAS URL for each allowed service on Microsoft Azure portal after generating SAS. The SAS URL format is https://<$storagename>.
AzureStorageQueueList

$service>.core.windows.net/<$sastoken>,
where <$storagename> is the storage account name, <$service> is the allowed service name (blob, file, queue or table), and <$sastoken> is the SAS token value. For more information, see Constructing the Account SAS URI.

Note that the SAS has valid period, you can set the start time at which the SAS becomes valid and the expiry time after which the SAS is no longer valid when generating it, and you need to make sure your SAS is still valid when running your Job.

Schema and Edit schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

- **Built-in**: You create and store the schema locally for this component only.
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

The schema of this component is predefined with one single column QueueName that stores the name of each queue to be returned.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

Die on error

Select the check box to stop the execution of the Job when an error occurs.

Advanced settings

- **tStatCatcher Statistics**: Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

Global Variables

- **NUMBER_OF_QUEUES**: The number of queues returned. This is an After variable and it returns an integer.
- **ERROR_MESSAGE**: The error message generated by the component when an error occurs. This is an After variable and it returns a string.
Usage

| Usage rule | This component is usually used as a start component of a Job or Subjob and it always needs an output link. |

Related scenario

No scenario is available for this component yet.
tAzureStorageQueueOutput

Adds messages to the back of an Azure queue.
Note that this component can only be used with Java 8.

tAzureStorageQueueOutput Standard properties

These properties are used to configure tAzureStorageQueueOutput running in the Standard Job framework.
The Standard tAzureStorageQueueOutput component belongs to the Cloud family.
The component in this framework is available in all Talend products.

Basic settings

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Select the way the connection details will be set.</th>
</tr>
</thead>

<tr>
<td>• Built-In</td>
<td>The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.</td>
</tr>
<tr>
<td>• Repository</td>
<td>The connection details stored centrally in Repository &gt; Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up Repository Content dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in. This property is not available when other connection component is selected from the Connection Component drop-down list.</td>
</tr>
</tbody>
</table>

| Connection Component | Select the component whose connection details will be used to set up the connection to Azure storage from the drop-down list. |

| Account Name | Enter the name of the storage account you need to access. A storage account name can be found in the Storage accounts dashboard of the Microsoft Azure Storage system to be used. Ensure that the administrator of the system has granted you the appropriate access permissions to this storage account. |

| Account Key | Enter the key associated with the storage account you need to access. Two keys are available for each account and by default, either of them can be used for this access. |

| Protocol | Select the protocol for this connection to be created. |

| Use Azure Shared Access Signature | Select this check box to use a shared access signature (SAS) to access the storage resources without need for the account key. For more information, see Using Shared Access Signatures (SAS). In the Azure Shared Access Signature field displayed, enter your account SAS URL between double quotation marks. You can get the SAS URL for each allowed service on Microsoft Azure portal after generating SAS. The |
SAS URL format is https://<$storagename>.< $service>.core.windows.net/<$sastoken>, where <$storagename> is the storage account name, < $service> is the allowed service name (blob, file, queue or table), and <$sastoken> is the SAS token value. For more information, see Constructing the Account SAS URI.

Note that the SAS has valid period, you can set the start time at which the SAS becomes valid and the expiry time after which the SAS is no longer valid when generating it, and you need to make sure your SAS is still valid when running your Job.

Queue name
Specify the name of the Azure queue to which the messages will be added.

Schema and Edit schema
A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.
- Built-In: You create and store the schema locally for this component only.
- Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

The schema of this component is predefined with one single column MessageContent that stores the body of each message.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:
- View schema: choose this option to view the schema only.
- Change to built-in property: choose this option to change the schema to Built-in for local changes.
- Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

Die on error
Select the check box to stop the execution of the Job when an error occurs.

Advanced settings

StatCatcher Statistics
Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

Global Variables

NB_LINE
The number of messages processed. This is an After variable and it returns an integer.
<table>
<thead>
<tr>
<th>NB_SUCCESS</th>
<th>The number of messages successfully enqueued. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td>NB_REJECT</td>
<td>The number of messages rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>ERROR_MESSAGE</td>
<td>The error message generated by the component when an error occurs. This is an After variable and it returns a string.</td>
</tr>
</tbody>
</table>

**Usage**

| Usage rule | This component is usually used as an end component of a Job or Subjob and it always needs an input link. |

# tBarChart

Generates a bar chart from the input data to ease technical analysis.
tBarChart reads data from an input flow and transforms the data into a bar chart in a PNG image file.

## tBarChart Standard properties

These properties are used to configure tBarChart running in the Standard Job framework.
The Standard tBarChart component belongs to the Business Intelligence family.
The component in this framework is available in all Talend products.

### Basic settings

| Schema and Edit schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
  - **View schema**: choose this option to view the schema only.  
  - **Change to built-in property**: choose this option to change the schema to Built-in for local changes.  
  - **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.  

**Note:**  
The schema of tBarChart contains three read-only columns named `series` (string), `category` (string), and `value` (integer) respectively, in a fixed order. The data in any extra columns will be only passed to the next component, if any, without being presented in the bar chart. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Built-in</td>
<td>The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Repository</td>
<td>The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Sync columns</td>
<td>Click to synchronize the output file schema with the input file schema. The Sync function only displays once the Row connection is linked with the output component.</td>
</tr>
</tbody>
</table>
### tBarChart

**Generated image path**
Name and path of the output image file.

**Chart title**
Enter the title of the bar chart to be generated.

**Include legend**
Select this check box if you want the bar chart to include a legend, indicating all series in different colors.

**3Dimensions**
Select this check box to create an image with 3D effect. By default, this check box is selected and the bars representing the series of each category will be stacked one over another. If this check box is cleared, a 2D image will be created, with the bars displayed one besides another along the category axis.

**Image width and Image height**
Enter the width and height of the image file, in pixels.

**Category axis name and Value axis name**
Enter the category axis name and value axis name.

**Foreground alpha**
Enter an integer in the range of 0 to 100 to define the transparency of the image. The smaller the number you enter, the more transparent the image will be.

**Plot orientation**
Select the plot orientation of the bar chart: VERTICAL or HORIZONTAL.

### Advanced settings

**tStat Catcher Statistics**
Select this check box to collect log data at the component level.

### Global Variables

**Global Variables**

- **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

### Usage

**Usage rule**
This component is mainly used as Output component. It requires an Input component and Row main link as input.
Creating a bar chart from the input data

This scenario describes a Job that reads source data from a CSV file and transforms the data into a bar chart showing a comparison of several large cities. The input file is shown below:

### City;Population (x1000);LandArea (km2);Population Density (people/km2)
- Beijing;10233;1418;7620
- Moscow;10452;1081;9644
- Seoul;10422;605;17215
- Tokyo;8731;617;14151
- Jakarta;8490;664;12738
- New York;8310;789;10452

Because the input file has a different structure than the one required by the `tBarChart` component, this use case uses the `tMap` component to adapt the source data to the three-column schema of `tBarChart` so that a temporary CSV file can be created as the input to the `tBarChart` component.

**Note:**
You will usually use the `tMap` component to adjust the input schema in accordance with the schema structure of the `tBarChart` component. For more information about how to use the `tMap` component, see Talend Studio User Guide and tMap on page 1962.

To ensure correct generation of the temporary input file, a pre-treatment subJob is used to delete the temporary file in case it already exists before the main Job is executed; as this temporary file serves this specific Job only, a post-treatment subJob is used to deleted it after the main Job is executed.

**Dropping and linking components**

**Procedure**

1. Drop the following components from the Palette to the design workspace: a `tPrejob`, a `tPostjob`, two `tFileDelete` components, two `tFileInputDelimited` components, a `tMap`, three `tFileOutputDelimited` components, and a `tBarChart`.
2. Connect the `tPrejob` component to one `tFileDelete` component using a Trigger > On Component Ok connection, and connect the `tPostjob` component to the other `tFileDelete` component using the same type of connection.
3. Connect the first `tFileInputDelimited` to the `tMap` component using a Row > Main connection.
4. Connect the `tMap` component to the first `tFileOutputDelimited` component using a Row > Main connection, and name the connection `Population`.
5. Repeat the step above to connect the `tMap` component to the other two `tFileOutputDelimited` components using Row > Main connections, and name the connections `Area` and `Density` respectively.
6. Connect the section `tFileInputDelimited` to the `tBarChart` component using a Row > Main connection.
7. Connect the first `tFileInputDelimited` component to the second `tFileInputDelimited` component using a Trigger > On Subjob Ok connection.
8. Relabel the components to best describe their functionality.
Results

Reading the source data

Procedure

1. Double-click the first tFileInputDelimited component, which is labelled Large_Cities, to display its Basic settings view.

2. Fill in the File name field by browsing to the input file.

3. In the Header field, specify the number of header rows. In this use case, you have only one header row.

4. Click Edit schema to describe the data structure of the input file. In this use case, the input schema is made of four columns: City, Population, Area, and Density. Upon defining the column names and data types, click OK to close the schema dialog box.
Adapting the source data to the tBarChart schema

Procedure

1. Double-click the tMap to open the Map Editor.
   You can see an input table on the input panel, row1 in this example, and three empty output tables, named Population, Area, and Density on the output panel.

2. Use the Schema editor to add three columns to each output table: series (string), category (string), and value (integer).

3. In the relevant Expression field of the output tables, enter the text to be presented in the legend area of the bar chart, "Population (x1000 people)", "Land area (km2)", and "Population density (people/km2)" respectively in this example.

4. Drop the City column of the input table onto the category column of each output table.

5. Drop the Population column of the input table onto the value column of the Population table.

6. Drop the Area column of the input table onto the value column of the Area table.

7. Drop the Density column of the input table onto the value column of the Density table.
8. Click OK to save the mappings and close the Map Editor and propagate the output schemas to the output components.

Generating the temporary input file

Procedure

1. Double-click the first tFileOutputDelimited component to display its Basic settings view.

2. In the File Name field, define a temporary CSV file to send the mapped data flows to. In this use case, we name this file Temp.csv. This file will be used as the input to the tBarChart component.

3. Select the Append check box.

4. Repeat the steps above to define the properties of the other two tFileOutputDelimited components, using exactly the same settings as in the first tFileOutputDelimited component.
Configuring bar chart generation

Procedure

1. Double-click the second tFileInputDelimited component, which is labelled Temp_Input, to display its Basic settings view.

2. Fill in the File name field with the path to the temporary input file generated by the tFileOutputDelimited components. In this use case, the temporary input file to the tBarChart is Temp.csv.

3. Double-click the tBarChart component to display its Basic settings view.

4. In the Generated image path field, define the file path of the image file to be generated.

5. In the Chart title field, define a title for the bar chart.

6. Define the category and series axis names.
7. Define the size and transparency degree of the image if needed. In this use case, we simply use the default settings.

8. Click **Edit schema** to open the schema dialog box.

9. Copy all the columns from the output schema to the input schema by clicking the left-pointing double arrow button. Then, click **OK** to close the schema dialog box.

**Deleting the temporary file**

**About this task**
As the **tPrejob** and **tPostjob** components simply trigger the connected subjobs and do not have any settings to define, all you need to do is to define the properties of the two **tFileDelete** components.

**Procedure**

1. Double-click the first **tFileDelete** component to display its **Basic settings** view.

2. Fill in the **File name** field with the path to the temporary input file.
   If the **Fail on error** check box is selected while the pre-treatment subjob fails because of errors such as the file to delete does not exist, this failure will prevent the main subjob from being launched. In this situation, you can clear the **Fail on error** check box to avoid this interruption.
3. Specify the same file path in the other `tFileDelete` component.

**Executing the Job**

**Procedure**

1. Press **Ctrl+S** to save your Job.
2. Press **F6** to launch it.
   
   A bar chart is generated, showing a graphical comparison of the specified large cities.

![Comparison of large cities](image.png)
**tBigQueryBulkExec**

Transfers given data to Google BigQuery.

The tBigQueryOutputBulk and tBigQueryBulkExec components are generally used together as parts of a two step process. In the first step, an output file is generated. In the second step, this file is used to feed a dataset. These two steps are fused together in the tBigQueryOutput component, detailed in a separate section. The advantage of using two separate components is that the data can be transformed before it is loaded in the dataset.

This component transfers a given file from Google Cloud Storage to Google BigQuery, or uploads a given file into Google Cloud Storage and then transfers it to Google BigQuery.

**tBigQueryBulkExec Standard properties**

These properties are used to configure tBigQueryBulkExec running in the Standard Job framework.

The Standard tBigQueryBulkExec component belongs to the Big Data family.

The component in this framework is available in all Talend products.

**Basic settings**

| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields. Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
| • View schema: choose this option to view the schema only.  
| • Change to built-in property: choose this option to change the schema to **Built-in** for local changes.  
| • Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window. |
| **Built-In**: You create and store the schema locally for this component only. |
| **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. |
| **Authentication mode** | Select the mode to be used to authenticate to your project.  
| • OAuth 2.0: authenticate the access using OAuth credentials. When selecting this mode, the parameters to be defined in the **Basic settings** view are **Client ID**, **Client secret** and **Authorization code**.  
| • Service account: authenticate using a Google account that is associated with your Google Cloud Platform |
project. When selecting this mode, the parameter to be defined in the **Basic settings** view is **Service account credentials file**.

<table>
<thead>
<tr>
<th>Service account credentials file</th>
<th>Enter the path to the credentials file created for the service account to be used. This file must be stored in the machine in which your Talend Job is actually launched and executed. For further information about how to create a Google service account and obtain the credentials file, see <a href="#">Getting Started with Authentication</a> from the Google documentation.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Client ID and Client secret</td>
<td>Paste the client ID and the client secret, both created and viewable on the API Access tab view of the project hosting the Google BigQuery service and the Cloud Storage service you need to use. To enter the client secret, click the [...] button next to the client secret field, and then in the pop-up dialog box enter the client secret between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td>Project ID</td>
<td>Paste the ID of the project hosting the Google BigQuery service you need to use. The ID of your project can be found in the URL of the Google API Console, or by hovering your mouse pointer over the name of the project in the BigQuery Browser Tool.</td>
</tr>
<tr>
<td>Authorization code</td>
<td>Paste the authorization code provided by Google for the access you are building. To obtain the authorization code, you need to execute the Job using this component and when this Job pauses execution to print out an URL address, you navigate to this address to copy the authorization code displayed.</td>
</tr>
<tr>
<td>Dataset</td>
<td>Enter the name of the dataset you need to transfer data to.</td>
</tr>
<tr>
<td>Table</td>
<td>Enter the name of the table you need to transfer data to. If this table does not exist, select the <strong>Create the table if it doesn’t exist</strong> check box.</td>
</tr>
</tbody>
</table>
| Action on data                  | Select the action to be performed from the drop-down list when transferring data to the target table. The action may be:  
  - **Truncate**: it empties the contents of the table and repopulates it with the transferred data.  
  - **Append**: it adds rows to the existing data in the table.  
  - **Empty**: it populates the empty table. |
| Bulk file already exists in Google storage | Select this check box to reuse the authentication information for Google Cloud Storage connection, then, complete the **File** and the **Header** fields. |
| Access key and Secret key       | Paste the authentication information obtained from Google for making requests to Google Cloud Storage. To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings. |
These keys can be consulted on the Interoperable Access tab view under the Google Cloud Storage tab of the project.

<table>
<thead>
<tr>
<th><strong>File to upload</strong></th>
<th>When the data to be transferred to Google BigQuery is not stored on Google Cloud Storage, browse to, or enter the path to it.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Bucket</strong></td>
<td>Enter the name of the bucket, the Google Cloud Storage container, which holds the data to be transferred to Google BigQuery.</td>
</tr>
</tbody>
</table>
| **File**           | Enter the directory of the data stored on Google Cloud Storage and to be transferred to Google BigQuery. This data must be stored directly under the bucket root. For example, enter `gs://my_bucket/my_file.csv`.  
If the data is not on Google Cloud Storage, this directory is used as the intermediate destination before the data is transferred to Google BigQuery. |
| **Header**         | Set values to ignore the header of the transferred data. For example, enter 0 to ignore no rows for the data without header. |
| **Die on error**   | This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows. |

**Advanced settings**

| **token properties File Name** | Enter the path to, or browse to the refresh token file you need to use.  
At the first Job execution using the **Authorization code** you have obtained from Google BigQuery, the value in this field is the directory and the name of that refresh token file to be created and used; if that token file has been created and you need to reuse it, you have to specify its directory and file name in this field.  
With only the token file name entered, **Talend Studio** considers the directory of that token file to be the root of the Studio folder.  
For further information about the refresh token, see the manual of Google BigQuery. |
| **Set the field delimiter** | Enter character, string or regular expression to separate fields for the transferred data. |
| **Encoding**        | Select the encoding from the list or select **Custom** and define it manually. This field is compulsory for database data handling. The supported encodings depend on the JVM that you are using. For more information, see [https://docs.oracle.com](https://docs.oracle.com). |
| **tStatCatcher Statistics** | Select this check box to collect the log data at the component level. |
Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | This is a standalone component. This component automatically detects and supports both multi-regional locations and regional locations. When using the regional locations, the buckets and the datasets to be used must be in the same locations. |

Related Scenario

For related topic, see Writing data in Google BigQuery on page 365
tBigQueryInput

Performs the queries supported by Google BigQuery.
This component connects to Google BigQuery and performs queries in it.

tBigQueryInput Standard properties

These properties are used to configure tBigQueryInput running in the Standard Job framework.
The Standard tBigQueryInput component belongs to the Big Data family.
The component in this framework is available in all Talend products.

Basic settings

| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:
| | • View schema: choose this option to view the schema only.
| | • Change to built-in property: choose this option to change the schema to Built-in for local changes.
| | • Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.
| Built-In: You create and store the schema locally for this component only.
| Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.
| Authentication mode | Select the mode to be used to authenticate to your project.
| | • OAuth 2.0: authenticate the access using OAuth credentials. When selecting this mode, the parameters to be defined in the Basic settings view are Client ID, Client secret and Authorization code.
| | • Service account: authenticate using a Google account that is associated with your Google Cloud Platform project. When selecting this mode, the parameter to be defined in the Basic settings view is Service account credentials file.
| Service account credentials file | Enter the path to the credentials file created for the service account to be used. This file must be stored in the machine in which your Talend Job is actually launched and executed.
For further information about how to create a Google service account and obtain the credentials file, see [Getting Started with Authentication](#) from the Google documentation.

**Client ID and Client secret**

Paste the client ID and the client secret, both created and viewable on the API Access tab view of the project hosting the Google BigQuery service and the Cloud Storage service you need to use.

To enter the client secret, click the [...] button next to the client secret field, and then in the pop-up dialog box enter the client secret between double quotes and click OK to save the settings.

**Project ID**

Paste the ID of the project hosting the Google BigQuery service you need to use.

The ID of your project can be found in the URL of the Google API Console, or by hovering your mouse pointer over the name of the project in the BigQuery Browser Tool.

**Authorization code**

Paste the authorization code provided by Google for the access you are building.

To obtain the authorization code, you need to execute the Job using this component and when this Job pauses execution to print out an URL address, you navigate to this address to copy the authorization code displayed.

**Query**

Enter the query you need to use.

**Result size**

Select the option depending on the volume of the query result.

By default, the Small option is used, but when the query result is larger than the maximum response size, you need to select the Large option.

If the volume of the result is not certain, select Auto.

**Advanced settings**

**token properties File Name**

Enter the path to, or browse to the refresh token file you need to use.

At the first Job execution using the Authorization code you have obtained from Google BigQuery, the value in this field is the directory and the name of that refresh token file to be created and used; if that token file has been created and you need to reuse it, you have to specify its directory and file name in this field.

With only the token file name entered, Talend Studio considers the directory of that token file to be the root of the Studio folder.

For further information about the refresh token, see the manual of Google BigQuery.

**Advanced Separator (for number)**

Select this check box to change the separator used for the numbers.

**Encoding**

Select the encoding from the list or select Custom and define it manually. This field is compulsory for database...
Performing a query in Google BigQuery

This scenario uses two components to perform the SELECT query in BigQuery and present the result in the Studio.

The following figure shows the schema of the table, **UScustomer**, we use as example to perform the SELECT query in.
We will select the State records and count the occurrence of each State among those records.

**Linking the components**

**Procedure**

1. In the **Integration** perspective of Studio, create an empty Job, named *BigQueryInput* for example, from the **Job Designs** node in the **Repository** tree view.
   
   For further information about how to create a Job, see the [Talend Studio User Guide](#).

2. Drop **tBigQueryInput** and **tLogRow** onto the workspace.

3. Connect them using the **Row > Main** link.

**Creating the query**

**Building access to BigQuery**

**Procedure**

1. Double-click **tBigQueryInput** to open its **Component** view.
2. Click **Edit schema** to open the editor.

3. Click the button twice to add two rows and enter the names of your choice for each of them in the **Column** column. In this scenario, they are: **States** and **Count**.

4. Click **OK** to validate these changes and accept the propagation prompted by the pop-up dialog box.

5. In the **Authentication** area, add the authentication information. In most cases, the **Service account** mode is more straight-forward and easy to handle.

<table>
<thead>
<tr>
<th>Authentication mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Service account</strong></td>
<td>Authenticate using a Google account that is associated with your Google Cloud Platform project. When selecting this mode, the <strong>Service account credentials file</strong> field is displayed. In this field, enter the path to the credentials file created for the service account to be used. This file must be stored in the machine in which your Talend Job is actually launched and executed. For further information about how to create a Google service account and obtain the credentials file, see Getting Started with Authentication from the Google documentation.</td>
</tr>
</tbody>
</table>
Authentication mode

**OAuth 2.0**

Description

Authenticate the access using OAuth credentials. When selecting this mode, the parameters to be defined in the Basic settings view are **Client ID**, **Client secret** and **Authorization code**.

1. Navigate to the Google APIs Console in your web browser to access the Google project hosting the BigQuery and the Cloud Storage services you need to use.
2. Click the API Access tab to open its view and copy Client ID, Client secret and Project ID.
3. In the Component view of the Studio, paste Client ID, Client secret and Project ID from the API Access tab view to the corresponding fields, respectively.
4. In the Run view of the Studio, click Run to execute this Job. The execution will pause at a given moment to print out in the console the URL address used to get the authorization code.
5. Navigate to this address in your web browser and copy the authorization code displayed.
6. In the Component view of tBigQueryOutput, paste the authorization code in the Authorization Code field.

Writing the query

**Procedure**

In the **Query** field, enter `select States, count (*) as Count from documentation.UScustomer group by States`

Executing the Job

**About this task**

The tLogRow component presents the execution result of the Job. You can configure the presentation mode on its Component view.

To do this, double-click tLogRow to open the Component view and in the Mode area, select the Table (print values in cells of a table) option.

**Procedure**

To execute this Job, press **F6**.
Results

Once done, the Run view is opened automatically, where you can check the execution result.

```
Starting job BigQuerySelect at 15:02 01/08/2012.

tBigQueryOutput

Transfers the data provided by its preceding component to Google BigQuery. This component writes the data it receives in a user-specified directory and transfers the data to Google BigQuery via Google Cloud Storage.

**tBigQueryOutput Standard properties**

These properties are used to configure tBigQueryOutput running in the Standard Job framework. The Standard tBigQueryOutput component belongs to the Big Data family. The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th><strong>Schema and Edit Schema</strong></th>
<th>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. <td>Select the mode to be used to authenticate to your project. • OAuth 2.0: authenticate the access using OAuth credentials. When selecting this mode, the parameters to be defined in the Basic settings view are Client ID, Client secret and Authorization code. • Service account: authenticate using a Google account that is associated with your Google Cloud Platform</td>
</tr>
</tbody>
</table>
When selecting this mode, the parameter to be defined in the **Basic settings** view is **Service account credentials file**.

### Service account credentials file
Enter the path to the credentials file created for the service account to be used. This file must be stored in the machine in which your Talend Job is actually launched and executed.

For further information about how to create a Google service account and obtain the credentials file, see [Getting Started with Authentication](#) from the Google documentation.

### Client ID and Client secret
Paste the client ID and the client secret, both created and viewable on the API Access tab view of the project hosting the Google BigQuery service and the Cloud Storage service you need to use.

To enter the client secret, click the [...] button next to the client secret field, and then in the pop-up dialog box enter the client secret between double quotes and click **OK** to save the settings.

### Project ID
Paste the ID of the project hosting the Google BigQuery service you need to use.

The ID of your project can be found in the URL of the Google API Console, or by hovering your mouse pointer over the name of the project in the BigQuery Browser Tool.

### Authorization code
Paste the authorization code provided by Google for the access you are building.

To obtain the authorization code, you need to execute the Job using this component and when this Job pauses execution to print out an URL address, you navigate to this address to copy the authorization code displayed.

### Dataset
Enter the name of the dataset you need to transfer data to.

### Table
Enter the name of the table you need to transfer data to.

If this table does not exist, select the **Create the table if it doesn’t exist** check box.

### Action on data
Select the action to be performed from the drop-down list when transferring data to the target table. The action may be:

- **Truncate**: it empties the contents of the table and repopulates it with the transferred data.
- **Append**: it adds rows to the existing data in the table.
- **Empty**: it populates the empty table.

### Access key and Secret key
Paste the authentication information obtained from Google for making requests to Google Cloud Storage.

To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

These keys can be consulted on the Interoperable Access tab view under the Google Cloud Storage tab of the project.
<table>
<thead>
<tr>
<th><strong>Bucket</strong></th>
<th>Enter the name of the bucket, the Google Cloud Storage container, which holds the data to be transferred to Google BigQuery.</th>
</tr>
</thead>
</table>
| **File**   | Enter the directory of the data stored on Google Cloud Storage and to be transferred to Google BigQuery. This data must be stored directly under the bucket root. For example, enter gs://my_bucket/my_file.csv.  
If the data is not on Google Cloud Storage, this directory is used as the intermediate destination before the data is transferred to Google BigQuery.  
Note that this file name must be identical with the name of the file specified in the **Local filename** field. |
| **Header** | Set values to ignore the header of the transferred data. For example, enter 0 to ignore no rows for the data without header and set 1 for the data with header at the first row. |
| **Die on error** | This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows. |

**Advanced settings**

| **token properties File Name** | Enter the path to, or browse to the refresh token file you need to use.  
At the first Job execution using the **Authorization code** you have obtained from Google BigQuery, the value in this field is the directory and the name of that refresh token file to be created and used; if that token file has been created and you need to reuse it, you have to specify its directory and file name in this field.  
With only the token file name entered, Talend Studio considers the directory of that token file to be the root of the Studio folder.  
For further information about the refresh token, see the manual of Google BigQuery. |
| **Field Separator** | Enter character, string or regular expression to separate fields for the transferred data. |
| **Create directory if not exists** | Select this check box to create the directory you defined in the **File** field for Google Cloud Storage, if it does not exist. |
| **Custom the flush buffer size** | Enter the number of rows to be processed before the memory is freed. |
| **Check disk space** | Select this check box to throw an exception during execution if the disk is full. |
| **Encoding** | Select the encoding from the list or select **Custom** and define it manually. This field is compulsory for database data handling. The supported encodings depend on the JVM that you are using. For more information, see https://docs.oracle.com. |
tStatCatcher Statistics

Select this check box to collect the log data at the component level.

Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | This is an output component used at the end of a Job. It receives data from its preceding component such as tFileInputDelimited, tMap or tMysqlInput. This component automatically detects and supports both multi-regional locations and regional locations. When using the regional locations, the buckets and the datasets to be used must be in the same locations. |

Writing data in Google BigQuery

This scenario uses two components to write data in Google BigQuery.

Linking the components

Procedure

1. In the Integration perspective of Talend Studio, create an empty Job, named WriteBigQuery for example, from the Job Designs node in the Repository tree view.
   For further information about how to create a Job, see the Talend Studio User Guide.
2. Drop tRowGenerator and tBigQueryOutput onto the workspace.
The **tRowGenerator** component generates the data to be transferred to Google BigQuery in this scenario. In the real-world case, you can use other components such as **tMysqlInput** or **tMap** in the place of **tRowGenerator** to design a sophisticated process to prepare your data to be transferred.

3. Connect them using the **Row > Main** link.

### Preparing the data to be transferred

**Procedure**

1. Double-click **tRowGenerator** to open its **Component** view.

![Component view of tRowGenerator](image)

2. Click **RowGenerator Editor** to open the editor.

3. Click three times to add three rows in the **Schema** table.

4. In the **Column** column, enter the name of your choice for each of the new rows. For example, **fname**, **lname** and **States**.

5. In the **Functions** column, select **TalendDataGenerator.getFirstName** for the **fname** row, **TalendDataGenerator.getLastName** for the **lname** row and **TalendDataGenerator.getUsState** for the **States** row.

6. In the **Number of Rows for RowGenerator** field, enter, for example, **100** to define the number of rows to be generated.

7. Click **OK** to validate these changes.
Configuring the access to BigQuery and Cloud Storage

Building access to Cloud Storage

Procedure

1. Double-click `tBigQueryOutput` to open its Component view.

2. Click Sync columns to retrieve the schema from its preceding component.

3. In the Local filename field, enter the directory where you need to create the file to be transferred to BigQuery.

4. Navigate to the Google APIs Console in your web browser to access the Google project hosting the BigQuery and the Cloud Storage services you need to use.

5. Click Google Cloud Storage > Interoperable Access to open its view.

6. In Google storage configuration area of the Component view, paste Access key, Access secret from the Interoperable Access tab view to the corresponding fields, respectively.

7. In the Bucket field, enter the path to the bucket you want to store the transferred data in. In this example, it is `talend/documentation`

   This bucket must exist in the directory in Cloud Storage.
8. In the **File** field, enter the directory where in Google Cloud Storage you receive and create the file to be transferred to BigQuery. In this example, it is `gs://talend/documentation/bigquery_UScustomer.csv`. The file name must be the same as the one you defined in the **Local filename** field.

   Troubleshooting: if you encounter issues such as *Unable to read source URI* of the file stored in Google Cloud Storage, check whether you put the same file name in these two fields.

9. Enter 0 in the **Header** field to ignore no rows in the transferred data.

### Building access to BigQuery

#### Procedure

1. In the **Dataset** field of the **Component** view, enter the dataset you need to transfer data in. In this scenario, it is `documentation`.

   This dataset must exist in BigQuery. The following figure shows the dataset used by this scenario.

   ![API Project](image)

   - documentation
   - demo
   - myDataset
   - publicdata:samples

   ![Dataset](image)

   - documentation

2. In the **Table** field, enter the name of the table you need to write data in, for example, `UScustomer`.

3. In the **Action on data** field, select the action. In this example, select **Truncate** to empty the contents, if there are any, of target table and to repopulate it with the transferred data.

4. In the **Authentication** area, add the authentication information. In most cases, the **Service account** mode is more straight-forward and easy to handle.

<table>
<thead>
<tr>
<th>Authentication mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Service account</td>
<td>Authenticate using a Google account that is associated with your Google Cloud Platform project. When selecting this mode, the <strong>Service account credentials file</strong> field is displayed. In this field, enter the path to the credentials file created for the service account to be used. This file...</td>
</tr>
<tr>
<td>Authentication mode</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>-------------</td>
</tr>
<tr>
<td></td>
<td>must be stored in the machine in which your Talend Job is actually launched and executed.</td>
</tr>
<tr>
<td></td>
<td>For further information about how to create a Google service account and obtain the credentials file, see <a href="#">Getting Started with Authentication</a> from the Google documentation.</td>
</tr>
</tbody>
</table>

**OAuth 2.0**

Authenticate the access using OAuth credentials. When selecting this mode, the parameters to be defined in the **Basic settings** view are **Client ID**, **Client secret** and **Authorization code**.

1. Navigate to the Google APIs Console in your web browser to access the Google project hosting the BigQuery and the Cloud Storage services you need to use.
2. Click the API Access tab to open its view.
3. In the **Component** view of the Studio, paste Client ID, Client secret and Project ID from the API Access tab view to the corresponding fields, respectively.

   In the **Advanced settings** tab, see the file path in the **token properties File Name** field. The Studio automatically generates this file during the first successful login and stores all future successful logins in it.

4. In the **Run** view of the Studio, click **Run** to execute this Job. The execution will pause at a given moment to print out in the console the URL address used to get the authorization code.
5. Navigate to this address in your web browser and copy the authorization code displayed.
6. In the **Component** view of **tBigQueryOutput**, paste the authorization code in the **Authorization Code** field.

5. If you have been using the **OAuth 2.0** authentication mode, in the **Action on data** field, select the action to be performed on your data. In this example, select **Truncate** to empty the contents, if there are any, of target table and to repopulate it with the transferred data. If your are using **Service account**, ignore this step.

   If the table to be used does not exist in BigQuery, select **Create the table if it doesn’t exist**.
Executing the Job

Procedure

Press F6.

Results

Once done, the Run view is opened automatically, where you can check the execution result.

The data is transferred to Google BigQuery.
```sql
SELECT name, lname, States FROM documentation.UScustomer
```

<table>
<thead>
<tr>
<th>Row</th>
<th>name</th>
<th>lname</th>
<th>States</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Richard</td>
<td>Carter</td>
<td>Delaware</td>
</tr>
<tr>
<td>2</td>
<td>Warren</td>
<td>Truman</td>
<td>New York</td>
</tr>
<tr>
<td>3</td>

<td>Wilson</td>
<td>Maryland</td>
</tr>
<tr>
<td>4</td>
<td>Andrew</td>
<td>Coolidge</td>
<td>Alaska</td>
</tr>
<tr>
<td>5</td>
<td>Ronald</td>
<td>Washington</td>
<td>Mississippi</td>
</tr>
</tbody>
</table>
tBigQueryOutputBulk

Creates a .txt or .csv file for the data of large size so that you can process it according to your needs before transferring it to Google BigQuery.

The tBigQueryOutputBulk and tBigQueryBulkExec components are generally used together as parts of a two step process. In the first step, an output file is generated. In the second step, this file is used to feed a dataset. These two steps are fused together in the tBigQueryOutput component, detailed in a separate section. The advantage of using two separate components is that the data can be transformed before it is loaded in the dataset.

This component writes given data into a .txt or .csv file, ready to be transferred to Google BigQuery.

tBigQueryOutputBulk Standard properties

These properties are used to configure tBigQueryOutputBulk running in the Standard Job framework.

The Standard tBigQueryOutputBulk component belongs to the Big Data family.

The component in this framework is available in all Talend products.

Basic settings

| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  

• View schema: choose this option to view the schema only.  

• Change to built-in property: choose this option to change the schema to Built-in for local changes.  

• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |
|---|---|
| Property type | Built-In: You create and store the schema locally for this component only.  

Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. |
| File name | Browse, or enter the path to the .txt or .csv file you need to generate. |
Append

Select the check box to write new data at the end of the existing data. Otherwise, the existing data will be overwritten.

Advanced settings

<table>
<thead>
<tr>
<th>Field Separator</th>
<th>Enter character, string or regular expression to separate fields for the transferred data.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create directory if not exists</td>
<td>Select this check box to create the directory you defined in the File field for Google Cloud Storage, if it does not exist.</td>
</tr>
<tr>
<td>Custom the flush buffer size</td>
<td>Enter the number of rows to be processed before the memory is freed.</td>
</tr>
<tr>
<td>Check disk space</td>
<td>Select this check box to throw an exception during execution if the disk is full.</td>
</tr>
<tr>
<td>Encoding</td>
<td>Select the encoding from the list or select Custom and define it manually. This field is compulsory for database data handling. The supported encodings depend on the JVM that you are using. For more information, see <a href="https://docs.oracle.com">https://docs.oracle.com</a>.</td>
</tr>
<tr>
<td>tStatCatcher Statistics</td>
<td>Select this check box to collect the log data at the component level/</td>
</tr>
</tbody>
</table>

Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th><strong>NB_LINE</strong>: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td></td>
<td>For further information about variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This is an output component which needs the data provided by its preceding component.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>This component automatically detects and supports both multi-regional locations and regional locations. When using the regional locations, the buckets and the datasets to be used must be in the same locations.</td>
</tr>
</tbody>
</table>
Related Scenario

For related topic, see Writing data in Google BigQuery on page 365
**tBonitaDeploy**

Deploys a specific Bonita process to a Bonita Runtime.

This component configures any Bonita Runtime engine and deploys a specific Bonita process (a .bar file exported from the Bonita solution) to this engine.

**tBonitaDeploy Standard properties**

These properties are used to configure tBonitaDeploy running in the Standard Job framework.

The Standard tBonitaDeploy component belongs to the Business family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bonita version</td>
<td>Select a version number for the Bonita Runtime engine.</td>
</tr>
<tr>
<td>Bonita Runtime Environment File</td>
<td>Browse to, or enter the path to the Bonita Runtime environment file.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> This field is displayed only when you select Bonita version 5.3.1 from the Bonita version list.</td>
</tr>
<tr>
<td>Bonita Runtime Home</td>
<td>Browse to, or enter the path to the Bonita Runtime environment directory.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> This field is displayed only when you select Bonita version 5.6.1 from the Bonita version list.</td>
</tr>
<tr>
<td>Bonita Runtime Jaas File</td>
<td>Browse to, or enter the path to the Bonita Runtime jaas file.</td>
</tr>
<tr>
<td>Business Archive</td>
<td>Browse to, or enter the path to the Bonita process .bar file you want to use.</td>
</tr>
<tr>
<td>User name</td>
<td>Type in your user name used to log in Bonita studio.</td>
</tr>
<tr>
<td>Password</td>
<td>Type in your password used to log in Bonita studio.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
</tbody>
</table>
Die on error

This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

Advanced settings

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

Global Variables

**Global Variables**

**ProcessDefinitionUUID**: the identifier number of the process being deployed. This is a Flow variable and it returns a string.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

Usage

**Usage rule**

Usually used as a stand-alone component.

To use this component, you have to manually download the Bonita solution you need to use.

**Connections**

Outgoing links (from this component to another):

**Trigger**: Run if; On Component Ok; On Component Error, On Subjob Ok, On Subjob Error.

Incoming links (from one component to this one):

**Trigger**: Run if, On Component Ok, On Component Error, On Subjob Ok, On Subjob Error

For further information regarding connections, see *Connection types in Talend Studio User Guide*.

**Limitation**

The Bonita Runtime environment file, the Bonita Runtime jaas file and the Bonita Runtime logging file must be all stored on the execution server of the Job using this component.

Related Scenario

For related topic, see *Executing a Bonita process via a Talend Job* on page 380.
### tBonitaInstantiateProcess

Starts an instance for a specific process deployed in a Bonita Runtime engine.
This component instantiates a process already deployed in a Bonita Runtime engine.

### tBonitaInstantiateProcess Standard properties

These properties are used to configure tBonitaInstantiateProcess running in the Standard Job framework.

The Standard tBonitaInstantiateProcess component belongs to the Business family.

The component in this framework is available in all Talend products.

#### Basic settings

| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

The schema of this component is read-only. You can click **Edit schema** to view the schema.

In this component the schema is related to the Module selected.

**Note:**
The `ProcessInstanceUUID` column is pre-defined in the schema of this component, reserved for the identifier number of the process instance being created. |
| **Bonita Client Mode** | Select the client mode you want to use to instantiate a Bonita process.

For more information about all the Bonita client modes, see Bonita’s manuals. |
| **URL** | Enter the URL of the Bonita Web application server you need to access for the process instantiation.

This field is available only in the HTTP client mode. |
| **Auth Username** and **Auth Password** | Enter the authentication details used to connect to the Bonita Web application server as technical user.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

The default authentication information is provided in these fields. For further information about them, see Bonita’s manuals.

These fields are available only in the HTTP client mode. |
<p>| <strong>Bonita version</strong> | Select the version number of the Bonita Runtime engine to be used. |</p>
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Notes</th>
<th>Java client mode</th>

<td>Browse to, or enter the path to the Bonita Runtime logging file. This field is available only in the Java client mode.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Use Process ID</td>
<td>Select this check box to instantiate an existing process. Once checked, the Process definition ID field is activated in which you can enter the Definition ID of this process. This field is available only in the Java client mode.</td>
<td>Note: The process definition ID is created when the process is deployed into the Bonita Runtime engine.</td>
<td></td>
</tr>
<tr>
<td>Process Name and Process Version</td>
<td>Enter the ID information of a specific process you want to instantiate. This information is used to automatically generate the ID of this process. This field is available in both of the Java client mode and the HTTP client mode.</td>
<td></td>
<td>Both modes</td>
</tr>
<tr>
<td>User name</td>
<td>Type in your user name used to instantiate this process. This field is available in both of the Java client mode and the HTTP client mode.</td>
<td></td>
<td>Both modes</td>
</tr>
<tr>
<td>Password</td>
<td>Type in your password used to instantiate this process. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. This field is available only in the Java client mode.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Die on error</td>
<td>This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### Advanced settings

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

### Global Variables

| Global Variables | ProcessInstanceUUID: the identifier number of the process instance being created. This is a Flow variable and it returns a string. It can also be retrieved over the Row > Main output link.  
ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.  
For further information about variables, see Talend Studio User Guide. |

### Usage

| Usage rule | Usually used as a stand-alone component or as an output component.  
To use this component, you have to manually download the Bonita solution you need to use. |

### Connections

| Connections | Outgoing links (from this component to another):  
Row: Main (providing the output parameters from this process)  
Incoming links (from one component to this one):  
Row: Main (providing the input parameters to this process)  
For further information regarding connections, see Connection types in Talend Studio User Guide. |

### Limitation

| Limitation | The Bonita Runtime environment file, the Bonita Runtime jaas file and the Bonita Runtime logging file must be all stored on the execution server of the Job using this component. |
Executing a Bonita process via a Talend Job

This scenario describes a Job that deploys a Bonita process into the Bonita Runtime and executes this process, in which a personnel request is treated.

The Job in this scenario uses three components.

- **tBonitaDeploy**: this component deploys a Bonita process into the Bonita Runtime.
- **tFixedFlowInput**: this component generates the schema used as execution parameters of this deployed process.
- **tBonitaInstantiateProcess**: this component executes this deployed process.

Before beginning to replicate this schema, prepare your Bonita.bar file. You need to manually export this file from the Bonita system and then deploy it into the Bonita Runtime engine, using, for example, **tBonitaDeploy** as presented later in this scenario. In this scenario, this file is *TEST--4.0.bar*. Once deployed, this process can be checked via the Bonita interface.

Setting up the Job

**Procedure**

1. Drop **tBonitaDeploy**, **tFixedFlowInput** and **tBonitaInstantiateProcess** onto the design workspace.
2. Right-click **tBonitaDeploy** and connect **tBonitaDeploy** to **tFixedFlowInput** using a Trigger> On Subjob Ok connection.
3. Right-click **tFixedFlowInput** and connect this component to **tBonitaInstantiateProcess** using a Row > Main connection.
Configuring the deployment of the process

About this task

To replicate this scenario, proceed as follows:

Procedure

1. Double-click tBonitaDeploy to open its Basic settings view.

2. Select Bonita version 5.3.1 from the Bonita version list. The version you select should be in sync with the version number of the Bonita Runtime engine you are using.

3. In the Bonita Runtime Configuration area, browse to the Bonita Runtime variable files. In the Bonita Runtime Environment File field, browse to the bonita-environnement.xml file; in the Bonita Runtime Jaas File field, browse to the jaas-standard.cfg file; in the Bonita Runtime Logging File field, browse to the logging.properties file.

   For users based on Bonita version 5.2.3, only the Bonita Runtime Jaas File field and the Bonita Runtime Logging File field need to be filled.

   For users based on Bonita version 5.6.1, in the Bonita Runtime Home field, browse to the Bonita Runtime environment directory.
4. In the **Business Archive** field, browse to the Bonita .bar file that is the process exported from your Bonita system and will be deployed into the Bonita Runtime engine.

5. In the **Username** and the **Password** fields, type in your authentication information to connect to your Bonita.

**Configuring the input flow**

**Procedure**

1. Double-click **tFixedFlowInput** to open its **Basic settings** view.

2. Click the three-dot button next to **Edit schema** to open the schema editor.
3. Click the plus button to add one row and rename it as *Name*. This name is identical with the parameter set in Bonita to execute the same process. This way, Bonita can recognize this column as valid parameter and read its value to instantiate this process.

4. Click *OK*.

5. In the **Mode** area of the **Basic settings** view, select the **Use inline table** option and click the plus button to add one row in the table.

6. In the inline table, click the added row and type in the person’s name from your personnel between the quotation marks: *ychen*, whose request will be treated by this deployed process.

**Configuring the Basic settings of tBonitalnstantiateProcess**

**Procedure**

1. Double-click **tBonitalnstantiateProcess** to open its **Basic settings** view.

2. Select Bonita version 5.3.1 from the **Bonita version** list. The version you select should be in sync with the version number of the Bonita Runtime engine you are using.

3. In the **Bonita Runtime Configuration** area, browse to the Bonita Runtime variable files. In the **Bonita Runtime Environment File** field, browse to the *bonita-environnement.xml* file; in the **Bonita Runtime Jaas File** field, browse to the *jaas-standard.cfg* file; in the **Bonita Runtime Logging File** field, browse to the *logging.properties* file.

   For users based on Bonita version 5.2.3, only the **Bonita Runtime Jaas File** field and the **Bonita Runtime Logging File** field need to be filled.
For users based on Bonita version 5.6.1, in the **Bonita Runtime Home** field, browse to the Bonita Runtime environment directory.

4. Select the **Use Process ID** check box to activate the **Process Definition Id** field.

5. In the **Process Definition Id** field, click between the quotation marks and press **Ctrl+space** to open the auto-completion drop-down list containing the available global variables for this Job.

6. Double-click the variable you need use to add it between the quotation marks. In this scenario, double-click `tBonitaDeploy_1_ProcessDefinitionUUID`, which retrieves the process definition ID of the process being deployed by `tBonitaDeploy`.

**Note:**

You can as well clear the **Use Process ID** check box to activate the **Process name** and the **Process version** fields and enter the corresponding information in the two fields. `tBonitaInstantiateProcess` concatenates the process name and the process version you type in to construct the process definition ID.

7. In the **Username** and **Password** fields, enter the username and password to connect to your Bonita.
Executing the Job

Procedure

Press **F6** to run the Job.

Results

This process is deployed into the Bonita Runtime and an instance is created for the personnel requests.

Outputting the process instance UUID over the Row > Main link

This scenario deploys a Bonita process into the Bonita Runtime, starts an instance and outputs the process instance UUID via the *Row > Main* link.

Linking the components

Procedure

1. Drop `tBonitaDeploy`, `tBonitaInstantiateProcess` and `tLogRow` onto the workspace.
2. Rename `tBonitaDeploy` as `deploy_process`, `tBonitaInstantiateProcess` as `start_instance` and `tLogRow` as `show_instance_uuid`.
3. Link `tBonitaDeploy` to `tBonitaInstantiateProcess` using the `OnSubjobOk` trigger.
4. Link `tBonitaInstantiateProcess` to `tLogRow` using a *Row > Main* connection.
Configuring the components

Procedure

1. Double-click **tBonitaDeploy** to open its **Basic settings** view.

2. In the **Bonita Runtime Jaas File** field, specify the path and name of the jaas file.
   In the **Bonita Runtime Logging File** field, specify the path and name of the logging file.
   In the **Business Archive** field, specify the path and name of the Bonita process.

3. In the **Username** and **Password** fields, enter the user authentication credentials.

4. Double-click **tBonitalnstantiateProcess** to open its **Basic settings** view.

5. In the **Bonita Runtime Jaas File** field, specify the path and name of the jaas file.
   In the **Bonita Runtime Logging File** field, specify the path and name of the logging file.

6. In the **Process Name** and **Process Version** fields, enter the process information.

7. In the **Username** and **Password** fields, enter the user authentication credentials.

8. Double-click **tLogRow** to open its **Basic settings** view.

9. In the **Mode** area, select **Table (print values in cells of a table)** for better display.
Executing the Job

Procedure

1. Press Ctrl+S to save the Job.
2. Press F6 to run the Job.

```plaintext
**** Instance Bonita_V523_Process--1.0--6 created ****
<table>
<thead>
<tr>
<th>show_instance_uuid</th>
<th>ProcessInstanceUUID</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bonita_V523_Process--1.0--6</td>
<td></td>
</tr>
</tbody>
</table>

[statistics] disconnected

As shown above, the instance is created and the UUID is output.
tBoxConnection

Creates a Box connection that the other Box components can reuse.
This component creates the connection to a given Box account.

**tBoxConnection Standard properties**

These properties are used to configure tBoxConnection running in the Standard Job framework.
The Standard tBoxConnection component belongs to the Cloud family.
The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Client Key</td>
<td>Enter the client key required by Box to access the Box API. To obtain the client key and client secret you need to create an account at <a href="https://developers.box.com/">https://developers.box.com/</a> and then create a Box App under the Box account to be used. The client key and client secret can be obtained from the account application settings.</td>
</tr>
<tr>
<td>Client Secret</td>
<td>Enter the client secret required by Box to access the Box API. To obtain the client key and client secret you need to create an account at <a href="https://developers.box.com/">https://developers.box.com/</a> and then create a Box App under the Box account to be used. The client key and client secret can be obtained from the account application settings.</td>
</tr>
<tr>
<td>Access token</td>
<td>Enter the access token required by Box to access a Box account and operate it. For how to get the access token and refresh token, check the Box documentation you can access from <a href="https://developers.box.com/">https://developers.box.com/</a>.</td>
</tr>
<tr>
<td>Refresh Token</td>
<td>Enter the refresh token required by Box to refresh the access token automatically. For how to get the access token and refresh token, check the Box documentation you can access from <a href="https://developers.box.com/">https://developers.box.com/</a>.</td>

<th>Usage rule</th>
</tr>
</thead>
<tbody>
<tr>
<td>This component is used standalone as a subJob to create the Box connection to be used. In a Job design, it is often connected to the other Box components using the Trigger links such as OnSubjobOk link.</td>
</tr>
</tbody>
</table>

### Related scenario

For a related scenario, see Uploading and downloading files from Box on page 401.
**tBoxCopy**

Copies or moves a given folder or file from Box.

**tBoxCopy Standard properties**

These properties are used to configure tBoxCopy running in the Standard Job framework.

The Standard tBoxCopy component belongs to the Cloud family.

The component in this framework is available in all Talend products.

### Basic settings

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Use existing connection</strong></td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td><strong>Connection/Client Key</strong></td>
<td>Enter the client key required by Box to access the Box API. To obtain the client key and client secret you need to create an account at <a href="https://developers.box.com/">https://developers.box.com/</a> and then create a Box App under the Box account to be used. The client key and client secret can be obtained from the account application settings.</td>
</tr>
<tr>
<td><strong>Connection/Client Secret</strong></td>
<td>Enter the client secret required by Box to access the Box API. To obtain the client key and client secret you need to create an account at <a href="https://developers.box.com/">https://developers.box.com/</a> and then create a Box App under the Box account to be used. The client key and client secret can be obtained from the account application settings.</td>
</tr>
<tr>
<td><strong>Connection/Access Token</strong></td>
<td>Enter the access token required by Box to access a Box account and operate it. For how to get the access token and refresh token, check the Box documentation you can access from <a href="https://developers.box.com/">https://developers.box.com/</a>.</td>
</tr>
<tr>
<td><strong>Connection/Refresh Token</strong></td>
<td>Enter the refresh token required by Box to refresh the access token automatically. For how to get the access token and refresh token, check the Box documentation you can access from <a href="https://developers.box.com/">https://developers.box.com/</a>.</td>
</tr>
<tr>
<td><strong>Connection/Use HTTP proxy</strong></td>
<td>If you are using a proxy, select this check box and enter the host and port information of that proxy in the corresponding fields that are displayed.</td>
</tr>
<tr>
<td><strong>Move Directory</strong></td>
<td>Select this check box to move a directory in Box.</td>
</tr>
<tr>
<td><strong>Copy Directory</strong></td>
<td>Select this check box to copy a directory in Box.</td>
</tr>
<tr>
<td><strong>File Name</strong></td>
<td>Enter file name with the path in Box you want to copy.</td>
</tr>
<tr>
<td><strong>Source Directory</strong></td>
<td>This option appears when the Move Directory or Copy Directory check box is selected. Enter the source directory in Box to be moved or copied.</td>
</tr>
</tbody>
</table>
**Destination Directory**
Enter the destination directory in Box where the specified file or directory will be copied or moved.

**Rename**
Select this check box to rename the file or directory to be copied. When copying a file, specify the new file name in the **Destination File Name** field. When copying a directory, enter the new directory name in the **New Directory Name** field.

**Remove Source File**
Select this check box to remove the source file during the copy action.

**Schema and Edit schema**
A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

Note that the schema of this component is read-only with four columns named `destinationFilePath`, `destinationFileName`, `sourceDirectory`, and `destinationDirectory`.

### Advanced settings

**tStatCatcher Statistics**
Select this check box to collect log data at the component level.

### Global Variables

**Global Variables**
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.
- **DESTINATION_FILENAME**: the destination file name. This is an After variable and it returns a string.
- **DESTINATION_FILEPATH**: the destination file path. This is an After variable and it returns a string.
- **SOURCE_DIRECTORY**: the source directory. This is an After variable and it returns a string.
- **DESTINATION_DIRECTORY**: the destination directory. This is an After variable and it returns a string.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

### Usage

**Usage rule**
This component is usually used standalone in a sublob to copy or move data from Box.
Related scenarios

No scenario is available for the Standard version of this component yet.
tBoxDelete

Removes a given folder or file from Box.

This component connects to a given Box account and removes a specified file or folder.

**tBoxDelete Standard properties**

These properties are used to configure tBoxDelete running in the Standard Job framework.

The Standard tBoxDelete component belongs to the Cloud family.

The component in this framework is available in all Talend products.

</table>
component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

Note that the schema of this component is read-only with two columns named `fileName` and `content`.

The `Schema` field is not available when you have selected the `Save as file` check box.

### Advanced settings

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

### Global Variables

| Global Variables | `ERROR_MESSAGE`: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the `Die on error` check box is cleared, if the component has this check box.  
`FILE_NAME`: the name of the file being processed. This is a Flow variable and it returns a string.  
`INPUT_STREAM`: the content of the file being fetched. This is a Flow variable and it returns an InputStream.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press `Ctrl + Space` to access the variable list and choose the variable to use from it.  
For further information about variables, see [Talend Studio User Guide](#). |

### Usage

| Usage rule | This component can be used alone or along with other components via the `Iterate` link or a trigger link such as `OnSubjobOk`. |

### Related scenario

For a related scenario, see [Uploading and downloading files from Box](#) on page 401.
tBoxList

Lists the files stored in a specified directory in Box.

This component reads the file(s) in Box held in the directory you specify and lists the metadata and the contents of that file or those files.

**tBoxList Standard properties**

These properties are used to configure tBoxList running in the Standard Job framework.

The Standard tBoxList component belongs to the Cloud family.

The component in this framework is available in all Talend products.

</tr>
</tbody>
</table>
component. When you create a Spark Job, avoid the reserved word line when naming the fields.

Note that the schema of this component is read-only with six columns named name, path, lastModified, size, id, and type.

Advanced settings

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. |
| | NAME: the name of the remote file being processed. This is a Flow variable and it returns a string. |
| | FILE_PATH: the path pointing to the folder or the file being processed on Box. This is a Flow variable and it returns a string. |
| | FILE_DIRECTORY: the directory of the folder or the file being processed on Box. This is a Flow variable and it returns a string. |
| | LAST_MODIFIED: the timestamp of the last modification of the file being processed. This is a Flow variable and it returns a long. |
| | SIZE: the volume of the file being processed. This is a Flow variable and it returns a long. |
| | ID: the ID of the folder or the file being processed on Box. This is a Flow variable and it returns a string. |
| | TYPE: the type of the objects being processed on Box, file or folder. This is a Flow variable and it returns a string. |
| | A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. |
| | To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. |
| | For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | This component is typically used standalone. |

Related scenarios

No scenario is available for the Standard version of this component yet.
tBoxPut

Uploads files to a Box account.

This component uploads data to Box from either a local file or a given data flow.

**tBoxPut Standard properties**

These properties are used to configure tBoxPut running in the Standard Job framework.

The Standard tBoxPut component belongs to the Cloud family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Setting</th>

<tr>
<td>Replace if Existing</td>
<td>Select this check box to use the uploaded file to replace the existing one.</td>
</tr>
<tr>
<td>Upload mode</td>
<td>Select the upload mode to be used:</td>
</tr>
</tbody>
</table>
- **Upload incoming content as file**: Select this radio button to read data directly from the input flow of the preceding component and write the data into the file specified in the Remote Path field.
- **Upload local file**: Select this radio button to upload a locally stored file to Box. In the File field that is displayed, you need to enter the path or browse to this file.
- **Expose as OutputStream**: Select this check box to expose the output stream of this component, which can be used by the other components to write the file content. For example, you can use the Use output stream feature of the tFileOutputDelimited component to feed a given tBoxPut’s exposed output stream. For further information, see tFileOutputDelimited on page 1106.

### Schema and Edit schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

Note that the schema of this component is read-only with a single column named content and it receives data from the content column of its input schema only. This means that you must use a content column in the input data flow to carry the data to be uploaded. This type of column is typically provided by the tFileInputRaw component. For further information, see tFileInputRaw on page 1078.

The Schema field is not available when you have selected the Expose as OutputStream or the Upload local file upload mode.

### Advanced settings

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

### Global Variables

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |
Usage

| Usage rule | This component is used either standalone in a subJob to directly upload a local file to Box or as an end component of a Job flow to upload given data being handled in this flow. |

Uploading and downloading files from Box

In this scenario, a three-component Job consisting of three subJobs is created to upload a file to Box and then download a file from Box to the local file system.

Before replicating this scenario, you need to create an account at https://developers.box.com/ and then create a Box App under the Box account to be used. For more information about Box App, see https://app.box.com/developers/services/edit/. The client key and client secret can be obtained from the account application settings. For how to get the access token and refresh token, check the Box documentation you can access from https://developers.box.com/.

Linking the components

Procedure

1. In the Integration perspective of the Studio, create an empty Job from the Job Designs node in the Repository tree view.
   For further information about how to create a Job, see Talend Studio User Guide.
2. In the workspace, enter the name of the component to be used and select this component from the list that opens. In this scenario, the components are tBoxConnection, tBoxPut and tBoxGet.
3. Connect tBoxConnection to tBoxPut using the Trigger > OnSubjobOk link.
4. Connect tBoxPut to tBoxGet using the Trigger > OnSubjobOk link.

Configuring the components

Procedure

1. Double-click tBoxConnection to open its Component view.
2. Enter the client key, client secret, access token and refresh token in double quotation marks in the relevant fields for accessing the Box account.

3. Double-click tBoxPut to open its Component view.

4. Select the Use Existing Connection check box to reuse the connection created by tBoxConnection. In the Remote Path field, enter the destination path where you want to upload the file. In the Upload mode area, select Upload Local File. In the File field, enter the file path or browse to the file you want to upload.

5. Double-click tBoxGet to open its Component view.

6. Select the Use Existing Connection check box to reuse the connection created by tBoxConnection. In the Path field, enter the path of the file that you want to download. Select the Save As File check box. In the Save To field, enter the file path where to save the file on the local file system.

7. Save the Job.

**Executing the Job**

Execute the Job by pressing F6 or clicking the Run button on the Run tab. The local file, hello.txt in this example, is uploaded in your Box.
The file *box.txt* from Box is downloaded to the local file system.
**tBufferInput**

Retrieves data bufferized via a tBufferOutput component, for example, to process it in another subJob.

This component retrieves bufferized data in order to process it in a second subJob.

**tBufferInput Standard properties**

These properties are used to configure tBufferInput running in the Standard Job framework.

The Standard tBufferInput component belongs to the Misc family.

The component in this framework is available in all Talend products.

**Basic settings**

| Schema and Edit Schema | A schema is a row description, it defines the number of fields that will be processed and passed on to the next component. The schema is either built-in or remote in the Repository. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
|---|---|
|  • View schema: choose this option to view the schema only.  
|  • Change to built-in property: choose this option to change the schema to Built-in for local changes.  
|  • Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.  |
| Built-in: You create the schema and store it locally for this component only. Related topic: see Talend Studio User Guide. |  |
| Repository: You have already created the schema and stored it in the Repository, hence can be reused in various projects and Job designs. Related topic: see Talend Studio User Guide. |

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_LINE: the number of rows processed. This is an After variable and it returns an integer. ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the</th>
</tr>
</thead>
</table>
Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule

This component is the start component of a secondary Job which is triggered automatically at the end of the main Job.

Retrieving bufferized data

This scenario describes a Job that retrieves bufferized data from a subJob and displays it on the console.

- Drop the following components from the Palette onto the design workspace: tFileInputDelimited and tBufferOutput.
- Select the tFileInputDelimited and on the Basic Settings tab of the Component view, set the access parameters to the input file.

  - In the File Name field, browse to the delimited file holding the data to be bufferized.
  - Define the Row and Field separators, as well as the Header.

  - In the File Name field, browse to the delimited file holding the data to be bufferized.
  - Define the Row and Field separators, as well as the Header.
• Click [...] next to the **Edit schema** field to describe the structure of the file.

<table>

</tbody>
</table>

• Describe the **Schema** of the data to be passed on to the **tBufferOutput** component.

• Select the **tBufferOutput** component and set the parameters on the **Basic Settings** tab of the **Component** view.

**Note:**
Generally speaking, the schema is propagated from the input component and automatically fed into the **tBufferOutput** schema. But you can also set part of the schema to be bufferized if you want to.

• Drop the **tBufferInput** and **tLogRow** components from the **Palette** onto the design workspace below the subjob you just created.

• Connect **tFileInputDelimited** and **tBufferInput** via a **Trigger > OnSubjobOk** link and connect **tBufferInput** and **tLogRow** via a **Row > Main** link.

• Double-click **tBufferInput** to set its **Basic settings** in the **Component** view.

• In the **Basic settings** view, click [...] next to the **Edit Schema** field to describe the structure of the file.

• Use the schema defined for the **tFileInputDelimited** component and click **OK**.

• The schema of the **tBufferInput** component is automatically propagated to the **tLogRow**. Otherwise, double-click **tLogRow** to display the **Component** view and click **Sync column**.

• Save your Job and press **F6** to execute it.

The standard console returns the data retrieved from the buffer memory.
tBufferOutput

Collects data in a buffer in order to access it later via webservice for example.

tBufferOutput has been designed to be exported as Webservice in order to access data on the web application server directly. For more information, see Talend Studio User Guide.

tBufferOutput Standard properties

These properties are used to configure tBufferOutput running in the Standard Job framework.

The Standard tBufferOutput component belongs to the Misc family.

The component in this framework is available in all Talend products.

</table>

Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

| Usage rule | This component is not startable (green background) and it requires an output component. |

Buffering data

This scenario describes an intentionally basic Job that bufferizes data in a child job while a parent Job simply displays the bufferized data onto the standard output console. For an example of how to use tBufferOutput to access output data directly on the Web application server, see Buffering output data on the webapp server on page 411.

- Create two Jobs: a first Job (BufferFatherJob) runs the second Job and displays its content onto the Run console. The second Job (BufferChildJob) stores the defined data into a buffer memory.
- On the first Job, drop the following components: tRunJob and tLogRow from the Palette to the design workspace.
- On the second Job, drop the following components: tFileInputDelimited and tBufferOutput the same way.

Let's set the parameters of the second Job first:

- Select the tFileInputDelimited and on the Basic Settings tab of the Component view, set the access parameters to the input file.
In **File Name**, browse to the delimited file whose data are to be bufferized.

- Define the **Row** and **Field separators**, as well as the **Header**.

- **tFileInputDelimited**

<table>
<thead>
<tr>
<th>Column</th>
<th>Key</th>
<th>Type</th>
<th>Nullable</th>
<th>Data Format</th>
<th>Length</th>

</tr>
</tbody>
</table>

- Describe the **Schema** of the data to be passed on to the **tBufferOutput** component.
- Select the **tBufferOutput** component and set the parameters on the **Basic Settings** tab of the **Component** view.

- Generally the schema is propagated from the input component and automatically fed into the **tBufferOutput** schema. But you could also set part of the schema to be bufferized if you want to.
- Now on the other Job (**BufferFatherJob**) Design, define the parameters of the **tRunJob** component.

- **tFileInputDelimited**

- **tBufferOutput**

- **tRunJob**

- Edit the Schema if relevant and select the column to be displayed. The schema can be identical to the bufferized schema or different.
- You could also define context parameters to be used for this particular execution. To keep it simple, the default context with no particular setting is used for this use case.

Press **F6** to execute the parent Job. The **tRunJob** looks after executing the child Job and returns the data onto the standard console:
Buffering data to be used as a source system

This scenario describes a Job that buffers data to be used as a source system by MDM.

An MDM process will invoke this Job to retrieve data by looking up the defined elements (agent region values) from the buffered data. The process can then display the retrieved data in the Talend MDM Web User Interface without really saving them in the MDM hub.

Creating a data buffer Job

Procedure

1. Create a Job named DetermineRegion.
2. Drop the following components from the Palette onto the design workspace: tJava, tFixedFlowInput, and tBufferOutput.
3. Connect tJava to tFixedFlowInput using a Trigger > On Component Ok link.
4. Connect tFixedFlowInput to tBufferOutput using a Row > Main link.

Configuring the Job to buffer data

Procedure

1. In the Contexts view, add a new context variable with the Name of xmlInput and the Type of String.

   In this example, the context variable xmlInput of the Job will be specified in the MDM process which wants to invoke this Job.

   You can search for further information about MDM processes on Talend Help Center (https://help.talend.com).
If you cannot find the **Contexts** view, go to **Window > Show view > Talend**, and select **Contexts**.

For more information about how to define context variables, see Talend Studio User Guide.

You can search for further information about how to define context variables on Talend Help Center (https://help.talend.com).

2. Double-click the **tJava** component to open its **Component** view, and in the **Code** area, enter the code according to your needs.

   In this example, enter `System.out.println("#######################
   "+context.xmlInput);`.

3. Double-click the **tFixedFlowInput** component to open its **Component** view.

4. Click the [...] button next to **Edit schema** to open the dialog box and define the schema for the data to be used by the source system.

   In this example, add one new column `col0` of the type **String**.

5. After the schema is defined, click **Yes** in the **Propagate** dialog box to propagate the schema changes to the following component **tBufferOutput**.

6. In the **Number of rows** field, enter 1.

7. In the **Mode** area, select **Use Single Table** and enter "Paris" in the **Value** column that corresponds to the column `col0` you have defined.

   In this example, the value of the `col0` provides the agent region information to be retrieved by MDM.

8. Double-click the **tBufferOutput** component to open its **Component** view, and then make sure its schema is synchronized with the previous component **tFixedFlowInput**.

9. Run the Job and make sure the execution succeeds.

## Buffering output data on the webapp server

This scenario describes a Job that is called as a Webservice and stores the output data in a buffer directly on the server of the Web application. This scenario creates first a Webservice oriented Job with context variables, and next exports the Job as a Webservice.

### Creating a Job

**Procedure**

1. Drop the following components from the **Palette** onto the design workspace: **tFixedFlowInput** and **tBufferOutput**.

2. Connect **tFixedFlowInput** to **tBufferOutput** using a **Row Main** link.
Creating a context variable

About this task

For this scenario, you will define two context variables: `nb_lines` and `lastname`. The first variable will set the number of lines the `tFixedFlowInput` component will generate, and the second one will set the last name to display in the output list. For more information about how to create and use context variables, see *Talend Studio User Guide*.

To define the two context variables:

Procedure

1. Select the **Contexts** tab view of your Job, and click the `[+]` button at the bottom of the view to add two variables, respectively `nb_lines` of type **Integer** and `lastname` of type **String**.

2. In the **Value** field for the variables, set the last name to be displayed and the number of lines to be generated, respectively *Ford* and *3* in this example.

![context_variables.png](image)

Configuring the input data

Procedure

1. In the design workspace, select **tFixedFlowInput**.

2. Click the **Component** tab to define the basic settings for **tFixedFlowInput**.

3. Click the three-dot `[...]` button next to **Edit Schema** to describe the data structure you want to create from internal variables. In this scenario, the schema is made of three columns, `now` of type **Date**, `firstname` of type **String**, and `lastname` of type **String**.

![schema.png](image)
4. Click OK to close the dialog box and accept propagating the changes when prompted by the system. The three defined columns display in the Values panel of the Basic settings view of tFixedFlowInput.

<table>
<thead>
<tr>
<th>Basic settings</th>
<th>Advanced settings</th>
<th>Dynamics settings</th>
<th>View</th>
<th>Documentation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Schema Type</td>
<td>Number of rows</td>
<td>Values</td>
<td></td>
<td></td>
</tr>
<tr>
<td>tFixedFlowInput_1</td>
<td>context_nb_lines</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Column</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>now</td>
<td>TalendDate.getCurrentDate()</td>
</tr>
<tr>
<td>firstname</td>
<td>talendDatagenerator.getFirstName()</td>
</tr>
<tr>
<td>lastname</td>
<td>context.lastname</td>
</tr>
</tbody>
</table>

5. Click in the Value cell of each of the first two defined columns and press Ctrl+Space to access the global variable list.

6. From the global variable list, select Talend Date.getCurrentDate() and talendDatagenerator.getFirst Name, for the now and firstname columns respectively.

7. Click in the Value cell of lastname column and press Ctrl+Space to access the global variable list.

8. From the global variable list, select context.lastname, the context variable you created for the last name column.

Building your Job as a Webservice

About this task
Before building your Job as a Web service, see Talend Studio User Guide for more information.

Procedure
1. In the Repository tree view, right-click on the above created Job and select Build Job. The Build Job dialog box appears.
2. Click the Browse... button to select a directory to archive your Job in.

3. In the Build type panel, select the build type you want to use in the Tomcat webapp directory (WAR in this example) and click Finish. The Build Job dialog box disappears.

4. Copy the War folder and paste it in a Tomcat webapp directory.

**Calling a Job with context variables from a browser**

This scenario describes how to call the Job you created in Buffering output data on the webapp server on page 411 from your browser with/without modifying the values of the context variables.

Type the following URL into your browser: `http://localhost:8080/export_job/services/export_job3?method=runJob` where “export_job” is the name of the webapp directory deployed in Tomcat and “export_job3” is the name of the Job.

Click Enter to execute your Job from your browser.
The Job uses the default values of the context variables: nb_lines and lastname, that is it generates three lines with the current date, first name and Ford as a last name.

You can modify the values of the context variables directly from your browser. To call the Job from your browser and modify the values of the two context variables, type the following URL:

%20 stands for a blank space in the URL language. In the first argument "arg1", you set the value of the context variable to display "MASSY" as last name. In the second argument "arg2", you set the value of the context variable to "2" to generate only two lines.

Click Enter to execute your Job from your browser.
The Job generates two lines with MASSY as last name.

**Calling a Job exported as Webservice in another Job**

This scenario describes a Job that calls another Job exported as a Webservice using the tWebServiceInput. This scenario will call the Job created in Buffering output data on the webapp server on page 411.

- Drop the following components from the Palette onto the design workspace: tWebServiceInput and tLogRow.
- Connect tWebServiceInput to tLogRow using a Row Main link.
- In the design workspace, select tWebServiceInput.
- Click the Component tab to define the basic settings for tWebServiceInput.
- Set the Schema Type to Built-In and click the three-dot [...] button next to Edit Schema to describe the data structure you want to call from the exported Job. In this scenario, the schema is made of three columns, now, firstname, and lastname.
• Click the plus button to add the three parameter lines and define your variables. Click OK to close the dialog box.

• In the WSDL field of the Basic settings view of tWebServiceInput, enter the URL http://localhost:8080/export_job/services/export_job3?WSDL where "export_job" is the name of the webapp directory where the Job to call is stored and "export_job3" is the name of the Job itself.

• In the Method name field, enter runJob.

• In the Parameters panel, Click the plus button to add two parameter lines to define your context variables.

• Click in the first Value cell to enter the parameter to set the number of generated lines using the following syntax: --context_param nb_line=3.

• Click in the second Value cell to enter the parameter to set the last name to display using the following syntax: --context_param lastname=Ford.

• Select tLogRow and click the Component tab to display the component view.

• Set the Basic settings for the tLogRow component to display the output data in a tabular mode. For more information, see tLogRow on page 1956.

• Save your Job and press F6 to execute it.
The system generates three columns with the current date, first name, and last name and displays them onto the log console in a tabular mode.

Starting job Call_Webservice_In_Job at 14:12 01/08/2008

</table>

Job Call_Webservice_In_Job ended at 14:12 01/08/2008. [exit code=0]
**tCassandraBulkExec**

Improves performance during Insert operations to a Cassandra column family.

The tCassandraOutputBulk and tCassandraBulkExec components are generally used together as parts of a two step process. In the first step, an SSTable is generated. In the second step, this SSTable is written into Cassandra. These two steps are fused together in the tCassandraOutputBulkExec component, detailed in a separate section. The advantage of using two separate components is that the data can be transformed before it is loaded into Cassandra.

tCassandraBulkExec writes data from an SSTable into Cassandra.

**tCassandraBulkExec Standard properties**

These properties are used to configure tCassandraBulkExec running in the Standard Job framework.

The Standard tCassandraBulkExec component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all [Talend products with Big Data](https://www.talend.com/products/big-data/) and in [Talend Data Fabric](https://www.talend.com/products/data-fabric/).

**Basic settings**

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global Variables**

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

**Usage**

| Usage rule | This component can be used as a standalone component. |
| Limitation | Currently, the execution of this component ends the entire Job. |

**Related scenarios**

No scenario is available for the Standard version of this component yet.
tCassandraClose

Disconnects a connection to a Cassandra server so as to release occupied resources.

**tCassandraClose Standard properties**

These properties are used to configure tCassandraClose running in the Standard Job framework.

The Standard tCassandraClose component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| Component List | Select an active Cassandra connection to be closed. |

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global Variables**

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

**Usage**

| Usage rule | This component is generally used with other Cassandra components, particularly tCassandraConnection. |

**Related Scenario**

For a scenario in which tCassandraClose is used, see Handling data with Cassandra on page 429.
tCassandraConnection

Enables the reuse of the connection it creates to a Cassandra server.
tCassandraConnection opens a connection to a Cassandra server.

**tCassandraConnection Standard properties**

These properties are used to configure tCassandraConnection running in the Standard Job framework. The Standard tCassandraConnection component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

<td>Type in the number of columns to be read between the start column and the end column.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global Variables**

| Global Variables | NB_LINE: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.  
ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.  
For further information about variables, see Talend Studio User Guide. |

Handling data with Cassandra

This scenario applies only to Talend products with Big Data.

This scenario describes a simple Job that reads the employee data from a CSV file, writes the data to a Cassandra keyspace, then extracts the personal information of some employees and displays the information on the console.

This scenario requires six components, which are:

- **tCassandraConnection**: opens a connection to the Cassandra server.
- **tFileInputDelimited**: reads the input file, defines the data structure and sends it to the next component.
- **tCassandraOutput**: writes the data it receives from the preceding component into a Cassandra keyspace.
- **tCassandraInput**: reads the data from the Cassandra keyspace.
- **tLogRow**: displays the data it receives from the preceding component on the console.
- **tCassandraClose**: closes the connection to the Cassandra server.
Dropping and linking the components

Procedure

1. Drop the following components from the Palette onto the design workspace: `tCassandraConnection`, `tFileInputDelimited`, `tCassandraOutput`, `tCassandraInput`, `tLogRow` and `tCassandraClose`.
2. Connect `tFileInputDelimited` to `tCassandraOutput` using a Row > Main link.
3. Do the same to connect `tCassandraInput` to `tLogRow`.
4. Connect `tCassandraConnection` to `tFileInputDelimited` using a Trigger > OnSubjobOk link.
5. Do the same to connect `tFileInputDelimited` to `tCassandraInput` and `tCassandraInput` to `tCassandraClose`.
6. Label the components to better identify their functions.

Configuring the components

Opening a Cassandra connection

Procedure

1. Double-click the `tCassandraConnection` component to open its Basic settings view in the Component tab.
   
   ![Open_Cassandra_Connection(tCassandraConnection_1)](image)

   - **PROPERTY** | **Built-In**
   - **DB Version** | `Cassandra 1.1.2`
   - **Server** | `localhost`
   - **Port** | `9160`
   
2. Select the Cassandra version that you are using from the DB Version list. In this example, it is `Cassandra 1.1.2`.
3. In the Server field, type in the hostname or IP address of the Cassandra server. In this example, it is `localhost`.
4. In the Port field, type in the listening port number of the Cassandra server.
5. If required, type in the authentication information for the Cassandra connection: Username and Password.

Reading the input data

Procedure

1. Double-click the `tFileInputDelimited` component to open its Component view.
2. Click the [...] button next to the File Name/Stream field to browse to the file that you want to read data from. In this scenario, the directory is D:/Input/Employees.csv. The CSV file contains four columns: id, age, name and ManagerID.

<table>
<thead>
<tr>
<th>id</th>
<th>age</th>
<th>name</th>
<th>ManagerID</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>20</td>
<td>Alex</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>40</td>
<td>Peter</td>
<td>1</td>
</tr>
<tr>
<td>3</td>
<td>25</td>
<td>Mark</td>
<td>1</td>
</tr>
<tr>
<td>4</td>
<td>26</td>
<td>Michael</td>
<td>1</td>
</tr>
<tr>
<td>5</td>
<td>30</td>
<td>Christophe</td>
<td>2</td>
</tr>
<tr>
<td>6</td>
<td>26</td>
<td>Stephane</td>
<td>3</td>
</tr>
<tr>
<td>7</td>
<td>37</td>
<td>Cedric</td>
<td>3</td>
</tr>
<tr>
<td>8</td>
<td>52</td>
<td>Bill</td>
<td>4</td>
</tr>
<tr>
<td>9</td>
<td>43</td>
<td>Jack</td>
<td>2</td>
</tr>
<tr>
<td>10</td>
<td>28</td>
<td>Andrews</td>
<td>4</td>
</tr>
</tbody>
</table>

3. In the Header field, enter 1 so that the first row in the CSV file will be skipped.

4. Click Edit schema to define the data to pass on to the tCassandraOutput component.

Writing data to a Cassandra keyspace

Procedure

1. Double-click the tCassandraOutput component to open its Basic settings view in the Component tab.
2. Type in required information for the connection or use the existing connection you have configured before. In this scenario, the **Use existing connection** check box is selected.

3. In the **Keyspace configuration** area, type in the name of the keyspace: *Employee* in this example, and select **Drop keyspace if exists and create** from the **Action on keyspace** list.

4. In the **Column family configuration** area, type in the name of the column family: *Employee_Info* in this example, and select **Drop column family if exists and create** from the **Action on column family** list.

   The **Define column family structure** check box appears. In this example, clear this check box.

5. In the **Action on data** list, select the action you want to carry on, *Upsert* in this example.

6. Click **Sync columns** to retrieve the schema from the preceding component.

7. Select the key column of the column family from the **Key column** list. In this example, it is *id*.

   If needed, select the **Include key in columns** check box.

**Reading data from the Cassandra keyspace**

**Procedure**

1. Double-click the **tCassandraInput** component to open its **Component** view.

2. Type in required information for the connection or use the existing connection you have configured before. In this scenario, the **Use existing connection** check box is selected.

3. In the **Keyspace configuration** area, type in the name of the keyspace: *Employee* in this example.
4. In the **Column family configuration** area, type in the name of the column family: *Employee_Info* in this example.

5. Select **Edit schema** to define the data structure to be read from the Cassandra keyspace. In this example, three columns *id*, *name* and *age* are defined.

![Extract_Info_from_Keyspace](image)

6. If needed, select the **Include key in output columns** check box, and then select the key column of the column family you want to include from the **Key column** list.

7. From the **Row key type** list, select *Integer* because *id* is of integer type in this example. Keep the **Default** option for the row key Cassandra type because its value will become the corresponding Cassandra type *Int32* automatically.

8. In the **Query configuration** area, select the **Specify row keys** check box and specify the row keys directly. In this example, three rows will be read. Next, select the **Specify columns** check box and specify the column names of the column family directly. This scenario will read three columns from the keyspace: *id*, *name* and *age*.

9. If needed, the **Key start** and the **Key end** fields allow you to define the range of rows, and the **Key limit** field allows you to specify the number of rows within the range of rows to be read. Similarly, the **Columns range start** and the **Columns range end** fields allow you to define the range of columns of the column family, and the **Columns range limit** field allows you to specify the number of columns within the range of columns to be read.

**Displaying the information of interest**

**Procedure**

1. Double-click the **tLogRow** component to open its **Component** view.
2. In the **Mode** area, select **Table (print values in cells of a table)**.

**Closing the Cassandra connection**

**Procedure**

1. Double-click the **tCassandraClose** component to open its **Component** view.
2. Select the connection to be closed from the **Component List**.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl+S** to save your Job.
2. Execute the Job by pressing **F6** or clicking **Run** on the **Run** tab.

The personal information of three employees is displayed on the console.

```
<table>
<thead>
<tr>
<th>Display_Info</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
</tr>
<tr>
<td>----</td>
</tr>
<tr>
<td>2</td>
</tr>
<tr>
<td>3</td>
</tr>
<tr>
<td>1</td>
</tr>
</tbody>
</table>
```
tCassandraOutput

Writes data into or deletes data from a column family of a Cassandra keyspace.
tCassandraOutput receives data from the preceding component, and writes data into Cassandra.

tCassandraOutput Standard properties

These properties are used to configure tCassandraOutput running in the Standard Job framework.
The Standard tCassandraOutput component belongs to the Big Data and the Databases NoSQL families.
The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

Basic settings

| Property type       | Either Built-In or Repository.  
|                     | Built-In: No property data stored centrally.  
|                     | Repository: Select the repository file where the properties are stored.  
| Use existing connection | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.  
| DB Version          | Select the Cassandra version you are using.  
| API type            | This drop-down list is displayed only when you have selected the 2.0 version (deprecated) of Cassandra from the DB version list. From this API type list, you can either select Datastax to use CQL 3 (Cassandra Query Language) with Cassandra, or select Hector (deprecated) to use CQL 2. Note that the Hector API is deprecated along with the support for Cassandra V2.0.
Along with the evolution of the CQL commands, the parameters to be set in the Basic settings view varies.  
| Host                | Hostname or IP address of the Cassandra server.  
| Port                | Listening port number of the Cassandra server.  
| Required authentication | Select this check box to provide credentials for the Cassandra authentication.  
|                     | This check box appears only if you do not select the Use existing connection check box.  
| Username            | Fill in this field with the username for the Cassandra authentication.  
| Password            | Fill in this field with the password for the Cassandra authentication.  

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

**Use SSL**

Select this check box to enable the SSL or TLS encrypted connection.

Then you need to use the **tSetKeystore** component in the same Job to specify the encryption information.

For further information about **tSetKeystore**, see [tSetKeystore on page 3464](#).

<table>
<thead>
<tr>
<th>Keyspace</th>
<th>Type in the name of the keyspace into which you want to write data.</th>

</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Action on data</th>
<th>On the data of the table defined, you can perform:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• <strong>Upsert</strong>: insert the columns if they do not exist or update the existing columns.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Insert</strong>: insert the columns if they do not exist. This action also updates the existing ones.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Update</strong>: update the existing columns or add the columns that do not exist. This action does not support the <strong>Counter</strong> Cassandra data type.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Delete</strong>: remove columns corresponding to the input flow.</td>
</tr>
</tbody>
</table>

Note that the action list varies depending on the **Hector** (deprecated) or **Datastax** API you are using. When the API is **Datastax**, more actions become available.

For more advanced actions, use the **Advanced settings** view.
### Schema and Edit schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

---

**Built-In**: You create and store the schema locally for this component only.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

---

**Sync columns**

Click this button to retrieve schema from the previous component connected in the Job.

---

**Die on error**

Clear the check box to skip any rows on error and complete the process for error-free rows. When errors are skipped, you can collect the rows on error using a **Row > Reject** link.

---

### Features available only with the Hector API (deprecated)

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Row key column</td>
<td>Select the row key column from the list.</td>
</tr>
<tr>
<td>Include row key in columns</td>
<td>Select this check box to include row key in columns.</td>
</tr>
<tr>
<td>Super columns</td>
<td>Select the super column from the list.</td>
</tr>
<tr>
<td>Include super columns in standard columns</td>
<td>Select this check box to include the super columns in standard columns.</td>
</tr>
<tr>
<td>Delete row</td>
<td>Select this check box to delete the row.</td>
</tr>
</tbody>
</table>
### Delete columns

Customize the columns you want to delete.

### Delete super columns

Select this check box to delete super columns.

This check box appears only if you select the **Delete Row** check box.

### Advanced settings

#### Batch Size

Number of lines in each processed batch.

When you are using the **Datastax API**, this feature is displayed only when you have selected the **Use unlogged batch** check box.

#### Use unlogged batch

Select this check box to handle data in batch but with Cassandra's UNLOGGED approach. This feature is available to the following three actions: **Insert**, **Update** and **Delete**.

Then you need to configure how the batch mode works:

- **Batch size**: enter the number of lines in each batch to be processed.
- **Group batch method**: select how to group rows into batches:
  
  - **Partition**: rows sharing the same partition keys are grouped.
  
  - **Replica**: rows to be written to the same replica are grouped.

  - **None**: rows are grouped randomly. This option is suitable for a single node Cassandra.

- **Cache batch group**: select this check box to load rows into memory before grouping them. This way, grouping is not impacted by the order of the rows.

  If you leave this check box clear, only successive rows that meet the same criteria are grouped.

- **Async execute**: select this check box if you want **tCassandraOutput** to send batches in parallel. If you leave it clear, **tCassandraOutput** waits for the result of a batch before sending another batch to Cassandra.

- **Maximum number of batches executed in parallel**: once you have selected **Async execute**, enter the number of batches to be sent in parallel to Cassandra.

  This number should not be a negative number or 0 and it is also recommended not to use too large a value.

The ideal situation to use batches with Cassandra is when a small number of tables must synchronize the data to be inserted or updated.

In this UNLOGGED approach, the Job does not write batches into Cassandra's batchlog system and thus avoids the performance issue incurred by this writing. For further information about Cassandra BATCH statement and UNLOGGED approach, see [Batches](#).

#### Insert if not exists

Select this check box to insert rows. This row insertion takes place only when they do not exist in the target table.

This feature is available to the **Insert** action only.
<table>
<thead>
<tr>
<th>Delete if exists</th>
<th>Select this check box to remove from the target table only the rows that have the same records in the incoming flow. This feature is available only to the Delete action.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use TTL</td>
<td>Select this check box to write the TTL data in the target table. In the column list that is displayed, you need to select the column to be used as the TTL column. The DB type of this column must be Int. This feature is available to the Insert action and the Update action only.</td>
</tr>
<tr>
<td>Use Timestamp</td>
<td>Select this check box to write the timestamp data in the target table. In the column list that is displayed, you need to select the column to be used to store the timestamp data. The DB type of this column must be Bigint. This feature is available to the following actions: Insert, Update and Delete.</td>
</tr>
<tr>
<td>IF condition</td>
<td>Add the condition to be met for the Update or the Delete action to take place. This condition allows you to be more precise about the columns to be updated or deleted.</td>
</tr>
</tbody>
</table>
| Special assignment operation | Complete this table to construct advanced SET commands of Cassandra to make the Update action more specific. For example, add a record to the beginning or a particular position of a given column. In the Update column column of this table, you need to select the column to be updated and then select the operations to be used from the Operation column. The following operations are available:  
  - **Append**: it adds incoming records to the end of the column to be updated. The Cassandra data types it can handle are Counter, List, Set and Map.  
  - **Prepend**: it adds incoming records to the beginning of the column to be updated. The only Cassandra data type it can handle is List.  
  - **Remove**: it removes records from the target table when the same records exist in the incoming flow. The Cassandra data types it can handle are Counter, List, Set and Map.  
  - **Assign based on position/key**: it adds records to a particular position of the column to be updated. The Cassandra data types it can handle are List and Map.  
  
  Once you select this operation, the Map key/list position column becomes editable. From this column, you need to select the column to be used as reference to locate the position to be updated.  
  
  For more details about these operations, see Datastax’s related documentation in http://docs.datastax.com/en/cql/3.1/cql_reference/update_r.html?scroll=reference_ds_g4h_q2q_xj__description_unique_34. |
| Row key in the List type  | Select the column to be used to construct the WHERE clause of Cassandra to perform the Update or the Delete action on only selected rows. The column(s) to be used in this table should be from the set of the Primary key columns of the Cassandra table. |
Delete collection column based on position/key

Select the column to be used as reference to locate the particular row(s) to be removed.
This feature is available only to the Delete action.

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global Variables**

| Global Variables | NB_LINE: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer. ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

**Usage**

| Usage rule | This component is used as an output component and it always needs an incoming link. |

**Related Scenario**

For a scenario in which tCassandraOutput is used, see Handling data with Cassandra on page 429.
tCassandraOutputBulk

Prepares an SSTable of large size and processes it according to your needs before loading this SSTable into a column family of a Cassandra keyspace.

The tCassandraOutputBulk and tCassandraBulkExec components are generally used together as parts of a two step process. In the first step, an SSTable is generated. In the second step, this SSTable is written into Cassandra. These two steps are fused together in the tCassandraOutputBulkExec component, detailed in a separate section. The advantage of using two separate components is that the data can be transformed before it is loaded into Cassandra.

tCassandraOutputBulk receives data from the preceding component, and creates an SSTable locally.

**tCassandraOutputBulk Standard properties**

These properties are used to configure tCassandraOutputBulk running in the Standard Job framework.

The Standard tCassandraOutputBulk component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
- View schema: choose this option to view the schema only.  
- Change to built-in property: choose this option to change the schema to Built-in for local changes.  
- Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-In</strong></td>
<td>You create and store the schema locally for this component only.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.</td>
</tr>
</tbody>
</table>
You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

| Table type | Select the type of the data model to be used for the table to be created. It can be **CQL** (actually CQL3) or **non-CQL** (the legacy thrift-based API of Cassandra before CQL3).

This drop-down list is available only when the **DB version** you are using is Cassandra 2.0.0 (deprecated). For the Cassandra versions later than 2.0.0, CQL becomes the only model used by this component and so this list is no longer available.

| DB Version | Select the Cassandra version you are using.

| Host | Hostname or IP address of the Cassandra server.

| Port | Listening port number of the Cassandra server.

| Required authentication | Select this check box to provide credentials for the Cassandra authentication.

| Username | Fill in this field with the username for the Cassandra authentication.

| Password | Fill in this field with the password for the Cassandra authentication.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

| Use configuration file | Select this check box and in the field that is displayed, enter the path, or browse to **cassandra.yaml**, the main configuration file for Cassandra.

This way, this component can import and directly use the configuration from **cassandra.yaml**, which can contain many advanced Cassandra properties, such as the properties for SSL encryption.

When you need to run your Job in different Cassandra environments, this feature allows your Job to easily switch between the configurations.

For further information about this **cassandra.yaml** file, see **Cassandra configuration**.

| Keyspace | Type in the name of the keyspace into which you want to write the SSTable.

| Column family | Type in the name of the column family into which you want to write the SSTable.

| Partitioner | Select the partitioner which determines how data is distributed across the Cassandra cluster.

- **Random**
- **Murmur3**
- **Order preserving**: not recommended because it assumes keys are UTF8 strings.
<table>
<thead>
<tr>
<th><strong>Schema statement</strong></th>
<th><strong>Insert statement</strong></th>
</tr>
</thead>
</table>
| Enter the statement to define the schema of the column family to be used or to be created on the fly.  
- This statement is a Cassandra prepared statement, which stores query results locally in the SSTable directory you define with this component before sending them to the server. For further information about the prepared statements, see Prepared statements.  
- A Cassandra column family is a container for a collection of rows of records that have a similar kind. Its schema must contain strictly the same columns as the component schema you have defined, that is to say, the column names and the order of the columns in both the schemas must be identical.  
An example of this schema statement is provided in the Schema statement field:  
```sql
create table ks.tb (id int, name text, birthday timestamp, primary key(id, birthday)) with clustering order by (birthday desc)
```
It will create a column family called `tb` containing the `id`, the `name` and the `birthday` columns under the keyspace `ks`.  
For further information about a column family, see Standard column family.  
This field is available only when the version of your Cassandra database is later than 2.0.0. When it is 2.0.0 (deprecated), it is available only when you have selected CQL from the Table type drop-down list. | Enter the statement to instruct how to write the data from the input flow into the columns of the column family to be used.  
This statement is a Cassandra prepared statement, which stores query results locally in the SSTable directory you define with this component before sending them to the server. For further information about the prepared statements, see Prepared statements.  
An example of this insert statement is provided in the Insert statement field:  
```sql
insert into ks.tb (id, name, birthday) values (?, ?, ?)
```
It will write data into the `id`, the `name` and the `birthday` columns, respectively, of a column family called `tb` in the keyspace `ks`. The question marks in the statement are the bind variable markers for the three columns. For further information about bind variables and their usage, see Bound parameters.  
This field is available only when the version of your Cassandra database is later than 2.0.0. When it is 2.0.0 (deprecated), it is available only when you have selected CQL from the Table type drop-down list. |
Column name comparator

Select the data type for the column names, which is used to sort columns. This list is not available when the data model to be used is CQL3.

For more information about the comparators, see http://www.datastax.com/docs/1.1/ddl/column_family#about-data-types-comparators-and-validators.

SSTable directory

Specify the local directory for the SSTable. Note that the complete path to the SSTable will be the local directory appended by the specified keyspace name and column family name.

For example, if you set the local directory to /home/talend/sstable, and specify testk as the keyspace name and testc as the column family name, the complete path to the SSTable will be /home/talend/sstable/testk/testc/.

Buffer size

Specify what size the SSTable must reach before it is written into Cassandra.

Advanced settings

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

Global Variables

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

**Usage rule**

This component always needs an incoming link.

Related scenarios

No scenario is available for the Standard version of this component yet.
tCassandraOutputBulkExec

Improves performance during Insert operations to a column family of a Cassandra keyspace.

The tCassandraOutputBulk and tCassandraBulkExec components are generally used together to output data to an SSTable and then to write the SSTable into Cassandra, in a two step process. These two steps are fused together in the tCassandraOutputBulkExec component.

tCassandraOutputBulkExec receives data from the preceding component, creates an SSTable and then writes the SSTable into Cassandra.

tCassandraOutputBulkExec Standard properties

These properties are used to configure tCassandraOutputBulkExec running in the Standard Job framework.

The Standard tCassandraOutputBulkExec component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

Basic settings

<table>
<thead>
<tr>
<th>Schema and Edit Schema</th>
<th>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:</th>
</tr>
</thead>
<tbody>
<tr>
<td>• View schema: choose this option to view the schema only.</td>
<td></td>
</tr>
<tr>
<td>• Change to built-in property: choose this option to change the schema to Built-in for local changes.</td>
<td></td>
</tr>
<tr>
<td>• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.</td>
<td></td>
</tr>
<tr>
<td>Built-In: You create and store the schema locally for this component only.</td>
<td></td>
</tr>
<tr>
<td>Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.</td>
<td></td>
</tr>
</tbody>
</table>
You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

**Table type**
Select the type of the data model to be used for the table to be created. It can be **CQL** (actually CQL3) or **non-CQL** (the legacy thrift-based API of Cassandra before CQL3).

This drop-down list is available only when the **DB version** you are using is Cassandra 2.0.0 (deprecated). For the Cassandra versions later than 2.0.0, CQL becomes the only model used by this component and so this list is no longer available.

**DB Version**
Select the Cassandra version you are using.

**Warning:**
- Cassandra 2.0.0 (deprecated) only works with JVM1.7.

**Host**
Hostname or IP address of the Cassandra server.

**Port**
Listening port number of the Cassandra server.

**Required authentication**
Select this check box to provide credentials for the Cassandra authentication.

**Username**
Fill in this field with the username for the Cassandra authentication.

**Password**
Fill in this field with the password for the Cassandra authentication.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

**Keyspace**
Type in the name of the keyspace into which you want to write the SSTable.

**Column family**
Type in the name of the column family into which you want to write the SSTable.

**Partitioner**
Select the partitioner which determines how the data is distributed across the Cassandra cluster.

- **Random**
- **Murmur3**
- **Order preserving**: not recommended because it assumes keys are UTF8 strings.

For more information about the partitioner, see [http://wiki.apache.org/cassandra/Partitioners](http://wiki.apache.org/cassandra/Partitioners).

**Schema statement**
Enter the statement to define the schema of the column family to be used or to be created on the fly.

- This statement is a Cassandra prepared statement, which stores query results locally in the **SSTable directory** you define with this component before sending them to the server. For further information...
A Cassandra column family is a container for a collection of rows of records that have a similar kind. Its schema must contain strictly the same columns as the component schema you have defined, that is to say, the column names and the order of the columns in both the schemas must be identical.

An example of this schema statement is provided in the Schema statement field:

```sql
create table ks.tb (id int, name text, birthday timestamp, primary key(id, birthday)) with clustering order by (birthday desc)
```

It will create a column family called `tb` containing the `id`, the `name` and the `birthday` columns under the keyspace `ks`.

For further information about a column family, see Standard column family.

This field is available only when the version of your Cassandra database is later than 2.0.0. When it is 2.0.0 (deprecated), it is available only when you have selected CQL from the Table type drop-down list.

### Insert statement

Enter the statement to instruct how to write the data from the input flow into the columns of the column family to be used.

This statement is a Cassandra prepared statement, which stores query results locally in the SSTable directory you define with this component before sending them to the server. For further information about the prepared statements, see Prepared statements.

An example of this insert statement is provided in the Insert statement field:

```sql
insert into ks.tb (id, name, birthday) values (?, ?, ?)
```

It will write data into the `id`, the `name` and the `birthday` columns, respectively, of a column family called `tb` in the keyspace `ks`. The question marks in the statement are the bind variable markers for the three columns. For further information about bind variables and their usage, see Bound parameters.

This field is available only when the version of your Cassandra database is later than 2.0.0. When it is 2.0.0 (deprecated), it is available only when you have selected CQL from the Table type drop-down list.

### Column name comparator

Select the data type for the column names, which is used to sort columns.

### SSTable directory

Specify the local directory for the SSTable. Note that the complete path to the SSTable will be the local directory.
appended by the specified keyspace name and column family name.

For example, if you set the local directory to /home/talend/sstable, and specify testk as the keyspace name and testc as the column family name, the complete path to the SSTable will be /home/talend/sstable/testk/testc/.

**Buffer size**

Specify what size the SSTable must reach before it is written into Cassandra.

**Advanced settings**

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

**Global Variables**

**Global Variables**

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see **Talend Studio User Guide**.

**Usage**

**Usage rule**

This component is mainly used when no particular transformation is required on the data to be loaded into the database.

**Limitation**

Currently, the execution of this component ends the entire Job.

**Related scenarios**

No scenario is available for the Standard version of this component yet.
tCassandraRow

Acts on the actual DB structure or on the data, depending on the nature of the query and the database.

tCassandraRow is the specific component for this database query. It executes the Cassandra Query Language (CQL) query stated in the specified database. The row suffix means the component implements a flow in the Job design although it does not provide output.

**tCassandraRow Standard properties**

These properties are used to configure tCassandraRow running in the Standard Job framework. The Standard tCassandraRow component belongs to the Big Data and the Databases NoSQL families. The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| Property type        | Either **Built-In** or **Repository**.  
|----------------------|----------------------------------------|
|                      | **Built-In**: No property data stored centrally.  
|                      | **Repository**: Select the repository file where the properties are stored.  
| Use existing connection | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.  
| DB Version           | Select the Cassandra version you are using.  
| Host                 | Type in the IP address or hostname of the Cassandra server.  
| Port                 | Type in the listening port number of the Cassandra server.  
| Required Authentication | Select this check box to provide credentials for the Cassandra authentication.  
|                      | This check box appears only if you do not select the Use existing connection check box.  
| Username             | Fill in this field with the username for the Cassandra authentication.  
| Password             | Fill in this field with the password for the Cassandra authentication.  
|                      | To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.  
| Keyspace             | Type in the name of the keyspace on which you want to execute the CQL commands.  
| Column family        | Name of the column family.  

**Schema and Edit Schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `LINE` when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Query**

Type in the CQL command to be executed.

By default, the query is not case-sensitive. This means that at runtime, the column names you put in the query are always taken in lower case. If you need to make the query case-sensitive, put the column names in double quotation marks.

**Die on error**

This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

**Advanced settings**

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

**Global Variables**

**Global Variables**

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

**Related scenario**

For related topics, see
• Removing and regenerating a MySQL table index on page 2508.
• Using PreparedStatement objects to query data on page 2509.
tCentricCRMInput

Extracts data from a Centric CRM DB based on a query.
Connects to a module of a Centric CRM database via the relevant Web service.

**tCentricCRMInput Standard properties**

These properties are used to configure tCentricCRMInput running in the Standard Job framework. The Standard tCentricCRMInput component belongs to the Business family. The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th><strong>CentricCRM URL</strong></th>
<th>Type in the Web service URL to connect to the CentricCRM DB.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Module</strong></td>
<td>Select the relevant module in the list.</td>
</tr>
<tr>
<td><strong>Server</strong></td>
<td>Type in the IP address of the DB server.</td>
</tr>
<tr>
<td><strong>UserID and Password</strong></td>
<td>Type in the Web service user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
</tbody>
</table>
| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
  • View schema: choose this option to view the schema only.  
  • Change to built-in property: choose this option to change the schema to Built-in for local changes.  
  • Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.  
  In this component the schema is related to the Module selected. |

Schema and Edit Schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

Click Sync columns to retrieve the schema from the previous component connected in the Job.
Advanced settings

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

Global Variables

| Global Variables | NB_LINE: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.  
ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.  
For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | Used as an output component. An Input component is required. |
| Limitation | This component requires installation of its related jar files. |

Related scenarios

No scenario is available for the Standard version of this component yet.
tChangeFileEncoding

Transforms the character encoding of a given file and generates a new file with the transformed character encoding.
tChangeFileEncoding changes the encoding of a given file.

**tChangeFileEncoding Standard properties**

These properties are used to configure tChangeFileEncoding running in the Standard Job framework. The Standard tChangeFileEncoding component belongs to the Data Quality and the File families. The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Use Custom Input Encoding</th>
<th>Select this check box to customize input encoding type. When it is selected, a list of input encoding types appears, allowing you to select an input encoding type or specify an input encoding type by selecting CUSTOM.</th>

<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
</tbody>
</table>
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

### Usage

| Usage rule | This component can be used as standalone component. |

### Transforming the character encoding of a file

This Java scenario describes a very simple Job that transforms the character encoding of a text file and generates a new file with the new character encoding.

### Procedure

**Procedure**

1. Drop a **tChangeFileEncoding** component onto the design workspace.

2. Double-click the **tChangeFileEncoding** component to display its **Basic settings** view.

3. Select **Use Custom Input Encoding** check box. Set the **Encoding** type to **GB2312**.

4. In the **Input File Name** field, enter the file path or browse to the input file.

5. In the **Output File Name** field, enter the file path or browse to the output file.

6. Select **CUSTOM** from the second **Encoding** list and enter **UTF-16** in the text field.
7. Press **F6** to execute the Job.

Results

The encoding type of the file *in.txt* is transformed and *out.txt* is generated with the UTF-16 encoding type.
tChronometerStart

Operates as a chronometer device that starts calculating the processing time of one or more subJobs in the main Job, or that starts calculating the processing time of part of your subJob. Starts measuring the time a subJob takes to be executed.

**tChronometerStart Standard properties**

These properties are used to configure tChronometerStart running in the Standard Job framework. The Standard tChronometerStart component belongs to the Logs & Errors family. The component in this framework is available in all Talend products.

**Global Variables**

| Global Variables | STARTTIME: the start time to calculate the processing time of subjob(s). This is a Flow variable and it returns a long. ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see *Talend Studio User Guide*. |

**Usage**

| Usage rule | You can use tChronometerStart as a start or middle component. It can precede one or more processing tasks in the subJob. It can precede one or more subJobs in the main Job. |

**Related scenario**

For related scenario, see Measuring the processing time of a subJob and part of a subJob on page 461.
tChronometerStop

Operates as a chronometer device that stops calculating the processing time of one or more subjobs in the main Job, or that stops calculating the processing time of part of your subJob. tChronometerStop displays the total execution time.

Measures the time a subjob takes to be executed.

tChronometerStop Standard properties

These properties are used to configure tChronometerStop running in the Standard Job framework.

The Standard tChronometerStop component belongs to the Logs & Errors family.

The component in this framework is available in all Talend products.

Basic settings

<table>
<thead>
<tr>
<th>Since options</th>

<td>When selected, it displays subjob execution information in readable time unites.</td>
</tr>
</tbody>
</table>

Global Variables

| Global Variables | STOPTIME: the stop time to calculate the processing time of subjob(s). This is a Flow variable and it returns a long. |
|                 | DURATION: the processing time of subjob(s). This is a Flow variable and it returns a long. |
|                 | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. |
|                 | A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. |
|                 | To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. |
**Usage**

| Usage rule | Cannot be used as a start component. |

**Measuring the processing time of a subJob and part of a subJob**

This scenario is a subJob that does the following in a sequence:

- generates 1,000,000 rows of first and last names,
- gathers first names with their corresponding last names,
- stores the output data in a delimited file,
- measures the duration of the subJob as a whole,
- measures the duration of the name replacement operation,
- displays the gathered information about the processing time on the Run log console.

To measure the processing time of the subJob:

- Drop the following components from the Palette onto the design workspace: **tRowGenerator**, **tMap**, **tFileOutputDelimited**, and **tChronometerStop**.
- Connect the first three components using Main Row links.

**Note:** When connecting **tMap** to **tFileOutputDelimited**, you will be prompted to name the output table. The name used in this example is "new_order".

- Connect **tFileOutputDelimited** to **tChronometerStop** using an OnComponentOk link.
- Select **tRowGenerator** and click the Component tab to display the component view.
- In the component view, click Basic settings. The Component tab opens on the Basic settings view by default.
Click **Edit schema** to define the schema of the **tRowGenerator**. For this Job, the schema is composed of two columns: *First_Name* and *Last_Name*, so click twice the **[+]** button to add two columns and rename them.

- Click the **RowGenerator Editor** three-dot button to open the editor and define the data to be generated.

- In the **RowGenerator Editor**, specify the number of rows to be generated in the **Number of Rows for RowGenerator** field and click **OK**. The **RowGenerator Editor** closes.
- You will be prompted to propagate changes. Click **Yes** in the popup message.
- Double-click on the **tMap** component to open the Map editor. The Map editor opens displaying the input metadata of the **tRowGenerator** component.

- In the **Schema editor** panel of the Map editor, click the plus button of the output table to add two rows and define them.
• In the Map editor, drag the First_Name row from the input table to the Last_Name row in the output table and drag the Last_Name row from the input table to the First_Name row in the output table.

• Click Apply to save changes.

• You will be prompted to propagate changes. Click Yes in the popup message.

• Click OK to close the editor.

• Select tFileOutputDelimited and click the Component tab to display the component view.

• In the Basic settings view, set tFileOutputDelimited properties as needed.

• Select tChronometerStop and click the Component tab to display the component view.

• In the Since options panel of the Basic settings view, select Since the beginning option to measure the duration of the subJob as a whole.
Select/clear the other check boxes as needed. In this scenario, we want to display the subjob duration on the console preceded by the component name.

If needed, enter a text in the Caption field.

Save your Job and press F6 to execute it.

Starting job tChronometerStop at 11:40 05/03/2010.
[statistics] connecting to socket on port 3399
[statistics] connected
[ tChronometerStop_1 ] 2 seconds duration of the subjob 2968 milliseconds
[statistics] disconnected
Job tChronometerStop ended at 11:40 05/03/2010. [exit code=0]

Note: You can measure the duration of the subjob the same way by placing tChronometerStop below tRowGenerator, and connecting the latter to tChronometerStop using an OnSubjobOk link.
tCloudStart

Starts instances on Amazon EC2 (Amazon Elastic Compute Cloud).

This component accesses the cloud provider to be used (Amazon EC2) and launches instances, which are virtual servers in that cloud. If an instance to be launched does not exist, tCloudStart creates it.

**tCloudStart Standard properties**

These properties are used to configure tCloudStart running in the Standard Job framework.

The Standard tCloudStart component belongs to the Cloud family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Access key and Secret key</th>
<th>Enter or paste the access key and the secret key required by Amazon to authenticate your requests to its web services. These access credentials are generated from the Security Credential tab of your Amazon account page. To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cloud provider</td>
<td>Select the cloud provider to be used.</td>
</tr>
<tr>
<td>Image</td>
<td>Enter the name of the Amazon Machine Image (AMI) to be used to launch an instance. This AMI defines the basic configuration of that instance.</td>
</tr>
<tr>
<td>Region and Zone</td>
<td>Enter the region and the zone to be used as the geographic location where you want to launch an instance. The syntax used to express a location is predefined by Amazon, for example, us-east-1 representing the US East (Northern Virginia) region and us-east-1a representing one of the Availability Zones within that region. For further information about available regions for Amazon, see Amazon’s documentation about regions and endpoints and as well Amazon’s FAQ about region and Availability Zone.</td>
</tr>
<tr>
<td>Instance name</td>
<td>Enter the name of the instance to be launched. For example, you can enter Talend. Note that the upper letter will be converted to lower letter.</td>
</tr>
<tr>
<td>Instance count</td>
<td>Enter the number of instances to be launched. At runtime, the name specified in the Instance name field, for example Talend, will be used as the initial part of each instance name, and letters and numbers will be randomly added to complete each name.</td>
</tr>
<tr>
<td>Instance type</td>
<td>Select the type of the instance(s) to be launched. Each type is predefined by Amazon and defines the performance of every instance you want to launch.</td>
</tr>
</tbody>
</table>
This drop-down list presents the API name of each instance type. For further information, see Amazon’s documentation about instance types.

### Proceed with a Key pair
Select this check box to use Amazon Key Pair for your login to Amazon EC2. Once selecting it, a drop-down list appears to allow you to select:
- **Use an existing Key Pair** to enter the name of that Key Pair in the field next to the drop-down list. If required, Amazon will prompt you at runtime to find and use that Key Pair.
- **Create a Key Pair** to enter the name of the new Key Pair in the field next to the drop-down list and define the location where you want to store this Key Pair in the Advanced settings tab view.

### Security group
Add rows to this table and enter the names of the security groups to which you need to assign the instance(s) to be launched. The security groups set in this table must exist on your Amazon EC2.

A security group applies specific rules on inbound traffic to instances assigned to the group, such as the ports to be used. For further information about security groups, see Amazon’s documentation about security groups.

Note that an instance can be assigned to a group by setting its security group name or key pair name to `jclouds#$group_name`, where `<$group_name>` identifies the group to which the instance belongs. In this way, you can change the status of all instances or running instances in one group at the same time using the tCloudStop component.

### Advanced settings

#### Key Pair folder
Browse to, or enter the path to the folder you use to store the created Key Pair file.

This field appears when you select **Creating a Key Pair** in the Basic settings tab view.

#### Volumes
Add rows and define the volume(s) to be created for the instances to be launched in addition to the volumes predefined and allocated by the given Amazon EC2.

The parameters to be set in this table are the same parameters used by Amazon for describing a volume.

If you need to remove automatically an additional volume after terminating its related instance, select the check box in the **Delete on termination** column.

#### tStatCatcher Statistics
Select this check box to collect the log data at the component level.

### Global Variables

| Global Variables | NODE_GROUP: the name of the instance. This is an After variable and it returns a string. |
**Usage**

| Usage rule | This component works standalone to launch an instance on Amazon EC2. You can use this component to start the instance you need to deploy Jobs on. |

**Related scenarios**

No scenario is available for the Standard version of this component yet.
tCloudStop

Changes the status of a launched instance on Amazon EC2 (Amazon Elastic Compute Cloud). This component accesses the cloud provider to be used (Amazon EC2) and suspends, resumes or terminates given instance(s).

**tCloudStop Standard properties**

These properties are used to configure tCloudStop running in the Standard Job framework.

The Standard tCloudStop component belongs to the Cloud family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Access key and Secret key</th>
<th>Enter or paste the access key and the secret key required by Amazon to authenticate your requests to its web services. These access credentials are generated from the Security Credential view of your Amazon account page. To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cloud provider</td>
<td>Select the cloud provider to be used.</td>
</tr>
<tr>
<td>Action</td>
<td>Select the action you need <strong>tCloudStop</strong> to take in order to change the status of a given instance. This action may be: • Suspend • Resume • Terminate Note that if you terminate an instance, this instance will be deleted, while a suspended instance can still be resumed.</td>
</tr>
<tr>
<td>Predicate</td>
<td>Select the instance(s) of which you need to change the status. The options are: • <strong>Running instances</strong>: status of all the running instances will be changed. • <strong>Instances in a specific group</strong>: status of the instances of a specific instance group will be changed. You need to enter the name of that group in the <strong>Group name</strong> field. • <strong>Running instances in a specific group</strong>: status of the running instances of a specific instance group will be changed. You need to enter the name of that group in the <strong>Group name</strong> field. • <strong>Instance with predefined id</strong>: status of a given instance will be changed. You need to enter the ID of that instance in the <strong>Id</strong> field. You can find this ID on your Amazon EC2. An instance group is composed of the instances using the same instance name you have defined in the <strong>Instance name</strong> field of <strong>tCloudStart</strong>.</td>
</tr>
</tbody>
</table>

**Access key** and **Secret key**

- Access key and Secret key
  - Enter or paste the access key and the secret key required by Amazon to authenticate your requests to its web services. These access credentials are generated from the Security Credential view of your Amazon account page.
  - To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

**Cloud provider**

- Select the cloud provider to be used.

**Action**

- Select the action you need **tCloudStop** to take in order to change the status of a given instance. This action may be:
  - Suspend
  - Resume
  - Terminate

Note that if you terminate an instance, this instance will be deleted, while a suspended instance can still be resumed.

**Predicate**

- Select the instance(s) of which you need to change the status. The options are:
  - Running instances: status of all the running instances will be changed.
  - Instances in a specific group: status of the instances of a specific instance group will be changed. You need to enter the name of that group in the **Group name** field.
  - Running instances in a specific group: status of the running instances of a specific instance group will be changed. You need to enter the name of that group in the **Group name** field.
  - Instance with predefined id: status of a given instance will be changed. You need to enter the ID of that instance in the **Id** field. You can find this ID on your Amazon EC2.

An instance group is composed of the instances using the same instance name you have defined in the **Instance name** field of **tCloudStart**.
Group name

Enter the name of the group in which you want to change the status of given instances whose security group name or key pair name is set to jclouds#<$group_name> in the tCloudStart component, where <$group_name> identifies the group to which the instance belongs.

This field is available only when Instances in a specific group or Running instances in a specific group is selected from the Predicate list.

Id

Enter the ID of the instance of which you need to change the status, for instance, "${region}/${instance id}". This field appears when you select Instance with predefined id from the Predicate list.

Advanced settings

tStatCatcher Statistics

Select this check box to collect the log data at the component level.

Global Variables

Global Variables

ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule

This component works standalone to change the status of given instances on Amazon EC2. You can use this component to suspend, resume or terminate the instance(s) you have deployed Jobs on.

This component often works alongside tCloudStart to change the status of the instances launched by the latter component.

Related scenarios

No scenario is available for the Standard version of this component yet.
tCombinedSQLAggregate

Provides a set of matrix based on values or calculations.

tCombinedSQLAggregate collects data values from one or more columns of a table for statistical purposes. This component has real-time capabilities since it runs the data transformation on the DBMS itself.

**tCombinedSQLAggregate Standard properties**

These properties are used to configure tCombinedSQLAggregate running in the Standard Job framework.

The Standard tCombinedSQLAggregate component belongs to the ELT family.

The component in this framework is available in all Talend products.

**Basic settings**

| Schema and Edit schema | A schema is a row description, it defines the number of fields that will be processed and passed on to the next component. The schema is either built-in or remote in the Repository.  
Click *Edit schema* to make changes to the schema. If the current schema is of the *Repository* type, three options are available:  
  - *View schema*: choose this option to view the schema only.  
  - *Change to built-in property*: choose this option to change the schema to *Built-in* for local changes.  
  - *Update repository connection*: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select *No* upon completion and choose this schema metadata again in the *Repository Content* window.  
Click *Sync columns* to retrieve the schema from the previous component connected in the Job. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-in</strong>:</td>
<td>You create and store the schema locally for this component only. Related topic: see <em>Talend Studio User Guide</em>.</td>
</tr>
<tr>
<td><strong>Repository</strong>:</td>
<td>You have already created the schema and stored it in the Repository. You can reuse it in various projects and Jobs. Related topic: see <em>Talend Studio User Guide</em>.</td>
</tr>
<tr>
<td><strong>Group by</strong></td>
<td>Define the aggregation sets, the values of which will be used for calculations.</td>
</tr>
<tr>
<td><strong>Output Column</strong>:</td>
<td>Select the column label in the list offered according to the schema structure you defined. You can add as many output columns as you wish to make more precise aggregations.</td>
</tr>
</tbody>
</table>
### Input Column
Select the input column label to match the output column’s expected content, in case the output label of the aggregation set needs to be different.

### Operations
Select the type of operation along with the value to use for the calculation and the output field.

### Output Column
Select the destination field in the list.

### Function
Select any of the following operations to perform on data: count, min, max, avg, sum, first, last, distinct and count (distinct).

### Input column
Select the input column from which you want to collect the values to be aggregated.

### Advanced settings

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

### Global Variables

| Global Variables | NB_LINE: the number of rows read by an input component or transferred to an output component. This is a Flow variable and it returns an integer. |
|------------------|QUERY: the query statement being processed. This is a Flow variable and it returns a string. |
|                  | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. |
|                  | A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. |
|                  | To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. |
|                  | For further information about variables, see Talend Studio User Guide. |

### Usage

| Usage rule | This component is an intermediary component. The use of the corresponding connection and commit components is recommended when using this component to allow a unique connection to be open and then closed during the Job execution. |
Filtering and aggregating table columns directly on the DBMS

The following scenario creates a Job that opens a connection to a MySQL database and:

- populates a database table with the input data,
- creates the output table for the filtered data,
- instantiates the schema from a database table in part (for column filtering),
- filters two columns in the same table to get only the data that meets two filtering conditions,
- collects data from the filtered column(s), grouped by specific value(s) and writes aggregated data in a target database table.
Adding and linking the components

Procedure
1. Drop the following components from the Palette onto the design workspace: tMysqlConnection, tFixedFlowInput, tMysqlOutput, tCreateTable, tCombinedSQLInput, tCombinedSQLFilter, tCombinedSQLAggregate, tCombinedSQLOutput, tMysqlCommit, tMysqlInput and tLogRow.
2. Connect tMysqlConnection to tFixedFlowInput using a Trigger > On Subjob Ok link.
3. Do the same to connect tFixedFlowInput to tCreateTable, tCreateTable to tCombinedSQLInput, tCombinedSQLInput to tMysqlCommit, and tMysqlCommit to tMysqlInput.
4. Connect tFixedFlowInput and tMysqlOutput using a Row > Main link.
5. Connect tCombinedSQLInput to tCombinedSQLFilter using a Row > Combine link.
6. Do the same to connect tCombinedSQLFilter to tCombinedSQLAggregate, and tCombinedSQLAggregate to tCombinedSQLOutput.
7. Connect tMysqlInput and tLogRow using a Row > Main link.

Configuring the components

The schema defined through tCombinedSQLInput can be different from that of the source table as you can just instantiate the desired columns of the source table. Therefore, tCombinedSQLInput also plays a role of column filtering.

In this scenario, the source database table has seven columns: id, first_name, last_name, city, state, date_of_birth, and salary while tCombinedSQLInput only instantiates four columns that are needed for the aggregation: id, state, date_of_birth, and salary from the source table.

Opening a MySQL connection

Procedure
1. Launch MySQL Workbench and start a local connection on port 3306.
2. Create a new schema and name it test.
3. Back in the design workspace, select tMysqlConnection and click the Component tab to define its basic settings.
4. In the Basic settings view, set the database connection details manually or select Repository from the Property Type list and select your DB connection if it has already been defined and stored in the Metadata area of the Repository tree view.

For more information on centralizing DB connection details in the Repository, see Talend Studio User Guide.

Populating the database table with input data

Procedure

1. In the design workspace, select tFixedFlowInput and click the Component tab to define its basic settings

2. In the Basic settings view, in the Number of rows field, enter 500.

3. In this scenario, the source database table has seven columns: id, first_name, last_name, city, state, date_of_birth, and salary

   Click the [...] button next to Edit schema to define the following data structure.
4. Click the floppy disk icon to save the schema as a generic schema for later reuse.
5. In the Select folder window, select default and click OK.
6. Choose a name for your generic schema and click Finish.
7. Click OK.
8. The first column of the Values table automatically reflects the data structure you entered previously.
9. In the Values table, enter a value for each column.
10. In the design workspace, select tMysqlOutput and click the Component tab to define its basic settings.

The output schema will automatically be the same as the previous component, in this case tFixedFlowInput.

Creating the target database table

Procedure
1. In the design workspace, select tCreateTable and click the Component tab to define its basic settings.
2. Click the [...] button next to Edit schema to define the following data structure.

The schema you enter at this step must reflect the different aggregation operations you want to perform on the input data.

**Extracting and filtering data**

**Procedure**

1. In the design workspace, select `tCombinedSQLInput` and click the Component tab to access the configuration panel.

2. Enter the source table name, in this case `employees` in the Table field.

3. In the Schema field, select Repository from the list and click the [...] button right to the empty field to load the schema you saved while configuring the settings for `tFixedFlowInput`.

4. In the Repository Content window, expand Generic schemas and select your schema.
5. Click the […] button right to Edit schema.
6. Select View schema, and in the first column of the table, clear the check boxes for first_name, last_name and city.

Filtering and aggregating the input data

Procedure

1. In the design workspace, select tCombinedSQLFilter and click the Component tab to access the configuration panel.

2. Click the Sync columns button to retrieve the schema from the previous component, or configure the schema manually by selecting Built-in from the Schema list and clicking the […] button next to Edit schema.

   When you define the data structure for tCombinedSQLFilter, column names automatically appear in the Input column list in the Conditions table.

   In this scenario, the tCombinedSQLFilter component instantiates four columns: id, state, date_of_birth, and salary.

3. In the Conditions table, set input parameters, operators and expected values in order to only extract the records that fulfill these criteria.

   Click two times on the [+] button under the Conditions table, and in Input column, select state and date_of_birth from the drop-down list.

   In this scenario, the tCombinedSQLFilter component filters the state and date_of_birth columns in the source table to extract the employees who were born after Oct. 19, 1960 and who live in the states Utah, Ohio and Iowa.

4. For the column state, select IN as operator from the drop-down list, and enter ('Utah','Ohio','Iowa') as value.

5. For the column date_of_birth, select > as operator from the drop-down list, and enter ('1960-10-19') as value.

6. Select And in the Logical operator between conditions list to apply the two conditions at the same time. You can also customize the conditions by selecting the Use custom SQL box and editing the conditions in the code box.

7. In the design workspace, select tCombinedSQLAggregate and click the Component tab to access the configuration panel.
8. Click on the [...] button next to Edit schema to enter the following configuration:

The tCombinedSQLAggregate component instantiates four columns: id, state, date_of_birth, and salary, coming from the previous component.

9. The Group by table helps you define the data sets to be processed based on a defined column. In this example: State.

   In the Group by table, click the [+ ] button to add one line.

10. In the Output column drop-down list, select State. This column will be used to hold the data filtered on State.

11. The Operations table helps you define the type of aggregation operations to be performed. The Output column list available depends on the schema you want to output (through the
tCombinedSQLAggregate component. In this scenario, we want to group employees based on the state they live in. Then we want to count the number of employees per state, calculate the average/lowest/highest salaries as well as the oldest/youngest employees for each state.

12. In the Operations table, click the [+] button to add a line and then click in the Output column list to select the output column that will hold the computed data.

13. In the Function field, select the relevant operation to be carried out.

Writing the output data into MySQL

Procedure

1. In the design workspace, select tCombinedSQLOutput and click the Component tab to access the configuration panel.

   ![Configuration panel](image)

2. On the Database type list, select the relevant database.

3. On the Component list, select the relevant database connection component if more than one connection is used.

4. In the Table field, enter the name of the target table which will store the results of the aggregation operations, empl_by_state in this case.

   The tCombinedSQLOutput component requires that an output table already exists in the database to work. That is why the empl_by_state table was created earlier in the scenario.

   In this example, the Schema field doesn’t need to be filled out as the database is not Oracle.

5. Click the Sync columns button to retrieve the schema from the previous component.

   In this scenario, tCombinedSQLOutput instantiates seven columns coming from the previous component in the Job design (tCombinedSQLAggregate): state, empl_count, avg_salary, min_salary, max_salary, oldest_empl and youngest_empl.

Committing the data into the database

Procedure

1. In the design workspace, select tCombinedSQLCommit and click the Component tab to access the configuration panel.

2. On the Component list, select the relevant database connection component if more than one connection is used.

3. Clear the check box Close Connection.
Retrieving the filtered and aggregated data

Procedure

1. In the design workspace, select **tMysqlInput** and click the **Component** tab to define its basic settings.

   ![tMysqlInput_1](image)

   - **Basic settings**
     - Use an existing connection
     - Scheme: Built-In
     - Table Name: "empl_by_state"
     - Query:
       ```sql
       select * from emp
       l_by_state
       ```

2. Select the check box **Use an existing connection** and choose **tMysqlConnection_1** from the list.

3. Click on the [...] button next to **Edit schema** to enter the following schema:

   ![tMysqlInput_1](image)

4. In the field **Table Name**, enter `empl_by_state` and in the **Query** field, enter `select * from emp
l_by_state`.

5. In the design workspace, select **tLogRow** and click the **Component** tab to define its basic settings.

   ![tLogRow_1](image)
6. Click the **Sync columns** button to retrieve the schema from the previous component and select the **Table (print values in cells of a table)** mode.

### Saving and executing the Job

**Procedure**

1. Save your Job and press **F6** to execute it.
2. The **Run** tab opens, where you can observe the result of the Job execution.
3. The output data retrieved by the **tLogRow** is visible in a table.

### Results

Rows are inserted into a seven-column table *empl_by_state* in the database. The table shows, per defined state, the number of employees, the average salary, the lowest and highest salaries as well as the oldest and youngest employees.

```plaintext
[statistics] connecting to socket on port 3933
[statistics] connected

---
state | empl_count | avg_salary | min_salary | max_salary | oldest_empl | youngest_empl
--- | ---------- |------------|------------|------------|-------------|-------------

[statistics] disconnected
Job Executed at 20:15 22-04-2016. [exit code=0]
```
**tCombinedSQLFilter**

Filters data by reorganizing, deleting or adding columns based on the source table and to filter the given data source using the filter conditions.

tCombinedSQLFilter allows you to alter the schema of a source table through column name mapping and to define a row filter on that table. Therefore, it can be used to filter columns and rows at the same time. This component has real-time capabilities since it runs the data filtering on the DBMS itself.

**tCombinedSQLFilter Standard properties**

These properties are used to configure tCombinedSQLFilter running in the Standard Job framework.

The Standard tCombinedSQLFilter component belongs to the ELT family.

The component in this framework is available in all Talend products.

### Basic settings

| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

Click **Sync columns** to retrieve the schema from the previous component connected in the Job. |
| **Built-in**: You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide. |
| **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Jobs. Related topic: see Talend Studio User Guide. |
| **Logical operator between conditions** | Select the logical operator between the filter conditions defined in the **Conditions** panel. Two operators are available: **Or**, **And**. |
## Conditions

Select the type of WHERE clause along with the values and the columns to use for row filtering.

### Input Column

Select the column to filter in the list.

### Operator

Select the type of the WHERE clause: `=`, `<>`, `>`, `<`, `>=`, `<=`, `LIKE`, `IN`, `NOT IN`, and `EXIST IN`.

### Values

Type in the values to be used in the WHERE clause.

### Negate

Select this check box to enable the condition that is opposite to the current setting.

### Use custom SQL

Customize a WHERE clause by selecting this check box and editing in the SQL Condition field.

## Advanced settings

### tStatCatcher Statistics

Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

## Global Variables

### Global Variables

- **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is a Flow variable and it returns an integer.
- **QUERY**: the query statement being processed. This is a Flow variable and it returns a string.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

## Usage

### Usage rule

This component is an intermediary component. The use of the corresponding connection and commit components is recommended when using this component to allow a unique connection to be open and then closed during the Job execution.

## Related Scenario

For a related scenario, see Filtering and aggregating table columns directly on the DBMS on page 472.
tCombinedSQLInput

Extracts fields from a database table based on its schema definition.

Then it passes on the field list to the next component via a Combine row link. The schema of tCombinedSQLInput can be different from that of the source database table but must correspond to it in terms of the column order.

tCombinedSQLInput extracts fields from a database table based on its schema. This component also has column filtering capabilities since its schema can be different from that of the database table.

**tCombinedSQLInput Standard properties**

These properties are used to configure tCombinedSQLInput running in the Standard Job framework.
The Standard tCombinedSQLInput component belongs to the ELT family.
The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Table</th>
<th>Name of the source database table.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Schema</td>
<td>Name of the source table’s schema. This field has to be filled if the database is Oracle.</td>
</tr>
</tbody>

**Schema and Edit schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `LINE` when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

Click **Sync columns** to retrieve the schema from the previous component connected in the Job.

**Built-in**: You create and store the schema locally for this component only. Related topic: see **Talend Studio User Guide**.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Jobs. Related topic: see **Talend Studio User Guide**.

**Action on data**

Select **INSERT** from the list to insert the records from the incoming flow to the target database table.
Advanced settings

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

Global Variables

| Global Variables | NB_LINE: the number of rows read by an input component or transferred to an output component. This is a Flow variable and it returns an integer. |
| | QUERY: the query statement being processed. This is a Flow variable and it returns a string. |
| | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. |
| | A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. |
| | To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. |
| | For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | This component is an intermediary component. The use of the corresponding connection and commit components is recommended when using this component to allow a unique connection to be open and then closed during the Job execution. |

Related scenario

For a related scenario, see Filtering and aggregating table columns directly on the DBMS on page 472.
**tContextDump**

Copies the context setup of the current Job to a flat file, a database table, etc., which can then be used by tContextLoad.

Together with tContextLoad, this component makes it simple to apply the context setup of one Job to another.

**tContextDump Standard properties**

These properties are used to configure tContextDump running in the Standard Job framework.

The Standard tContextDump component belongs to the Misc family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Schema and Edit schema</th>
<th>A schema is a row description, it defines the fields that will be processed and passed on to the next component.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Note:</strong></td>
<td>The schema of tContextDump is read only and made up of two columns, Key and Value, corresponding to the parameter name and the parameter value of the Job context.</td>
</tr>
</tbody>
</table>

| Hide Password | Select this check box to hide the value of context parameter password, namely displaying the value of context parameters whose Type is Password as "." |

**Global Variables**

| Global Variables | **NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.  
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.  
For further information about variables, see Talend Studio User Guide. |
|------------------|----------------------------------------------------------------------------------------------------------|
Usage

| Usage rule | As a start component, tContextDump dumps the context setup of the current Job to a file, a database table, etc. |

Related scenarios

No scenario is available for the Standard version of this component yet.
tContextLoad

Loads a context from a flow.

This component performs also two controls. It warns when the parameters defined in the incoming flow are not defined in the context, and the other way around, it also warns when a context value is not initialized in the incoming flow. But note that this does not block the processing.

tContextLoad modifies dynamically the values of the active context.

**tContextLoad Standard properties**

These properties are used to configure tContextLoad running in the Standard Job framework.

The Standard tContextLoad component belongs to the Misc family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Schema and Edit schema</th>
<th>A schema is a row description, it defines the fields that will be processed and passed on to the next component. In tContextLoad, the schema must be made of two columns, including the parameter name and the parameter value to be loaded.</th>
</tr>
</thead>
<tbody>
<tr>
<td>If a variable loaded, but not in the context</td>
<td>If a variable is loaded but does not appear in the context, select how the notification must be displayed. In the shape of an Error, a warning or an information (info).</td>
</tr>
<tr>
<td>If a variable in the context, but not loaded</td>
<td>If a variable appears in the context but is not loaded, select how the notification must be displayed. In the shape of an Error, a warning or an information (info).</td>
</tr>
<tr>
<td>Print operations</td>
<td>Select this check box to display the context parameters set in the Run view.</td>
</tr>
<tr>
<td>Disable errors</td>
<td>Select this check box to prevent the error from displaying.</td>
</tr>
<tr>
<td>Disable warnings</td>
<td>Select this check box to prevent the warning from displaying.</td>
</tr>
<tr>
<td>Disable infos</td>
<td>Select this check box to prevent the information from displaying.</td>
</tr>
<tr>
<td>Die on error</td>
<td>This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStat Catcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |
Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_LINE: the number of rows processed. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>KEY_NOT_INCONTEXT: the variables are loaded but do not appear in the context. This is an After variable and it returns a string.</td>
</tr>
<tr>
<td></td>
<td>KEY_NOT_LOADED: the variables not loaded but appear in the context. This is an After variable and it returns a string.</td>
</tr>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component relies on the data flow to load the context values to be used, therefore it requires a preceding input component and thus cannot be a start component.</th>
</tr>
</thead>
</table>

Dynamic settings

<table>
<thead>
<tr>
<th>Dynamic settings</th>
<th>Click the [*] button to add a row in the table and fill the Code field with a context variable to turn on or off the Print operations option dynamically at runtime.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>When a dynamic parameter is defined, the corresponding Print operations option in the Basic settings view becomes unusable.</td>
</tr>
<tr>
<td></td>
<td>For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

Limitation

| Limitation | tContextLoad does not create any non-defined variable in the default context. |

Reading data from different MySQL databases using dynamically loaded connection parameters

The Job in this scenario is made of two subjobs. The first subjob aims at dynamically loading the context parameters from two text files, and the second subjob uses the loaded context parameters to connect to two different databases and to display the content of an existing database table of each
of them. With the context settings in the Job, we can decide which database to connect to and choose whether to display the set context parameters on the console dynamically at runtime.

**Dropping and linking the components**

**Procedure**

1. Drop a `tFileInputDelimited` component and a `tContextLoad` component from the **Palette** onto the design workspace, and link them using a **Row > Main** connection to form the first subJob.
2. Drop a `tMysqlInput` component and a `tLogRow` component onto the design workspace, and link them using a **Row > Main** connection to form the second subJob.
3. Link the two subJobs using a **Trigger > On Subjob Ok** connection.

![Diagram of dropped and linked components]

**Preparing the contexts and context variables**

**Procedure**

1. Create two delimited files corresponding to the two contexts in this scenario, namely two databases we will access, and name them `test_connection.txt` and `prod_connection.txt`, which contain the database connection details for testing and actual production purposes respectively. Each file is made of two columns, containing the parameter names and the corresponding values respectively. Below is an example:

```plaintext
host;localhost
port;3306
database;test
username;root
password;talend
```

2. Select the **Contexts** view of the Job, and click the `[+]` button at the bottom of the view to add seven rows in the table to define the following parameters:

- `host`, String type
- `port`, String type
- `database`, String type
- `username`, String type
- `password`, Password type
- `filename`, File type
- `printOperations`, Boolean type
Note that the `host, port, database, username` and `password` parameters correspond to the parameter names in the delimited files and are used to set up the desired database connection, the `filename` parameter is used to define the delimited file to read at Job execution, the `printOperations` parameter is used to decide whether to print the context parameters set by the `tContextLoad` component on the console.

3. Click the **Contexts** tab and click the `[+]` button at the upper right corner of the panel to open the **Configure Contexts** dialog box.

4. Select the default context, click the **Edit** button and rename the context to **Test**.

5. Click **New** to add a new context named **Production**. Then click **OK** to close the dialog box.

6. Back in the **Contexts** tab view, define the value of the `filename` variable under each context by clicking in the respective **Value** field and browse to the corresponding delimited file.

7. Select the **Prompt** check box next to the **Value** field of the `filename` variable for both contexts to show the **Prompt** fields and enter the prompt message to be displayed at the execution time.

8. For the `printOperations` variable, click in the **Value** field under the **Production** context and select `false` from the list; click in the **Value** field under the **Test** context and select `true` from the list. Then select the **Prompt** check box under both contexts and enter the prompt message to be displayed at the execution time.
Configuring the components

Procedure

1. In the tFileInputDelimited component Basic settings panel, fill the File name/Stream field with the relevant context variable we just defined: context.filename.

2. Define the file schema manually (Built-in). It contains two columns defined as: key and value.

3. Accept the defined schema to be propagated to the next component (tContextLoad).

4. In the Dynamic settings view of the tContextLoad component, click the [+] button to add a row in the table, and fill the Code field with context.printOperations to use context variable printOperations we just defined. Note that the Print operations check box in the Basic settings view now becomes highlighted and unusable.

5. Then double-click to open the tMySqlInput component Basic settings view.

6. Fill the Host, Port, Database, Username, and Password fields with the relevant variables stored in the delimited files and defined in the Contexts tab view: context.host, context.port, context.database, context.username, and context.password respectively in this example, and fill the Table Name field with the actual database table name to read data from, customers for both databases in this example.
7. Then fill in the Schema information. If you stored the schema in the Repository Metadata, then you can retrieve it by selecting Repository and the relevant entry in the list. In this example, the schema of both database tables is made of four columns: id (INT, 2 characters long), firstName (VARCHAR, 15 characters long), lastName (VARCHAR, 15 characters long), and city (VARCHAR, 15 characters long).

8. In the Query field, type in the SQL query to be executed on the DB table specified. In this example, simply click Guess Query to retrieve all the columns of the table, which will be displayed on the Run tab, through the tLogRow component.

9. In the Basic settings view of the tLogRow component, select the Table option to display data records in the form of a table.

**Executing the Job**

**Procedure**

1. Press Ctrl+S to save the Job, and press F6 to run the Job using the default context, which is Test in this use case.

   A dialog box appears to prompt you to specify the delimited file to read and decide whether to display the set context parameters on the console.
You can specify a file other than the default one if needed, and clear the Show loaded variables check box if you do not want to see the set context variables on the console. To run the Job using the default settings, click OK.

The context parameters and content of the database table in the Test context are all displayed on the Run console.

2. Now select the Production context and press F6 to launch the Job again. When the prompt dialog box appears, simply click OK to run the Job using the default settings.
The content of the database table in the *Production* context is displayed on the Run console. Because the `printOperations` variable is set to `false`, the set context parameters are not displayed on the console this time.
tConvertType

Converts one Talend java type to another automatically, and thus avoid compiling errors.
tConvertType allows specific conversions at runtime from one Talend java type to another.

**tConvertType Standard properties**

These properties are used to configure tConvertType running in the Standard Job framework.
The Standard tConvertType component belongs to the Processing family.
The component in this framework is available in all Talend products.

**Basic settings**

| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:
| • **View schema**: choose this option to view the schema only.
| • **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
| • **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |
| **Built-In**: You create and store the schema locally for this component only. |
| **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. |
| **Auto Cast** | This check box is selected by default. It performs an automatic java type conversion. |
| **Manual Cast** | This mode is not visible if the Auto Cast check box is selected. It allows you to precise manually the columns where a java type conversion is needed. |
| **Set empty values to Null before converting** | This check box is selected to set the empty values of String or Object type to null for the input data. |
| **Die on error** | This check box is selected to kill the Job when an error occurs. |
tConvertType

**Advanced settings**

**tStatCatcher Statistics**
Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

**Global Variables**

**Global Variables**

`ERROR_MESSAGE`: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

`NB_LINE`: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](https://www.talend.com/docs/user-guide/).

**Usage**

**Usage rule**
This component cannot be used as a start component as it requires an input flow to operate.

**Converting java types**

This Java scenario describes a four-component Job where the **tConvertType** component is used to convert Java types in three columns, and a **tMap** is used to adapt the schema and have as an output the first of the three columns and the sum of the two others after conversion.

**Note:**

In this scenario, the input schemas for the input delimited file are stored in the repository, you can simply drag and drop the relevant file node from **Repository - Metadata - File delimited** onto the design workspace to automatically retrieve the **tFileInputDelimited** component’s setting. For more information, see [Talend Studio User Guide](https://www.talend.com/docs/user-guide/).
**Dropping the components**

**Procedure**

1. Drop the following components from the Palette onto the design workspace: tConvertType, tMap, and tLogRow.

2. In the Repository tree view, expand Metadata and from File delimited drag the relevant node, JavaTypes in this scenario, to the design workspace.

   The Components dialog box displays.

3. From the component list, select tFileInputDelimited and click Ok.

   A tFileInputComponent called Java types displays in the design workspace.

4. Connect the components using Row > Main links.

![Diagram of component connections]

**Configuring the components**

**Procedure**

1. Double-click tFileInputDelimited to enter its Basic settings view.

2. Set Property Type to Repository since the file details are stored in the repository. The fields to follow are pre-defined using the fetched data.

![Basic settings of tFileInputDelimited component]

The input file used in this scenario is called *input*. It is a text file that holds string, integer, and float java types.

![Input file content]

Fill in all other fields as needed. For more information, see tFileInputDelimited on page 1008. In this scenario, the header and the footer are not set and there is no limit for the number of processed rows.
3. Click **Edit schema** to describe the data structure of this input file. In this scenario, the schema is made of three columns, *StringToInteger*, *IntegerField*, and *FloatToInteger*.

![Schema of Java Types](image)

4. Click **Ok** to close the dialog box.

5. Double-click **tConvertType** to enter its **Basic settings** view.

![tConvertType_1](image)

6. Set **Schema Type** to **Built in**, and click **Sync columns** to automatically retrieve the columns from the **tFileInputDelimited** component.

7. Click **Edit schema** to describe manually the data structure of this processing component.

![Schema oftConvertType_1](image)

In this scenario, we want to convert a string type data into an integer type and a float type data into an integer type.

Click **OK** to close the **Schema of tConvertType** dialog box.

8. Double-click **tMap** to open the Map editor.

The Map editor displays the input metadata of the **tFileInputDelimited** component.
9. In the **Schema editor** panel of the Map editor, click the plus button of the output table to add two rows and name them to *StringToInteger* and *Sum*.

10. In the Map editor, drag the *StringToInteger* row from the input table to the *StringToInteger* row in the output table.

11. In the Map editor, drag each of the *IntegerField* and the *FloatToInteger* rows from the input table to the *Sum* row in the output table and click **OK** to close the Map editor.

12. In the design workspace, select **tLogRow** and click the **Component** tab to define its basic settings. For more information, see *tLogRow* on page 1956.
**Executing the Job**

**Procedure**

1. Press **Ctrl+S** to save the Job.
2. Press **F6** to execute it.

```
Starting job tConvertType at 18:03 19/11/2008.
<table>
<thead>
<tr>
<th>tLogRow_1</th>
<th>StringToInteger</th>
<th>sum</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>1579</td>
<td></td>
</tr>
</tbody>
</table>
```

The string type data is converted into an integer type and displayed in the `StringToInteger` column on the console. The float type data is converted into an integer and added to the `IntegerField` value to give the addition result in the `Sum` column on the console.
tCosmosDBBulkLoad

Imports data files in different formats (CSV, TSV or JSON) into the specified Cosmos database so that the data can be further processed.

**tCosmosDBBulkLoad Standard properties**

These properties are used to configure tCosmosDBBulkLoad running in the Standard Job framework.

The Standard tCosmosDBBulkLoad component belongs to the Cloud and the Databases families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields. Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
  - View schema: choose this option to view the schema only.  
  - Change to built-in property: choose this option to change the schema to **Built-in** for local changes.  
  - Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window. |
| **MongoDB directory** | Fill in this field with the MongoDB home directory. |
| **Use replica set address or multiple query routers** | Select this check box to show the **Server addresses** table. In the **Server addresses** table, define the sharded MongoDB databases or the MongoDB replica sets you want to connect to. |
| **Server and Port** | Enter the IP address and listening port of the database server. Available when the **Use replica set address or multiple query routers** check box is not selected. |
| **Database** | Enter the name of the MongoDB database to be connected to. |
| **Collection** | Type in the name of the collection to import data to. |
| **Drop collection if exist** | Select this check box to remove the collection if it already exists. |
### Authentication mechanism

Among the mechanisms listed on the **Authentication mechanism** drop-down list, the **NEGO7IATE** one is recommended if you are not using Kerberos, because it automatically select the authentication mechanism the most adapted to the MongoDB version you are using.

For details about the other mechanisms in this list, see [MongoDB Authentication](from the MongoDB documentation).

### Set Authentication database

If the username to be used to connect to MongoDB has been created in a specific Authentication database of MongoDB, select this check box to enter the name of this Authentication database in the **Authentication database** field that is displayed.

For further information about the MongoDB Authentication database, see [User Authentication database](.

### Username and Password

DB user authentication data.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

Available when the **Required authentication** check box is selected.

If the security system you have selected from the **Authentication mechanism** drop-down list is Kerberos, you need to enter the **User principal**, the **Realm** and the **KDC server** fields instead of the **Username** and the **Password** fields.

### Data file

Type in the full path of the file from which the data will be imported or click the [...] button to browse to the desired data file.

Make sure that the data file is in standard format. For example, the fields in CSV files should be separated with commas.

### File type

Select the proper file type from the list. CSV, TSV and JSON are supported.

### The JSON file starts with an array

Select this check box to allow tCosmosDBBulkload to read the JSON files starting with an array.

This check box appears when the **File type** you have selected is JSON.

### Action on data

Select the action that you want to perform on the data.

- **Insert**: Insert the data into the database.
  
  Note that when inserting data from CSV or TSV files into the MongoDB database, you need to specify fields either by selecting the **First line is header** check box or defining them in the schema.

- **Upsert**: Insert the data if they do not exist or update the existing data.
  
  Note that when upserting data into the MongoDB database, you need to specify a list of fields for the query portion of the upsert operation.
**Upsert fields**

Customize the fields that you want to upsert as needed. This table is available when you select **Upsert** from the **Action on data** list.

<table>
<thead>
<tr>
<th>First line is header</th>
<th>Select this check box to use the first line in CSV or TSV files as a header. This check box is available only when you select CSV or TSV from the <strong>File type</strong> list.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ignore blanks</td>
<td>Select this check box to ignore the empty fields in CSV or TSV files. This check box is available only when you select CSV or TSV from the <strong>File type</strong> list.</td>
</tr>
<tr>
<td>Print log</td>
<td>Select this check box to print logs.</td>
</tr>
</tbody>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th>Additional arguments</th>
<th>Complete this table to use the additional arguments as required. For example, you can use the argument &quot;--jsonArray&quot; to accept the import of data expressed with multiple MongoDB documents within a single JSON array. For more information about the additional arguments, go to <a href="http://docs.mongodb.org/manual/reference/program/mongoimport/">http://docs.mongodb.org/manual/reference/program/mongoimport/</a> and read the description of options.</th>
</tr>
</thead>
<tbody>
<tr>
<td>tStatCatcher Statistics</td>
<td>Select this check box to collect the log data at a component level.</td>
</tr>
</tbody>
</table>

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component can be used together with the <strong>tCosmosDBInput</strong> component to verify if the data is imported as expected.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limitation</td>
<td>The MongoDB client tool needs to be installed on the machine where Jobs using this component are executed.</td>
</tr>
</tbody>
</table>
tCosmosDBConnection

Creates a connection to a CosmosDB database and reuse that connection in other components.

**tCosmosDBConnection Standard properties**

These properties are used to configure tCosmosDBConnection running in the Standard Job framework.

The Standard tCosmosDBConnection component belongs to the Cloud and the Databases families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
</table>
| API | Select the database API to be used. Then the corresponding parameters to be defined are displayed in the Component view.  
In the current version of this component, only the MongoDB API is supported. For this reason, MongoDB database is often mentioned in the documentation of the CosmosDB components. |
| Use replica set address or multiple query routers | Select this check box to show the Server addresses table.  
In the Server addresses table, define the sharded MongoDB databases or the MongoDB replica sets you want to connect to. |
| Server and Port | Enter the IP address and listening port of the database server.  
Available when the Use replica set address or multiple query routers check box is not selected. |
| Database | Enter the name of the MongoDB database to be connected to. |
| Authentication mechanism | Among the mechanisms listed on the Authentication mechanism drop-down list, the NEGOTIATE one is recommended if you are not using Kerberos, because it automatically select the authentication mechanism the most adapted to the MongoDB version you are using.  
For details about the other mechanisms in this list, see MongoDB Authentication from the MongoDB documentation. |
| Set Authentication database | If the username to be used to connect to MongoDB has been created in a specific Authentication database of MongoDB, select this check box to enter the name of this Authentication database in the Authentication database field that is displayed.  
For further information about the MongoDB Authentication database, see User Authentication database. |
| Username and Password | DB user authentication data. |
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

Available when the Use authentication check box is selected.

If the security system you have selected from the Authentication mechanism drop-down list is Kerberos, you need to enter the User principal, the Realm and the KDC server fields instead of the Username and the Password fields.

**Advanced settings**

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
<th>Select this check box to collect the log data at a component level.</th>
</tr>
</thead>
<tbody>
<tr>
<td>No query timeout</td>
<td>Select this check box to prevent MongoDB servers from stopping idle cursors at the end of 10-minute inactivity of these cursors. In this situation, an idle cursor will stay open until either the results of this cursor are exhausted or you manually close it using the cursor.close() method. A cursor for MongoDB is a pointer to the result set of a query. By default, that is to say, with this check box being clear, a MongoDB server automatically stops idle cursors after a given inactivity period to avoid excess memory use. For further information about MongoDB cursors, see <a href="https://docs.mongodb.org/manual/core/cursors/">https://docs.mongodb.org/manual/core/cursors/</a>.</td>
</tr>
</tbody>
</table>

**Usage**

| Usage rule | This component is generally used with other CosmosDB components, particularly tCosmosClose. |
tCosmosDBInput

Retrieves certain documents from a Cosmos database collection by supplying a query document containing the fields the desired documents should match.

**tCosmosDBInput Standard properties**

These properties are used to configure tCosmosDBInput running in the Standard Job framework.

The Standard tCosmosDBInput component belongs to the Cloud and the Databases families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>

<tr>
<td>Server and Port</td>
<td>Enter the IP address and listening port of the database server. Available when the Use replica set address or multiple query routers check box is not selected.</td>
</tr>
<tr>
<td>Database</td>
<td>Enter the name of the MongoDB database to be connected to.</td>
</tr>
<tr>
<td>Set read preference</td>
<td>Select this check box and from the Read preference drop-down list that is displayed, select the member to which you need to direct the read operations.</td>
</tr>
<tr>
<td></td>
<td>If you leave this check box clear, the Job uses the default Read preference, that is to say, uses the primary member in a replica set.</td>
</tr>
<tr>
<td></td>
<td>For further information, see MongoDB’s documentation about Replication and its Read preferences.</td>
</tr>
<tr>
<td>Authentication mechanism</td>
<td>Among the mechanisms listed on the Authentication mechanism drop-down list, the NEGOTIATE one is recommended if you are not using Kerberos, because it automatically select the authentication mechanism the most adapted to the MongoDB version you are using.</td>
</tr>
</tbody>
</table>
For details about the other mechanisms in this list, see [MongoDB Authentication](https://docs.mongodb.com/manual/reference/authorization/) from the MongoDB documentation.

<table>
<thead>
<tr>
<th><strong>Set Authentication database</strong></th>
</tr>
</thead>
</table>
| If the username to be used to connect to MongoDB has been created in a specific Authentication database of MongoDB, select this check box to enter the name of this Authentication database in the **Authentication database** field that is displayed.  

For further information about the MongoDB Authentication database, see [User Authentication database](https://docs.mongodb.com/manual/core/authentication/). |

<table>
<thead>
<tr>
<th><strong>Username and Password</strong></th>
</tr>
</thead>
</table>
| DB user authentication data.  

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.  

Available when the **Use authentication** check box is selected.  

If the security system you have selected from the **Authentication mechanism** drop-down list is Kerberos, you need to enter the **User principal**, the **Realm** and the **KDC server** fields instead of the **Username** and the **Password** fields. |

<table>
<thead>
<tr>
<th><strong>Collection</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Name of the collection in the database.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Schema and Edit Schema</strong></th>
</tr>
</thead>
</table>
| A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.  

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  

• **View schema**: choose this option to view the schema only.  

• **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  

• **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No upon completion** and choose this schema metadata again in the **Repository Content** window.  

If a column in the database is a JSON document and you need to read the entire document, put an asterisk (*) in the **DB column** column, without quotation marks around. |

<table>
<thead>
<tr>
<th><strong>Query</strong></th>
</tr>
</thead>
</table>
| Specify the query condition. This field is available only when you have selected **Find query** from the **Query type** drop-down list.  

For example, type in "{id: 4}" to retrieve the record whose id is 4 from the collection specified in the **Collection** field.  

Different from the query statements required in the MongoDB client software, the query here refers to the contents inside `find()`, such as the query here `{id: 4}`. |
versus the MongoDB client query `db.blog.find({id:4}).`

### Mapping

Each column of the schema defined for this component represents a field of the documents to be read. In this table, you need to specify the parent nodes of these fields, if any.

For example, in the document reading as follows

```json
{
  _id: ObjectId("5099803df3f4948bd2f98391"),
  person: { first: "Joe", last: "Walker" }
}
```

The `first` and the `last` fields have `person` as their parent node but the `_id` field does not have any parent node. So once completed, this Mapping table should read as follows:

<table>
<thead>
<tr>
<th>Column</th>
<th>Parent node path</th>
</tr>
</thead>
<tbody>
<tr>
<td>_id</td>
<td></td>
</tr>
<tr>
<td>first</td>
<td>&quot;person&quot;</td>
</tr>
<tr>
<td>last</td>
<td>&quot;person&quot;</td>
</tr>
</tbody>
</table>

### Sort by

Specify the column and choose the order for the sort operation.

This field is available only when you have selected `Find query` from the `Query type` drop-down list.

### Limit

Type in the maximum number of records to be retrieved.

This field is available only when you have selected `Find query` from the `Query type` drop-down list.

### Advanced settings

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
<th>Select this check box to collect the log data at the component level.</th>
</tr>
</thead>
<tbody>
<tr>
<td>No query timeout</td>
<td>Select this check box to prevent MongoDB servers from stopping idle cursors at the end of 10-minute inactivity of these cursors. In this situation, an idle cursor will stay open until either the results of this cursor are exhausted or you manually close it using the <code>cursor.close()</code> method. A cursor for MongoDB is a pointer to the result set of a query. By default, that is to say, with this check box being clear, a MongoDB server automatically stops idle cursors after a given inactivity period to avoid excess memory use. For further information about MongoDB cursors, see <a href="https://docs.mongodb.org/manual/core/cursors/">https://docs.mongodb.org/manual/core/cursors/</a>.</td>
</tr>
<tr>
<td>Enable external sort</td>
<td>Since the aggregation pipeline stages have a maximum memory use limit (100 megabytes) and a stage exceeding this limit will produce errors, when handling large datasets, select this check box to avoid aggregation stages exceeding this limit. For further information about this external sort, see Large sort operation with external sort.</td>
</tr>
</tbody>
</table>
### Usage

| Usage rule | As a start component, **tCosmosDBInput** allows you to retrieve records from a collection in the Cosmos database and transfer them to the following component for display or storage. |

---
tCosmosDBOutput

Inserts, updates, upserts or deletes documents in a Cosmos database collection based on the incoming flow from the preceding component in the Job.

**tCosmosDBOutput Standard properties**

These properties are used to configure tCosmosDBOutput running in the Standard Job framework.

The Standard tCosmosDBOutput component belongs to the Cloud and the Databases families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Use existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>API</strong></td>
<td>Select the database API to be used. Then the corresponding parameters to be defined are displayed in the Component view. In the current version of this component, only the MongoDB API is supported. For this reason, MongoDB database is often mentioned in the documentation of the CosmosDB components.</td>
</tr>
<tr>
<td><strong>Use replica set address or multiple query routers</strong></td>
<td>Select this check box to show the Server addresses table. In the Server addresses table, define the sharded MongoDB databases or the MongoDB replica sets you want to connect to.</td>
</tr>
<tr>
<td><strong>Server</strong> and <strong>Port</strong></td>
<td>Enter the IP address and listening port of the database server. Available when the Use replica set address or multiple query routers check box is not selected.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Enter the name of the MongoDB database to be connected to.</td>
</tr>
<tr>
<td><strong>Set write concern</strong></td>
<td>Select this check box to set the level of acknowledgements requested from for write operations. Then you need to select the level of this operation. For further information, see the related MongoDB documentation on <a href="http://docs.mongodb.org/manual/core/write-concern/">http://docs.mongodb.org/manual/core/write-concern/</a>.</td>
</tr>
<tr>
<td><strong>Bulk write</strong></td>
<td>Select this check box to insert, update or remove data in bulk. Note this feature is available only when the version of MongoDB you are using is 2.6+. Then you need to select Ordered or Unordered to define how the MongoDB database processes the data sent by the Studio.</td>
</tr>
</tbody>
</table>
- If you select **Ordered**, MongoDB processes the queries sequentially.
- If you select **Unordered**, MongoDB optimizes the bulk write operations without keeping the order in which the individual operations were inserted in the bulk write.

In the **Bulk write size** field, enter the size of each query group to be processed by MongoDB. In the documentation of MongoDB, some restrictions and expected behaviors as to this size are explained. You can find the details on [http://docs.mongodb.org/manual/core/bulk-write-operations/](http://docs.mongodb.org/manual/core/bulk-write-operations/).

<table>
<thead>
<tr>
<th>Authentication mechanism</th>
</tr>
</thead>
<tbody>
<tr>
<td>Among the mechanisms listed on the <strong>Authentication mechanism</strong> drop-down list, the <strong>NEGOTIATE</strong> one is recommended if you are not using Kerberos, because it automatically select the authentication mechanism the most adapted to the MongoDB version you are using. For details about the other mechanisms in this list, see <strong>MongoDB Authentication</strong> from the MongoDB documentation.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Set Authentication database</th>
</tr>
</thead>
<tbody>
<tr>
<td>If the username to be used to connect to MongoDB has been created in a specific Authentication database of MongoDB, select this check box to enter the name of this Authentication database in the <strong>Authentication database</strong> field that is displayed. For further information about the MongoDB Authentication database, see <strong>User Authentication database</strong>.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Username and Password</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB user authentication data. To enter the password, click the [... ] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings. Available when the <strong>Use authentication</strong> check box is selected. If the security system you have selected from the <strong>Authentication mechanism</strong> drop-down list is Kerberos, you need to enter the <strong>User principal</strong>, the <strong>Realm</strong> and the <strong>KDC server</strong> fields instead of the <strong>Username</strong> and the <strong>Password</strong> fields.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Collection</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name of the collection in the database.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Drop collection if exist</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select this check box to drop the collection if it already exists.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Action on data</th>
</tr>
</thead>
</table>
| The following operations are available:  
  - **Insert**: insert documents.  
  - **Set**: modifies the existing fields of an existing document and appends a field if it does not exist in this document.  
    
    If you need to apply this action on all the documents in the collection to be used, select the **Update all document** check box that is displayed; otherwise, only the first document is updated. |
- **Update**: replaces the existing documents with the incoming data but keeps the technical ID of these documents.
- **Upsert**: inserts a document if it does not exist otherwise it applies the same rules as **Update**.
- **Upsert with set**: inserts a document if it does not exist otherwise it applies the same rules as **Set**

If you need to apply this action on all the documents in the collection to be used, select the **Update all document** check box that is displayed; otherwise, only the first document is updated.

- **Delete**: delete documents.

### Schema and Edit Schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

Click **Sync columns** to retrieve the schema from the previous component connected in the Job.

### Built-In

- **Built-In**: You create and store the schema locally for this component only.

### Repository

- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

### Mapping

Each column of the schema defined for this component represents a field of the documents to be read. In this table, you need to specify the parent nodes of these fields, if any.

For example, in the document reading as follows

```json
{  
    _id: ObjectId("5099803df3f4948bd2f98391"),
    person: { first: "Joe", last: "Walker" }
}
```
The first and the last fields have person as their parent node but the _id field does not have any parent node. So once completed, this Mapping table should read as follows:

<table>
<thead>
<tr>
<th>Column</th>
<th>Parent node path</th>
</tr>
</thead>
<tbody>
<tr>
<td>_id</td>
<td></td>
</tr>
<tr>
<td>first</td>
<td>&quot;person&quot;</td>
</tr>
<tr>
<td>last</td>
<td>&quot;person&quot;</td>
</tr>
</tbody>
</table>

Not available when the Generate JSON Document check box is selected in Advanced settings.

**Die on error**

This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

**Advanced settings**

**Generate JSON Document**

Select this check box for JSON configuration:

- **Configure JSON Tree**: click the [...] button to open the interface for JSON tree configuration. For more information, see Configuring a JSON Tree on page 3987.
- **Group by**: click the [+] button to add lines and choose the input columns for grouping the records.
- **Remove root node**: select this check box to remove the root node.
- **Data node** and **Query node** (available for update and upsert actions): type in the name of data node and query node configured on the JSON tree.

These nodes are mandatory for update and upsert actions. They are intended to enable the update and upsert actions though will not be stored in the database.

**No query timeout**

Select this check box to prevent MongoDB servers from stopping idle cursors at the end of 10-minute inactivity of these cursors. In this situation, an idle cursor will stay open until either the results of this cursor are exhausted or you manually close it using the cursor.close() method.

A cursor for MongoDB is a pointer to the result set of a query. By default, that is to say, with this check box being clear, a MongoDB server automatically stops idle cursors after a given inactivity period to avoid excess memory use. For further information about MongoDB cursors, see https://docs.mongodb.org/manual/core/cursors/.

**tStatCatcher Statistics**

Select this check box to collect the log data at the component level.

**Usage**

**Usage rule**

tCosmosDBOutput executes the action defined on the collection in the database based on the flow incoming from the preceding component in the Job.

**Limitation**

- The "multi" parameter, which allows to update multiple documents at a time, is not supported. Therefore, if two documents have the same key, the first is always updated, but the second never will.
<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• For the update operation, the key cannot be a JSON array.</td>
</tr>
</tbody>
</table>
tCosmosDBRow

Executes the commands of the Cosmos database.

**tCosmosDBRow Standard properties**

These properties are used to configure tCosmosDBRow running in the Standard Job framework.

The Standard tCosmosDBRow component belongs to the Cloud and the Databases families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td>API</td>
<td>Select the database API to be used. Then the corresponding parameters to be defined are displayed in the Component view.</td>
</tr>
<tr>
<td></td>
<td>In the current version of this component, only the MongoDB API is supported. For this reason, MongoDB database is often mentioned in the documentation of the CosmosDB components.</td>
</tr>
<tr>
<td>Use replica set address or multiple query routers</td>
<td>Select this check box to show the Server addresses table.</td>
</tr>
<tr>
<td></td>
<td>In the Server addresses table, define the sharded MongoDB databases or the MongoDB replica sets you want to connect to.</td>
</tr>
<tr>
<td>Server and Port</td>
<td>Enter the IP address and listening port of the database server.</td>
</tr>
<tr>
<td></td>
<td>Available when the Use replica set address or multiple query routers check box is not selected.</td>
</tr>
<tr>
<td>Database</td>
<td>Enter the name of the MongoDB database to be connected to.</td>
</tr>
<tr>
<td>Authentication mechanism</td>
<td>Among the mechanisms listed on the Authentication mechanism drop-down list, the NEGOTIATE one is recommended if you are not using Kerberos, because it automatically select the authentication mechanism the most adapted to the MongoDB version you are using.</td>
</tr>
<tr>
<td></td>
<td>For details about the other mechanisms in this list, see MongoDB Authentication from the MongoDB documentation.</td>
</tr>
<tr>
<td>Set Authentication database</td>
<td>If the username to be used to connect to MongoDB has been created in a specific Authentication database of MongoDB, select this check box to enter the name of this Authentication database in the Authentication database field that is displayed.</td>
</tr>
</tbody>
</table>
For further information about the MongoDB Authentication database, see User Authentication database.

**Username and Password**

DB user authentication data.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

Available when the Use authentication check box is selected.

If the security system you have selected from the Authentication mechanism drop-down list is Kerberos, you need to enter the User principal, the Realm and the KDC server fields instead of the Username and the Password fields.

**Schema and Edit Schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

Click Sync columns to retrieve the schema from the previous component connected in the Job.

**Execute command**

Select this check box to enter MongoDB commands in the Command field for execution.

- **Command**: in this field, enter the command to be executed, if this command contains one single variable.

  For example, if you need to construct the command
  ```
  {"isMaster": 1}
  ```

  You need simply enter isMaster within quotation marks.

- **Construct command from keys and values**: if the command to be executed contains multiple variables, select this check box and in the Command keys and values table, add the variables and their respective values to be used.
For example, if you need to construct the following command

```
{ renameCollection : "<source_namespace>" , to : "<target_namespace>" ,
  dropTarget : < true | false > }
```

You need to add three rows to the **Command keys and values** table and enter one variable-value pair to each row within quotation marks:

<table>
<thead>
<tr>
<th>Command key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>renameCollection</td>
<td>old_name</td>
</tr>
<tr>
<td>to</td>
<td>new_name</td>
</tr>
<tr>
<td>dropTarget</td>
<td>false</td>
</tr>
</tbody>
</table>

- **Construct command from a JSON string**: if you want to directly enter the command to be used, select this check box and enter this command in the **JSON string command** field that is displayed. Only one command is allowed per **tCosmosDBRow**.

For example:

```
"{createIndexes: 'restaurants',
  indexes : [{key : {restaurant_id : 1}, name: 'id_index_2', unique: true}]}"
```

Note that you must use single quotation marks to surround the string values used in the command and double quotation marks to surround the command itself.

For further information about the MongoDB commands you can use in this field, see [https://docs.mongodb.org/manual/reference/command/](https://docs.mongodb.org/manual/reference/command/).

**Die on error**

This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

**Advanced settings**

- **tStatCatcher Statistics**: select this check box to collect the log data at the component level.

**Usage**

- **Usage rule**: **tCosmosDBRow** allows you to manipulate the Cosmos database through the MongoDB commands.
tCouchbaseInput

Queries the documents from the Couchbase database.

**tCouchbaseInput Standard properties**

These properties are used to configure tCouchbaseInput running in the Standard Job framework.

The Standard tCouchbaseInput component belongs to the Databases NoSQL family.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Bucket</strong></td>
<td>Enter, within double quotation marks, the name of the data bucket in the Couchbase database.</td>
</tr>
<tr>
<td></td>
<td>If you are using Couchbase V5.0, this bucket name is the user name you have created in the Security tab of your Couchbase UI.</td>
</tr>
<tr>
<td></td>
<td>Since version 7.1, Couchbase V5.5 and V6.0 are supported.</td>
</tr>
<tr>
<td><strong>Password</strong></td>
<td>Provide the authentication credentials to a bucket.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td></td>
<td>If you are using Couchbase V5.0, enter the same value you put in the <strong>Bucket</strong> field as password, because in Couchbase V5.0, no password is associated with a bucket.</td>
</tr>
<tr>
<td></td>
<td>However, on Couchbase, you need to create a user with appropriate role to access the buckets.</td>
</tr>
<tr>
<td></td>
<td>For further information about the access control and other important requirements on the Couchbase V5.0 side, see Couchbase V5.0 release note: Major Behavior Changes.</td>
</tr>
<tr>
<td><strong>Bootstrap nodes</strong></td>
<td>Enter the name or IP of the node to be bootstrapped by Couchbase SDK. As Couchbase recommends to specify multiple nodes to bootstrap, enter the names or IPs of these nodes in this field, separating them using commas (,).</td>
</tr>
<tr>
<td></td>
<td>For further information about Couchbase bootstrapping, see How Couchbase SDKs connect to the cluster.</td>
</tr>
<tr>
<td><strong>Schema and Edit Schema</strong></td>

<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td></td>
<td>Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:</td>
</tr>
</tbody>
</table>
• **View schema**: choose this option to view the schema only.

• **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.

• **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

Click **Sync columns** to retrieve the schema from the previous component connected in the Job.

**Built-In**: You create and store the schema locally for this component only.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

**Field to use as ID**

Enter, within double quotation marks, the name of the column from the schema of tCouchbaseOutput to provide IDs for the documents to be written to Couchbase.

**Die on error**

Select the check box to stop the execution of the Job when an error occurs.

Clear the check box to skip any rows on error and complete the process for error-free rows.

### Advanced settings

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

**Global Variables**

- **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.

- **NB_SUCCESS**: the number of rows successfully processed. This is an After variable and it returns an integer.

- **NB_REJECT**: the number of rows rejected. This is an After variable and it returns an integer.

- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

## Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>Preceded by an input component, tCouchbaseOutput wraps flat data into documents for storage in the Couchbase database.</th>
</tr>
</thead>
</table>
**tCouchDBClose**

Disconnects a connection to a CouchDB server in order to release the occupied resources.

**tCouchDBClose Standard properties**

These properties are used to configure tCouchDBClose running in the Standard Job framework.

The Standard tCouchDBClose component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| Component List | Select an active CouchDB connection to be closed. |

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global Variables**

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it. For further information about variables, see *Talend Studio User Guide*. |

**Usage**

| Usage rule | This component is generally used with other CouchDB components, particularly **tCouchDBConnection**. |

**Related Scenario**

For a scenario in which **tCouchDBClose** is used, see *Replicating data from the source database to the target database* on page 536.
**tCouchDBConnection**

Opens a connection to a CouchDB server to be reused by the other CouchDB components.

You can also configure replication parameters if a replication is triggered between the source database and the target database.

**tCouchDBConnection Standard properties**

These properties are used to configure tCouchDBConnection running in the Standard Job framework.

The Standard tCouchDBConnection component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

Usage

| Usage rule | This component is generally used with other CouchDB components, particularly tCouchDBClose. |

Related scenario

For a scenario in which tCouchDBConnection is used, see Replicating data from the source database to the target database on page 536.
tCouchDBInput

Extracts the desired JSON data out of a CouchDB database to make transformation to it, migrates it to another target format, or processes it before inserting it to the same database.

## tCouchDBInput Standard properties

These properties are used to configure tCouchDBInput running in the Standard Job framework.

The Standard tCouchDBInput component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

<td>Node within the JSON field, on which the loop is based.</td>
</tr>
</tbody>
</table>
| **Mapping** | **Schema output column**: schema defined to hold the data extracted from the JSON field.  
**XPath query**: XPath query to specify the node within the JSON field to be extracted.  
**Get Nodes**: select this check box if you need to get values from a nested node within the JSON field. |
| **Limit** | Enter the maximum number of rows to process. |
| **Die on error** | This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows. |

**Advanced settings**

| **tStatCatcher Statistics** | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global Variables**

| **Global Variables** | **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.  
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
For further information about variables, see **Talend Studio User Guide**. |

**Usage**

| **Usage rule** | This component always needs an output link. |
Related Scenario

For a scenario in which tCouchDBInput is used, see Replicating data from the source database to the target database on page 536.
tCouchDBOutput

Loads JSON documents, writes data into or remove data from them and then saves the documents back to the database on a CouchDB server.

tCouchDBOutput receives data from the preceding component, and writes data into CouchDB.

**tCouchDBOutput Standard properties**

These properties are used to configure tCouchDBOutput running in the Standard Job framework.

The Standard tCouchDBOutput component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Schema and Edit schema</th>
<th>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. </tbody>
</table>
Configure JSON Tree

Click the [...] button to open the window for JSON tree configuration. For more information, see Configuring a JSON Tree on page 3987.

Group by

Customize the input columns based on which you want to group the data.

Remove root node

Select this check box to remove the root node.

Die on error

This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

Advanced settings

tStatCatcher Statistics

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

Global Variables

Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE</strong></td>
<td>the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_INSERTED</strong></td>
<td>the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>ERROR_MESSAGE</strong></td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule

This component is used as an output component and it always needs an incoming link.

Replicating data from the source database to the target database

This scenario applies only to Talend products with Big Data.

This scenario describes a Job that writes the information of books into a CouchDB database, replicates the data to the target database, and then displays some replicated information of interest on the console.
Linking the components

Procedure
1. Drop the following components from the Palette onto the design workspace: tCouchDBConnection, tFileInputDelimited, tCouchDBOutput, tCouchDBInput, tLogRow and tCouchDBClose.
2. Connect tFileInputDelimited to tCouchDBOutput using a Row > Main link.
3. Do the same to connect tCouchDBInput to tLogRow.
4. Connect tCouchDBConnection to tFileInputDelimited using a Trigger > OnSubjobOk link.
5. Do the same to connect tFileInputDelimited to tCouchDBInput and tCouchDBInput to tCouchDBClose.
6. Label the components to better identify their functions.

Configuring the components

Opening a CouchDB connection and triggering replication

Procedure
1. Double-click the tCouchDBConnection component to open its Basic settings view in the Component tab.
2. In the Server and Port fields, type in the connection details.
3. In the Database field, type in the name of the database you want to use: bookstore_old in this example.
4. Select the CouchDB version that you are using from the DB Version list.
5. Select the Use trigger replication check box.
6. In the Replicate target database area, click [+] to add one line for database replication settings.
7. Enter the name of the target database name: bookstore_new in this example.
8. Select the Continuous check box to continue the replication upon the server restart.
9. In this example, the target database does not exist. Select the Create target DB check box to create the target database.
10. Select the Is Canceled check box to cancel the replication between bookstore_old and bookstore_new at the end of the Job.

Reading the input data

Procedure

1. Double-click the tFileInputDelimited component to open its Component view.

2. Click the [...] button next to the File name/Stream field to browse to the file that you want to read data from. In this scenario, it is D:/Input/bookstore.txt. The file contains six columns: _id, title, author, category, ISBN, and abstract _id;title;author;category;ISBN;abstract
001;Computer Networks: A Systems Approach;Larry L. Peterson, Bruce S. Davie;Computer Science;0123850606;This best-selling and classic book teaches you the key principles of computer networks with examples drawn from the real world of network and protocol design. 002;David Copperfield;Charles Dickens;Language&Literature;1555763227;This adaptation of the original story is presented in the format of a novel study, complete with exercises and vocabulary lists, and is geared to the language arts classes of grades 4 and 5. 003;Life of Pi;Yann Martel;Language&Literature;0547350651;The son of a zookeeper, Pi Patel has an encyclopedic knowledge of animal behavior and a fervent love of stories. 004;Les Miserables: Easyread Comfort Edition;Victor Hugo;Language&Literature;1425048250;Expressing the author's ideas about society, religion and politics, it is in the backdrop of Napoleonic Wars and ensuing years that the story unravels. Grace, moral philosophy, law and history of France are discussed. 005;Computer Security;Dieter Gollmann;Computer Science;0470741155;This text moves away from the 'multi-level' security approach to compare and evaluate design alternatives in computer security. 006;Advanced Database Systems;Carlo Zaniolo;Database;155860443X;This book, written by a team of leading specialists in their fields, introduces the research issues at the forefront of database technology and supports them with a variety of examples.

3. In the **Header** field, type in 1 so that the header of the file will be skipped.

4. Click **Edit schema** to define the data to pass on to the **tCouchDBOutput** component.
Writing data into one database and replicating the data

Procedure

1. Double-click the **tCouchDBOutput** component to open its **Basic settings** view in the **Component** tab.

2. Click **Sync columns** to retrieve the schema from the preceding component.

3. Select the **Use an existing connection** check box. In this example, the replication is triggered when opening the CouchDB connection.

4. Select **Upsert** from the **Action on data** drop-down list.

Extracting the replicated data of interest

Procedure

1. Double-click the **tCouchDBInput** component to open its **Component** view.
2. Click **Edit schema** to define the data structure to be read from the CouchDB database. By default, the **Include docs** check box is selected, so the **id**, **key**, **value** and **jsonDoc** columns are available in the schema.

   In this example, we define four columns to be extracted: **id**, **title**, **author** and **category**.
3. Enter the **Server** and **Port** information.

4. In the **Database** field, enter the name of the database from which the replicated data will be read. In this example, it is *bookstore_new*.

5. In the **Querying options** area, type in the start key and end key to set the range of the data to be read: "001" and "006" in this example.

6. Select the **Extract JSON field** check box to extract the desired data.

7. Select **jsonDoc** from the **JSON field** list.

8. In the **Mapping** area, click [+] to add items. Select the schema output column from the list and then type in the proper XPath query.

**Displaying the extracted data**

**Procedure**

1. Double-click the **tLogRow** component to open its **Component** view.

2. Click **Edit schema** to define the data structure to be displayed on the console. In this example, we need to remove the **jsonDoc** column.

3. In the **Mode** area, select **Table (print values in cells of a table)**.

**Closing the CouchDB connection**

**Procedure**

1. Double-click the **tCouchDBClose** component to open its **Component** view.
2. Select the connection to be closed from the Component List.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl+S** to save your Job.
2. Execute the Job by pressing **F6** or clicking **Run** on the **Run** tab.

```

The book information read from the replicated database is shown on the console.
tCreateTable

Creates a table for a specific type of database.

**tCreateTable Standard properties**

These properties are used to configure tCreateTable running in the Standard Job framework.

The Standard tCreateTable component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Database Type</th>
<th>Select the type of the database. The connection properties may differ slightly according to the database type selected.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property Type</td>
<td>Select the way the connection details will be set.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Built-In:</strong> The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Repository:</strong> The connection details stored centrally in Repository &gt; Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up Repository Content dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in.</td>
</tr>

</table>
This property is available only for the Teradata database type.

**Schema and Edit Schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

- **Built-In**: You create and store the schema locally for this component only.
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Advanced settings**

**Additional JDBC Parameters**

Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the **Use an existing connection** check box in the **Basic settings**.

This property is available for the AS/400 and MSSQL Server database types.

**Create projection**

Select this check box to create a projection.

This property is available only for the Vertica database type.

**Enforce database delimited identifiers**

Select this check box to enable delimited identifiers.

This property is available only for the **Snowflake** database type.

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.
Global Variables

<table>
<thead>
<tr>
<th>QUERY</th>
<th>The query statement being processed. This is a Flow variable and it returns a string.</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERROR_MESSAGE</td>
<td>The error message generated by the component when an error occurs. This is an After variable and it returns a string.</td>
</tr>
</tbody>
</table>

Usage

| Usage rule | This component can be used as a standalone component of a Job or Subjob. |

Creating new table in a Mysql Database

The Job described below aims at creating a table in a database, made of a dummy schema taken from a delimited file schema stored in the Repository. This Job is composed of a single component.

Procedure

1. Drop a `tCreateTable` component from the Databases family in the Palette to the design workspace.
2. In the Basic settings view, and from the Database Type list, select Mysql for this scenario.
3. From the Table Action list, select Create table.
4. Select the Use Existing Connection check box only if you are using a dedicated DB connection component `tMysqlConnection` on page 2436. In this example, we won’t use this option.
5. In the Property type field, select Repository so that the connection fields that follow are automatically filled in. If you have not defined your DB connection metadata in the DB connection directory under the Metadata node, fill in the details manually as Built-in.
6. In the Table Name field, fill in a name for the table to be created.
7. If you want to retrieve the Schema from the Metadata (it doesn’t need to be a DB connection Schema metadata), select Repository then the relevant entry.
8. In any case (Built-in or Repository) click Edit Schema to check the data type mapping. Click Edit Schema to define the data structure.

9. Click the Reset DB Types button in case the DB type column is empty or shows discrepancies (marked in orange). This allows you to map any data type to the relevant DB data type. Then, click OK to validate your changes and close the dialog box.

10. Save your Job and press F6 to execute it.

Results

The table is created empty but with all columns defined in the Schema.

```
SELECT * FROM 'newcarstable';
```

<table>
<thead>
<tr>
<th>ID_Owners</th>
<th>Reg.Car</th>
<th>Make</th>
<th>Color</th>
<th>ID_Reseller</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
tCreateTemporaryFile

Creates a temporary file in a specified directory. This component allows you to either keep the temporary file or delete it after the Job execution.

**tCreateTemporaryFile Standard properties**

These properties are used to configure tCreateTemporaryFile running in the Standard Job framework. The Standard tCreateTemporaryFile component belongs to the File family. The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Remove file when execution is over</td>
<td>Select this check box to delete the temporary file after the Job execution.</td>
</tr>
<tr>
<td><strong>Use default temporary system directory</strong></td>
<td>Select this check box to create the file in the default system temporary directory.</td>
</tr>
</tbody>
</table>
| Directory                              | Specify the directory under which the temporary file will be created.  
This field is available only when the **Use default temporary system directory** check box is cleared. |
| Template                               | Enter the temporary file name which should contain the characters XXXX, such as talend_XXXX.                                               |
| Suffix                                 | Enter the filename extension of the temporary file.                                                                                       |

**Advanced settings**

**tStatCatcher Statistics**  
Select this check box to collect log data at the component level.

**Global Variables**

| Global Variables | FILEPATH: the path where the file was created. This is an After variable and it returns a string.  
ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
For further information about variables, see Talend Studio User Guide. |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
Creating a temporary file and writing data into it

This scenario describes a Job that creates a temporary file in the default system temporary directory, writes data into the file, and finally displays the data in the file on the console.
## Adding and linking the components

### Procedure

1. Create a new Job and add the following components by typing their names in the design workspace or dropping them from the Palette: a `tCreateTemporaryFile` component, a `tJava` component, a `tRowGenerator` component, a `tFileOutputDelimited` component, a `tFileInputDelimited` component, and a `tLogRow` component.

2. Connect `tRowGenerator` to `tFileOutputDelimited` using a Row > Main connection.

3. Do the same to connect `tFileInputDelimited` to `tLogRow`.

4. Connect `tCreateTemporaryFile` to `tJava` using a Trigger > OnSubjobOk connection.

5. Do the same to connect `tJava` to `tRowGenerator` and connect `tRowGenerator` to `tFileInputDelimited`.

## Configuring the components

### Creating the temporary file

#### Procedure

1. Double-click `tCreateTemporaryFile` to open its Basic settings view.

2. Select the **Remove file when execution is over** check box to delete the created temporary file after the Job execution.

3. Select the **Use default temporary system directory** check box to create the file in the default system temporary directory.

4. In the **Template** field, enter the temporary file name which should contain the characters `XXXX`. In this example, it is `talend_XXXX`.

5. In the **Suffix** field, enter the filename extension of the temporary file. In this example, it is `dat`.

6. Double-click `tJava` to open its Basic settings view.
7. In the **Code** field, enter the following code to display the default system temporary directory and the path to the temporary file that will be created on the console:

```java
System.out.println("The default system temporary directory is:\r" + (String)System.getProperty("java.io.tmpdir"));
System.out.println("The path to the temporary file is:\r" + (String)globalMap.get("tCreateTemporaryFile_1_FILEPATH"));
```

**Writing the data into the file**

**Procedure**

1. Double-click **tRowGenerator** to open its **RowGenerator Editor**.

   ![RowGenerator Editor](image)

   2. Click the [+ ] button to add two columns: **id** of Integer type and **name** of String type. Then in the **Functions** column, select the predefined function `Numeric.sequence(String,int,int)` for **id** and `TalendDataGenerator.getFirstName()` for **name**.

   3. In the **Number of Rows for RowGenerator** field, enter **5** to generate five rows.

   4. Click **OK** to validate the changes and accept the propagation prompted by the pop-up dialog box.

2. Double-click **tFileOutputDelimited** to open its **Basic settings** view.

   ![File Output Delimited](image)

   6. In the **File Name** field, press **Ctrl+Space** and from the global variable list displayed select `((String)globalMap.get("tCreateTemporaryFile_1_FILEPATH"))`. 

553
Reading the data from the file

Procedure

1. Double-click **tFileInputDelimited** to open its **Basic settings** view.

2. In the **File name/Stream** field, press **Ctrl+Space** and from the global variable list displayed select
   
   ```
   ((String)globalMap.get("tCreateTemporaryFile_1_FILEPATH"))
   ```

3. Click the [...] button next to **Edit schema** and in the dialog box displayed define the schema by
   adding two columns: **id** of Integer type and **name** of String type.

4. Click **OK** to validate the changes and accept the propagation prompted by the pop-up dialog box.

5. Double-click **tLogRow** to open its **Basic settings** view.

6. In the **Mode** area, select **Table (print values in cells of a table)** to display the output data in a
   better way.
Saving and executing the Job

Procedure

1. Press Ctrl+S to save the Job.
2. Press F6 or click Run on the Run tab to run the Job.

<table>
<thead>
<tr>
<th>statistics</th>
<th>connecting to socket on port 3406</th>
</tr>
</thead>
<tbody>
<tr>
<td>statistics</td>
<td>connected</td>
</tr>
</tbody>
</table>

The default system temporary directory is:
C:\Users\lena_li\AppData\Local\Temp\n
The path to the temporary file is:
C:\Users\lena_li\AppData\Local\Temp\talend_MHTI.dat

 ttkLogRow_1
--------
id|name
--------
1 | Franklin
2 | Lyndon
3 | Richard
4 | Thomas
5 | Theodore

--------

[statistics] disconnected

The file talend_MHTI.dat is created under the default system temporary directory C:\Users\lena_li\AppData\Local\Temp\ during the Job execution, the five generated rows of data is written into it, then the file is deleted after the Job execution.
tDB2BulkExec

Executes the Insert action on the provided data and gains in performance during Insert operations to a DB2 database.

### tDB2BulkExec Standard properties

These properties are used to configure tDB2BulkExec running in the Standard Job framework.

The Standard tDB2BulkExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

---

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

---

### Basic settings

- **Database**
  - Select a type of database from the list and click **Apply**.

- **Property type**
  - Either **Built-in** or **Repository**.
    - **Built-in**: No property data stored centrally.
    - **Repository**: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.

- **Use an existing connection**
  - Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined.

  **Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:
  1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
  2. In the child level, use a dedicated connection component to read that registered database connection.

  *For an example about how to share a database connection across Job levels, see Talend Studio User Guide.*

- **Host**
  - Database server IP address

- **Port**
  - Listening port number of DB server.

- **Database**
  - Name of the database
<table>

</tr>
<tr>
<td></td>
<td>- <strong>Update repository connection</strong>: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.</td>
</tr>
<tr>
<td></td>
<td>Select this check box to populate data into DB2 using the INGEST command. For more information about the INGEST command, see <a href="http://www.ibm.com/developerworks/data/library/techarticle/dm-1304ingestcmd">http://www.ibm.com/developerworks/data/library/techarticle/dm-1304ingestcmd</a> and <a href="https://www-01.ibm.com/support/knowledgecenter/SSEPGG_10">https://www-01.ibm.com/support/knowledgecenter/SSEPGG_10</a></td>
</tr>
</tbody>
</table>
| **Load From** | Select the source of the data to be populated.  
| | • **FILE**: loads data from a file.  
| | • **PIPE**: loads data from a pipe.  
| | • **FOLDER**: loads data from multiple files in a folder.  
| | This list is available only when the **Use Ingest Command** check box is selected. |
| **Data File** | Name of the file to be loaded.  
| | **Warning:**  
| | This file is located on the machine specified by the URI in the **Host** field so it should be on the same machine as the database server.  
| | This field is not visible when **PIPE** or **FOLDER** is selected from the **Load From** drop-down list. |
| **Pipe Name** | Enter the name of the pipe.  
| | This field is available only when **PIPE** is selected from the **Load From** drop-down list. |
| **Folder** | Specify the path to the folder holding the files to be loaded.  
| | This field is available only when **FOLDER** is selected from the **Load From** drop-down list. |
| **Action on Data** | On the data of the table defined, you can perform one of the following operations:  
| | • **Insert**: Add new records to the table. If duplicates are found, Job stops.  
| | • **Replace**: Add new records to the table. If an old record in the table has the same value as a new record for a PRIMARY KEY or a UNIQUE index, the old record is deleted before the new record is inserted.  
| | • **Update**: Make changes to existing records.  
| | • **Delete**: Remove the records that match the input data.  
| | • **Merge**: Merge the input data to the table.  
| | **Delete** and **Merge** are available only when the **Use Ingest Command** check box is selected. |
| **File Glob Pattern** | Specify the global expression for the files to be loaded.  
| | This field is available only when **FOLDER** is selected from the **Load From** drop-down list. |
| **Where Clause** | Enter the WHERE clause to filter the data to be processed.  
| | This field is available only when **update** or **delete** is selected from the **Action on Data** drop-down list. |
| **Custom Insert Values Clause** | Select this check box and in the **Insert Values Clause** field displayed enter the VALUES clause for the **insert** operation.  
| | This check box is available only when the **Use Ingest Command** check box is selected and **insert** is selected from the **Action on Data** drop-down list. |
| **Custom Update Set Clause** | Select this check box and specify the SET clause for the update operation by completing the Set Mapping table.  
This check box is available only when the **Use Ingest Command** check box is selected and **update** is selected from the **Action on Data** drop-down list. |
|-------------------------------|-------------------------------------------------------------------------------------------------------------|
| **Set Mapping** | Complete this table to specify the SET clause for the update operation.  
- **Column**: the name of the column. By default, the fields in the **Column** column are same as what they are in the schema.  
- **Expression**: the expression for the corresponding column.  
This table is available only when the **Custom Update Set Clause** check box is selected. |
| **Merge Clause** | Specify the MERGE clause for the merge operation.  
This table is available only when the **Use Ingest Command** check box is selected and **merge** is selected from the **Action on Data** drop-down list. |
| **Content Format** | Select the format of the input file, either Delimited or Positional.  
This list is available only when the **Use Ingest Command** check box is selected. |
| **Delimited By** | Enter the character that separates the fields in the delimited file.  
This field is available only when Delimited is selected from the **Content Format** drop-down list. |
| **Optionally Enclosed By** | Enter the character that encloses the string in the delimited file.  
This field is available only when Delimited is selected from the **Content Format** drop-down list. |
| **Fixed Length** | Enter the length (in bytes) of the record in the positional file.  
This field is available only when Positional is selected from the **Content Format** drop-down list. |
| **Mapping** | Complete this table to specify the mapping relationship between the source column and the DB2 table column.  
- **Column**: the name of the column. By default, the fields in the **Column** column are same as what they are in the schema.  
- **Is Table Column**: select the check box if the corresponding column is a table column.  
- **Start Position**: the starting position of the corresponding column.  
- **End Position**: the ending position of the corresponding column.  
The **Start Position** and **End Position** columns are available only when Positional is selected from the **Content Format** drop-down list. |
This table is available only when the **Use Ingest Command** check box is selected.

| Script Generated Folder | Specify the directory under which the script file will be created. This field is available only when the **Use Ingest Command** check box is selected. |

**Advanced settings**

| Additional JDBC parameters | Specify additional connection properties for the DB connection you are creating.  

*Note:* You can set the encoding parameters through this field. |
| Field terminated by | Character, string or regular expression to separate fields.  
| Date Format | Use this field to define the way months and days are ordered. |
| Time Format | Use this field to define the way hours, minutes and seconds are ordered. |
| Timestamp Format | Use this field to define the way date and time are ordered.  
| Remove load pending | When the box is ticked, tables blocked in ’pending” status following a bulk load are de-blocked. |
| Load options | Click + to add data loading options:  
*Parameter:* select a loading parameter from the list.  
*Value:* enter a value for the parameter selected. |
| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Global Variables**

| Global Variables | **NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.  
| | **NB_LINE_UPDATED**: the number of rows updated. This is an After variable and it returns an integer.  
| | **NB_LINE_INSERTED**: the number of rows inserted. This is an After variable and it returns an integer.  
| | **NB_LINE_DELETED**: the number of rows deleted. This is an After variable and it returns an integer.  
| | **QUERY**: the query statement processed. This is an After variable and it returns a string.  
| | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. |
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

| Usage rule | This dedicated component offers performance and flexibility of DB2 query handling. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |

Related scenarios

For tDB2BulkExec related topics, see:

- Inserting transformed data in MySQL database on page 2493.
- Truncating and inserting file data into an Oracle database on page 2700.
tDB2Close

Closes a transaction committed in the connected DB.

**tDB2Close Standard properties**

These properties are used to configure tDB2Close running in the Standard Job framework.

The Standard tDB2Close component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Advanced settings**

**tStat Catcher Statistics**  Select this check box to collect log data at the component level.

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is to be used along with DB2 components, especially with tDB2Connection and tDB2Commit.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic settings</td>
<td>Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.  Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.  For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>
Related scenarios

No scenario is available for the Standard version of this component yet.
**tDB2Commit**

Commits in one go a global transaction instead of doing that on every row or every batch and thus provides gain in performance.

tDB2Commit validates the data processed through the Job into the connected DB.

**tDB2Commit Standard properties**

These properties are used to configure tDB2Commit running in the Standard Job framework.
The Standard tDB2Commit component belongs to the Databases family.
The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tDB2Connection component in the list if more than one connection are planned for the current Job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Warning:**

If you want to use a Row > Main connection to link tDB2Commit to your Job, your data will be committed row by row. In this case, do not select the Close connection check box or your connection will be closed before the end of your first row commit.

### Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

### Usage

| Usage rule | This component is more commonly used with other tDB2* components, especially with the tDB2Connection and tDB2Rollback components. |
| Dynamic settings | Click the [*] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to acces |
s database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenario

For tDB2Commit related scenario, see Inserting data in mother/daughter tables on page 2437
tDB2Connection

Opens a connection to the specified database that can then be reused in the subsequent subjob or subjobs.

tDB2Connection Standard properties

These properties are used to configure tDB2Connection running in the Standard Job framework. The Standard tDB2Connection component belongs to the Databases and the ELT families. The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td><strong>Property type</strong></td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><strong>Host name</strong></td>
<td>Database server IP address.</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database.</td>
</tr>
<tr>
<td><strong>Table Schema</strong></td>
<td>Name of the schema.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data. To enter the password, click the [... button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td><strong>Encoding</strong></td>
<td>Select the encoding from the list or select <strong>Custom</strong> and define it manually. This field is compulsory for DB data handling.</td>
</tr>
<tr>
<td><strong>Use or register a shared DB Connection</strong></td>
<td>Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the <strong>Shared DB Connection Name</strong> field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child.</td>
</tr>
</tbody>
</table>
This option is incompatible with the **Use dynamic job** and **Use an independent process to run subjob** options of the **tRunJob** component. Using a shared connection together with a **tRunJob** component with either of these two options enabled will cause your Job to fail.

This check box is not available when the **Specify a data source alias** check box is selected.

### Specify a data source alias

Select this check box and specify the alias of a data source created on the **Talend Runtime** side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in **Talend Runtime**.

This check box is not visible when the **Use or register a shared DB Connection** check box is selected.

### Data source alias

Enter the alias of the data source created on the **Talend Runtime** side.

This field is available only when the **Specify a data source alias** check box is selected.

### Advanced settings

**Additional JDBC parameters**

Specify additional connection properties for the DB connection you are creating.

**Note:**

You can set the encoding parameters through this field.

**Auto Commit**

Select this check box to commit any changes to the database automatically upon the transaction.

With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component.

Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component.

**tStatCatcher Statistics**

Select this check box to gather the job processing metadata at a Job level as well as at each component level.

### Usage

**Usage rule**

This component is more commonly used with other **tDB2** components, especially with the **tDB2Commit** and **tDB2Rollback** components.
Related scenarios

For tDB2Connection related scenario, see tMysqlConnection on page 2436
tDB2Input

Executes a DB query with a strictly defined order which must correspond to the schema definition. Then tDB2Input passes on the field list to the next component via a Row > Main link.

If double quotes exist in the column names of a table, the double quotation marks cannot be retrieved when retrieving the column. Therefore, it is recommended not to use double quotes in column names in a DB2 database table.

**tDB2Input Standard properties**

These properties are used to configure tDB2Input running in the Standard Job framework.

The Standard tDB2Input component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
<td></td>
</tr>
<tr>
<td>Click this icon to open a database connection wizard and store the database connection parameters you set in the component Basic settings view. For more information about setting up and storing database connection parameters, see Talend Studio User Guide.</td>
<td></td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th>Host</th>
<th>Database server IP address</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>

<tr>
<td>Schema</td>
<td>Name of the schema</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td><strong>Schema and Edit Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <strong>line</strong> when naming the fields.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-in</strong>: The schema is created and stored locally for this component only. Related topic: see <em>Talend Studio User Guide</em>.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see <em>Talend Studio User Guide</em>.</td>
</tr>
<tr>
<td></td>
<td>Click <strong>Edit schema</strong> to make changes to the schema. If the current schema is of the <strong>Repository</strong> type, three options are available:</td>
</tr>
<tr>
<td></td>
<td>• <strong>View schema</strong>: choose this option to view the schema only.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Change to built-in property</strong>: choose this option to change the schema to <strong>Built-in</strong> for local changes.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Update repository connection</strong>: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select <strong>No</strong> upon completion and choose this schema metadata again in the <strong>Repository Content</strong> window.</td>
</tr>
<tr>
<td><strong>Table name</strong></td>
<td>Select the source table where to capture any changes made on data.</td>
</tr>
<tr>
<td><strong>Query type and Query</strong></td>
<td>Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.</td>
</tr>
</tbody>
</table>
| **Specify a data source alias** | Select this check box and specify the alias of a data source created on the Talend Runtime side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in Talend Runtime.  
This check box is not available when the Use an existing connection check box is selected. |
| **Data source alias** | Enter the alias of the data source created on the Talend Runtime side.  
This field is available only when the Specify a data source alias check box is selected. |

**Advanced settings**

| **Additional JDBC parameters** | Specify additional connection properties for the DB connection you are creating.  
**Note:**  
You can set the encoding parameters through this field. |
| **Trim all the String/Char columns** | Select this check box to remove leading and trailing whitespace from all the String/Char columns. |
| **Trim column** | Remove leading and trailing whitespace from defined columns. |
| **tStat Catcher Statistics** | Select this check box to collect log data at the component level. |

**Global Variables**

| **Global Variables** | **NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.  
**QUERY**: the query statement being processed. This is a Flow variable and it returns a string.  
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it. |
|
For further information about variables, see *Talend Studio User Guide*.

## Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component covers all possible SQL queries for DB2 databases.</th>
</tr>
</thead>
</table>

### Dynamic settings

Click the [+ ] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see *Reading data from databases through context-based dynamic connections* on page 2457 and *Reading data from different MySQL databases using dynamically loaded connection parameters* on page 491. For more information on **Dynamic settings** and context variables, see *Talend Studio User Guide*.

## Related scenarios

For related topics, see:

See also the related topic in *Reading data from different MySQL databases using dynamically loaded connection parameters* on page 491.
tDB2Output

Executes the action defined on the table and/or on the data contained in the table, based on the flow incoming from the preceding component in the Job.

tDB2Output writes, updates, makes changes or suppresses entries in a database.

**tDB2Output Standard properties**

These properties are used to configure tDB2Output running in the Standard Job framework.

The Standard tDB2Output component belongs to the Databases family.

The component in this framework is available in all Talend products.

---

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

---

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>

<td><strong>Repository</strong></td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><img src="image" alt="icon" /></td>
<td>Click this icon to open a database connection wizard and store the database connection parameters you set in the component <strong>Basic settings</strong> view.</td>
</tr>
</tbody>
</table>
For more information about setting up and storing database connection parameters, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th>Host</th>
<th>Database server IP address</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database</td>
</tr>
<tr>
<td>Table schema</td>
<td>Name of the DB schema.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Table</td>
<td>Name of the table to be written. Note that only one table can be written at a time</td>
</tr>
</tbody>
</table>

**Action on table**

On the table defined, you can perform one of the following operations:

- **Default**: No operation is carried out.
- **Drop and create a table**: The table is removed and created again.
- **Create a table**: The table does not exist and gets created.
- **Create a table if not exists**: The table is created if it does not exist.
- **Drop a table if exists and create**: The table is removed if it already exists and created again.
- **Clear a table**: The table content is deleted.
- **Truncate table**: The table content is deleted. You do not have the possibility to rollback the operation.
- **Truncate table with reuse storage**: The table content is deleted. You do not have the possibility to rollback the operation. However, you can reuse the existing storage allocated to the table, even if the storage is considered empty.

**Warning:**

If you select the *Use an existing connection* check box, and then select *Truncate table* or *Truncate table with reuse storage* from the *Action on table* list, a commit statement will be invoked before the truncate operation because the truncate statement must be the first statement in a transaction.

**Action on data**

On the data of the table defined, you can perform:

- **Insert**: Add new entries to the table. If duplicates are found, Job stops.
- **Update**: Make changes to existing entries
- **Insert or update**: Insert a new record. If the record with the given reference already exists, an update would be made.
**Update or insert:** Update the record with the given reference. If the record does not exist, a new record would be inserted.

**Delete:** Remove entries corresponding to the input flow.

**Warning:**
You must specify at least one column as a primary key on which the Update and Delete operations are based. You can do that by clicking Edit Schema and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the Advanced settings view where you can simultaneously define primary keys for the update and delete operations. To do that: Select the Use field options check box and then in the Key in update column, select the check boxes next to the column name on which you want to base the update operation. Do the same in the Key in delete column for the deletion operation.

<table>
<thead>
<tr>
<th>Schema and Edit Schema</th>

<tr>
<td></td>
<td>For further information about variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>This component must be used as an output component. It allows you to carry out actions on a table or on the data of a</td>
</tr>
</tbody>
</table>
table in a DB2 database. It also allows you to create a reject flow using a Row > Rejects link to filter data in error. For an example of tMySqlOutput in use, see Retrieving data in error with a Reject link on page 2485.

### Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

---

**Related scenarios**

For tDB2Output related topics, see

- Inserting a column and altering data using tMysqlOutput on page 2477.
tDB2Rollback

Avoids to commit part of a transaction involuntarily.
tDB2Rollback cancels the transaction committed in the connected DB.

**tDB2Rollback Standard properties**

These properties are used to configure tDB2Rollback running in the Standard Job framework.
The Standard tDB2Rollback component belongs to the Databases family.
The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tDB2Connection component in the list if more than one connection are planned for the current Job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is more commonly used with other tDB2* components, especially with the tDB2Connection and tDB2Commit components. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection |
Related scenarios

For **tDB2Rollback** related scenario, see Rollback from inserting data in mother/daughter tables on page 2440 of the **tMysqlRollback**.
tDB2Row

Acts on the actual DB structure or on the data (although without handling data) depending on the nature of the query and the database. The SQLBuilder tool helps you write easily your SQL statements.

tDB2Row is the specific component for this database query. It executes the SQL query stated onto the specified database. The row suffix means the component implements a flow in the job design although it doesn’t provide output.

**tDB2Row Standard properties**

These properties are used to configure tDB2Row running in the Standard Job framework.

The Standard tDB2Row component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see [Talend Studio User Guide](#).

<table>
<thead>
<tr>
<th>Property type</th>

<td><strong>Parameter Index:</strong> Enter the parameter position in the SQL instruction.</td>
</tr>
<tr>
<td></td>
<td><strong>Parameter Type:</strong> Enter the parameter type.</td>
</tr>
<tr>
<td></td>
<td><strong>Parameter Value:</strong> Enter the parameter value.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> This option is very useful if you need to execute the same query several times. Performance levels are increased</td>
</tr>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>
**Global Variables**

- **QUERY**: the query statement being processed. This is a Flow variable and it returns a string.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press `Ctrl + Space` to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component offers the flexibility of the DB query and covers all possible SQL queries.</th>
</tr>
</thead>
</table>

**Dynamic settings**

- Click the `+` button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see [Reading data from databases through context-based dynamic connections](#) and [Reading data from different MySQL databases using dynamically loaded connection parameters](#). For more information on **Dynamic settings** and context variables, see [Talend Studio User Guide](#).

**Related scenarios**

For **tDB2Row** related topics, see:

- [Combining two flows for selective output](#) on page 2514
- [Procedure](#) on page 625
- [Removing and regenerating a MySQL table index](#) on page 2508.
tDB2SCD

Addresses Slowly Changing Dimension needs, reading regularly a source of data and logging the changes into a dedicated SCD table.
tDB2SCD reflects and tracks changes in a dedicated DB2 SCD table.

tDB2SCD Standard properties

These properties are used to configure tDB2SCD running in the Standard Job framework.
The Standard tDB2SCD component belongs to the Business Intelligence and the Databases families.
The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-in or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Built-in: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td>Repository: Select the Repository file where properties are stored. The following fields are pre-filled in using fetched data.</td>
<td></td>
</tr>
<tr>
<td>Host</td>
<td>Database server IP address.</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database.</td>
</tr>
<tr>
<td><strong>Table Schema</strong></td>
<td>Name of the DB schema.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Table</strong></td>
<td>Name of the table to be written. Note that only one table can be written at a time.</td>
</tr>
</tbody>
</table>
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
  • View schema: choose this option to view the schema only.  
  • Change to built-in property: choose this option to change the schema to Built-in for local changes.  
  • Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |
| **Built-in** | The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide. |
| **Repository** | The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide. |
| **SCD Editor** | The SCD editor helps to build and configure the data flow for slowly changing dimension outputs. For more information, see SCD management methodology on page 2522. |
| **Use memory saving Mode** | Select this check box to maximize system performance. |
| **Die on error** | This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows. |

**Advanced settings**

| **Additional JDBC parameters** | Specify additional connection properties for the DB connection you are creating. |
Note:
You can set the encoding parameters through this field.

**End date time details**
Specify the time value of the SCD end date time setting in the format of *HH:mm:ss*. The default value for this field is *12:00:00*.

This field appears only when SCD Type 2 is used and **Fixed year value** is selected for creating the SCD end date.

**Debug mode**
Select this check box to display each step during processing entries in a database.

**tStatCatcher Statistics**
Select this check box to collect log data at the component level.

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE_UPDATED</strong></td>
<td>the number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_INSERTED</strong></td>
<td>the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_REJECTED</strong></td>
<td>the number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>ERROR_MESSAGE</strong></td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Usage rule</strong></td>
<td>This component is used as Output component. It requires an Input component and Row main link as input.</td>
</tr>
</tbody>
</table>

**Dynamic settings**
Click the **[+]** button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the
### Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>Limitation</th>
<th>This component does not support using SCD type 0 together with other SCD types.</th>
</tr>
</thead>
</table>

## Related scenarios

For related topics, see tMysqlSCD on page 2519.
tDB2SCDELT

Addresses Slowly Changing Dimension needs through SQL queries (server-side processing mode), and logs the changes into a dedicated DB2 SCD table.

**tDB2SCDELT Standard properties**

These properties are used to configure tDB2SCDELT running in the Standard Job framework.

The Standard tDB2SCDELT component belongs to the Business Intelligence and the Databases families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>

<td>You can set the encoding parameters through this field.</td>
</tr>
</tbody>
</table>
**Debug mode**

Select this check box to display each step during processing entries in a database.

**tStat Catcher Statistics**

Select this check box to collect log data at the component level.

## Global Variables

**Global Variables**

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

## Usage

**Usage rule**

This component is used as an output component. It requires an input component and Row main link as input.

**Dynamic settings**

Click the **[+]** button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on **Dynamic settings** and context variables, see [Talend Studio User Guide](#).

## Related scenario

For related scenarios, see:

- Tracking data changes in a Snowflake table using the tJDBCSCDELT component on page 1859.
• Tracking data changes in a PostgreSQL table using the tPostgreSQLSCDELT component on page 3039.
tDB2SP

Offers a convenient way to call the database stored procedures.

**tDB2SP Standard properties**

These properties are used to configure tDB2SP running in the Standard Job framework.

The Standard tDB2SP component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either <strong>Built-in</strong> or <strong>Repository</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-in:</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository:</strong></td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

| Host | Database server IP address |
| Port | Listening port number of DB server. |
| Database | Name of the database |
| Username and Password | DB user authentication data. |
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

**Schema and Edit Schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `LINE` when naming the fields.

**Built-In:** You create and store the schema locally for this component only.

**Repository:** You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema:** choose this option to view the schema only.
- **Change to built-in property:** choose this option to change the schema to **Built-In** for local changes.
- **Update repository connection:** choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the jobs upon completion. If you just want to propagate the changes to the current job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**SP Name**

Type in the exact name of the Stored Procedure

**Is Function / Return result in**

Check this box, if a value only is to be returned.

Select on the list the schema column, the value to be returned is based on.

**Parameters**

Click the Plus button and select the various **Schema Columns** that will be required by the procedures. Note that the SP schema can hold more columns than there are parameters used in the procedure.

Select the **Type** of parameter:

**IN:** Input parameter

**OUT:** Output parameter/return value

**IN OUT:** Input parameters is to be returned as value, likely after modification through the procedure (function).

**RECORDSET:** Input parameters is to be returned as a set of values, rather than single value.

**Note:**

Check [Inserting data in mother/daughter tables](#) on page 2437 if you want to analyze a set of records from a database table or DB query and return single records.

**Specify a data source alias**

Select this check box and specify the alias of a data source created on the **Talend Runtime** side to use the shared
connection pool defined in the data source configuration. This option works only when you deploy and run your Job in Talend Runtime. This check box is not available when the Use an existing connection check box is selected.

<table>
<thead>
<tr>
<th>Data source alias</th>
<th>Enter the alias of the data source created on the Talend Runtime side. This field is available only when the Specify a data source alias check box is selected.</th>
</tr>
</thead>
</table>

**Advanced settings**

| Additional JDBC parameters | Specify additional connection properties for the DB connection you are creating.  
**Note:**  
You can set the encoding parameters through this field. |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

<table>
<thead>
<tr>
<th>tStat Catcher Statistics</th>
<th>Select this check box to collect log data at the component level.</th>
</tr>
</thead>
</table>

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is used as intermediary component. It can be used as start component but only input parameters are thus allowed.</th>
</tr>
</thead>
</table>

**Dynamic settings**

| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.  
The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.  
For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

**Related scenarios**

For related scenarios, see:
• Retrieving personal information using a stored procedure on page 2415.
• Using tMysqlSP to find a State Label using a stored procedure on page 2539.
• Checking number format using a stored procedure on page 2754.
• Executing a stored procedure using tMDMSP on page 2159.

Check Inserting data in mother/daughter tables on page 2437 as well if you want to analyze a set of records from a database table or DB query and return single records.
Dynamic database components

Talend provides a number of database components that allow you to change dynamically the type of database you want to work on. These components are available in the Database Common group under the Databases family of the Palette for standard data integration Jobs.

Each of these components has only one property, the Database list, on its Basic settings view for you to select the type of database of your interest.

For more information on these dynamic database components, see:

- tDBBulkExec on page 599
- tDBClose on page 600
- tDBCOLUMNList on page 601
- tDBCommit on page 602
- tDBConnection on page 603
- tDBInput on page 604
- tDBLastInsertId on page 606
- tDBOutput on page 607
- tDBOutputBulk on page 609
- tDBOutputBulkExec on page 610
- tDBRollback on page 611
- tDBRow on page 612
- tDBSCD on page 613
- tDBSCDELT on page 614
- tDBSP on page 615
- tDBTableList on page 616
tDBBulkExec

Offers gains in performance while executing the Insert operations on a database.

This component works with a variety of databases depending on your selection.

The tDBOutputBulk and tDBBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT statement used to feed a database the selected database type. These two steps are fused together in the tDBOutputBulkExec component, detailed in a separate section. The advantage of using two separate steps is that the data can be transformed before it is loaded in the database.

**tDBBulkExec Standard properties**

These properties are used to configure tDBBulkExec running in the Standard Job framework.

The Standard tDBBulkExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Basic settings**

This component serves as an entry point for the following databases. To configure this component, select a type of database from the **Database** list and click **Apply** on its **Basic settings** view. For more information about specific database properties, see the relevant documentation:

- Access (*tAccessBulkExec* on page 81)
- Amazon (*tRedshiftBulkExec* on page 3056)
- Greenplum (*tGreenplumBulkExec* on page 1303)
- IBM DB2 (*tDB2BulkExec* on page 556)
- Informix (*tInformixBulkExec* on page 1689)
- Ingres (*tIngresBulkExec* on page 1730)
- Microsoft SQL Server (*tMSSqlBulkExec* on page 2359)
- MySQL (*tMysqlBulkExec* on page 2423)
- Netezza (*tNetezzaBulkExec* on page 2627)
- Oracle (*tOracleBulkExec* on page 2695)
- ParAccel (*tParAccelBulkExec* on page 2822)
- PostgreSQL (*tPostgresqlBulkExec* on page 2999)
- PostgresPlus (*tPostgresPlusBulkExec* on page 2959)
- Snowflake (*tSnowflakeBulkExec* on page 3474)
- Sybase (ASE and IQ) (*tSybaseBulkExec* on page 3752)
- Sybase IQ (*tSybaseIQBulkExec* on page 3767)
- Vertica (*tVerticaBulkExec* on page 3914)
tDBClose

Closes the transaction committed in a connected database.
This component works with a variety of databases depending on your selection.

**tDBClose Standard properties**

These properties are used to configure tDBClose running in the Standard Job framework.
The Standard tDBClose component belongs to the Databases family.
The component in this framework is available in all Talend products.

**Basic settings**

This component serves as an entry point for the following databases. To configure this component,
select a type of database from the Database list and click Apply on its Basic settings view. For more
information about specific database properties, see the relevant documentation:

- Access ([tAccessClose](#) on page 84)
- Amazon Aurora ([tAmazonAuroraClose](#) on page 148)
- Amazon Mysql ([tAmazonMysqlClose](#) on page 187)
- Amazon Oracle ([tAmazonOracleClose](#) on page 209)
- Amazon Redshift ([tRedshiftClose](#) on page 3072)
- AS400 ([tAS400Close](#) on page 239)
- FireBird ([tFirebirdClose](#) on page 1172)

- Teradata ([tTeradataClose](#) on page 3818)
- Vertica ([tVerticaClose](#) on page 3920)
tDBColumnList

Iterates on all columns of a given database table and lists column names.
This component works with a variety of databases depending on your selection.

tDBColumnList Standard properties

These properties are used to configure tDBColumnList running in the Standard Job framework.
The Standard tDBColumnList component belongs to the Databases family.
The component in this framework is available in all Talend products.

Basic settings

This component serves as an entry point for the following databases. To configure this component,
select a type of database from the Database list and click Apply on its Basic settings view. For more
information about specific database properties, see the relevant documentation:

- Microsoft SQL Server (tMSSqlColumnList on page 2366)
- MySQL (tMysqlColumnList on page 2429)
tDBCommit

Validates the data processed through the Job into the connected database.
This component works with a variety of databases depending on your selection.

**tDBCommit Standard properties**

These properties are used to configure tDBCommit running in the Standard Job framework.
The Standard tDBCommit component belongs to the Databases family.
The component in this framework is available in all Talend products.

**Basic settings**

This component serves as an entry point for the following databases. To configure this component, select a type of database from the **Database** list and click **Apply** on its **Basic settings** view. For more information about specific database properties, see the relevant documentation:

- Access ([tAccessCommit](#) on page 86)
- Amazon Aurora ([tAmazonAuroraCommit](#) on page 150)
- Amazon Mysql ([tAmazonMysqlCommit](#) on page 189)
- Amazon Oracle ([tAmazonOracleCommit](#) on page 211)
- AS400 ([tAS400Commit](#) on page 241)
- Amazon Redshift ([tRedshiftCommit](#) on page 3074)
- FireBird ([tFirebirdCommit](#) on page 1174)
- Greenplum ([tGreenplumCommit](#) on page 1309)
- IBM DB2 ([tDB2Commit](#) on page 564)

- Vertica ([tVerticaCommit](#) on page 3922)
**tDBConnection**

Opens a connection to a database to be reused in the subsequent subJob or subjobs.
This component works with a variety of databases depending on your selection.

**tDBConnection Standard properties**

These properties are used to configure tDBConnection running in the Standard Job framework.
The Standard tDBConnection component belongs to the Databases family.
The component in this framework is available in all Talend products.

**Basic settings**

This component serves as an entry point for the following databases. To configure this component, select a type of database from the **Database** list and click **Apply** on its **Basic settings** view. For more information about specific database properties, see the relevant documentation:

- Access (**tAccessConnection** on page 88)
- Amazon Aurora (**tAmazonAuroraConnection** on page 152)
- Amazon Mysql (**tAmazonMysqlConnection** on page 191)
- Amazon Oracle (**tAmazonOracleConnection** on page 213)
- Amazon Redshift (**tRedshiftConnection** on page 3076)
- AS400 (**tAS400Connection** on page 243)
- Exasol (**tEXAConnection** on page 892)
- FireBird (**tFirebirdConnection** on page 1176)

- Snowflake (**tSnowflakeConnection** on page 3488)
- Sybase (ASE and IQ) (**tSybaseConnection** on page 3761)
- Teradata (**tTeradataConnection** on page 3822)
- VectorWise (**tVectorWiseConnection** on page 3897)
- Vertica (**tVerticaConnection** on page 3924)
tDBInput

Extracts data from a database.
This component works with a variety of databases depending on your selection.

tDBInput Standard properties

These properties are used to configure tDBInput running in the Standard Job framework.
The Standard tDBInput component belongs to the Databases family.
The component in this framework is available in all Talend products.

Basic settings

This component serves as an entry point for the following databases. To configure this component, select a type of database from the Database list and click Apply on its Basic settings view. For more information about specific database properties, see the relevant documentation:

- Access (tAccessInput on page 93)
- Amazon Aurora (tAmazonAuroraInput on page 155)
- Amazon Mysql (tAmazonMysqlInput on page 194)
- Amazon Oracle (tAmazonOracleInput on page 216)
- Amazon Redshift (tRedshiftInput on page 3079)
- AS400 (tAS400Input on page 245)
- Exasol (tEXAInput on page 895)
- FireBird (tFirebirdInput on page 1178)
- Greenplum (tGreenplumInput on page 1319)
- IBM DB2 (tDB2Input on page 569)
- Informix (tInformixInput on page 1700)
- Ingres (tIngresInput on page 1740)
- Interbase (tInterbaseInput on page 1772)
- JDBC (tJDBCInput on page 1841)
- MemSQL (tMemSQLInput on page 2195)
- Microsoft SQL Server (tMSSqlInput on page 2379)
- MySQL (tMysqlInput on page 2448)
- Netezza (tNetezzaInput on page 2637)
- Oracle (tOracleInput on page 2711)
- ParAccel (tParAccelInput on page 2832)
- PostgreSQL (tPostgresqlInput on page 3009)
- PostgresPlus (tPostgresPlusInput on page 2969)
- SAPHana (tSAPHanaInput on page 3395)
- SAS (tSasInput on page 3409)
- SQLite (tSQLiteInput on page 3598)
- Snowflake (tSnowflakeInput on page 3490)
- Sybase (ASE and IQ) (tSybaseInput on page 3763)
- Teradata (tTeradataInput on page 3834)
- VectorWise (tVectorWiseInput on page 3899)
• Vertica (tVerticalInput on page 3926)
tDBLastInsertId

Obtains the primary key value of the record that was last inserted in a database table by a user. This component works with a variety of databases depending on your selection.

tDBLastInsertId Standard properties

These properties are used to configure tDBLastInsertId running in the Standard Job framework. The Standard tDBLastInsertId component belongs to the Databases family. The component in this framework is available in all Talend products.

Basic settings

This component serves as an entry point for the following databases. To configure this component, select a type of database from the Database list and click Apply on its Basic settings view. For more information about specific database properties, see the relevant documentation:

- AS400 (tAS400LastInsertId on page 252)
- Microsoft SQL Server (tMSSqlLastInsertId on page 2383)
- MySQL (tMysqlLastInsertId on page 2464)
tDBOutput

Writes, updates, makes changes or suppresses entries in a database.
This component works with a variety of databases depending on your selection.

经营活动

经营活动 Standard properties

These properties are used to configure tDBOutput running in the Standard Job framework.
The Standard tDBOutput component belongs to the Databases family.
The component in this framework is available in all Talend products.

基本设置

This component serves as an entry point for the following databases. To configure this component, select a type of database from the Database list and click Apply on its Basic settings view. For more information about specific database properties, see the relevant documentation:

- Access (tAccessOutput on page 97)
- Amazon Aurora (tAmazonAuroraOutput on page 165)
- Amazon Mysql (tAmazonMysqlOutput on page 197)
- Amazon Oracle (tAmazonOracleOutput on page 220)
- Amazon Redshift (tRedshiftOutput on page 3088)
- AS400 (tAS400Output on page 254)
- Exasol (tEXAOoutput on page 899)
- FireBird (tFirebirdOutput on page 1181)
- Greenplum (tGreenplumOutput on page 1322)
- IBM DB2 (tDB2Output on page 573)
- Informix (tInformixOutput on page 1703)

- SQLite (tSQLiteOutput on page 3603)
- Snowflake (tSnowflakeOutput on page 3498)
- Sybase (ASE and IQ) (tSybaseOutput on page 3783)
- Teradata (tTeradataOutput on page 3841)
- VectorWise (tVectorWiseOutput on page 3903)
• Vertica (tVerticaOutput on page 3930)
tDBOutputBulk

Writes a file with columns based on the defined delimiter and the standards of the selected database type.

This component works with a variety of databases depending on your selection.

The tDBOutputBulk and tDBBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT statement used to feed a database the selected database type. These two steps are fused together in the tDBOutputBulkExec component, detailed in a separate section. The advantage of using two separate steps is that the data can be transformed before it is loaded in the database.

tDBOutputBulk Standard properties

These properties are used to configure tDBOutputBulk running in the Standard Job framework.

The Standard tDBOutputBulk component belongs to the Databases family.

The component in this framework is available in all Talend products.

Basic settings

This component serves as an entry point for the following databases. To configure this component, select a type of database from the Database list and click Apply on its Basic settings view. For more information about specific database properties, see the relevant documentation:

- Access (tAccessOutputBulk on page 103)
- Amazon Redshift (tRedshiftOutputBulk on page 3094)
- Greenplum (tGreenplumOutputBulk on page 1327)
- Informix (tInformixOutputBulk on page 1709)
- Ingres (tIngresOutputBulk on page 1748)
- Microsoft SQL Server (tMSSqlOutputBulk on page 2393)
- MySQL (tMysqlOutputBulk on page 2491)
- Oracle (tOracleOutputBulk on page 2725)
- ParAccel (tParAccelOutputBulk on page 2842)
- PostgreSQL (tPostgresqlOutputBulk on page 3019)
- PostgreSQLPlus (tPostgresPlusOutputBulk on page 2979)
- Snowflake (tSnowflakeOutputBulk on page 3502)
- Sybase (ASE and IQ) (tSybaseOutputBulk on page 3788)
- Vertica (tVerticaOutputBulk on page 3936)
tDBOutputBulkExec

Executes the Insert action in a database.

This component works with a variety of databases depending on your selection.

The tDBOutputBulk and tDBBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT statement used to feed a database the selected database type. These two steps are fused together in the tDBOutputBulkExec component, detailed in a separate section. The advantage of using two separate steps is that the data can be transformed before it is loaded in the database.

**tDBOutputBulkExec Standard properties**

These properties are used to configure tDBOutputBulkExec running in the Standard Job framework. The Standard tDBOutputBulkExec component belongs to the Databases family. The component in this framework is available in all Talend products.

**Basic settings**

This component serves as an entry point for the following databases. To configure this component, select a type of database from the Database list and click Apply on its Basic settings view. For more information about specific database properties, see the relevant documentation:

- Access ([tAccessOutputBulk](on page 103)
- Amazon Redshift ([tRedshiftOutputBulk](on page 3094)
- Greenplum ([tGreenplumOutputBulk](on page 1327)
- Informix ([tInformixOutputBulk](on page 1709)

- Sybase (ASE and IQ) ([tSybaseOutputBulk](on page 3788)
- Vertica ([tVerticaOutputBulk](on page 3936)
tDBRollback

Cancels the transaction commit in a connected database to avoid committing part of a transaction involuntarily.

This component works with a variety of databases depending on your selection.

**tDBRollback Standard properties**

These properties are used to configure tDBRollback running in the Standard Job framework.

The Standard tDBRollback component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Basic settings**

This component serves as an entry point for the following databases. To configure this component, select a type of database from the **Database** list and click **Apply** on its **Basic settings** view. For more information about specific database properties, see the relevant documentation:

- Access (tAccessRollback on page 110)
- Amazon Aurora (tAmazonAuroraRollback on page 172)
- Amazon Mysql (tAmazonMysqlRollback on page 203)
- Amazon Oracle (tAmazonOracleRollback on page 226)
- Amazon Redshift (tRedshiftRollback on page 3104)
- AS400 (tAS400Rollback on page 259)
- Exasol (tEXARollback on page 905)
- FireBird (tFirebirdRollback on page 1186)
- Greenplum (tGreenplumRollback on page 1333)
- IBM DB2 (tDB2Rollback on page 579)
- Informix (tInformixRollback on page 1716)
- Ingres (tIngresRollback on page 1757)
- Interbase (tInterbaseRollback on page 1782)
- JDBC (tJDBCRollback on page 1850)
- Microsoft SQL Server (tMSSqlRollback on page 2401)
- MySQL (tMysqlRollback on page 2502)
- Netezza (tNetezzaRollback on page 2654)
- Oracle (tOracleRollback on page 2734)
- ParAccel (tParAccelRollback on page 2849)
- PostgreSQL (tPostgresqlRollback on page 3026)
- PostgresPlus (tPostgresPlusRollback on page 2985)
- SAPHana (tSAPHanaRollback on page 3404)
- SQLite (tSQLiteRollback on page 3608)
- Sybase (ASE and IQ) (tSybaseRollback on page 3796)
- Teradata (tTeradataRollback on page 3847)
- VectorWise (tVectorWiseRollback on page 3908)
- Vertica (tVerticaRollback on page 3944)
tDBRow

Executes the stated SQL query onto a database.
This component works with a variety of databases depending on your selection.

**tDBRow Standard properties**

These properties are used to configure tDBRow running in the Standard Job framework.
The Standard tDBRow component belongs to the Databases family.
The component in this framework is available in all Talend products.

**Basic settings**

This component serves as an entry point for the following databases. To configure this component, select a type of database from the Database list and click Apply on its Basic settings view. For more information about specific database properties, see the relevant documentation:

- Access ([tAccessRow](#) on page 112)
- Amazon Mysql ([tAmazonMysqlRow](#) on page 205)
- Amazon Oracle ([tAmazonOracleRow](#) on page 228)

- VectorWise ([tVectorWiseRow](#) on page 3910)
- Vertica ([tVerticaRow](#) on page 3946)
tDBSCD

Reflects and tracks changes in a dedicated database SCD table.
This component works with a variety of databases depending on your selection.

**tDBSCD Standard properties**

These properties are used to configure tDBSCD running in the Standard Job framework.
The Standard tDBSCD component belongs to the Databases family.
The component in this framework is available in all Talend products.

**Basic settings**

This component serves as an entry point for the following databases. To configure this component, select a type of database from the **Database** list and click **Apply** on its **Basic settings** view. For more information about specific database properties, see the relevant documentation:

- Greenplum ([tGreenplumSCD on page 1339](#))
- IBM DB2 ([tDB2SCD on page 585](#))
- Informix ([tInformixSCD on page 1722](#))
- Ingres ([tIngresSCD on page 1763](#))
- Microsoft SQL Server ([tMSSqlSCD on page 2408](#))
- MySQL ([tMysqlSCD on page 2519](#))
- Netezza ([tNetezzaSCD on page 2660](#))
- Oracle ([tOracleSCD on page 2741](#))
- ParAccel ([tParAccelSCD on page 2855](#))
- PostgreSQL ([tPostgresqlSCD on page 3032](#))
- PostgresPlus ([tPostgresPlusSCD on page 2991](#))
- Sybase (ASE and IQ) ([tSybaseSCD on page 3802](#))
- Teradata ([tTeradataSCD on page 3854](#))
- Vertica ([tVerticaSCD on page 3950](#))
**tDBSCDELT**

Reflects and tracks changes in a dedicated SCD table through SQL queries. This component works with a variety of databases depending on your selection.

**tDBSCDELT Standard properties**

These properties are used to configure tDBSCDELT running in the Standard Job framework. The Standard tDBSCDELT component belongs to the Databases family. The component in this framework is available in all Talend products.

**Basic settings**

This component serves as an entry point for the following databases. To configure this component, select a type of database from the *Database* list and click *Apply* on its *Basic settings* view. For more information about specific database properties, see the relevant documentation:

- IBM DB2 (*tDB2SCDELT* on page 589)
- MySQL (*tMysqlSCDELT* on page 2533)
- Oracle (*tOracleSCDELT* on page 2745)
- PostgreSQL (*tPostgresqlSCDELT* on page 3036)
- PostgresPlus (*tPostgresPlusSCDELT* on page 2995)
- Sybase (ASE and IQ) (*tSybaseSCDELT* on page 3806)
- Teradata (*tTeradataSCDELT* on page 3858)
tDBSP

Calls a database stored procedure.
This component works with a variety of databases depending on your selection.

**tDBSP Standard properties**

These properties are used to configure tDBSP running in the Standard Job framework.
The Standard tDBSP component belongs to the Databases family.
The component in this framework is available in all Talend products.

**Basic settings**

This component serves as an entry point for the following databases. To configure this component, select a type of database from the Database list and click Apply on its Basic settings view. For more information about specific database properties, see the relevant documentation:

- IBM DB2 (tDB2SP on page 594)
- Informix (tInformixSP on page 1726)
- JDBC (tJDBCSP on page 1869)
- Microsoft SQL Server (tMSSqlSP on page 2412)
- MySQL (tMysqlSP on page 2537)
- Oracle (tOracleSP on page 2750)
- Sybase (ASE and IQ) (tSybaseSP on page 3810)
tDBTableList

Lists the names of specified database tables using a SELECT statement based on a WHERE clause. This component works with a variety of databases depending on your selection.

tDBTableList Standard properties

These properties are used to configure tDBSP running in the Standard Job framework. The Standard tDBSP component belongs to the Databases family. The component in this framework is available in all Talend products.

Basic settings

This component serves as an entry point for the following databases. To configure this component, select a type of database from the Database list and click Apply on its Basic settings view. For more information about specific database properties, see the relevant documentation:

- Microsoft SQL Server (tMSSqlTableList on page 2421)
- MySQL (tMysqlTableList on page 2543)
- Oracle (tOracleTableList on page 2758)
**tDBFSCConnection**

Connects to a given DBFS (Databricks Filesystem) system so that the other DBFS components can reuse the connection it creates to communicate with this DBFS.

The DBFS (Databricks Filesystem) components are designed for quick and straightforward data transferring with Databricks. If you need to handle more sophisticated scenarios for optimal performance, use Spark Jobs with Databricks.

**tDBFSCConnection Standard properties**

These properties are used to configure tDBFSCConnection running in the Standard Job framework. The Standard tDBFSCConnection component belongs to the Big Data and the File families. The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

### Basic settings

| Property type | Either **Built-In** or **Repository**.  
|---------------|------------------------------------------------|
|               | **Built-In**: No property data stored centrally.  
|               | **Repository**: Select the repository file where the properties are stored.  |
| Endpoint      | In the **Endpoint** field, enter the URL address of your Azure Databricks workspace. This URL can be found in the **Overview** blade of your Databricks workspace page on your Azure portal. For example, this URL could look like https://westeurope.azuredatabricks.net.  |
| Token         | Click the [...] button next to the **Token** field to enter the authentication token generated for your Databricks user account. You can generate or find this token on the **User settings** page of your Databricks workspace. For further information, see **Token management** from the Azure documentation.  |

### Advanced settings

- **tStatCatcher Statistics**: Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Usage

- **Usage rule**: This component is generally used with other DBFS components.
tDBFSGet

Copies files from a given DBFS (Databricks Filesystem) system, pastes them in a user-defined directory and if needs be, renames them.

The DBFS (Databricks Filesystem) components are designed for quick and straightforward data transferring with Databricks. If you need to handle more sophisticated scenarios for optimal performance, use Spark Jobs with Databricks.

**tDBFSGet Standard properties**

These properties are used to configure tDBFSGet running in the Standard Job framework.

The Standard tDBFSGet component belongs to the Big Data and the File families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either <strong>Built-In</strong> or <strong>Repository</strong>. <strong>Built-In</strong>: No property data stored centrally. <strong>Repository</strong>: Select the repository file where the properties are stored.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Use an existing connection</strong></td>
<td>Select this check box and in the <strong>Component List</strong> click the HDFS connection component from which you want to reuse the connection details already defined. Note that when a Job contains the parent Job and the child Job, <strong>Component List</strong> presents only the connection components in the same Job level.</td>
</tr>
<tr>
<td><strong>Endpoint</strong></td>
<td>In the <strong>Endpoint</strong> field, enter the URL address of your Azure Databricks workspace. This URL can be found in the <strong>Overview</strong> blade of your Databricks workspace page on your Azure portal. For example, this URL could look like <a href="https://westeurope.azuredatabricks.net">https://westeurope.azuredatabricks.net</a>.</td>
</tr>
<tr>
<td><strong>Token</strong></td>
<td>Click the [...] button next to the <strong>Token</strong> field to enter the authentication token generated for your Databricks user account. You can generate or find this token on the <strong>User settings</strong> page of your Databricks workspace. </tr>
<tr>
<td></td>
<td>- <strong>New name</strong>: give a new name to the loaded file.</td>
</tr>
<tr>
<td><strong>Die on error</strong></td>
<td>Select the check box to stop the execution of the Job when an error occurs. Clear the check box to skip any rows on error and complete the process for error-free rows.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| **tStatCatcher Statistics** | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Usage**

| **Usage rule** | This component combines DBFS connection and data extraction, thus usually used as a single-component subjob to copy data from a user-defined local directory to DBFS. It runs standalone and does not generate input or output flow for the other components. It is often connected to the Job using **OnSubjobOk** or **OnComponentOk** link, depending on the context. |
tDBSQLRow

Acts on the actual DB structure or on the data (although without handling data) depending on the nature of the query and the database. The SQLBuilder tool helps you write easily your SQL statements.

tDBSQLRow is the generic component for database query. It executes the SQL query stated onto the specified database. The row suffix means the component implements a flow in the job design although it does not provide output. For performance reasons, specific DB component should always be preferred to the generic component.

To use this component, relevant DBMSs' ODBC drivers should be installed and the corresponding ODBC connections should be configured via the database connection configuration wizard.

**tDBSQLRow Standard properties**

These properties are used to configure tDBSQLRow running in the Standard Job framework.

The Standard tDBSQLRow component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Property type</strong></td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td><strong>Built-in</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><strong>Datasource</strong></td>
<td>Name of the data source defined via the database connection configuration wizard.</td>
</tr>
</tbody>
</table>
| **Username and Password** | DB user authentication data.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.  
Built-In: You create and store the schema locally for this component only.  
Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.  
Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available: |
- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

<table>
<thead>
<tr>
<th>Table Name</th>
<th>Name of the source table where changes made to data should be captured.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Query type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-in</strong>: Fill in manually the query statement or build it graphically using SQLBuilder.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: Select the relevant query stored in the Repository. The Query field gets accordingly filled in.</td>
</tr>
<tr>
<td>Query</td>
<td>Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.</td>
</tr>
<tr>
<td>Die on error</td>
<td>This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows. If needed, you can retrieve the rows on error via a <strong>Row &gt; Rejects</strong> link.</td>
</tr>
</tbody>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th>Additional JDBC parameters</th>
<th>Specify additional connection properties for the database connection you are creating.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Note</strong>: You can set the encoding parameters through this field.</td>
</tr>
<tr>
<td>Propagate QUERY’s recordset</td>
<td>Select this check box to insert the result of the query into a COLUMN of the current flow. Select this column from the <strong>use column</strong> list.</td>
</tr>
<tr>
<td>Use PreparedStatement</td>
<td>Select this check box if you want to query the database using a PreparedStatement. In the <strong>Set PreparedStatement Parameter</strong> table, define the parameters represented by &quot;?&quot; in the SQL instruction of the <strong>Query</strong> field in the <strong>Basic Settings</strong> tab.</td>
</tr>
<tr>
<td></td>
<td><strong>Parameter Index</strong>: Enter the parameter position in the SQL instruction.</td>
</tr>
<tr>
<td></td>
<td><strong>Parameter Type</strong>: Enter the parameter type.</td>
</tr>
<tr>
<td></td>
<td><strong>Parameter Value</strong>: Enter the parameter value.</td>
</tr>
</tbody>
</table>
This option is very useful if you need to execute the same query several times. Performance levels are increased.

Commit every
Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions.

tStatCatcher Statistics
Select this check box to collect log data at the component level.

Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>QUERY: the query statement being processed. This is a Flow variable and it returns a string.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td></td>
<td>For further information about variables, see Talend Studio User Guide.</td>

</tbody>
</table>

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component offers the flexibility of the DB query and covers all possible SQL queries.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Note that the relevant DBRow component should be preferred according to your DBMSs. Most of the DBMSs have their specific DBRow components.</td>
</tr>
</tbody>
</table>

Resetting a DB auto-increment

This scenario describes a single component Job which aims at re-initializing the DB auto-increment to 1. This job has no output and is generally to be used before running a script.

Warning:
As a prerequisite of this Job, the relevant DBMS’s ODBC driver must have been installed and the corresponding ODBC connection must have been configured.
Procedure

1. Drag and drop a tDBSQLRow component from the Palette to the design workspace.

2. Double-click tDBSQLRow to open its Basic settings view.

3. Select Repository in the Property Type list as the ODBC connection has been configured and saved in the Repository. The follow-up fields get filled in automatically.
   For more information on storing DB connections in the Repository, see Talend Studio User Guide.

4. The Schema is built-in for this Job and it does not really matter in this example as the action is made on the table auto-increment and not on data.

5. The Query type is also built-in. Click on the [...] button next to the Query statement box to launch the SQLbuilder editor, or else type in directly in the statement box:
   Alter table <TableName> auto_increment = 1

6. Press Ctrl+S to save the Job and F6 to run.
   The database autoincrement is reset to 1.
tDenormalize

Denormalizes the input flow based on one column.

**tDenormalize Standard properties**

These properties are used to configure tDenormalize running in the Standard Job framework.

The Standard tDenormalize component belongs to the Processing family.

The component in this framework is available in all Talend products.

### Basic settings

| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word **line** when naming the fields. Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:
| | • **View schema**: choose this option to view the schema only.
| | • **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
| | • **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.
| **Built-In**: You create and store the schema locally for this component only.
| **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.
| **To denormalize** | In this table, define the parameters used to denormalize your columns.
| **Column**: Select the column to denormalize.
| **Delimiter**: Type in the separator you want to use to denormalize your data between double quotes.
| **Merge same value**: Select this check box to merge identical values.

### Advanced settings

| **tStatCatcher Statistics** | Select this check box to collect the log data at component level. Note that this check box is not available in the Map/Reduce version of the component.
Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERROR_MESSAGE</td>
<td>The error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td>NB_LINE</td>
<td>The number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Denormalizing on one column

This scenario illustrates a Job denormalizing one column in a delimited file.

1. Drop the following components: tFileInputDelimited, tDenormalize, tLogRow from the Palette to the design workspace.
2. Connect the components using Row main connections.
3. On the tFileInputDelimited Component view, set the filepath to the file to be denormalized.
4. Define the **Header**, **Row Separator** and **Field Separator** parameters.

5. The input file schema is made of two columns, *Fathers* and *Children*.

6. In the **Basic settings** of **tDenormalize**, define the column that contains multiple values to be grouped.

7. In this use case, the column to denormalize is *Children*.

8. Set the **Delimiter** to separate the grouped values. Beware as only one column can be denormalized.

9. Select the **Merge same value** check box, if you know that some values to be grouped are strictly identical.

10. Save your Job and press **F6** to execute it.
Results

Starting job tDenormalize at 10:50 09/03/2016.

Michael | Cécile
Stéphane | Agathe | Clémence
Pierrick | Erwan | Tiphaine
Robert | Xenon
Richard | Romeo
Fabrice | Martin

Job tDenormalize ended at 10:50 09/03/2016. [exit code=0]

All values from the column Children (set as column to denormalize) are grouped by their Fathers column. Values are separated by a comma.

**Denormalizing on multiple columns**

This scenario illustrates a Job denormalizing two columns from a delimited file.

![Diagram of the Job design](image)

**Procedure**

1. Drop the following components: `tFileInputDelimited`, `tDenormalize`, `tLogRow` from the Palette to the design workspace.
2. Connect all components using a Row main connection.
3. On the `tFileInputDelimited` Basic settings panel, set the filepath to the file to be denormalized.
4. Define the Row and Field separators, the Header and other information if required.
5. The file schema is made of four columns including: Name, FirstName, HomeTown, WorkTown.
6. In the **tDenormalize** component **Basic settings**, select the columns that contain the repetition. These are the columns which are meant to occur multiple times in the document. In this use case, *FirstName*, *HomeCity* and *WorkCity* are the columns against which the denormalization is performed.

7. Add as many line to the table as you need using the plus button. Then select the relevant columns in the drop-down list.

8. In the **Delimiter** column, define the separator between double quotes, to split concatenated values. For *FirstName* column, type in “#”, for *HomeCity*, type in “§”, ans for *WorkCity*, type in “¤”.

9. Save your Job and press **F6** to execute it.

The result shows the denormalized values concatenated using a comma.

10. Back to the **tDenormalize** components **Basic settings**, in the To denormalize table, select the **Merge same value** check box to remove the duplicate occurrences.

11. Save your Job again and press **F6** to execute it.
Results

Starting job tDenormalize2 at 13:44 08/03/2010.

Moore|Demi|New York|Rio de Janeiro|Paris
Joli|Angelina|Berlin|Los Angeles|Berlin|Los Angeles
Pitt|Brad|Beverly Hills|Paris|Los Angeles|London
Willie|Bruce|Paris|Madrid|Roma|Los Angeles|Madrid|Dublin

Job tDenormalize2 ended at 13:44 08/03/2010. [exit code=0]

This time, the console shows the results with no duplicate instances.
**tDenormalizeSortedRow**

Synthesizes sorted input flow to save memory.

tDenormalizeSortedRow combines in a group all input sorted rows. Distinct values of the denormalized sorted row are joined with item separators.

**tDenormalizeSortedRow Standard properties**

These properties are used to configure tDenormalizeSortedRow running in the Standard Job framework.

The Standard tDenormalizeSortedRow component belongs to the Processing family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| **Schema and Edit Schema**    | A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either **Built-in** or stored remotely in the **Repository**. Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
  • **View schema**: choose this option to view the schema only.  
  • **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
  • **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.  
  Click **Sync columns** to retrieve the schema from the previous component in the Job. |                                                                                                                                                                                                                                                                          |
| **Built-in**                   | You create the schema and store it locally for the relevant component. Related topic: see Talend Studio User Guide.                                                                                                                                                                                                                     |
| **Repository**                | The schema already exists and is stored in the Repository, hence can be reused in various projects and Job flowcharts. Related topic: see Talend Studio User Guide.                                                                                                                                                                   |
| **Input rows count**          | Enter the number of input rows.                                                                                                                                                                                                                                                                                                           |
| **To denormalize**            | Enter the name of the column to denormalize.                                                                                                                                                                                                                                                                                             |

Usage

| Usage rule | This component handles flows of data therefore it requires input and output components. |

Regrouping sorted rows

This Java scenario describes a four-component Job. It aims at reading a given delimited file row by row, sorting input data by sort type and order, denormalizing all input sorted rows and displaying the output on the Run log console.

- Drop the following components from the Palette onto the design workspace: tFileInputDelimited, tSortRow, tDenormalizeSortedRow, and tLogRow.
- Connect the four components using Row Main links.

- In the design workspace, select tFileInputDelimited.
- Click the Component tab to define the basic settings for tFileInputDelimited.
• Set **Property Type** to **Built-In**.
• Fill in a path to the processed file in the **File Name** field. The *name_list* file used in this example holds two columns, id and first name.

<table>
<thead>
<tr>
<th>1</th>
<th>Harrison</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>Jerry</td>
</tr>
<tr>
<td>3</td>
<td>James</td>
</tr>
<tr>
<td>4</td>
<td>Goldman</td>
</tr>
<tr>
<td>5</td>
<td>Bill</td>
</tr>
<tr>
<td>6</td>
<td>Ford</td>
</tr>
</tbody>
</table>

• If needed, define row and field separators, header and footer, and the number of processed rows.
• Set **Schema** to **Built in** and click the three-dot button next to **Edit Schema** to define the data to pass on to the next component. The schema in this example consists of two columns, *id* and *name*.

<table>
<thead>
<tr>
<th>Column</th>
<th>Key</th>
<th>Type</th>
<th>Nullable</th>
<th>Date Pattern</th>
<th>Len</th>
<th>Pre</th>
<th>D</th>
<th>Co</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td></td>
<td>Integer</td>
<td>✔️</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>name</td>
<td></td>
<td>String</td>
<td>✔️</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

• In the design workspace, select **tSortRow**.
• Click the **Component** tab to define the basic settings for **tSortRow**.
• Set the **Schema Type** to **Built-In** and click **Sync columns** to retrieve the schema from the `tFileInputDelimited` component.

• In the **Criteria** panel, use the plus button to add a line and set the sorting parameters for the schema column to be processed. In this example we want to sort the `id` columns in ascending order.

• In the design workspace, select `tDenormalizeSortedRow`.

• Click the **Component** tab to define the basic settings for `tDenormalizeSortedRow`.

• Set the **Schema Type** to **Built-In** and click **Sync columns** to retrieve the schema from the `tSortRow` component.

• In the **Input rows count** field, enter the number of the input rows to be processed or press `Ctrl+Space` to access the context variable list and select the variable: `tFileInputDelimited_1_NB_LINE`.

• In the **To denormalize** panel, use the plus button to add a line and set the parameters to the column to be denormalize. In this example we want to denormalize the `name` column.

• In the design workspace, select `tLogRow` and click the **Component** tab to define its basic settings. For more information about `tLogRow`, see `tLogRow` on page 1956.

• Save your Job and press **F6** to execute it.
The result displayed on the console shows how the name column was denormalize.
tDie

Triggers the tLogCatcher component for exhaustive log before killing the Job.

Both tDie and tWarn components are closely related to the tLogCatcher component. They generally make sense when used alongside a tLogCatcher in order for the log data collected to be encapsulated and passed on to the output defined.

This component throws an error and kills the job. If you simply want to throw a warning, see tWarn on page 3971.

tDie Standard properties

These properties are used to configure tDie running in the Standard Job framework.

The Standard tDie component belongs to the Logs & Errors family.

The component in this framework is available in all Talend products.

Basic settings

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Die message</td>
<td>Enter the message to be displayed before the Job is killed.</td>
</tr>
<tr>
<td>Error code</td>
<td>Enter the error code if need be, as an integer.</td>
</tr>
<tr>
<td>Priority</td>
<td>Set the level of priority, as an integer</td>
</tr>
</tbody>
</table>

Note:
Note that any value greater than 255 can not be used as an error code on Linux.

Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DIE_MESSAGES</td>
<td>the die message. This is an After variable and it returns a string.</td>
</tr>
<tr>
<td>DIE_CODE</td>
<td>the error code of the die message. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>DIE_PRIORITY</td>
<td>the priority level of the die message. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>ERROR_MESSAGE</td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.
Usage

| Usage rule | This component cannot be used as a start component and it is generally used with a tLogCatcher for the log purpose. |

Related scenarios

For use cases in relation with tDie, see tLogCatcher scenarios:

- Catching messages triggered by a tWarn component on page 1950
- Catching the message triggered by a tDie component on page 1952
tDotNETInstantiate

Invokes the constructor of a .NET object that is intended for later reuse.
tDotNETInstantiate instantiates an object in the .NET for later reuse.

**tDotNETInstantiate Standard properties**

These properties are used to configure tDotNETInstantiate running in the Standard Job framework.
The Standard tDotNETInstantiate component belongs to the DotNET family.
The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Dll to load</th>
<th>Type in the path, or browse to the DLL library containing the classe(s) of interest or enter the assembly’s name to be used. For example, System.Data, Version=2.0.0.0, Culture=neutral, PublicKeyToken=b77a5c561934e089 for an OleDb assembly.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fully qualified class name(i.e. ClassLibrary1.NameSpace 2.Class1)</td>
<td>Enter a fully qualified name for the class of interest.</td>
</tr>
<tr>
<td>Value(s) to pass to the constructor</td>
<td>Click the plus button to add one or more values to be passed to the constructor for the object. Or, leave this table empty to call a default constructor for the object. The valid value(s) should be the parameters required by the class to be used.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

**Global Variables**

| Global Variables | INSTANCE: the instance of a .NET object. This is an After variable and it returns an object. ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

For further information about variables, see *Talend Studio User Guide*. |
### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component can be used as a start component in a flow or an independent subJob</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>To use this component, you must first install the runtime DLLs, for example janet-win32.dll for Windows 32-bit version and janet-win64.dll for Windows 64-bit version, from the corresponding Microsoft Visual C++ Redistributable Package. This allows you to avoid errors like the UnsatisfiedLinkError on dependent DLL.</td>
</tr>
<tr>
<td></td>
<td>So ensure that the runtime and all of the other DLLs which the DLL to be called depends on are installed and their versions are consistent among one another.</td>
</tr>
</tbody>
</table>

**Note:**

The required DLLs can be installed in the System32 folder or in the bin folder of the Java runtime to be used.

If you need to export a Job using this component to run it outside the Studio, you have to specify the runtime container of interest by setting the -Djava.library.path argument accordingly.

For users of Talend solutions with ESB, to run a Job using this component in ESB Runtime, you need to copy the runtime DLLs to the %KARAF_HOME%/lib/wrapper/directory.

### Related scenario

For a related scenario, see Utilizing .NET in Talend on page 643.
tDotNETRow

Facilitates data transform by utilizing custom or built-in .NET classes.

tDotNETRow sends data to and from libraries and classes within .NET or other custom DLL files.

**tDotNETRow Standard properties**

These properties are used to configure tDotNETRow running in the Standard Job framework.

The Standard tDotNETRow component belongs to the DotNET family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th><strong>Schema and Edit schema</strong></th>
<th>A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either built-in or remotely stored in the Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-in</strong></td>

<td>This component is utilized to integrate with .NET objects. To use this component, you must first install the runtime DLLs, for example janet-win32.dll for Windows 32-bit version and janet-win64.dll for Windows 64-bit version, from the corresponding Microsoft Visual C++ Redistributabl</td>
</tr>
</tbody>
</table>
Utilizing .NET in Talend

This scenario describes a three-component Job that uses a DLL library containing a class called `Test1.Class1` and invokes a method on it that processes the value and output the result onto the console.

Prerequisites

Before replicating this scenario, you need first to build up your runtime environment.

- Create the DLL to be loaded by `tDotNETInstantiate`

  This example class built into .NET reads as follows:

```csharp
using System;
using System.Collections.Generic;
using System.Text;

namespace Test1
{
    public class Class1
    {
        string s = null;
    }
```
public Class1(string s)
{
    this.s = s;
}

public string getValue()
{
    return "Return Value from Class1: " + s;
}

This class reads the input value and adds the text Return Value from Class1: in front of this value. It is compiled using the latest .NET.

- Install the runtime DLL from the latest .NET. In this scenario, we use janet-win32.dll on Windows 32-bit version and place it in the System32 folder.

  Thus the runtime DLL is compatible with the DLL to be loaded.

### Connecting components

**Procedure**

1. Drop the following components from the Palette to the design workspace: tDotNETInstantiate, tDotNETRow and tLogRow.
2. Connect tDotNETInstantiate to tDotNETRow using a Trigger On Subjob OK connection.
3. Connect tDotNETRow to tLogRow using a Row Main connection.

### Configuring tDotNETInstantiate

**Procedure**

1. Double-click tDotNETInstantiate to display its Basic settings view and define the component properties.

   ![Configuration Screen](image)

   - **Dll to load**: `C:\Program Files\ClassLibrary1\bin\Debug\ClassLibrary1.dll`
   - **Value(s) to pass to the constructor**: "Hello world"

2. Click the three-dot button next to the Dll to load field and browse to the DLL file to be loaded. Alternatively, you can fill the field with an assembly. In this example, we use:

   "C:\Program Files\ClassLibrary1\bin\Debug\ClassLibrary1.dll"

3. Fill the Fully qualified class name field with a valid class name to be used. In this example, we use:
4. Click the plus button beneath the **Value(s) to pass to the constructor** table to add a new line for the value to be passed to the constructor.

In this example, we use: "Hello world"

**Configuring tDotNETRow**

**Procedure**

1. Double-click **tDotNETRow** to display its **Basic settings** view and define the component properties.

2. Select **Propagate data to output** check box.

3. Select **Use an existing instance** check box and select **tDotNETInstantiate_1** from the **Existing instance to use** list on the right.

4. Fill the **Method Name** field with a method name to be used. In this example, we use "getValue", a custom method.

5. Click the three-dot button next to **Edit schema** to add one column to the schema.

Click the plus button beneath the table to add a new column to the schema and click **OK** to save the setting.

6. Select **newColumn** from the **Output value target column** list.
Configuring tLogRow

Procedure

1. Double-click tLogRow to display its Basic settings view and define the component properties.

2. Click Sync columns button to retrieve the schema defined in the preceding component.

3. Select Table in the Mode area.

Results

Save your Job and press F6 to execute it.

From the result, you can read that the text Return Value from Class1 is added in front of the retrieved value Hello world.
tDropboxConnection

Creates a Dropbox connection to a given account that the other Dropbox components can reuse.

**tDropboxConnection Standard properties**

These properties are used to configure tDropboxConnection running in the Standard Job framework.

The Standard tDropboxConnection component belongs to the Cloud family.

The component in this framework is available in all Talend products.

**Basic settings**

<td>• <strong>Replace if Existing</strong>: the uploaded file replaces the existing one.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Update specified Revision</strong>: the file you are uploading is used to update a specific revision of that file. If the revision you specify is the latest revision, then the existing file on Dropbox is replaced; if it is an older revision, the file you are uploading is renamed to indicate that a conflict is encountered; if the revision does not exist, an error is returned.</td>
</tr>
<tr>
<td>Upload Incoming content as File</td>
<td>Select this radio button to read data directly from the input flow of the preceding component and write the data into the file specified in the Path field.</td>
</tr>
</tbody>
</table>
### A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

Note that the schema of this component is read-only with a single column named `content` and it receives data from the `content` column of its input schema only. This means that you must use a `content` column in the input data flow to carry the data to be uploaded. This type of column is typically provided by the `tFileInputRaw` component. For further information, see `tFileInputRaw` on page 1078.

The **Schema** field is not available when you have selected the **Expose as OutputStream** or the **Upload local file** radio button.

### Upload local file

Select this radio button to upload a locally stored file to Dropbox. In the File field that is displayed, you need to enter the path or browse to this file.

### Expose as OutputStream

Select this check box to expose the output stream of this component as a variable named `OUTPUTSTREAM` so that the other components can reuse this variable to write the contents to be uploaded into the exposed output stream.

For example, you can use the **Use output stream** feature of the `tFileOutputDelimited` component to feed a given `tDropboxPut`'s exposed output stream. For further information, see `tFileOutputDelimited` on page 1106.

### Advanced settings

#### tStatCatcher Statistics

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

**ERROR_MESSAGE**

The error message generated by the component when an error occurs. This is an After variable and it returns a string.

### Usage

**Usage rule**

This component is used either standalone in a subJob to directly upload a local file to Dropbox or as an end component of a Job flow to upload given data being handled in this flow.

### Uploading files to Dropbox

In this scenario, a six-component Job consisting of three subJobs is created to write data onto Dropbox using different upload modes.
Before replicating this scenario, you need to create a Dropbox App under the Dropbox account to be used. In this scenario, the Dropbox App to be used is named to `talenddrop` and thus the root folder in which files are uploaded is `talenddrop`, too. In addition, the access token to this folder has been generated from the App console provided by Dropbox.

For further information about a Dropbox App, see https://www.dropbox.com/developers/apps/.

**Linking the components**

**Procedure**

1. In the Integration perspective of the Studio, create an empty Job from the Job Designs node in the Repository tree view. For further information about how to create a Job, see Talend Studio User Guide.

2. In the workspace, enter the name of the component to be used and select this component from the list that appears. In this scenario, the components are `tDropboxConnection`, `tFixedFlowInput`, `tFileOutputDelimited`, `tFileInputRaw` and two `tDropboxPut` components.

   The `tFixedFlowInput` component generates some data to be uploaded to Dropbox in this scenario. In the real-world case, you can use other components such as `tMysqlInput` or `tMap` in the place of `tFixedFlowInput` to design a sophisticated process to prepare your data to be handled.

3. Connect `tFixedFlowInput` to `tFileOutputDelimited` using the Row > Main link.

4. Do the same to connect `tFileOutputDelimited` to one of the two `tDropboxPut` components and connect `tFileInputRaw` to the other `tDropboxPut` component.

5. Connect `tDropboxConnection` to `tFixedFlowInput` using the Trigger > On Subjob Ok link. Then connect `tFixedFlowInput` to `tFileInputRaw` using the same type of link.

**Connecting to Dropbox**

**Procedure**

1. Double-click `tDropboxConnection` to open its Component view.
2. In the **Access token** field, paste the token that you have generated via the App console of Dropbox for accessing the Dropbox App folder to be used.

**Generating the output stream**

**Defining the input data**

**Procedure**

1. Double-click **tFixedFlowInput** to open its **Component** view.

![Component view of tFixedFlowInput](image)

In this scenario, only three rows of sample data are created to indicate three countries and their calling codes.

33; France  
86; China  
81; Japan

2. Click the [...] button next to **Edit schema** to open the schema editor.

3. Click the [+] button twice to add two rows and in the **Column** column, rename them to **code** and **country**, respectively.
4. Click **OK** to validate these changes and accept the propagation prompted by the pop-up dialog box.

5. In the **Mode** area, select the **Use Inline Table** radio button. The *code* and the *country* column have been automatically created in this table.

6. Enter the sample data mentioned above in this table.

**Defining the output stream**

**Procedure**

1. Double-click **tFileOutputDelimited** to open its **Component** view.

2. Select the **Use output stream** check box to write the data to be outputted into a given output stream.

3. In the **Output stream** field, enter the code to define the output stream you need to write data in. In this scenario, it is the output stream of the **tDropboxPut_1** component linked with the current component. Thus the code used to write the data reads as follows: `((java.io.OutputStream)globalMap.get("tDropboxPut_1_OUTPUTSTREAM"))`  
   Note that in this example code, the **tDropboxPut** component has the number 1 as its affix, which represents its component ID distributed automatically within this Job. If the **tDropboxPut** component you are using has a different ID, you need to adapt the code to that ID number.

4. Click **Edit schema** to verify that the schema of this component is identical with that of the preceding **tFixedFlowInput** component. If not so, click the **Sync columns** button to make both of the schemas identical.

5. Navigate to the **Advanced settings** tab.
6. Mark the **Custom the flush buffer size** check box. This automatically adds 1 in the **Row number** field.

**Exposing the tDropboxPut output stream**

**Procedure**

1. Double-click the **tDropboxPut** component linked with **tFileOutputDelimited** to open its **Component** view.

2. Select the **Use existing connection** check box to reuse the connection created by **tDropboxConnection**.

3. In the **Path** field, enter the path pointing to the file you need to write data in, with a slash (/) at the beginning of the path. For example, enter `/calling_code.csv`.

4. In the **Upload mode** area, select the **Rename if Existing** radio button.

5. Select the **Expose As OutputStream** radio button to expose the output stream of this component so that the other component, **tFileOutputDelimited** in this scenario, can write data in the stream.

**Defining the media data to be uploaded**

**Procedure**

1. Double-click **tFileInputRaw** to open its **Component** view.

This component is used to read a picture named `esb_architecture.png` into the data flow. In the real-world practice, this file can be of many other formats, such as pdf, xls, ppt or mp3.
2. In the **Filename** field, enter the path or browse to the file you need to upload.

3. In the **Mode** area, select the **Read the file as a bytes array** radio button.

**Uploading the incoming contents**

**Procedure**

1. Double-click the **tDropboxPut** component linked with **tFileInputRaw** to open its **Component** view.

2. Select the **Use existing connection** check box to reuse the connection created by **tDropboxConnection**.

3. In the **Path** field, enter the path pointing to the file you need to write data in, with a slash (/) at the beginning of the path. For example, enter `/architecture.png`.

4. In the **Upload mode** area, select **Rename if existing**.

5. Select the **Upload incoming content as file** radio button. This displays the **Edit schema** button to allow you to view the read-only schema of this component.

**Executing the Job**

Then you can press **F6** to run this Job.

Once done, check the uploaded files in the Dropbox App folder of your Dropbox, in this scenario, the *talenddrop* folder.
tDTDValidator

Helps at controlling data and structure quality of the file to be processed
Validates the XML input file against a DTD file and sends the validation log to the defined output.

**tDTDValidator Standard properties**

These properties are used to configure tDTDValidator running in the Standard Job framework.
The Standard tDTDValidator component belongs to the XML family.
The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Schema and Edit Schema</th>
<th>A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema of this component is read-only. It contains standard information regarding the file validation.</th>
</tr>
</thead>
<tbody>
<tr>
<td>DTD file</td>
<td>Filepath to the reference DTD file.</td>
</tr>
<tr>
<td>XML file</td>
<td>Filepath to the XML file to be validated.</td>
</tr>
<tr>
<td>If XML is valid, display</td>
<td>If XML is invalid, display</td>
</tr>
<tr>
<td>Print to console</td>
<td>Select this check box to display the validation message.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the processing metadata at the Job level as well as at each component level.                                                                                  |

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>DIFFERENCE: the result of the validation. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td></td>
<td>VALID: the validation result. This is a Flow variable and it returns a boolean.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.</td>
</tr>
</tbody>
</table>
**Usage**

| Usage rule | This component can be used as standalone component but it is usually linked to an output component to gather the log data. |

**Validating XML files**

This scenario describes a Job that validates the specified type of files from a folder, displays the validation result on the Run tab console, and outputs the log information for the invalid files into a delimited file.

**Procedure**

1. Drop the following components from the Palette to the design workspace: **tFileList**, **tDTDValidator**, **tMap**, **tFileOutputDelimited**.
2. Connect the **tFileList** to the **tDTDValidator** with an **Iterate** link and the remaining component using a **main** row.
3. Set the **tFileList** component properties, to fetch an XML file from a folder.

   - **Directory**: 
     ```
     "D:/Input"
     ```
   - **File List Type**: Files
   - **Includes subdirectories**: No
   - **Generate Error if no file found**: Off
   - **Case Sensitive**: No
   - **Use Glob Expressions as Filemask**: On

   ![Filemask Configuration](image)

   Click the plus button to add a filemask line and enter the filemask: `*.xml`. Remember Java code requires double quotes.

   Set the path of the XML files to be verified.

   Select **No** from the Case Sensitive drop-down list.
4. In the tDTDValidator Component view, the schema is read-only as it contains standard log information related to the validation process.

<table>
<thead>
<tr>
<th>Schema</th>
<th>Built-In</th>
<th>Edit schema</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dtd file</td>
<td>&quot;C:/input/employee.dtd&quot;</td>
<td>![image]</td>
</tr>
<tr>
<td>Xml file</td>
<td>((String)globalMap.get(&quot;tFileList_1_CURRENT_FILE&quot;))</td>
<td>![image]</td>
</tr>
</tbody>
</table>

If XML is valid, display "[job" + jobName + "]" + ((String)globalMap.get("tFileList_1_CURRENT_FILE")) + " is Valid".
If XML is invalid, display ""[job" + jobName + "]" + ((String)globalMap.get("tFileList_1_CURRENT_FILE")) + " is Invalid".

In the Dtd file field, browse to the DTD file to be used as reference.

5. Click in the XML file field, press Ctrl+Space bar to access the variable list, and double-click the current filepath global variable: tFileList.CURRENT_FILEPATH.

6. In the various messages to display in the Run tab console, use the jobName variable to recall the job name tag. Recall the filename using the relevant global variable: ((String)globalMap.get("tFileList_1_CURRENT_FILE")). Remember Java code requires double quotes. Select the Print to Console check box.

7. In the tMap component, drag and drop the information data from the standard schema that you want to pass on to the output file.

8. Once the Output schema is defined as required, add a filter condition to only select the log information data when the XML file is invalid.

   Follow the best practice by typing first the wanted value for the variable, then the operator based on the type of data filtered then the variable that should meet the requirement. In this case: 0 == row1.validate.

9. Then connect (if not already done) the tMap to the tFileOutputDelimited component using a Row > Main connection. Name it as relevant, in this example: log_errorsOnly.

10. In the tFileOutputDelimited Basic settings, define the destination filepath, the field delimiters and the encoding.

11. Save your Job and press F6 to run it.

Starting job tDTDValidator_job at 14:28 14/10/2010.
[statistics] connecting to socket on port 3420
[statistics] connected
[job tDTDValidator_job] employee_1.xml is valid
[job tDTDValidator_job] employee_2.xml is Invalid
[job tDTDValidator_job] employee_3.xml is Valid
[job tDTDValidator_job] employee_4.xml is Valid
[job tDTDValidator_job] employee_5.xml is Invalid
[statistics] disconnected
Job tDTDValidator_job ended at 14:28 14/10/2010. [exit code=0]
On the **Run** console the messages defined display for each of the files. At the same time the output file is filled with the log data for invalid files.
**tDynamoDBInput**

Retrieves data from an Amazon DynamoDB table and sends them to the component that follows for transformation.

**tDynamoDBInput Standard properties**

These properties are used to configure tDynamoDBInput running in the Standard Job framework.

The Standard tDynamoDBInput component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all **Talend products with Big Data** and in **Talend Data Fabric**.

**Basic settings**

<table>
<thead>

<td></td>
</tr>
<tr>
<td><strong>Action</strong></td>
<td>Select the operation to be performed from the drop-down list, either <strong>Query</strong> or <strong>Scan</strong>. For more information, see Query and Scan Operations in DynamoDB.</td>
<td></td>
</tr>
</tbody>
</table>
### Schema and Edit schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

- **Built-In**: You create and store the schema locally for this component only.
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

### Table Name

Specify the name of the table to be queried or scanned.

### Use advanced key condition expression

Select this check box and in the **Advanced key condition expression** field displayed, specify the key condition expressions used to determine the items to be read from the table or index.

### Key condition expression

Specify the key condition expressions used to determine the items to be read. Click the `[+]` button to add as many rows as needed, each row for a key condition expression, and set the following attributes for each expression:

- **Key Column**: Enter the name of the key column.
- **Function**: Select the function for the key condition expression.
- **Value1**: Specify the value used in the key condition expression.
- **Value2**: Specify the second value used in the key condition expression if needed, depending on the function you selected.

Note that only the items that meet all the key conditions defined in this table can be returned.

This table is not available when the **Use advanced key condition expression** check box is selected.

### Use filter expression

Select this check box to use the filter expression for the query or scan operation.

### Use advanced filter expression

Select this check box and in the **Advanced filter expression** field displayed, specify the filter expressions used to refine the data after it is queried or scanned and before it is returned to you.

This check box is available when the **Use filter expression** check box is selected.
Filter expression

Specify the filter expressions used to refine the results returned to you. Click the [+] button to add as many rows as needed, each row for a filter expression, and set the following attributes for each expression:

- **Column**: Enter the name of the column used to refine the results.
- **Function**: Select the function for the filter expression.
- **Value1**: Specify the value used in the filter expression.
- **Value2**: Specify the second value used in the filter expression if needed, depending on the function you selected.

Note that only the items that meet all the filter conditions defined in this table can be returned.

This table is available when the **Use filter expression** check box is selected and the **Use advanced filter expression** check box is cleared.

Value mapping

Specify the placeholders for the expression attribute values.

- **value**: Enter the expression attribute value.
- **placeholder**: Specify the placeholder for the corresponding value.

For more information, see Expression Attribute Values.

Name mapping

Specify the placeholders for the attribute names that conflict with the DynamoDB reserved words.

- **name**: Enter the name of the attribute that conflicts with a DynamoDB reserved word.
- **placeholder**: Specify the placeholder for the corresponding attribute name.

For more information, see Expression Attribute Names.

Advanced settings

**STS Endpoint**

Select this check box and in the field displayed, specify the AWS Security Token Service endpoint, for example, `sts.amazonaws.com`, where session credentials are retrieved from.

This check box is available only when the **Assume role** check box is selected.

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

Global Variables

**Global Variables**

- **NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.
- **QUERY**: the query statement being processed. This is a Flow variable and it returns a string.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

### Usage

| Usage rule | This component is usually used as a start component of a Job or Subjob and it always needs an output link. |

### Related scenarios

No scenario is available for the Standard version of this component yet.
**tDynamoDBOutput**

Creates, updates or deletes data in an Amazon DynamoDB table.

**tDynamoDBOutput Standard properties**

These properties are used to configure tDynamoDBOutput running in the Standard Job framework.

The Standard tDynamoDBOutput component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th><strong>Access Key</strong></th>
<th>Enter the access key ID that uniquely identifies an AWS Account. For further information about how to get your Access Key and Secret Key, see Getting Your AWS Access Keys.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Secret Key</strong></td>
<td>Enter the secret access key, constituting the security credentials in combination with the access key. To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Inherit credentials from AWS role</strong></td>
<td>Select this check box to leverage the instance profile credentials. These credentials can be used on Amazon EC2 instances, and are delivered through the Amazon EC2 metadata service. To use this option, your Job must be running within Amazon EC2 or other services that can leverage IAM Roles for access to resources. For more information, see Using an IAM Role to Grant Permissions to Applications Running on Amazon EC2 Instances.</td>
</tr>
<tr>
<td><strong>Assume role</strong></td>
<td>If you temporarily need some access permissions associated to an AWS IAM role that is not granted to your user account, select this check box to assume that role. Then specify the values for the following parameters to create a new assumed role session.</td>
</tr>
<tr>
<td><strong>Use End Point</strong></td>
<td>Select this check box and in the Server Url field displayed, specify the Web service URL of the DynamoDB database service.</td>
</tr>
<tr>
<td><strong>Region</strong></td>
<td>Specify the AWS region by selecting a region name from the list or entering a region between double quotation marks (e.g. &quot;us-east-1&quot;) in the list. For more information about the AWS Region, see Regions and Endpoints.</td>
</tr>
</tbody>
</table>
| **Action on table** | Select an operation to be performed on the table defined.  
  • **Default**: No operation is carried out.  
  • **Drop and create table**: The table is removed and created again. |
- **Create table**: The table does not exist and gets created.  
- **Create table if does not exist**: The table is created if it does not exist.  
- **Drop table if exist and create**: The table is removed if it already exists and created again.

### Action on data

On the data of the table defined, you can perform one of the following operations:

- **Insert**: Insert new items from the input flow.  
- **Update**: Update existing items according to the input flow.  
- **Delete**: Remove existing items according to the input flow.

### Schema and Edit schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

- **Built-In**: You create and store the schema locally for this component only.  
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.  
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

If the data to be written to DynamoDB is JSON data, select the **JSON** from the **DB type** drop-down list when you edit the schema. This ensures this data to be properly displayed in a tree structure when you access this data in DynamoDB.

### Table Name

Specify the name of table to be written.

### Partition Key

Specify the partition key of the specified table.

### Sort Key

Specify the sorted key of the specified table.

### Advanced settings

### STS Endpoint

Select this check box and in the field displayed, specify the AWS Security Token Service endpoint, for example, `sts.amazonaws.com`, where session credentials are retrieved from.

This check box is available only when the **Assume role** check box is selected.
Read Capacity Unit
Specify the number of read capacity units. For more information, see Amazon DynamoDB Provisioned Throughput.

Write Capacity Unit
Specify the number of write capacity units. For more information, see Amazon DynamoDB Provisioned Throughput.

tStatCatcher Statistics
Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

Global Variables

Global Variables

- **NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.
- **QUERY**: the query statement being processed. This is a Flow variable and it returns a string.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

Usage

Usage rule
This component is usually used as an end component of a Job or Subjob and it always needs an input link.

Related scenarios

No scenario is available for the Standard version of this component yet.
tEDIFACTtoXML

Transforms an EDIFACT message file into the XML format for better readability to users and compatibility with processing tools.

This component reads a United Nations/Electronic Data Interchange For Administration, Commerce and Transport (UN/EDIFACT) message and transforms it into the XML format according to the EDIFACT version and the EDIFACT family.

### tEDIFACTtoXML Standard properties

These properties are used to configure tEDIFACTtoXML running in the Standard Job framework.

The Standard tEDIFACTtoXML component belongs to the XML family.

The component in this framework is available in all Talend products.

#### Basic settings

<table>
<thead>
<tr>
<th><strong>Schema and Edit Schema</strong></th>
<th>A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema of this component is fixed and read-only, with only one column: <em>document</em>.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>EDI filename</strong></td>
<td>Filepath to the EDIFACT message file to be transformed.</td>
</tr>
<tr>
<td><strong>EDI version</strong></td>
<td>Select the EDIFACT version of the input file.</td>
</tr>
<tr>
<td><strong>Ignore new line</strong></td>
<td>Select this check box to skip carriage returns in the input file.</td>
</tr>
<tr>
<td><strong>Die on error</strong></td>
<td>Select this check box to stop Job execution when an error is encountered. By default, this check box is cleared, and therefore illegal rows are skipped and the process is completed for the error free rows.</td>
</tr>
</tbody>
</table>

#### Advanced settings

| **tStatCatcher Statistics** | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

#### Global Variables

<table>
<thead>
<tr>
<th><strong>Global Variables</strong></th>
<th><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</th>
</tr>
</thead>
</table>
To fill up a field or expression with a variable, press `Ctrl + Space` to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

| Usage rule | This component is usually linked to an output component to gather the transformation result. |

### Reading an EDIFACT message file and saving it to XML

This scenario describes a simple Job that reads a UN/EDIFACT Customs Cargo (CUSCAR) message file and saves it as an XML file.

### Adding and linking the components

**Procedure**

1. Drop the `tEDIFACTtoXML` component and the `tFileOutputXML` component from the **Palette** to the design workspace.
2. Connect the `tEDIFACTtoXML` component and the `tFileOutputXML` component using a **Row > Main** connection.

### Results

![Diagram of EDIFACTtoXML component with Row > Main connection]

### Configuring the components

**Procedure**

1. Double-click the `tEDIFACTtoXML` component to show its **Basic settings** view.

   ![Basic settings view]

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>EDI filename</strong></td>
<td><code>/input/EDIFACT/99a_cuscar.edi</code></td>
</tr>
<tr>
<td><strong>ED1 version</strong></td>
<td>D99A</td>
</tr>
</tbody>
</table>

2. Fill the **EDI filename** field with the full path to the input EDIFACT message file.

   In this use case, the input file is `99a_cuscar.edi`. 
3. From **EDI version** list, select the EDIFACT version of the input file, D99A in this use case.

4. Select the **Ignore new line** check box to skip the carriage return characters in the input file during the transformation.

5. Leave the other parameters as they are.

6. Double-click the **tFileOutputXML** component to show its **Basic settings** view.

7. Fill the **File Name** field with the full path to the output XML file you want to generate.

   In this use case, the output XML is **99a_cuscar.xml**.

8. Leave the other parameters as they are.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl+S** to save the Job.
2. Press **F6** to run the Job.

**Results**

The input EDIFACT CUSCAR message file is transformed into the XML format and the output XML file is generated as defined.

tELTGreenplumInput

Adds as many Input tables as required for the most complicated Insert statement.

The three ELT Greenplum components are closely related, in terms of their operating conditions. These components should be used to handle Greenplum DB schemas to generate Insert statements, including clauses, which are to be executed in the DB output table defined.

Provides the table schema to be used for the SQL statement to execute.

**tELTGreenplumInput Standard properties**

These properties are used to configure tELTGreenplumInput running in the Standard Job framework.

The Standard tELTGreenplumInput component belongs to the ELT family.

The component in this framework is available in all Talend products.

### Basic settings

| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
  • View schema: choose this option to view the schema only.  
  • Change to built-in property: choose this option to change the schema to Built-in for local changes.  
  • Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-in</strong></td>
<td>The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Default Table Name</th>
<th>Type in the default table name.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Schema Name</td>
<td>Type in the default schema name.</td>
</tr>
</tbody>
</table>

### Advanced settings

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |
Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | tELTGreenplumInput is to be used along with the tELTGreenplumMap. Note that the Output link to be used with these components must correspond strictly to the syntax of the table name. Note: Note that the ELT components do not handle actual data flow but only schema information. |

Related scenarios

- Mapping data using a simple implicit join on page 680
- Aggregating table columns and filtering on page 739
- Mapping date using using an Alias table on page 743
- Aggregating Snowflake data using context variables as table and connection names on page 719
tELTGreenplumMap

Uses the tables provided as input to feed the parameter in the built statement. The statement can include inner or outer joins to be implemented between tables or between one table and its aliases.

The three ELT Greenplum components are closely related, in terms of their operating conditions. These components should be used to handle Greenplum DB schemas to generate Insert statements, including clauses, which are to be executed in the DB output table defined.

Helps you to build the SQL statement graphically, using the table provided as input.

tELTGreenplumMap Standard properties

These properties are used to configure tELTGreenplumMap running in the Standard Job framework.

The Standard tELTGreenplumMap component belongs to the ELT family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Note:</td>
<td>When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:</td>
</tr>
<tr>
<td>1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.</td>
<td></td>
</tr>
<tr>
<td>2. In the child level, use a dedicated connection component to read that registered database connection.</td>
<td></td>
</tr>
<tr>
<td>For an example about how to share a database connection across Job levels, see Talend Studio User Guide.</td>
<td></td>
</tr>
</tbody>
</table>

| ELT Greenplum Map Editor | The ELT Map editor allows you to define the output schema and make a graphical build of the SQL statement to be executed. The column names of schema can be different from the column names in the database. |

<table>
<thead>
<tr>
<th>Style link</th>
<th>Select the way in which links are displayed.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Auto: By default, the links between the input and output schemas and the Web service parameters are in the form of curves.</td>
<td></td>

<tr>
<td>Bezier curve: Links between the schema and the Web service parameters are in the form of curve.</td>
<td></td>
</tr>
<tr>
<td>Line: Links between the schema and the Web service parameters are in the form of straight lines.</td>
<td>This option slightly optimizes performance.</td>
</tr>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>---------------</td>
<td>--------------------------------</td>
</tr>
<tr>
<td>Built-in:</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository:</td>
<td>Select the Repository file where Properties are stored. The following fields are pre-filled in using fetched data.</td>
</tr>
</tbody>
</table>

**Host**
Database server IP address.

**Port**
Listening port number of DB server.

**Database**
Name of the database.

**Username and Password**
DB user authentication data.
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

### Advanced settings

**Additional JDBC parameters**
Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the **Use an existing connection** check box in the **Basic settings**.

**tStatCatcher Statistics**
Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

### Global Variables

**Global Variables**

- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.
- A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.
- To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.
- For further information about variables, see **Talend Studio User Guide**.

### Usage

**Usage rule**

- **tELTGreenplumMap** is used along with **tELTGreenplumInput** and **tELTGreenplumOutput**. Note that the Output link to be used with these components must correspond strictly to the syntax of the table name.
Mapping data using a simple implicit join

In this scenario, a tELTGreenplumMap component is deployed to retrieve the data from the source table employee_by_statecode, compares its statecode column against the table statecode, and then maps the desired columns from the two tables to the output table employee_by_state.

Before the Job execution, the three tables, employee_by_statecode, statecode and employee_by_state look like:

<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
<th>statecode</th>
<th>state</th>
<th>statecode</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Andy</td>
<td>86</td>
<td>China</td>
<td>86</td>
</tr>
<tr>
<td>3</td>
<td>Mike</td>
<td>39</td>
<td>Mexico</td>
<td>52</td>
</tr>
<tr>
<td>2</td>
<td>John</td>
<td>52</td>
<td>Italy</td>
<td>39</td>
</tr>
</tbody>
</table>

Dropping components

Procedure

1. Drop tGreenplumConnection, tELTGreenplumInput (two), tELTGreenplumMap, tELTGreenplumOutput, tGreenplumCommit, tGreenplumInput and tLogRow from the Palette onto the workspace.
2. Rename tGreenplumConnection as connect_to_greenplum_host, two tELTGreenplumInput components as employee+statecode and statecode, tELTGreenplumMap as match+map, tELTGreenplumOutput as map_data_output, tGreenplumCommit as commit_to_host, tGreenplumInput as read_map_output_table and tLogRow as show_map_data.
3. Link tGreenplumConnection to tELTGreenplumMap using an OnSubjobOk trigger.
Link **tELTGreenplumMap** to **tGreenplumCommit** using an **OnSubjobOk** trigger.
Link **tGreenplumCommit** to **tGreenplumInput** using an **OnSubjobOk** trigger.

4. Link **tGreenplumInput** to **tLogRow** using a **Row > Main** connection.

The two **tELTGreenplumInput** components and **tELTGreenplumOutput** will be linked to **tELTGreenplumMap** later once the relevant tables have been defined.

### Configuring the components

**Procedure**

1. Double-click **tGreenplumConnection** to open its **Basic settings** view in the **Component** tab.

   In the **Host** and **Port** fields, enter the context variables for the Greenplum server.
   
   In the **Database** field, enter the context variable for the Greenplum database.
   
   In the **Username** and **Password** fields, enter the context variables for the authentication credentials.
   
   For more information on context variables, see *Talend Studio User Guide*.

2. Double-click **employee+statecode** to open its **Basic settings** view in the **Component** tab.
In the Default table name field, enter the name of the source table, namely employee_by_statecode.

Click the [...] button next to the Edit schema field to open the schema editor.

Click the [+] button to add three columns, namely id, name and statecode, with the data type as INT4, VARCHAR, and INT4 respectively.

Click OK to close the schema editor.

Link employee+statecode to tELTGreenplumMap using the output employee_by_statecode.

3. Double-click statecode to open its Basic settings view in the Component tab.

In the Default table name field, enter the name of the lookup table, namely statecode.

4. Click the [...] button next to the Edit schema field to open the schema editor.
Click the [+] button to add two columns, namely state and statecode, with the data type as VARCHAR and INT4 respectively.

Click OK to close the schema editor.

Link statecode to tELTGreenplumMap using the output statecode.

5. Click tELTGreenplumMap to open its Basic settings view in the Component tab.

Select the Use an existing connection check box.

6. Click the [...] button next to the ELT Greenplum Map Editor field to open the map editor.
Click the [+ ] button on the upper left corner to open the table selection box.

Select tables `employee_by_statecode` and `statecode` in sequence and click Ok.

The tables appear on the left panel of the editor.

8. On the upper right corner, click the [+ ] button to add an output table, namely `employee_by_state`. Click Ok to close the map editor.

9. Double-click `tELTGreenplumOutput` to open its Basic settings view in the Component tab.
In the **Default table name** field, enter the name of the output table, namely *employee_by_state*.

**10.** Click the [...] button next to the **Edit schema** field to open the schema editor.

![Schema editor](image)

Click the [+] button to add three columns, namely *id*, *name* and *state*, with the data type as *INT4*, *VARCHAR*, and *VARCHAR* respectively.

Click **OK** to close the schema editor.

Link *tELTGreenplumMap* to *tELTGreenplumOutput* using the table output *employee_by_state*.

Click **OK** on the pop-up window below to retrieve the schema of *tELTGreenplumOutput*.

![Pop-up window](image)

Now the map editor's output table *employee_by_state* shares the same schema as that of *tELTGreenplumOutput*.

**11.** Double-click *tELTGreenplumMap* to open the map editor.

Drop the column *statecode* from table *employee_by_statecode* to its counterpart of the table *statecode*, looking for the records in the two tables that have the same *statecode* values.

Drop the columns *id* and *name* from table *employee_by_statecode* as well as the column *statecode* from table *statecode* to their counterparts in the output table *employee_by_state*. 
Click **Ok** to close the map editor.

12. Double-click **tGreenplumInput** to open its **Basic settings** view in the **Component** tab.

   ![tGreenplumInput settings](image)

   Select the **Use an existing connection** check box.

   In the **Table name** field, enter the name of the source table, namely \*employee_by_state*.

   In the **Query** field, enter the query statement, namely "SELECT * FROM "employee_by_state"".

13. Double-click **tLogRow** to open its **Basic settings** view in the **Component** tab.

   ![tLogRow settings](image)

   In the **Mode** area, select **Table (print values in cells of a table)** for a better display.

### Executing the Job

**Procedure**

1. Press **Ctrl+S** to save the Job.
2. Press **F6** to run the Job.

   ```
   --> 3 rows inserted.
<p>| show_map_data |</p>
<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
<th>state</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>John</td>
<td>Mexico</td>
</tr>
<tr>
<td>1</td>
<td>Andy</td>
<td>China</td>
</tr>
<tr>
<td>3</td>
<td>Mike</td>
<td>Italy</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
   [statistics] disconnected
   ```

As shown above, the desired employee records have been written to the table **employee_by_state**, presenting clearer geographical information about the employees.

- Mapping data using a subquery on page 794, a related scenario using subquery
- Aggregating Snowflake data using context variables as table and connection names on page 719
tELTGreenplumOutput

Executes the SQL Insert, Update and Delete statement to the Greenplum database

The three ELT Greenplum components are closely related, in terms of their operating conditions. These components should be used to handle Greenplum DB schemas to generate Insert statements, including clauses, which are to be executed in the DB output table defined.

Carries out the action on the table specified and inserts the data according to the output schema defined the ELT Mapper.

**tELTGreenplumOutput Standard properties**

These properties are used to configure tELTGreenplumOutput running in the Standard Job framework. The Standard tELTGreenplumOutput component belongs to the ELT family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Action on data</th>
<th>On the data of the table defined, you can perform the following operation:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Insert</strong>: Adds new entries to the table.</td>
</tr>
<tr>
<td></td>
<td><strong>Update</strong>: Updates entries in the table.</td>
</tr>
<tr>
<td></td>
<td><strong>Delete</strong>: Deletes the entries which correspond to the entry flow.</td>
</tr>
</tbody>
</table>

**Schema and Edit Schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

- **Built-in**: The schema is created and stored locally for this component only. Related topic: see *Talend Studio User Guide*.

- **Repository**: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see *Talend Studio User Guide*.
<table>
<thead>
<tr>
<th><strong>Where clauses for (for UPDATE and DELETE only)</strong></th>
<th>Enter a clause to filter the data to be updated or deleted during the update or delete operations.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Default Table Name</strong></td>
<td>Enter the default table name, between double quotation marks.</td>
</tr>
<tr>
<td><strong>Default Schema Name</strong></td>
<td>Enter the default schema name, between double quotation marks.</td>
</tr>
<tr>
<td><strong>Table name from connection name is variable</strong></td>
<td>Select this check box when the name of the connection to this component is set to a variable, such as a context variable.</td>
</tr>
<tr>
<td><strong>Use different table name</strong></td>
<td>Select this check box to define a different output table name, between double quotation marks, in the Table name field which appears.</td>
</tr>
<tr>
<td><strong>Mapping</strong></td>
<td>Specify the metadata mapping file for the database to be used. The metadata mapping file is used for the data type conversion between database and Java. For more information about the metadata mapping, see the related documentation for Type mapping.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| **tStatCatcher Statistics**                      | Select this check box to gather the Job processing metadata at a Job level as well as at each component level.                      |

**Global Variables**

| **Global Variables**                             | **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.  
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>NB_LINE_INSERTED</strong>: the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>

</tr>
<tr>
<td></td>
<td>For further information about variables, see <strong>Talend Studio User Guide</strong>.</td>
</tr>
</tbody>
</table>

**Usage**

| **Usage rule**                                   | **tELTGgreenplumOutput** is to be used along with the **tELTGgreenplumMap**. Note that the Output link to be used with these components must correspond strictly to the syntax of the table name. |

689
Note:
Note that the ELT components do not handle actual data flow but only schema information.

Related scenarios

- Mapping data using a simple implicit join on page 680
- Aggregating table columns and filtering on page 739
- Mapping date using using an Alias table on page 743
- Aggregating Snowflake data using context variables as table and connection names on page 719
**tELTHiveInput**

Replicates the schema, which the tELTHiveMap component that follows will use, of the input Hive table.

The three ELT Hive components are closely related, in terms of their operating conditions. These components should be used to handle Hive DB schemas to generate Insert statements, including clauses, which are to be executed in the DB output table defined.

This component provides, for the tELTHiveMap component that follows, the input schema of the Hive table to be used.

**tELTHiveInput Standard properties**

These properties are used to configure tELTHiveInput running in the Standard Job framework.

The Standard tELTHiveInput component belongs to the ELT family.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Schema</th>
<th>A schema is a row description. It defines the number of fields to be processed and passed on to the next component. The schema is either Built-in or stored remotely in the Repository.</th>
</tr>
</thead>
</table>
|        | **Built-In**: You create and store the schema locally for this component only.  
**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. |

**Edit schema**

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the **Repository Content** window.

**Default table name**

Enter the name of the input table to be used.

**Default schema name**

Enter the name of the database schema to which the input table to be used is related.
Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

Global Variables

Global Variables

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

Usage

Usage rule

**tELTHiveMap** is used along with a **tELTHiveInput** and **tELTHiveOutput**. Note that the Output link to be used with these components must correspond strictly to the syntax of the table name.

If the Studio used to connect to a Hive database is operated on Windows, you must manually create a folder called tmp in the root of the disk where this Studio is installed.

**Note:**
The ELT components do not handle actual data flow but only schema information.

Usage with Dataproc

The ELT Hive components require Tez to be installed on the Google Cloud Dataproc cluster to be used.

- Use the initialization action explained in this Google Cloud Platform documentation: [Apache Tez on Dataproc](#).
- For more details about the general concept of the initialization actions in a Google Cloud Dataproc cluster, see the related Google documentation: Initialization actions.

Related scenarios

- [Joining table columns and writing them into Hive](#) on page 704
- [Aggregating Snowflake data using context variables as table and connection names](#) on page 719
tELTHiveMap

Builds graphically the Hive QL statement in order to transform data.

The three ELT Hive components are closely related, in terms of their operating conditions. These components should be used to handle Hive DB schemas to generate Insert statements, including clauses, which are to be executed in the DB output table defined.

This component uses the tables provided as input, to feed the parameter in the built statement. The statement can include inner or outer joins to be implemented between tables or between one table and its aliases.

tELTHiveMap Standard properties

These properties are used to configure tELTHiveMap running in the Standard Job framework.

The Standard tELTHiveMap component belongs to the ELT family.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

Basic settings

Connection configuration:

- When you use this component with Qubole on AWS:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>API Token</td>
<td>Click the ... button next to the API Token field to enter the authentication token generated for the Qubole user account to be used. For further information about how to obtain this token, see Manage Qubole account from the Qubole documentation. This token allows you to specify the user account you want to use to access Qubole. Your Job automatically uses the rights and permissions granted to this user account in Qubole.</td>
</tr>
<tr>
<td>Cluster label</td>
<td>Select the Cluster label check box and enter the name of the Qubole cluster to be used. If leaving this check box clear, the default cluster is used. If you need details about your default cluster, ask the administrator of your Qubole service. You can also read this article from the Qubole documentation to find more information about configuring a default Qubole cluster.</td>
</tr>
<tr>
<td>Change API endpoint</td>
<td>Select the Change API endpoint check box and select the region to be used. If leaving this check box clear, the default region is used. For further information about the Qubole Endpoints supported on QDS-on-AWS, see Supported Qubole Endpoints on Different Cloud Providers.</td>
</tr>
</tbody>
</table>

- When you use this component with Google Dataproc:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Project identifier</td>
<td>Enter the ID of your Google Cloud Platform project.</td>
</tr>
</tbody>
</table>
If you are not certain about your project ID, check it in the Manage Resources page of your Google Cloud Platform services.

<table>
<thead>
<tr>
<th>Cluster identifier</th>
<th>Enter the ID of your Dataproc cluster to be used.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Region</td>
<td>Leave the default value global as is, since this is the only region which the Studio supports for Google Cloud Platform.</td>
</tr>
<tr>
<td>Google Storage staging bucket</td>
<td>As a Talend Job expects its dependent jar files for execution, specify the Google Storage directory to which these jar files are transferred so that your Job can access these files at execution. The directory to be entered must end with a slash (/). If not existing, the directory is created on the fly but the bucket to be used must already exist.</td>
</tr>
<tr>
<td>Database</td>
<td>Fill this field with the name of the database.</td>
</tr>
<tr>
<td>Provide Google Credentials in file</td>
<td>Leave this check box clear, when you launch your Job from a given machine in which Google Cloud SDK has been installed and authorized to use your user account credentials to access Google Cloud Platform. In this situation, this machine is often your local machine. For further information about this Google Credentials file, see the administrator of your Google Cloud Platform or visit Google Cloud Platform Auth Guide.</td>
</tr>
</tbody>
</table>

- When you use this component with HDInsight:

<table>
<thead>
<tr>
<th>WebHCat configuration</th>
<th>Enter the address and the authentication information of the Microsoft HD Insight cluster to be used. For example, the address could be your_hdinsight_cluster_name.azurehdinsight.net and the authentication information is your Azure account name: ychen. The Studio uses this service to submit the Job to the HD Insight cluster. In the Job result folder field, enter the location in which you want to store the execution result of a Job in the Azure Storage to be used.</th>
</tr>
</thead>
<tbody>
<tr>
<td>HDInsight configuration</td>
<td>• The Username is the one defined when creating your cluster. You can find it in the SSH + Cluster login blade of your cluster. • The Password is defined when creating your HDInsight cluster for authentication to this cluster.</td>
</tr>
<tr>
<td>Windows Azure Storage configuration</td>
<td>Enter the address and the authentication information of the Azure Storage account to be used. In this configuration, you do not define where to read or write your business data but define where to deploy your Job only. Therefore always use the Azure Storage system for this configuration. In the Container field, enter the name of the container to be used. You can find the available containers in the Blob blade of the Azure Storage account to be used.</td>
</tr>
</tbody>
</table>
In the **Deployment Blob** field, enter the location in which you want to store the current Job and its dependent libraries in this Azure Storage account.

In the **Hostname** field, enter the Primary Blob Service Endpoint of your Azure Storage account without the https:// part. You can find this endpoint in the **Properties** blade of this storage account.

In the **Username** field, enter the name of the Azure Storage account to be used.

In the **Password** field, enter the access key of the Azure Storage account to be used. This key can be found in the **Access keys** blade of this storage account.

**Database**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Fill this field with the name of the database.</strong></td>
<td></td>
</tr>
</tbody>
</table>

- **When you use the other distributions:**

<table>
<thead>
<tr>
<th>Connection mode</th>
<th>Select a connection mode from the list. The options vary depending on the distribution you are using.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Hive server</strong></td>
<td>Select the Hive server through which you want the Job using this component to execute queries on Hive.</td>
</tr>
<tr>
<td><strong>Host</strong></td>
<td>Database server IP address.</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Fill this field with the name of the database.</td>
</tr>
<tr>
<td><strong>Username</strong> and <strong>Password</strong></td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Use kerberos authentication</strong></td>
<td>If you are accessing a Hive Metastore running with Kerberos security, select this check box and then enter the relevant parameters in the fields that appear.</td>
</tr>
<tr>
<td></td>
<td>• If this cluster is a MapR cluster of the version 5.0.0 or later, you can set the MapR ticket authentication configuration in addition or as an alternative by following the explanation in <strong>Connecting to a security-enabled MapR</strong> on page 1629.</td>
</tr>
</tbody>
</table>
Keep in mind that this configuration generates a new MapR security ticket for the username defined in the Job in each execution. If you need to reuse an existing ticket issued for the same username, leave both the Force MapR ticket authentication check box and the Use Kerberos authentication check box clear, and then MapR should be able to automatically find that ticket on the fly.

The values of the following parameters can be found in the hive-site.xml file of the Hive system to be used.

1. **Hive principal** uses the value of hive.metastore.kerberos.principal. This is the service principal of the Hive Metastore.

2. **HiveServer2 local user principal** uses the value of hive.server2.authentication.kerberos.principal.

3. **HiveServer2 local user keytab** uses the value of hive.server2.authentication.kerberos.keytab

4. **Metastore URL** uses the value of javax.jdo.option.ConnectionURL. This is the JDBC connection string to the Hive Metastore.

5. **Driver class** uses the value of javax.jdo.option.ConnectionDriverName. This is the name of the driver for the JDBC connection.

6. **Username** uses the value of javax.jdo.option.ConnectionUserName. This, as well as the Password parameter, is the user credential for connecting to the Hive Metastore.

7. **Password** uses the value of javax.jdo.option.ConnectionPassword.

For the other parameters that are displayed, please consult the Hadoop configuration files they belong to. For example, the **Namenode principal** can be found in the hdfs-site.xml file or the hdfs-default.xml file of the distribution you are using.

This check box is available depending on the Hadoop distribution you are connecting to.

---

### Use a keytab to authenticate

Select the Use a keytab to authenticate check box to log into a Kerberos-enabled system using a given keytab file. A keytab file contains pairs of Kerberos principals and encrypted keys. You need to enter the principal to be used in the Principal field and the access path to the keytab file itself in the Keytab field. This keytab file must be stored in the machine in which your Job actually runs, for example, on a Talend Jobserver.

Note that the user that executes a keytab-enabled Job is not necessarily the one a principal designates but must have the right to read the keytab file being used. For example, the user name you are using to execute a Job is user1 and the principal to be used is guest; in this situation, ensure that user1 has the right to read the keytab file to be used.

---

### Use SSL encryption

Select this check box to enable the SSL or TLS encrypted connection.

Then in the fields that are displayed, provide the authentication information:
In the **Trust store path** field, enter the path, or browse to the TrustStore file to be used. By default, the supported TrustStore types are **JKS** and **PKCS 12**.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

This feature is available only to the HiveServer2 in the **Standalone** mode of the following distributions:

- Hortonworks Data Platform 2.0 +
- Cloudera CDH4 +
- Pivotal HD 2.0 +
- Amazon EMR 4.0.0 +

### Set Resource Manager

Select this check box and in the displayed field, enter the location of the ResourceManager of your distribution. For example, `tal-qa114.talend.lan:8050`.

Then you can continue to set the following parameters depending on the configuration of the Hadoop cluster to be used (if you leave the check box of a parameter clear, then at runtime, the configuration about this parameter in the Hadoop cluster to be used will be ignored):

1. Select the **Set resourcemanager scheduler address** check box and enter the Scheduler address in the field that appears.
2. Select the **Set jobhistory address** check box and enter the location of the JobHistory server of the Hadoop cluster to be used. This allows the metrics information of the current Job to be stored in that JobHistory server.
3. Select the **Set staging directory** check box and enter this directory defined in your Hadoop cluster for temporary files created by running programs. Typically, this directory can be found under the `yarn.app.mapreduce.am.staging-dir` property in the configuration files such as `yarn-site.xml` or `mapred-site.xml` of your distribution.
4. Allocate proper memory volumes to the **Map** and the **Reduce** computations and the **ApplicationMaster** of YARN by selecting the **Set memory** check box in the **Advanced settings** view.
5. Select the **Set Hadoop user** check box and enter the user name under which you want to execute the Job. Since a file or a directory in Hadoop has its specific owner with appropriate read or write rights, this field allows you to execute the Job directly under the user name that has the appropriate rights to access the file or directory to be processed.
6. Select the **Use datanode hostname** check box to allow the Job to access datanodes via their hostnames. This actually sets the `dfs.client.use.datanode.hostname` property to true. When connecting to a S3N filesystem, you must select this check box.

For further information about these parameters, see the documentation or contact the administrator of the Hadoop cluster to be used.

### Set NameNode URI
Select this check box and in the displayed field, enter the URI of the Hadoop NameNode, the master node of a Hadoop system. For example, assuming that you have chosen a machine called `masternode` as the NameNode, then the location is `hdfs://masternode:portnumber`. If you are using WebHDFS, the location should be `webhdfs://masternode:portnumber`; WebHDFS with SSL is not supported yet.

The other properties:

<table>
<thead>
<tr>
<th>Property type</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Property type</strong></td>
<td>Either <strong>Built-In</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-In</strong>: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: Select the repository file where the properties are stored.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
<td></td>
</tr>
</tbody>
</table>

**Note**: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see [Talend Studio User Guide](http://hadoop.apache.org).

### ELT Hive Map editor
The ELT Map editor helps you to define the output schema as well as build graphically the Hive QL statement to be executed. The column names of schema can be different from the column names in the database.

If you use context variables in the **Expression** column in the Map editor to map the input and the output schemas, put single quotation marks around these context variables, for example, `"context.v_erpName"`.

### Style link
Select the way in which links are displayed.

**Auto**: By default, the links between the input and output schemas and the Web service parameters are in the form of curves.

**Bezier curve**: Links between the schema and the Web service parameters are in the form of curve.
### Distribution

Select the cluster you are using from the drop-down list. The options in the list vary depending on the component you are using. Among these options, the following ones requires specific configuration:

- If available in this **Distribution** drop-down list, the **Microsoft HD Insight** option allows you to use a Microsoft HD Insight cluster. For this purpose, you need to configure the connections to the HD Insight cluster and the Windows Azure Storage service of that cluster in the areas that are displayed. For detailed explanation about these parameters, search for configuring the connection manually on Talend Help Center ([https://help.talend.com](https://help.talend.com)).

- If you select **Amazon EMR**, you can find more details about how to configure an Amazon EMR cluster in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

- The **Custom** option allows you to connect to a cluster different from any of the distributions given in this list, that is to say, to connect to a cluster not officially supported by **Talend**.

1. Select **Import from existing version** to import an officially supported distribution as base and then add other required jar files which the base distribution does not provide.

2. Select **Import from zip** to import the configuration zip for the custom distribution to be used. This zip file should contain the libraries of the different Hadoop elements and the index file of these libraries.

   In **Talend Exchange**, members of **Talend** community have shared some ready-for-use configuration zip files which you can download from this **Hadoop configuration** list and directly use them in your connection accordingly. However, because of the ongoing evolution of the different Hadoop-related projects, you might not be able to find the configuration zip corresponding to your distribution from this list; then it is recommended to use the **Import from existing version** option to take an existing distribution as base to add the jars required by your distribution.

Note that custom versions are not officially supported by **Talend**. **Talend** and its community provide you with the opportunity to connect to custom versions from the Studio but cannot guarantee that the configuration of whichever version you choose will be easy, due to the wide range of different Hadoop distributions and versions that are available. As such, you should only attempt to set up such a connection if you have sufficient Hadoop experience to handle any issues on your own.
Note:
In this dialog box, the active check box must be kept selected so as to import the jar files pertinent to the connection to be created between the custom distribution and this component.

For a step-by-step example about how to connect to a custom distribution and share this connection, see [Connecting to a custom Hadoop distribution on page 1569](#).

<table>
<thead>
<tr>
<th><strong>Hive version</strong></th>
<th>Select the version of the Hadoop distribution you are using. The available options vary depending on the component you are using.</th>
</tr>
</thead>
</table>

| **Execution engine** | Select this check box and from the drop-down list, select the framework you need to use to run the Job. This list is available only when you are using the **Embedded** mode for the Hive connection and the distribution you are working with is:  
  • Custom: this option allows you connect to a distribution supporting Tez but not officially supported by Talend.  
Before using Tez, ensure that the Hadoop cluster you are using supports Tez. You will need to configure the access to the relevant Tez libraries via the **Advanced settings** view of this component.  
For further information about Hive on Tez, see Apache’s related documentation in [https://cwiki.apache.org/confluence/display/Hive/Hive+on+Tez](https://cwiki.apache.org/confluence/display/Hive/Hive+on+Tez). Some examples are presented there to show how Tez can be used to gain performance over MapReduce. |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------|

When you need to enable Hive components to access HBase:

These parameters are available only when the **Use an existing connection** check box is clear.

| **Store by HBase** | Select this check box to display the parameters to be set to allow the Hive components to access HBase tables:  
  • Once this access is configured, you will be able to use, in `tHiveRow` and `tHiveInput`, the Hive QL statements to read and write data in HBase.  
  • If you are using the Kerberos authentication, you need to define the HBase related principals in the corresponding fields that are displayed.  
For further information about this access involving Hive and HBase, see Apache’s Hive documentation about Hive/HBase integration. |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------|

<table>
<thead>
<tr>
<th><strong>Zookeeper quorum</strong></th>
<th>Type in the name or the URL of the Zookeeper service you use to coordinate the transaction between your Studio and your database. Note that when you configure the Zookeeper, you might need to explicitly set the <code>zookeeper.znode.parent</code> property to define the path to the root znode that contains all the znodes created and used by your database; then select the <strong>Set Zookeeper znode parent</strong> check box to define this property.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Zookeeper client port</strong></td>
<td>Type in the number of the client listening port of the Zookeeper service you are using.</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-----------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>Define the jars to register for HBase</strong></td>
<td>Select this check box to display the <strong>Register jar for HBase</strong> table, in which you can register any missing jar file required by HBase, for example, the Hive Storage Handler, by default, registered along with your Hive installation.</td>
</tr>
<tr>
<td><strong>Register jar for HBase</strong></td>
<td>Click the [+] button to add rows to this table, then, in the <strong>Jar name</strong> column, select the jar file(s) to be registered and in the <strong>Jar path</strong> column, enter the path(s) pointing to that or those jar file(s).</td>
</tr>
</tbody>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th><strong>Tez lib</strong></th>
<th>Select how the Tez libraries are accessed:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• <strong>Auto install</strong>: at runtime, the Job uploads and deploys the Tez libraries provided by the Studio into the directory you specified in the <strong>Install folder in HDFS</strong> field, for example, /tmp/usr/tez.</td>
</tr>
<tr>
<td></td>
<td>If you have set the <strong>tez.lib.uris</strong> property in the properties table, this directory overrides the value of that property at runtime. But the other properties set in the properties table are still effective.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Use exist</strong>: the Job accesses the Tez libraries already deployed in the Hadoop cluster to be used. You need to enter the path pointing to those libraries in the <strong>Lib path (folder or file)</strong> field.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Lib jar</strong>: this table appears when you have selected <strong>Auto install</strong> from the <strong>Tez lib</strong> list and the distribution you are using is <strong>Custom</strong>. In this table, you need to add the Tez libraries to be uploaded.</td>
</tr>
</tbody>
</table>

| **Temporary path** | If you do not want to set the Jobtracker and the NameNode when you execute the query `select * from your_table_name`, you need to set this temporary path. For example, \C:/select_all in Windows. |

<table>
<thead>
<tr>
<th><strong>Hadoop properties</strong></th>
<th><em>Talend Studio</em> uses a default configuration for its engine to perform operations in a Hadoop distribution. If you need to use a custom configuration in a specific situation, complete this table with the property or properties to be customized. Then at runtime, the customized property or properties will override those default ones.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• <strong>Note that if you are using the centrally stored metadata from the Repository</strong>, this table automatically inherits the properties defined in that metadata and becomes uneditable unless you change the <strong>Property type</strong> from <strong>Repository</strong> to <strong>Built-in</strong>.</td>
</tr>
<tr>
<td></td>
<td>For further information about the properties required by Hadoop and its related systems such as HDFS and Hive, see the documentation of the Hadoop distribution you are using or see Apache's Hadoop documentation on <a href="http://hadoop.apache.org/docs">http://hadoop.apache.org/docs</a> and then select the version of the documentation you want. For demonstration purposes, the links to some properties are listed below:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Typically, the HDFS-related properties can be found in the hdfs-default.xml file of your distribution</strong>, such as</td>
</tr>
</tbody>
</table>
**Hive properties**

_Talend Studio_ uses a default configuration for its engine to perform operations in a Hive database. If you need to use a custom configuration in a specific situation, complete this table with the property or properties to be customized. Then at runtime, the customized property or properties will override those default ones. For further information for Hive dedicated properties, see https://cwiki.apache.org/confluence/display/Hive/AdminManual+Configuration.

- If you need to use Tez to run your Hive Job, add `hive.execution.engine` to the **Properties** column and `Tez` to the **Value** column, enclosing both of these strings in double quotation marks.
- Note that if you are using the centrally stored metadata from the _Repository_, this table automatically inherits the properties defined in that metadata and becomes uneditable unless you change the **Property type** from _Repository_ to _Built-in_.

**Mapred job map memory mb** and **Mapred job reduce memory mb**

You can tune the map and reduce computations by selecting the Set memory check box to set proper memory allocations for the computations to be performed by the Hadoop system.

In that situation, you need to enter the values you need in the **Mapred job map memory mb** and the **Mapred job reduce memory mb** fields, respectively. By default, the values are both 1000 which are normally appropriate for running the computations.

**Path separator in server**

Leave the default value of the **Path separator in server** as it is, unless you have changed the separator used by your Hadoop distribution's host machine for its PATH variable or in other words, that separator is not a colon (:). In that situation, you must change this value to the one you are using in that host.

**tStatCatcher Statistics**

Select this check box to collect log data at the component level.

**Temporary path**

If you do not want to set the Jobtracker and the NameNode when you execute the query `select * from your_table_name`, you need to set this temporary path. For example, `/C:/select_all` in Windows.

**Global Variables**

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule

tELTHiveMap is used along with a tELTHiveInput and tELTHiveOutput. Note that the Output link to be used with these components must correspond strictly to the syntax of the table name.

If the Studio used to connect to a Hive database is operated on Windows, you must manually create a folder called tmp in the root of the disk where this Studio is installed.

Note: The ELT components do not handle actual data flow but only schema information.

Usage with Dataproc

The ELT Hive components require Tez to be installed on the Google Cloud Dataproc cluster to be used.

• Use the initialization action explained in this Google Cloud Platform documentation: Apache Tez on Dataproc.

• For more details about the general concept of the initialization actions in a Google Cloud Dataproc cluster, see the related Google documentation: Initialization actions.

Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Prerequisites

The Hadoop distribution must be properly installed, so as to guarantee the interaction with Talend Studio. The following list presents MapR related information for example.

• Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR
client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native. For example, the library for Windows is \lib\native\MapRClient.dll in the MapR client jar file. For further information, see the following link from MapR: http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr.

Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path.

- Set the -Djava.library.path argument, for example, in the Job Run VM arguments area of the Run/Debug view in the Preferences dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

---

Joining table columns and writing them into Hive

This scenario applies only to Talend products with Big Data.

This scenario uses a four-component Job to join the columns selected from two Hive tables and write them into another Hive table.

### Preparing the Hive tables

**Procedure**

1. Create the Hive table you want to write data in. In this scenario, this table is named as `agg_result`, and you can create it using the following statement in `tHiveRow`:

   ```sql
   CREATE TABLE agg_result
   (id int, name string, address string, sum1 string, postal string, state string, capital string, mostpopulouscity string) partitioned by
   ```
In this statement, `/user/ychen/hive/table/agg_result` is the directory used in this scenario to store this created table in HDFS. You need to replace it with the directory you want to use in your environment.

For further information about `tHiveRow`, see `tHiveRow` on page 1617.

2. Create two input Hive tables containing the columns you want to join and aggregate these columns into the output Hive table, `agg_result`. The statements to be used are:
   ```sql
create table customer (id int, name string, address string, idState int, id2 int, regTime string, registerTime string, sum1 string, sum2 string) row format delimited fields terminated by ';' location '/user/ychen/hive/table/customer'
and create table state_city (id int, postal string, state string, capital int, mostpopulouscity string) row format delimited fields terminated by ';' location '/user/ychen/hive/table/state_city'
```

3. Use `tHiveRow` to load data into the two input tables, `customer` and `state_city`. The statements to be used are:
   ```sql"LOAD DATA LOCAL INPATH 'C:/tmp/customer.csv' OVERWRITE INTO TABLE customer" and "LOAD DATA LOCAL INPATH 'C:/tmp/State_City.csv' OVERWRITE INTO TABLE state_city"
```

   The two files, `customer.csv` and `State_City.csv`, are two local files we created for this scenario. You need to create your own files to provide data to the input Hive tables. The data schema of each file should be identical with their corresponding table.

   You can use `tRowGenerator` and `tFileOutputDelimited` to create these two files easily. For further information about these two components, see `tRowGenerator` on page 3224 and `tFileOutputDelimited` on page 1106.

### Linking the components

**Procedure**

1. In the **Integration** perspective of **Talend Studio**, create an empty Job from the **Job Designs** node in the **Repository** tree view.

   For further information about how to create a Job, see **Talend Studio User Guide**.

2. Drop two `tELTHiveInput` components and `tELTHiveMap` and `tELTHiveOutput` onto the workspace.

3. Connect them using the **Row > Main** link.

   Each time when you connect two components, a wizard pops up to prompt you to name the link you are creating. This name must be the same as that of the Hive table you want the active component to process. In this scenario, the input tables the two `tELTHiveInput` components will handle are `customer` and `state_city` and the output table `tELTHiveOutput` will handle is `agg_result`.

### Configuring the input schemas

**Procedure**

1. Double-click the `tELTHiveInput` component using the `customer` link to open its **Component** view.
2. Click the [...] button next to Edit schema to open the schema editor.

3. Click the button as many times as required to add columns and rename them to replicate the schema of the customer table we created earlier in Hive.

4. In the Default table name field, enter the name of the input table, customer, to be processed by this component.

5. Double-click the other tELTHiveInput component using the state_city link to open its Component view.

6. Click the [...] button next to Edit schema to open the schema editor.
7. Click the button as many times as required to add columns and rename them to replicate the schema of the state_city table we created earlier in Hive.

8. In the Default table name field, enter the name of the input table, state_city, to be processed by this component.

Mapping the input and the output schemas

Configuring the connection to Hive

Procedure

1. Click tELTHiveMap, then, click Component to open its Component view.

2. In the Version area, select the Hadoop distribution you are using and the Hive version.

3. In the Connection mode list, select the connection mode you want to use. If your distribution is HortonWorks, this mode is Embedded only.
4. In the **Host** field and the **Port** field, enter the authentication information for the component to connect to Hive. For example, the host is *talend-hdp-all* and the port is 9083.

5. Select the **Set Jobtracker URI** check box and enter the location of the Jobtracker. For example, *talend-hdp-all:50300*.

6. Select the **Set NameNode URI** check box and enter the location of the NameNode. For example, *hdfs://talend-hdp-all:8020*. If you are using WebHDFS, the location should be *webhdfs://master:portnumber*; WebHDFS with SSL is not supported yet.

**Mapping the schemas**

**Procedure**

1. Click **ELT Hive Map Editor** to map the schemas

2. On the input side (left in the figure), click the **Add alias** button to add the table to be used.

3. In the pop-up window, select the **customer** table, then click **OK**.

4. Repeat the operations to select the **state_city** table.

5. Drag and drop the `idstate` column from the **customer** table onto the `id` column of the **state_city** table. Thus an inner join is created automatically.

6. On the output side (the right side in the figure), the **agg_result** table is empty at first. Click at the bottom of this side to add as many columns as required and rename them to replicate the schema of the **agg_result** table you created earlier in Hive.
7. From the customer table, drop id, name, address, and sum1 to the corresponding columns in the agg_result table.

8. From the state_city table, drop postal, state, capital and mostpopulouscity to the corresponding columns in the agg_result table.

In this scenario, context variables are not used in the Expression column in the Map editor. If you use context variables, put them in single quotation marks. For example:

9. Click OK to validate these changes.

**Configuring the output schema**

**Procedure**

1. Double-click tELTHiveOutput to open its Component view.
2. If this component does not have the same schema of the preceding component, a warning icon appears. In this case, click the Sync columns button to retrieve the schema from the preceding one and once done, the warning icon disappears.

3. In the Default table name field, enter the output table you want to write data in. In this example, it is agg_result.

4. In the Field partition table, click to add one row. This allows you to write data in the partition column of the agg_result table.
   This partition column was defined the moment we created the agg_result table using partitioned by (type string) in the Create statement presented earlier. This partition column is type, which describes the type of a customer.

5. In Partition column, enter type without any quotation marks and in Partition value, enter prospective in single quotation marks.

**Executing the Job**

**Procedure**

Press F6 to run this Job.

**Results**

Once done, verify agg_result in Hive using, for example,

```
select * from agg_result;
```
This figure presents only a part of the table. You can find that the selected input columns are aggregated and written into the `agg_result` table and the partition column is filled with the value `prospective`.

**Related scenarios**

- Joining table columns and writing them into Hive on page 704
- Mapping data using a subquery on page 794, a related scenario using subquery
- Aggregating Snowflake data using context variables as table and connection names on page 719
**tELTHiveOutput**

Works alongside tELTHiveMap to write data into the Hive table.

The three ELT Hive components are closely related, in terms of their operating conditions. These components should be used to handle Hive DB schemas to generate Insert statements, including clauses, which are to be executed in the DB output table defined.

This component executes the query built by the preceding tELTHiveMap component to write data into the specified Hive table.

**tELTHiveOutput Standard properties**

These properties are used to configure tELTHiveOutput running in the Standard Job framework.

The Standard tELTHiveOutput component belongs to the ELT family.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Action on data</th>
<th>Select the action to be performed on the data to be written in the Hive table. With the Insert option, the data to be written in the Hive table will be appended to the existing data if there is any.</th>
</tr>

<tr>
<td>Schema</td>
<td>A schema is a row description. It defines the number of fields to be processed and passed on to the next component. The schema is either Built-in or stored remotely in the Repository.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-In:</strong> You create and store the schema locally for this component only. <strong>Repository:</strong> You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
</tr>
</tbody>
</table>

**Edit schema**

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- View schema: choose this option to view the schema only.
- Change to built-in property: choose this option to change the schema to Built-in for local changes.
- Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

**Default table name**

Enter the default name of the output table you want to write data in.
<table>
<thead>
<tr>
<th><strong>Default schema name</strong></th>
<th>Enter the name of the default database schema to which the output table to be used is related to.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Table name from connection name is variable</strong></td>
<td>Select this check box when the name of the connection to this component is set to a variable, such as a context variable.</td>
</tr>
</tbody>
</table>
| **Use different table name** | Select this check box to define a different output table name, between double quotation marks, in the *Table name* field that appears.  
If this table is related to a different database schema from the default one, you also need to enter the name of that database schema. The syntax is `schema_name.table_name`. |
| **The target table uses the Parquet format** | If the table in which you need to write data is a PARQUET table, select this check box.  
Then from the *Compression* list that appears, select the compression mode you need to use to handle the PARQUET file. The default mode is *Uncompressed*. |
| **Field Partition** | In *Partition Column*, enter the name, without any quotation marks, of the partition column of the Hive table you want to write data in.  
In *Partition Value*, enter the value you want to use, in single quotation marks, for its corresponding partition column. |
| **Mapping** | Specify the metadata mapping file for the database to be used. The metadata mapping file is used for the data type conversion between database and Java. For more information about the metadata mapping, see the related documentation for Type mapping. |

**Advanced settings**

| **tStatCatcher Statistics** | Select this check box to collect log data at the component level. |

**Global Variables**

| **Global Variables** | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the *Die on error* check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press `Ctrl + Space` to access the variable list and choose the variable to use from it.  
For further information about variables, see *Talend Studio User Guide*. |

Usage

Usage rule

**tELTHiveMap** is used along with a **tELTHiveInput** and **tELTHiveOutput**. Note that the Output link to be used with these components must correspond strictly to the syntax of the table name.

If the Studio used to connect to a Hive database is operated on Windows, you must manually create a folder called *tmp* in the root of the disk where this Studio is installed.

**Note:**
The ELT components do not handle actual data flow but only schema information.

Usage with Dataproc

The ELT Hive components require Tez to be installed on the Google Cloud Dataproc cluster to be used.

- Use the initialization action explained in this Google Cloud Platform documentation: [Apache Tez on Dataproc](https://cloud.google.com/dataproc/docs/concepts/tez).
- For more details about the general concept of the initialization actions in a Google Cloud Dataproc cluster, see the related Google documentation: [Initialization actions](https://cloud.google.com/dataproc/docs/concepts/initialization).

Related scenarios

- **Joining table columns and writing them into Hive** on page 704.
- **Aggregating Snowflake data using context variables as table and connection names** on page 719
tELTInput

Adds as many Input tables as required for the SQL statement to be executed.

The three ELT components are closely related, in terms of their operating conditions. These components should be used to handle DB schemas to generate Insert statements, including clauses, which are to be executed in the DB output table defined.

Note that it is highly recommended to use the ELT components for a specific type of database (if any) instead of the ELT components. For example, for Teradata, it is recommended to use the tELTTeradataInput, tELTTeradataMap and tELTTeradataOutput components instead.

tELTInput Standard properties

These properties are used to configure tELTInput running in the Standard Job framework.

The Standard tELTInput component belongs to the ELT family.

The component in this framework is available in all Talend products.

- Mapping date using using an Alias table on page 743
- Aggregating Snowflake data using context variables as table and connection names on page 719
tELTMap

Uses the tables provided as input to feed the parameter in the built SQL statement. The statement can include inner or outer joins to be implemented between tables or between one table and its aliases.

The three ELT components are closely related, in terms of their operating conditions. These components should be used to handle DB schemas to generate Insert statements, including clauses, which are to be executed in the DB output table defined.

Note that it is highly recommended to use the ELT components for a specific type of database (if any) instead of the ELT components. For example, for Teradata, it is recommended to use the tELTTeradataInput, tELTTeradataMap and tELTTeradataOutput components instead.

tELTMap Standard properties

These properties are used to configure tELTMap running in the Standard Job framework.

The Standard tELTMap component belongs to the ELT family.

The component in this framework is available in all Talend products.

Basic settings

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Note:</strong> When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:</td>
</tr>
<tr>
<td></td>
<td>1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.</td>
</tr>
<tr>
<td></td>
<td>2. In the child level, use a dedicated connection component to read that registered database connection.</td>
</tr>
<tr>
<td></td>
<td>For an example about how to share a database connection across Job levels, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>ELT Map Editor</th>
<th>The ELT Map editor allows you to define the output schema and make a graphical build of the SQL statement to be executed. The column names of schema can be different from the column names in the database.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Style link</th>
<th>Select the way in which links are displayed.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Auto:</strong> By default, the links between the input and output schemas and the Web service parameters are in the form of curves.</td>

</tr>
<tr>
<td></td>
<td>• Repository: Select the repository file where the properties are stored.</td>
</tr>
</tbody>
</table>

| JDBC URL | The JDBC URL of the database to be used. For example, the JDBC URL for the Amazon Redshift database is `jdbc:redshift://endpoint:port/database`. |

| Driver JAR | Complete this table to load the driver JARs needed. To do this, click the `[+]` button under the table to add as many rows as needed, each row for a driver JAR, then select the cell and click the `[…]` button at the right side of the cell to open the Select Module wizard from which you can select the driver JAR to be used. For example, the driver jar `RedshiftJDBC41-1.1.13.1013.jar` for the Redshift database. |

| Class name | Enter the class name for the specified driver between double quotation marks. For example, for the `RedshiftJDBC41-1.1.13.1013.jar` driver, the name to be entered is `com.amazon.redshift.jdbc41.Driver`. |

| Username and Password | DB user authentication data. To enter the password, click the `[…]` button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |

| Mapping | Specify the metadata mapping file for the database to be used. The metadata mapping file is used for the data type conversion between database and Java. For more information about the metadata mapping, see the related documentation for Type mapping. |

### Advanced settings

| Additional JDBC parameters | Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the Use an existing connection check box in the Basic settings. |

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

### Global Variables

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. |

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. |
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

### Usage rule

tELTMap is used along with tELTInput and tELTOutput. Note that the Output link to be used with these components must correspond strictly to the syntax of the table name.

#### Note:

Note that the ELT components do not handle actual data flow but only schema information.

### Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Aggregating Snowflake data using context variables as table and connection names

Here is an example of aggregating Snowflake data from two source tables STUDENT and TEACHER to one target table FULLINFO using the ELT components. In this example, all input and output table names and connection names are set to context variables.

Creating a Job for aggregating Snowflake data
Before you begin

- A new Job has been created and the context variables $SourceTableS$ with the value STUDENT, $SourceTableT$ with the value TEACHER, and $TargetTable$ with the value FULLINFO have been added to the Job. For more information about how to use context variables, see the related documentation about using contexts and variables.

- The source table $STUDENT$ with three columns, $SID$ and $TID$ of NUMBER(38,0) type and $SNAME$ of VARCHAR(50) type, has been created in Snowflake, and the following data has been written into the table.

<table>
<thead>
<tr>
<th>#SID</th>
<th>SNAME</th>
<th>TID</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>Alex</td>
<td>22</td>
</tr>
<tr>
<td>12</td>
<td>Mark</td>
<td>23</td>
</tr>
<tr>
<td>13</td>
<td>Stephane</td>
<td>21</td>
</tr>
<tr>
<td>14</td>
<td>Cedric</td>
<td>22</td>
</tr>
<tr>
<td>15</td>
<td>Bill</td>
<td>21</td>
</tr>
<tr>
<td>16</td>
<td>Jack</td>
<td>23</td>
</tr>
<tr>
<td>17</td>
<td>John</td>
<td>22</td>
</tr>
<tr>
<td>18</td>
<td>Andrew</td>
<td>23</td>
</tr>
</tbody>
</table>

- The source table $TEACHER$ with three columns, $TID$ of NUMBER(38,0) type and $TNAME$ and $TPHONE$ of VARCHAR(50) type, has been created in Snowflake, and the following data has been written into the table.

<table>
<thead>
<tr>
<th>#TID</th>
<th>TNAME</th>
<th>TPHONE</th>
</tr>
</thead>
<tbody>
<tr>
<td>21</td>
<td>Peter</td>
<td>+86 15812343456</td>
</tr>
<tr>
<td>22</td>
<td>Michael</td>
<td>+86 13178964532</td>
</tr>
<tr>
<td>23</td>
<td>Candice</td>
<td>+86 13923187456</td>
</tr>
</tbody>
</table>

Procedure

1. Add a `tSnowflakeConnection` component, a `tSnowflakeClose` component, two `tELTInput` components, a `tELTMap` component, and a `tELTOutput` component to your Job.

2. On the Basic setting view of the first `tELTInput` component, enter the name of the first source table in the Default Table Name field. In this example, it is the context variable `context.SourceTableS`.

3. Do the same to set the value of the default table name for the second tELTInput component and the tELTOutput component to `context.SourceTableT` and `context.TargetTable` respectively.

4. Link the first tELTInput component to the tELTMap component using the Link > `context.SourceTableS (Table)` connection.

5. Link the second tELTInput component to the tELTMap component using the Link > `context.SourceTableT (Table)` connection.

6. Link the tELTMap component to the tELTOutput component using the Link > *New Output* (Table) connection. The link will be renamed automatically to `context.TargetTable (Table)`.

7. Link the tSnowflakeConnection component to the tELTMap component using a Trigger > On Subjob Ok connection.

8. Do the same to link the tELTMap component to the tSnowflakeClose component.

**Connecting to Snowflake**

Configure the tSnowflakeConnection component to connect to Snowflake.

**Procedure**

1. Double-click the tSnowflakeConnection component to open its Basic settings view.

2. In the Account field, enter the account name assigned by Snowflake.

3. In the Snowflake Region field, select the region where the Snowflake database locates.

4. In the User Id and the Password fields, enter the authentication information accordingly.

   Note that this user ID is your user login name. If you do not know your user login name yet, ask the administrator of your Snowflake system for details.

5. In the Warehouse field, enter the name of the data warehouse to be used in Snowflake.

6. In the Schema field, enter the name of the database schema to be used.

7. In the Database field, enter the name of the database to be used.

**Configuring the input components for aggregating Snowflake data**

**Procedure**

1. Double-click the first tELTInput component to open its Basic settings view.
2. Click the [...] button next to Edit schema and in the schema dialog box displayed, define the schema by adding three columns, SID and TID of INT type and SNAME of VARCHAR type.

3. Select Mapping Snowflake from the Mapping drop-down list.

4. Repeat the previous steps to configure the second tELTInput component, and define its schema by adding three columns, TID of INT type and TNAME and TPHONE of VARCHAR type.

**Configuring the output component for aggregating Snowflake data**

**Procedure**

1. Double-click the tELTOutput component to open its Basic settings view.

2. Select Create table from the Action on table drop-down list to create the target table.

3. Select the Table name from connection name is variable check box.

4. Select Mapping Snowflake from the Mapping drop-down list.

**Configuring the map component for aggregating Snowflake data**

**Procedure**

1. Click the tELTMap component to open its Basic settings view.

2. Select the Use an existing connection check box and from the Component List displayed, select the connection component you have configured to open the Snowflake connection.

3. Select Mapping Snowflake from the Mapping drop-down list.

4. Click the [...] button next to ELT Map Editor to open its map editor.

5. Add the first input table context.SourceTableS by clicking the [+] button in the upper left corner of the map editor and then selecting the relevant table name from the drop-down list in the pop-up dialog box.

6. Do the same to add the second input table context.SourceTableT.

7. Drag the column TID from the first input table context.SourceTableS and drop it onto the corresponding column TID in the second input table context.SourceTableT.

8. Drag all columns from the input table context.SourceTableS and drop them onto the output table context.TargetTable in the upper right panel.

9. Do the same to drag two columns TNAME and TPHONE from the input table context.SourceTableT and drop them onto the bottom of the output table. When done, click OK to close the map editor.

10. Click the Sync columns button on the Basic settings view of the tELTOutput component to set its schema.
Closing the Snowflake connection

Configure the **tSnowflakeClose** component to close the connection to Snowflake.

**Procedure**

1. Double-click the **tSnowflakeClose** component to open the **Component** tab.
2. From the **Connection Component** drop-down list, select the component that opens the connection you need to close, **tSnowflakeConnection_1** in this example.

Executing the Job for aggregating Snowflake data

**Procedure**

1. Press **Ctrl + S** to save the Job.
2. Press **F6** to execute the Job.

As shown above, the Job is executed successfully and eight rows are inserted into the target table.

You can then create and run another Job to retrieve data from the target table by using the **tSnowflakeInput** component and the **tLogRow** component. You will find that the aggregated data will be displayed on the console as shown in below screenshot.

For more information about how to retrieve data from Snowflake, see the example Writing data into and reading data from a Snowflake table on page 3492.

Related scenarios

- Aggregating table columns and filtering on page 739.
- Mapping date using using an Alias table on page 743.
- Mapping data using a subquery on page 794, a related scenario using subquery
tELTOutput

Carries out the action on the table specified and inserts the data according to the output schema defined in the ELT Mapper.

The three ELT components are closely related, in terms of their operating conditions. These components should be used to handle DB schemas to generate Insert statements, including clauses, which are to be executed in the DB output table defined.

Note that it is highly recommended to use the ELT components for a specific type of database (if any) instead of the ELT components. For example, for Teradata, it is recommended to use the tELTTeradataInput, tELTTeradataMap and tELTTeradataOutput components instead.

**tELTOutput Standard properties**

These properties are used to configure tELTOutput running in the Standard Job framework.

The Standard tELTOutput component belongs to the ELT family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Action on table</th>
<th>Select an operation to be performed on the table defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Action on data</td>
<td>On the data of the table defined, you can perform the following operation:</td>
</tr>
<tr>
<td>Schema and Edit schema</td>
<td>A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either built-in or remotely stored in the Repository. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:</td>
</tr>
</tbody>
</table>

- **None**: No operation is carried out.
- **Drop and create table**: The table is removed and created again.
- **Create table**: The table does not exist and gets created.
- **Create table if does not exist**: The table is created if it does not exist.
- **Drop table if exist and create**: The table is removed if it already exists and created again.
- **Clear table**: The table content is deleted. You have the possibility to rollback the operation.
- **Truncate table**: The table content is deleted. You do not have the possibility to rollback the operation.

- **Insert**: Adds new entries to the table. If duplicates are found, Job stops.
- **Update**: Updates entries in the table.
- **Delete**: Deletes the entries which correspond to the entry flow.

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-in</strong></td>
<td>The schema is created and stored locally for this component only. Related topic: see <em>Talend Studio User Guide</em>.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>The schema already exists and is stored in the Repository, hence can be reused. Related topic: see <em>Talend Studio User Guide</em>.</td>
</tr>
</tbody>
</table>

**Where clauses for** (for UPDATE and DELETE only)
Enter a clause to filter the data to be updated or deleted during the update or delete operations.

**Default Table Name**
Enter the default table name, between double quotation marks.

**Default Schema Name**
Enter the default schema name, between double quotation marks.

**Table name from connection name is variable**
Select this check box when the name of the connection to this component is set to a variable, such as a context variable.

**Use different table name**
Select this check box to define a different output table name, between double quotation marks, in the **Table name** field which appears.

**Mapping**
Specify the metadata mapping file for the database to be used. The metadata mapping file is used for the data type conversion between database and Java. For more information about the metadata mapping, see the related documentation for Type mapping.

### Advanced settings

**tStatCatcher Statistics**
Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

### Global Variables

**NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.

**NB_LINE_INSERTED**: the number of rows inserted. This is an After variable and it returns an integer.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>tELTOutput is to be used along with the tELTMap. Note that the Output link to be used with these components must correspond strictly to the syntax of the table name. Note that the ELT components do not handle actual data flow but only schema information.</th>
</tr>
</thead>
</table>

| Limitation | Avoid using any keyword for the database as the table/column name or using any special character in the table/column name. If you want to, you can enclose the table/column name in a pair of " to see whether it works. For example, when you want to use the keyword number as an Oracle database column name, you can have the Db Column value in the schema editor set to "number". But note that this solution does not always work. |

Related scenarios

- Aggregating table columns and filtering on page 739
- Mapping date using using an Alias table on page 743
- Aggregating Snowflake data using context variables as table and connection names on page 719
tELTMSSqlInput

Adds as many Input tables as required for the most complicated Insert statement.

The three ELT MSSql components are closely related, in terms of their operating conditions. These components should be used to handle MSSql DB schemas to generate Insert statements, including clauses, which are to be executed in the DB output table defined.

Provides the table schema to be used for the SQL statement to execute.

tELTMSSqlInput Standard properties

These properties are used to configure tELTMSSqlInput running in the Standard Job framework.

The Standard tELTMSSqlInput component belongs to the ELT family.

The component in this framework is available in all Talend products.

Basic settings

| **Schema and Edit schema** | A schema is a row description, it defines the nature and number of fields to be processed. The schema is either built-in or remotely stored in the Repository. The Schema defined is then passed on to the ELT Mapper to be included to the Insert SQL statement.
Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:
• View schema: choose this option to view the schema only.
• Change to built-in property: choose this option to change the schema to Built-in for local changes.
• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |

| **Built-in** | The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide. |
| **Repository** | The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide. |
| **Default Table Name** | Type in the default table name. |
| **Default Schema Name** | Type in the default schema name. |
Advanced settings

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | tELTMySSqlInput is to be used along with the tELTMSSsqlMap. Note that the Output link to be used with these components must correspond strictly to the syntax of the table name. Note: Note that the ELT components do not handle actual data flow but only schema information. |

Related scenarios

- Aggregating table columns and filtering on page 739
- Mapping date using using an Alias table on page 743
- Aggregating Snowflake data using context variables as table and connection names on page 719
tELTMSSqlMap

Uses the tables provided as input to feed the parameter in the built statement. The statement can include inner or outer joins to be implemented between tables or between one table and its aliases.

The three ELT MSSql components are closely related, in terms of their operating conditions. These components should be used to handle MSSql DB schemas to generate Insert statements, including clauses, which are to be executed in the DB output table defined.

Helps you to build the SQL statement graphically, using the table provided as input.

tELTMSSqlMap Standard properties

These properties are used to configure tELTMSSqlMap running in the Standard Job framework.

The Standard tELTMSSqlMap component belongs to the ELT family.

The component in this framework is available in all Talend products.

Basic settings

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Note:</strong> When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:</td>
</tr>
<tr>
<td></td>
<td>1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.</td>
</tr>
<tr>
<td></td>
<td>2. In the child level, use a dedicated connection component to read that registered database connection.</td>
</tr>
<tr>
<td></td>
<td>For an example about how to share a database connection across Job levels, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

| ELT MSSql Map Editor      | The ELT Map editor allows you to define the output schema and make a graphical build of the SQL statement to be executed. The column names of schema can be different from the column names in the database. |

<table>
<thead>
<tr>
<th>Style link</th>
<th>Select the way in which links are displayed.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Auto:</strong> By default, the links between the input and output schemas and the Web service parameters are in the form of curves.</td>
</tr>
<tr>
<td></td>
<td><strong>Bezier curve:</strong> Links between the schema and the Web service parameters are in the form of curve.</td>
</tr>
<tr>
<td></td>
<td><strong>Line:</strong> Links between the schema and the Web service parameters are in the form of straight lines.</td>
</tr>
</tbody>
</table>
|                           | This option slightly optimizes performance.
**Property type**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the Repository file where Properties are stored. The following fields are pre-filled in using fetched data.</td>
</tr>
</tbody>
</table>

**Host**

Database server IP address.

**Port**

Listening port number of DB server.

**Database**

Name of the database.

**Username and Password**

DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

**Advanced settings**

**Additional JDBC parameters**

Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the Use an existing connection check box in the Basic settings.

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

**Global Variables**

**Global Variables**

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

**Usage**

**Usage rule**

tELTMSSqlMap is used along with a tELTMSSqlInput and tELTMSSqlOutput. Note that the Output link to be used with these components must correspond strictly to the syntax of the table name.
Note:
Note that the ELT components do not handle actual data flow but only schema information.

Dynamic settings

Click the [+ ] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

- Mapping data using a subquery on page 794, a related scenario using subquery
- Aggregating Snowflake data using context variables as table and connection names on page 719
tELTMSSqlOutput

Executes the SQL Insert, Update and Delete statement to the MSSql database

The three ELT MSSql components are closely related, in terms of their operating conditions. These components should be used to handle MSSql DB schemas to generate Insert statements, including clauses, which are to be executed in the DB output table defined.

Carries out the action on the table specified and inserts the data according to the output schema defined the ELT Mapper.

tELTMSSqlOutput Standard properties

These properties are used to configure tELTMSSqlOutput running in the Standard Job framework.

The Standard tELTMSSqlOutput component belongs to the ELT family.

The component in this framework is available in all Talend products.

Basic settings

| Action on data | On the data of the table defined, you can perform the following operation:
|               | Insert: Adds new entries to the table. If duplicates are found, Job stops.
|               | Update: Updates entries in the table.
|               | Delete: Deletes the entries which correspond to the entry flow. |

Schema and Edit schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- View schema: choose this option to view the schema only.
- Change to built-in property: choose this option to change the schema to Built-in for local changes.
- Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

Built-in: The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide.

Repository: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide.
### Where clauses for (for UPDATE and DELETE only)

Enter a clause to filter the data to be updated or deleted during the update or delete operations.

### Default Table Name

Enter the default table name, between double quotation marks.

### Default Schema Name

Enter the default schema name, between double quotation marks.

### Table name from connection name is variable

Select this check box when the name of the connection to this component is set to a variable, such as a context variable.

### Use different table name

Select this check box to define a different output table name, between double quotation marks, in the Table name field which appears.

### Mapping

Specify the metadata mapping file for the database to be used. The metadata mapping file is used for the data type conversion between database and Java. For more information about the metadata mapping, see the related documentation for Type mapping.

---

### Advanced settings

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

---

### Global Variables

**Global Variables**

- **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.
- **NB_LINE_INSERTED**: the number of rows inserted. This is an After variable and it returns an integer.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

---

### Usage

**Usage rule**

tELTMSSqlOutput is to be used along with the tELTMSSqlMap. Note that the Output link to be used with these components must correspond strictly to the syntax of the table name.
Note:
Note that the ELT components do not handle actual data flow but only schema information.

Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

Related scenarios

- Aggregating table columns and filtering on page 739
- Mapping date using using an Alias table on page 743
- Aggregating Snowflake data using context variables as table and connection names on page 719
tELTMysqlInput

Adds as many Input tables as required for the most complicated Insert statement.

The three ELT Mysql components are closely related, in terms of their operating conditions. These components should be used to handle Mysql DB schemas to generate Insert statements, including clauses, which are to be executed in the DB output table defined.

tELTMysqlInput provides the table schema to be used for the SQL statement to execute.

**tELTMysqlInput Standard properties**

These properties are used to configure tELTMysqlInput running in the Standard Job framework.

The Standard tELTMysqlInput component belongs to the ELT family.

The component in this framework is available in all Talend products.

**Basic settings**

| Schema and Edit Schema | A schema is a row description, it defines the nature and number of fields to be processed. The schema is either built-in or remotely stored in the Repository. The Schema defined is then passed on to the ELT Mapper to be included to the Insert SQL statement.
Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:
- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |
<table>
<thead>
<tr>
<th></th>

<td><strong>Repository</strong>: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide.</td>
<td></td>
</tr>
<tr>
<td>Default Table Name</td>
<td>Enter the default table name, between double quotation marks.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |
Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it. For further information about variables, see *Talend Studio User Guide.* |

Usage

| Usage rule | **tELTMysqlInput** is to be used along with the **tELTMysqlMap**. Note that the Output link to be used with these components must correspond strictly to the syntax of the table name. **Note:** Note that the ELT components do not handle actual data flow but only schema information. |

Related scenarios

- Aggregating table columns and filtering on page 739
- Mapping date using using an Alias table on page 743
- Aggregating Snowflake data using context variables as table and connection names on page 719
tELTMySQLMap

Uses the tables provided as input to feed the parameter in the built statement. The statement can include inner or outer joins to be implemented between tables or between one table and its aliases.

The three ELT Mysql components are closely related, in terms of their operating conditions. These components should be used to handle Mysql DB schemas to generate Insert statements, including clauses, which are to be executed in the DB output table defined.

tELTMySQLMap helps to graphically build the SQL statement using the table provided as input.

**tELTMySQLMap Standard properties**

These properties are used to configure tELTMySQLMap running in the Standard Job framework.

The Standard tELTMySQLMap component belongs to the ELT family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
</table>
| Use an existing connection    | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.  
**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:  
1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.  
2. In the child level, use a dedicated connection component to read that registered database connection.  
For an example about how to share a database connection across Job levels, see Talend Studio User Guide. |
| ELT Mysql Map editor          | The ELT Map editor allows you to define the output schema as well as build graphically the SQL statement to be executed. The column names of schema can be different from the column names in the database. |
| Style link                    | Select the way in which links are displayed.  
**Auto:** By default, the links between the input and output schemas and the Web service parameters are in the form of curves.  
**Bezier curve:** Links between the schema and the Web service parameters are in the form of curve.  
**Line:** Links between the schema and the Web service parameters are in the form of straight lines.  
This option slightly optimizes performance. |
**Property type**

Either **Built-in** or **Repository**.

**Built-in**: No property data stored centrally.

**Repository**: Select the Repository file where Properties are stored. The following fields are pre-filled in using fetched data.

**Host**
Database server IP address.

**Port**
Listening port number of DB server.

**Database**
Name of the database.

**Username** and **Password**
DB user authentication data.
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

---

**Advanced settings**

**tStatCatcher Statistics**
Select this check box to collect log data at the component level.

**Global Variables**

**Global Variables**

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

**Usage**

**Usage rule**

**tELTMySqlMap** is used along with a **tELTMySqlInput** and **tELTMySqlOutput**. Note that the Output link to be used with these components must correspond strictly to the syntax of the table name.

**Note:**
The ELT components do not handle actual data flow but only schema information.

**Dynamic settings**

Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned.
**Aggregating table columns and filtering**

This scenario describes a Job that gathers together several input DB table schemas and implementing a clause to filter the output using an SQL statement.

- Drop the following components from the Palette onto the design workspace: three `tELTMysqlInput` components, a `tELTMysqlMap`, and a `tELTMysqlOutput`. Label these components to best describe their functionality.
- Double-click the first `tELTMysqlInput` component to display its Basic settings view.
Select **Repository** from the **Schema** list, click the three dot button preceding **Edit schema**, and select your DB connection and the desired schema from the **Repository Content** dialog box.

The selected schema name appears in the **Default Table Name** field automatically.

In this use case, the DB connection is **Talend_MySQL** and the schema for the first input component is **owners**.

Set the second and third **tELTMysqlInput** components in the same way but select **cars** and **resellers** respectively as their schema names.

---

**Note:** In this use case, all the involved schemas are stored in the **Metadata** node of the **Repository** tree view for easy retrieval. For further information concerning metadata, see **Talend Studio User Guide**.

You can also select the three input components by dropping the relevant schemas from the **Metadata** area onto the design workspace and double-clicking **tELTMysqlInput** from the **Components** dialog box. Doing so allows you to skip the steps of labeling the input components and defining their schemas manually.

---

Connect the three **tELTMysqlInput** components to the **tELTMysqlMap** component using links named following strictly the actual DB table names: **owners**, **cars** and **resellers**.

Connect the **tELTMysqlMap** component to the **tELTMysqlOutput** component and name the link **agg_result**, which is the name of the database table you will save the aggregation result to.

Click the **tELTMysqlMap** component to display its **Basic settings** view.

---

Select **Repository** from the **Property Type** list, and select the same DB connection that you use for the input components.

All the database details are automatically retrieved.

Leave all the other settings as they are.

Double-click the **tELTMysqlMap** component to launch the ELT Map editor to set up joins between the input tables and define the output flow.
• Add the input tables by clicking the green plus button at the upper left corner of the ELT Map editor and selecting the relevant table names in the Add a new alias dialog box.
• Drop the ID_Owner column from the owners table to the corresponding column of the cars table.
• In the cars table, select the Explicit join check box in front of the ID_Owner column. As the default join type, INNER JOIN is displayed on the Join list.
• Drop the ID_Reseller column from the cars table to the corresponding column of the resellers table to set up the second join, and define the join as an inner join in the same way.
• Select the columns to be aggregated into the output table, agg_result.
• Drop the ID_Owner, Name, and ID_Insurance columns from the owners table to the output table.
• Drop the Registration, Make, and Color columns from the cars table to the output table.
• Drop the Name_Reseller and City columns from the resellers table to the output table.
• With the relevant columns selected, the mappings are displayed in yellow and the joins are displayed in dark violet.
• Set up a filter in the output table. Click the Add filter row button on top of the output table to display the Additional clauses expression field, drop the City column from the resellers table to the expression field, and complete a WHERE clause that reads resellers.City = 'Augusta'.

As the default join type, INNER JOIN is displayed on the Join list.
• Click the **Generated SQL Select query** tab to display the corresponding SQL statement.

```sql
SELECT
FROM
owners INNER JOIN cars ON (cars.ID_Owners = owners.ID_Owner)
INNER JOIN resellers ON (resellers.ID_Reseller = cars.ID_Reseller)
WHERE resellers.City = 'Augusta'
```

• Click **OK** to save the ELT Map settings.
• Double-click the **tELTMySqlOutput** component to display its **Basic settings** view.

• Select an action from the **Action on data** list as needed.
• Select **Repository** as the schema type, and define the output schema in the same way as you defined the input schemas. In this use case, select *agg_result* as the output schema, which is the name of the database table used to store the mapping result.

**Note:** You can also use a built-in output schema and retrieve the schema structure from the preceding component; however, make sure that you specify an existing target table having the same data structure in your database.

• Leave all the other settings as they are.
• Save your Job and press **F6** to launch it.

All selected data is inserted in the *agg_result* table as specified in the SQL statement.

### Mapping date using using an Alias table

This scenario describes a Job that maps information from two input tables and an alias table, serving as a virtual input table, to an output table. The *employees* table contains employees’ IDs, their department numbers, their names, and the IDs of their respective managers. The managers are also considered as employees and hence included in the *employees* table. The *dept* table contains the department information. The alias table retrieves the names of the managers from the *employees* table.

• Drop two **tELTMysqlInput** components, a **tELTMysqlMap** component, and a **tELTMysqlOutput** component to the design workspace, and label them to best describe their functionality.
• Double-click the first **tELTMysqlInput** component to display its **Basic settings** view.
Select **Repository** from the **Schema** list, and define the DB connection and schema by clicking the three dot button preceding **Edit schema**.

The DB connection is **Talend_MySQL** and the schema for the first input component is **employees**.

**Note:**
In this use case, all the involved schemas are stored in the **Metadata** node of the **Repository** tree view for easy retrieval. For further information concerning metadata, see **Talend Studio User Guide**.

Set the second **tELTMysqlInput** component in the same way but select **dept** as its schema.

Double-click the **tELTMysqlOutput** component to display its **Basic settings** view.

Select an action from the **Action on data** list as needed, **Insert** in this use case.

Select **Repository** as the schema type, and define the output schema in the same way as you defined the input schemas. In this use case, select **result** as the output schema, which is the name of the database table used to store the mapping result.

The output schema contains all the columns of the input schemas plus a **ManagerName** column.

Leave all the other parameters as they are.

Connect the two **tELTMysqlInput** components to the **tELTMysqlMap** component using **Link** connections named strictly after the actual input table names, **employees** and **dept** in this use case.

Connect the **tELTMysqlMap** component to the **tELTMysqlOutput** component using a **Link** connection. When prompted, click **Yes** to allow the ELT Mapper to retrieve the output table structure from the output schema.

Click the **tELTMysqlMap** component and select the **Component** tab to display its **Basic settings** view.
• Select **Repository** from the **Property Type** list, and select the same DB connection that you use for the input components.

  All the DB connection details are automatically retrieved.

• Leave all the other parameters as they are.

• Click the three-dot button next to **ELT Mysql Map Editor** or double-click the **tELTMysqlMap** component on the design workspace to launch the ELT Map editor.

  With the **tELTMysqlMap** component connected to the output component, the output table is displayed in the output area.

• Add the input tables, **employees** and **dept**, in the input area by clicking the green plus button and selecting the relevant table names in the **Add a new alias** dialog box.

• Create an alias table based on the **employees** table by selecting **employees** from the **Select the table to use** list and typing in **Managers** in the **Type in a valid alias** field in the **Add a new alias** dialog box.

• Drop the **DeptNo** column from the **employees** table to the **dept** table.

• Select the **Explicit join** check box in front of the **DeptNo** column of the **dept** table to set up an inner join.

• Drop the **ManagerID** column from the **employees** table to the **ID** column of the **Managers** table.

• Select the **Explicit join** check box in front of the **ID** column of the **Managers** table and select **LEFT OUTER JOIN** from the **Join** list to allow the output rows to contain Null values.
• Drop all the columns from the employees table to the corresponding columns of the output table.
• Drop the DeptName and Location columns from the dept table to the corresponding columns of the output table.
• Drop the Name column from the Managers table to the ManagerName column of the output table.

• Click on the Generated SQL Select query tab to display the SQL query statement to be executed.

• Save your Job and press F6 to run it.

The output database table result contains all the information about the employees, including the names of their respective managers.

tELTNetezzaInput

Allows you to add as many Input tables as required for the most complicated Insert statement.

The three ELT Netezza components are closely related, in terms of their operating conditions. These components should be used to handle Netezza database table schemas to generate SQL statements, including clauses, which are to be executed in the database output table defined.

Provides the table schema to be used for the SQL statement to execute.

tELTNetezzaInput Standard properties

These properties are used to configure tELTNetezzaInput running in the Standard Job framework.

The Standard tELTNetezzaInput component belongs to the ELT family.

The component in this framework is available in all Talend products.

Basic settings

| **Schema and Edit Schema** | A schema is a row description, it defines the number of fields that will be processed and passed on to the next component. Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
| • **View schema**: choose this option to view the schema only.  
| • **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
| • **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window. |

| **Built-in** | The schema is created and stored locally for this component only. Related topic: see *Talend Studio User Guide User Guide*. |

| **Repository** | The schema already exists and is stored in the Repository, hence can be reused. Related topic: see *Talend Studio User Guide*. |

**Default Table Name**

Type in the default table name.

Advanced settings

| **tStatCatcher Statistics** | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |
## Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

## Usage

| Usage rule | tELTNetezzaInput is to be used along with the tELTNetezzaMap. Note that the Output link to be used with these components must correspond strictly to the syntax of the table name |

### Related scenarios

- Mapping data using a simple implicit join on page 680
- Aggregating table columns and filtering on page 739
- Mapping date using using an Alias table on page 743
- Aggregating Snowflake data using context variables as table and connection names on page 719
tELTNetezzaMap

Uses the tables provided as input, to feed the parameter in the built statement. The statement can include inner or outer joins to be implemented between tables or between one table and its aliases.

The three ELT Netezza components are closely related, in terms of their operating conditions. These components should be used to handle Netezza database table schemas to generate SQL statements, including clauses, which are to be executed in the database output table defined.

Helps you to build the SQL statement graphically, using the table provided as input.

tELTNetezzaMap Standard properties

These properties are used to configure tELTNetezzaMap running in the Standard Job framework.

The Standard tELTNetezzaMap component belongs to the ELT family.

The component in this framework is available in all Talend products.

Basic settings

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Note:</strong> When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:</td>
<td></td>
</tr>
<tr>
<td>1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.</td>
<td></td>
</tr>
<tr>
<td>2. In the child level, use a dedicated connection component to read that registered database connection.</td>
<td></td>
</tr>
<tr>
<td>For an example about how to share a database connection across Job levels, see <a href="#">Talend Studio User Guide</a>.</td>
<td></td>
</tr>
</tbody>
</table>

| ELT Netezza Map Editor | The ELT Map editor allows you to define the output schema and make a graphical build of the SQL statement to be executed. The column names of schema can be different from the column names in the database. |

<table>
<thead>
<tr>
<th>Style link</th>
<th>Select the way in which links are displayed.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Auto:</strong> By default, the links between the input and output schemas and the Web service parameters are in the form of curves.</td>
<td></td>
</tr>
<tr>
<td><strong>Bezier curve:</strong> Links between the schema and the Web service parameters are in the form of curve.</td>
<td></td>
</tr>
<tr>
<td><strong>Line (fastest):</strong> Links between the schema and the Web service parameters are in the form of straight lines. This option slightly optimizes performance.</td>
<td></td>
</tr>
</tbody>
</table>
Property type | Either Built-in or Repository.
--- | ---

**Built-in**: No property data stored centrally.

**Repository**: Select the Repository file where Properties are stored. The following fields are filled in using fetched data.

**Host** | Database server IP address.
**Port** | Listening port number of DB server.
**Database** | Name of the database.
**Username and Password** | DB user authentication data.
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

**Advanced settings**

**Additional JDBC parameters** | Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the **Use an existing connection** check box in the **Basic settings**.

**tStatCatcher Statistics** | Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

**Global Variables**

**Global Variables** | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.
For further information about variables, see [Talend Studio User Guide](#).

**Usage**

**Usage rule** | **tELNTnetezzaMap** is used along with **tELNTnetezzaInput** and **tELNTnetezzaOutput**. Note that the Output link to be used with these components must correspond strictly to the syntax of the table name.
Note:
Note that the ELT components do not handle actual data flow but only schema information.

Dynamic settings
Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

- Mapping data using a subquery on page 794, a related scenario using subquery
- Aggregating Snowflake data using context variables as table and connection names on page 719
tELTNetezzaOutput

Performs the action (insert, update or delete) on data in the specified Netezza table through the SQL statement generated by the tELTNetezzaMap component.

The three ELT Netezza components are closely related, in terms of their operating conditions. These components should be used to handle Netezza database table schemas to generate SQL statements, including clauses, which are to be executed in the database output table defined.

tELTNetezzaOutput Standard properties

These properties are used to configure tELTNetezzaOutput running in the Standard Job framework.

The Standard tELTNetezzaOutput component belongs to the ELT family.

The component in this framework is available in all Talend products.

Basic settings

<table>
<thead>
<tr>
<th>Action on data</th>
<th>On the data of the table defined, you can perform the following operation:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Insert</td>
<td>Adds new entries to the table.</td>
</tr>
<tr>
<td>Update</td>
<td>Updates entries in the table.</td>
</tr>
<tr>
<td>Delete</td>
<td>Deletes the entries which correspond to the entry flow.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Schema and Edit Schema</th>
<th>A schema is a row description, it defines the number of fields that will be processed and passed on to the next component.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:</td>
</tr>
<tr>
<td></td>
<td>• View schema: choose this option to view the schema only.</td>
</tr>
<tr>
<td></td>
<td>• Change to built-in property: choose this option to change the schema to Built-in for local changes.</td>
</tr>
<tr>
<td></td>
<td>• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.</td>
</tr>
<tr>
<td></td>
<td>Click Sync columns to retrieve the schema from the previous component connected in the Job.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Built-in</th>
<th>The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Repository</td>
<td>The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>
### Where clauses for (for UPDATE and DELETE only)

Enter a clause to filter the data to be updated or deleted during the update or delete operations.

### Default Table Name

Enter the default table name, between double quotation marks.

### Table name from connection name is variable

Select this check box when the name of the connection to this component is set to a variable, such as a context variable.

### Use different table name

Select this check box to define a different output table name, between double quotation marks, in the **Table name** field that appears.

### Mapping

Specify the metadata mapping file for the database to be used. The metadata mapping file is used for the data type conversion between database and Java. For more information about the metadata mapping, see the related documentation for Type mapping.

### Advanced settings

#### tStatCatcher Statistics

Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

### Global Variables

**Global Variables**

- **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.
- **NB_LINE_INSERTED**: the number of rows inserted. This is an After variable and it returns an integer.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

### Usage

#### Usage rule

**tELTNetezzaOutput** is to be used along with the **tELTNetezzaMap**. Note that the Output link to be used with these components must correspond strictly to the syntax of the table name.
Note:
Note that the ELT components do not handle actual data flow but only schema information.

Related scenarios

- Mapping data using a simple implicit join on page 680
- Aggregating table columns and filtering on page 739
- Mapping date using using an Alias table on page 743
- Aggregating Snowflake data using context variables as table and connection names on page 719
**tELTOracleInput**

Provides the Oracle table schema that will be used by the tELTOracleMap component to generate the SQL SELECT statement.

The three ELT Oracle components are closely related, in terms of their operating conditions. These components should be used to handle Oracle database table schemas to generate SQL statements, including clauses, which are to be executed in the database output table defined.

**tELTOracleInput Standard properties**

These properties are used to configure tELTOracleInput running in the Standard Job framework.

The Standard tELTOracleInput component belongs to the ELT family.

The component in this framework is available in all Talend products.

**Basic settings**

| Schema and Edit schema | A schema is a row description, it defines the nature and number of fields to be processed. The schema is either built-in or remotely stored in the Repository. The Schema defined is then passed on to the ELT Mapper to be included to the Insert SQL statement. Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
• **View schema**: choose this option to view the schema only.  
• **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
• **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the Repository Content window. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-in</strong>: The schema is created and stored locally for this component only. Related topic: see <strong>Talend Studio User Guide</strong>.</td>
<td></td>
</tr>
<tr>
<td><strong>Repository</strong>: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see <strong>Talend Studio User Guide</strong>.</td>
<td></td>
</tr>
<tr>
<td>Default Table Name</td>
<td>Enter the default table name, between double quotation marks.</td>
</tr>
<tr>
<td>Default Schema Name</td>
<td>Enter the default schema name, between double quotation marks.</td>
</tr>
</tbody>
</table>
Advanced settings

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | tELTOracleInput is to be used along with the tELTOracleMap. Note that the Output link to be used with these components must correspond strictly to the syntax of the table name. Note: The ELT components do not handle actual data flow but only schema information. |

Related scenarios

- Updating Oracle DB entries on page 763
- Aggregating Snowflake data using context variables as table and connection names on page 719
tELTOracleMap

Builds the SQL SELECT statement using the table schema(s) provided by one or more tELTOracleInput components.

The three ELT Oracle components are closely related, in terms of their operating conditions. These components should be used to handle Oracle database table schemas to generate SQL statements, including clauses, which are to be executed in the database output table defined.

**tELTOracleMap Standard properties**

These properties are used to configure tELTOracleMap running in the Standard Job framework.

The Standard tELTOracleMap component belongs to the ELT family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th><strong>Use an existing connection</strong></th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Note:</strong> When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:</td>
<td></td>
</tr>
<tr>
<td>1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.</td>
<td></td>
</tr>
<tr>
<td>2. In the child level, use a dedicated connection component to read that registered database connection.</td>
<td></td>
</tr>
<tr>
<td>For an example about how to share a database connection across Job levels, see Talend Studio User Guide.</td>
<td></td>
</tr>
</tbody>
</table>

| **ELT Oracle Map Editor** | The ELT Map editor allows you to define the output schema and make a graphical build of the SQL statement to be executed. The column names of schema can be different from the column names in the database. |

<table>
<thead>
<tr>
<th><strong>Style link</strong></th>
<th><strong>Auto:</strong> By default, the links between the input and output schemas and the Web service parameters are in the form of curves.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Bezier curve:</strong> Links between the schema and the Web service parameters are in the form of curve.</td>
</tr>
<tr>
<td></td>
<td><strong>Line:</strong> Links between the schema and the Web service parameters are in the form of straight lines.</td>
</tr>
<tr>
<td></td>
<td>This option slightly optimizes performance.</td>
</tr>
</tbody>
</table>

| **Property type** | Either Built-in or Repository. |
**Built-in:** No property data stored centrally.

**Repository:** Select the Repository file where Properties are stored. The following fields are pre-filled in using fetched data.

**Connection type**
Drop-down list of the available drivers.

**DB Version**
Select the Oracle version you are using.

**Host**
Database server IP address

**Port**
Listening port number of DB server.

**Database**
Name of the database

**Username and Password**
DB user authentication data.
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

**Mapping**
Automatically set mapping parameter.

### Advanced settings

**Additional JDBC Parameters**
Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the Use an existing connection check box in the Basic settings.

**Use Hint Options**
Select this check box to activate the hint configuration area to help you optimize a query’s execution. In this area, parameters are:
- **HINT:** specify the hint you need, using the syntax /*+ 
  */.
- **POSITION:** specify where you put the hint in a SQL statement.
- **SQL STMT:** select the SQL statement you need to use.

**tStatCatcher Statistics**
Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

### Global Variables

**Global Variables**

**ERROR_MESSAGE:** the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.
## Usage

### Usage rule

`tELTOracleMap` is used along with a `tELTOracleInput` and `tELTOracleOutput`. Note that the Output link to be used with these components must correspond strictly to the syntax of the table name.

**Note:**

Note that the ELT components do not handle actual data flow but only schema information.

### Dynamic settings

Click the `[+]` button to add a row in the table and fill the `Code` field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The `Dynamic settings` table is available only when the `Use an existing connection` check box is selected in the `Basic settings` view. Once a dynamic parameter is defined, the `Component List` box in the `Basic settings` view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on `Dynamic settings` and context variables, see Talend Studio User Guide.

### Updating Oracle DB entries

This scenario is based on the data aggregation scenario, Aggregating table columns and filtering on page 739. As the data update action is available in Oracle DB, this scenario describes a Job that updates particular data in the `agg_result` table.
As described in Aggregating table columns and filtering on page 739, set up a Job for data aggregation using the corresponding ELT components for Oracle DB, tELTOracleInput, tELTOracleMap, and tELTOraceleOutput, and execute the Job to save the aggregation result in a database table named agg_result.

Note:
When defining filters in the ELT Map editor, note that strings are case sensitive in Oracle DB.

• Launch the ELT Map editor and add a new output table named update_data.
• Add a filter row to the update_data table to set up a relationship between input and output tables: owners.ID_OWNER = agg_result.ID_OWNER.
• Drop the MAKE column from the cars table to the update_data table.
• Drop the NAME_RESELLER column from the resellers table to the update_data table.
• Add a model enclosed in single quotation marks, A8 in this use case, to the MAKE column from the cars table, preceded by a double pipe.
• Add Sold by enclosed in single quotation marks in front of the NAME_RESELLER column from the resellers table, with a double pipe in between.

• Check the Generated SQL select query tab to be executed.
Click OK to validate the changes in the ELT Mapper. Deactivate the tELTOracleOutput component labeled Agg_Result by right-clicking it and selecting Deactivate Agg_Result from the contextual menu.

Drop a new tELTOracleOutput component from the Palette to the design workspace, and label it Update_Data to better identify its functionality.

Connect the tELTOracleMap component to the new tELTOracleOutput component using the link corresponding to the new output table defined in the ELT Mapper, update_data in this use case.

Double-click the new tELTOracleOutput component to display its Basic settings view.

From the Action on data list, select Update.

Check the schema, and click Sync columns to retrieve the schema structure from the preceding component if necessary.

In the WHERE clauses area, add a clause that reads agg_result.MAKE = 'Audi' to update data relating to the make of Audi in the database table agg_result.

Fill the Default Table Name field with the name of the output link, update_data in this use case.

Select the Use different table name check box, and fill the Table name field with the name of the database table to be updated, agg_result in this use case.

Leave the other parameters as they are.

Save your Job and press F6 to run it.

The relevant data in the database table is updated as defined.

<table>
<thead>
<tr>
<th>ID_OWNER</th>
<th>NAME</th>
<th>ID_INSpection</th>
<th>REGISTERATION</th>
<th>MAKE</th>
<th>COLOR</th>
<th>NAME_RESELLER</th>
<th>CITY</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>Martin ADAMS</td>
<td>167 ZZP 346</td>
<td>Audi A6</td>
<td>grey</td>
<td>Sold by Rutherford HARRISON</td>
<td>AUGUSTA</td>
<td></td>
</tr>
<tr>
<td>11</td>
<td>Andrew COOLIDGE</td>
<td>104 ZYX 387</td>

</tr>
</tbody>
</table>
Related scenario

- Updating Oracle DB entries on page 763
- Mapping data using a subquery on page 794, a related scenario using subquery
- Aggregating Snowflake data using context variables as table and connection names on page 719
tELTOracleOutput

Performs the action (insert, update, delete, or merge) on data in the specified Oracle table through the SQL statement generated by the tELTOracleMap component.

The three ELT Oracle components are closely related, in terms of their operating conditions. These components should be used to handle Oracle database table schemas to generate SQL statements, including clauses, which are to be executed in the database output table defined.

tELTOracleOutput Standard properties

These properties are used to configure tELTOracleOutput running in the Standard Job framework. The Standard tELTOracleOutput component belongs to the ELT family. The component in this framework is available in all Talend products.

Basic Settings

<table>
<thead>
<tr>
<th>Action on data</th>
<th>On the data of the table defined, you can perform the following operation:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Insert</td>
<td>Add new entries to the table. If duplicates are found, the Job stops.</td>
</tr>
<tr>
<td>Update</td>
<td>Updates entries in the table.</td>
</tr>
<tr>
<td>Delete</td>
<td>Deletes the entries which correspond to the entry flow.</td>
</tr>
<tr>
<td>MERGE</td>
<td>Updates and/or adds data to the table. Note that the options available for the MERGE operation are different to those available for the Insert, Update or Delete operations.</td>
</tr>
</tbody>
</table>

Note:
Following global variables are available:
- NB_LINE_INSERTED: Number of lines inserted during the Insert operation.
- NB_LINE_UPDATED: Number of lines updated during the Update operation.
- NB_LINE_DELETED: Number of lines deleted during the Delete operation.
- NB_LINE_MERGED: Number of lines inserted and/or updated during the MERGE operation.

<table>
<thead>
<tr>
<th>Schema and Edit schema</th>
<th>A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either built-in or remotely stored in the Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Click Edit schema</td>
<td>Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:</td>
</tr>
<tr>
<td>View schema</td>
<td>View schema: choose this option to view the schema only.</td>
</tr>
<tr>
<td>Change to built-in property</td>
<td>Change to built-in property: choose this option to change the schema to Built-in for local changes.</td>
</tr>
</tbody>
</table>
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

<table>
<thead>
<tr>
<th>Built-in: The schema is created and stored locally for this component only. Related topic: see <em>Talend Studio User Guide.</em></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Repository</strong>: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see <em>Talend Studio User Guide.</em></td>
</tr>
</tbody>
</table>

**Where clauses for (for UPDATE and DELETE only)** Enter a clause to filter the data to be updated or deleted during the update or delete operations.

**Use Merge Update (for MERGE)** Select this check box to update the data in the output table.

- **Column**: Lists the columns in the entry flow.
- **Update**: Select the check box which corresponds to the name of the column you want to update.
- **Use Merge Update Where Clause**: Select this check box and enter the WHERE clause required to filter the data to be updated, if necessary.
- **Use Merge Update Delete Clause**: Select this check box and enter the WHERE clause required to filter the data to be deleted and updated, if necessary.

**Use Merge Insert (for MERGE)** Select this check box to insert the data in the table.

- **Column**: Lists the entry flow columns.
- **Check All**: Select the check box corresponding to the name of the column you want to insert.
- **Use Merge Update Where Clause**: Select this check box and enter the WHERE clause required to filter the data to be inserted.

**Default Table Name** Enter a default name for the table, between double quotation marks.

**Default Schema Name** Enter a name for the default Oracle schema, between double quotation marks.

**Table name from connection name is variable** Select this check box when the name of the connection to this component is set to a variable, such as a context variable.

**Use different table name** Select this check box to define a different output table name, between double quotation marks, in the **Table name** field which appears.

**Mapping** Specify the metadata mapping file for the database to be used. The metadata mapping file is used for the data type conversion between database and Java. For more information about the metadata mapping, see the related documentation for Type mapping.
Advanced settings

Use Hint Options
Select this check box to activate the hint configuration area when you want to use a hint to optimize a query’s execution. In this area, parameters are:
- **HINT**: specify the hint you need, using the syntax `/*+ */`.
- **POSITION**: specify where you put the hint in a SQL statement.
- **SQL STMT**: select the SQL statement you need to use.

StatCatcher Statistics
Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

Global Variables

Global Variables

**NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.

**NB_LINE_INSERTED**: the number of rows inserted. This is an After variable and it returns an integer.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press `Ctrl + Space` to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

Usage

Usage rule

**tELTOracleOutput** is to be used along with the **tELTOracleInput** and **tELTOracleMap** components. Note that the Output link to be used with these components must correspond strictly to the syntax of the table name.

**Note:**
Note that the ELT components do not handle actual data flow but only schema information.

Using the Oracle MERGE function to update and add data simultaneously

This scenario describes a Job that allows you to add new customer information and update existing customer information in a database table using the Oracle MERGE command.
Linking the components

Procedure

1. Drop the following components from the Palette to the design workspace: tELTOracleInput, tELTOracleMap, and tELTOracleOutput.
2. Label tELTOracleInput as new_customer, tELTOracleMap as ELT Mapper, and tELTOracleOutput as merge_data.
3. Link tELTOracleInput to tELTOracleMap using a Row > New Output (table) connection. In the pop-up box, enter NEW_CUSTOMERS as the table name, which should be the actual database table name.
4. Link tELTOracleMap to tELTOracleOutput using a Row > New Output (table) connection. In the pop-up box, enter customers_merge as the name of the database table, which holds the merge results.

Configuring the components

Procedure

1. Double-click the tELTOracleInput component to display its Basic settings view.
2. Select Repository from the Schema list, click the [...] button preceding Edit schema, and select your database connection and the desired schema from the Repository Content dialog box.

The selected schema name appears in the Default Table Name field automatically.

In this use case, the database connection is Talend_Oracle and the schema is new_customers.

In this use case, the input schema is stored in the Metadata node of the Repository tree view for easy retrieval. For further information concerning metadata, see Talend Studio User Guide.
You can also select the input component by dropping the relevant schema from the Metadata area onto the design workspace and double-clicking tELTOracleInput from the Components dialog box. Doing so allows you to skip the steps of labeling the input component and defining its schema manually.

3. Click the tELTOracleMap component to display its Basic settings view.

4. Select Repository from the Property Type list, and select the same database connection that you use for the input components.
   All the database details are automatically retrieved.
   Leave the other settings as they are.

5. Double-click the tELTOracleMap component to launch the ELT Map editor to set up the data transformation flow.
   Display the input table by clicking the green plus button at the upper left corner of the ELT Map editor and selecting the relevant table name in the Add a new alias dialog box.
   In this use case, the only input table is new_customers.

6. Select all the columns in the input table and drop them to the output table.
7. Click the **Generated SQL Select query tab** to display the query statement to be executed.

```
SELECT NEW_CUSTOMERS.ID, NEW_CUSTOMERS.FIRSTNAME, NEW_CUSTOMERS.LASTNAME, NEW_CUSTOMERS.ADDRESS,
       NEW_CUSTOMERS.REVENUE, NEW_CUSTOMERS.STATES
FROM NEW_CUSTOMERS
```

Click **OK** to validate the ELT Map settings and close the ELT Map editor.

8. Double-click the **tELTOracleOutput component** to display its **Basic settings** view.

   From the **Action on data** list, select **MERGE**.

   Click the **Sync columns** button to retrieve the schema from the preceding component.

   Select the **Use Merge Update** check box to update the data using Oracle’s MERGE function.

9. In the table that appears, select the check boxes for the columns you want to update.

   In this use case, we want to update all the data according to the customer ID. Therefore, select all
   the check boxes except the one for the **ID** column.

   **Warning:** The columns defined as the primary key cannot and must not be made subject to updates.

10. Select the **Use Merge Insert** check box to insert new data while updating the existing data by
    leveraging Oracle’s MERGE function.

    In the table that appears, select the check boxes for the columns into which you want to insert new data.
In this use case, we want to insert all the new customer data. Therefore, select all the check boxes by clicking the **Check All** check box.

11. Fill the **Default Table Name** field with the name of the target table already existing in your database. In this example, fill in *customers_merge*.

12. Leave the other parameters as they are.

---

**Executing the Job**

**Procedure**

1. Press **Ctrl + S** to save the Job.
2. Press **F6** to run the Job.

   The data is updated and inserted in the database. The query used is displayed on the console.

```sql
[statistics] connecting to socket on port 3712
[statistics] connected
Merge with
MERGE INTO customers_merge target USING (SELECT NEW_CUSTOMERS.ID , NEW_CUSTOMERS.FIRSTNAME , NEW_CUSTOMERS.LASTNAME , NEW_CUSTOMERS.ADDRESS , NEW_CUSTOMERS.REVENUE , NEW_CUSTOMERS.STATE FROM NEW_CUSTOMERS) source ON (target.ID = source.ID) WHEN MATCHED THEN UPDATE SET target.FIRSTNAME = source.FIRSTNAME , target.LASTNAME = source.LASTNAME , target.ADDRESS = source.ADDRESS , target.REVENUE = source.REVENUE , target.REGISTERDATE = source.REGISTERDATE , target.DATE = source.DATE WHEN NOT MATCHED THEN INSERT (target.ID , target.FIRSTNAME , target.LASTNAME , target.ADDRESS , target.REVENUE , target.REGISTERDATE , target.DATE , target.STATE)
Merging...
[statistics] disconnected
```
tELTPostgresqlInput

Provides the Postgresql table schema that will be used by the tELTPostgresqlMap component to generate the SQL SELECT statement.

The three ELT Postgresql components are closely related, in terms of their operating conditions. These components should be used to handle Postgresql database table schemas to generate SQL statements, including clauses, which are to be executed in the database output table defined.

tELTPostgresqlInput Standard properties

These properties are used to configure tELTPostgresqlInput running in the Standard Job framework.

The Standard tELTPostgresqlInput component belongs to the ELT family.

The component in this framework is available in all Talend products.

Basic settings

<table>
<thead>
<tr>
<th>Schema and Edit schema</th>
<th>A schema is a row description, it defines the nature and number of fields to be processed. The schema is either built-in or remotely stored in the Repository. The Schema defined is then passed on to the ELT Mapper to be included to the Insert SQL statement. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available: • View schema: choose this option to view the schema only. • Change to built-in property: choose this option to change the schema to Built-in for local changes. • Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-in</strong></td>
<td>The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Default Table Name</td>
<td>Enter the default table name, between double quotation marks.</td>
</tr>
<tr>
<td>Default Schema Name</td>
<td>Enter the default schema name, between double quotation marks.</td>
</tr>
</tbody>
</table>
Advanced settings

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>tELTPostgresqlInput</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
<td>tELTPostgresqlMap. Note that the Output link to be used with these components must correspond strictly to the syntax of the table name.</td>
</tr>
<tr>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
<td>Note: Note that the ELT components do not handle actual data flow but only schema information.</td>
</tr>
<tr>
<td>To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.</td>
<td></td>
</tr>
<tr>
<td>For further information about variables, see Talend Studio User Guide.</td>
<td></td>
</tr>
</tbody>
</table>

Usage

| Usage rule | tELTPostgresqlInput is to be used along with the tELTPostgresqlMap. Note that the Output link to be used with these components must correspond strictly to the syntax of the table name. |

Related scenarios

- Aggregating table columns and filtering on page 739
- Mapping date using using an Alias table on page 743
- Aggregating Snowflake data using context variables as table and connection names on page 719
tELTPostgresqlMap

Builds the SQL SELECT statement using the table schema(s) provided by one or more tELTPostgresql Input components.

The three ELT Postgresql components are closely related, in terms of their operating conditions. These components should be used to handle Postgresql database table schemas to generate SQL statements, including clauses, which are to be executed in the database output table defined.

**tELTPostgresqlMap Standard properties**

These properties are used to configure tELTPostgresqlMap running in the Standard Job framework. The Standard tELTPostgresqlMap component belongs to the ELT family. The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
</table>

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>ELT Postgresql Map Editor</th>
<th>The ELT Map editor allows you to define the output schema and make a graphical build of the SQL statement to be executed. The column names of schema can be different from the column names in the database.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Style link</th>
<th>Select the way in which links are displayed.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Auto</strong></td>
<td>By default, the links between the input and output schemas and the Web service parameters are in the form of curves.</td>
</tr>
<tr>
<td><strong>Bezier curve</strong></td>
<td>Links between the schema and the Web service parameters are in the form of curve.</td>
</tr>
<tr>
<td><strong>Line</strong></td>
<td>Links between the schema and the Web service parameters are in the form of straight lines.</td>
</tr>
</tbody>
</table>

This option slightly optimizes performance.
**Property type**

<table>
<thead>
<tr>
<th>Either Built-in or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-in</strong>: No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong>: Select the Repository file where Properties are stored. The following fields are pre-filled in using fetched data.</td>
</tr>
</tbody>
</table>

**Host**

Database server IP address

**Port**

Listening port number of DB server.

**Database**

Name of the database

**Username and Password**

DB user authentication data.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

**Advanced settings**

**Additional JDBC parameters**

Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the **Use an existing connection** check box in the **Basic settings**.

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

**Global Variables**

**Global Variables**

`ERROR_MESSAGE`: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

**Usage**

**Usage rule**

`tELTPostgresqlMap` is used along with a `tELTPostgresql Input` and `tELTPostgresql Output`. Note that the Output link to be used with these components must correspond strictly to the syntax of the table name.
Note:
Note that the ELT components do not handle actual data flow but only schema information.

Dynamic settings
Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenarios
• Aggregating table columns and filtering on page 739
• Mapping date using using an Alias table on page 743
• Mapping data using a subquery on page 794, a related scenario using subquery
• Aggregating Snowflake data using context variables as table and connection names on page 719
tELTPostgresqlOutput

Performs the action (insert, update or delete) on data in the specified Postgresql table through the SQL statement generated by the tELTPostgresqlMap component.

The three ELT Postgresql components are closely related, in terms of their operating conditions. These components should be used to handle Postgresql database table schemas to generate SQL statements, including clauses, which are to be executed in the database output table defined.

tELTPostgresqlOutput Standard properties

These properties are used to configure tELTPostgresqlOutput running in the Standard Job framework. The Standard tELTPostgresqlOutput component belongs to the ELT family.
The component in this framework is available in all Talend products.

Basic settings

| Action on data | On the data of the table defined, you can perform the following operation:
|               | **Insert**: Add new entries to the table. If duplicates are found, Job stops.
|               | **Update**: Updates entries in the table.
|               | **Delete**: Deletes the entries which correspond to the entry flow. |

| Schema and Edit schema | A schema is a row description, that is to say, it defines the number of fields to be processed and passed on to the next component. The schema is either built-in or remotely stored in the Repository.
|                        | Click **Edit schema** to make changes to the schema. If the current schema is of the Repository type, three options are available:
|                        | • **View schema**: choose this option to view the schema only.
|                        | • **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
|                        | • **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the Repository Content window. |

<p>| Built-in | The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide. |
| Repository | The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide. |</p>
<table>
<thead>
<tr>
<th><strong>Where clauses for</strong> (for UPDATE and DELETE only)</th>
<th>Enter a clause to filter the data to be updated or deleted during the update or delete operations.</th>
</tr>
</thead>

- Aggregating Snowflake data using context variables as table and connection names on page 719
tELTSybaseInput

Provides the Sybase table schema that will be used by the tELTSybaseMap component to generate the SQL SELECT statement.

The three ELT Sybase components are closely related, in terms of their operating conditions. These components should be used to handle Sybase database table schemas to generate SQL statements, including clauses, which are to be executed in the database output table defined.

tELTSybaseInput Standard properties

These properties are used to configure tELTSybaseInput running in the Standard Job framework.
The Standard tELTSybaseInput component belongs to the ELT family.
The component in this framework is available in all Talend products.

Basic settings

| Schema and Edit schema | A schema is a row description, it defines the number and nature of the fields to be processed. The schema is either built-in (local) or stored remotely in the Repository. The Schema defined is then passed on to the ELT Mapper for inclusion in the Insert SQL statement.
Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:
- View schema: choose this option to view the schema only.
- Change to built-in property: choose this option to change the schema to Built-in for local changes.
- Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

| Built-in: The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide. |
| Repository: The schema already exists and is stored in the Repository. Hence, it can be re-used for other projects and Jobs. Related topic: see Talend Studio User Guide. |
| Default Table Name | Enter a default name for the table, between double quotation marks. |
| Default Schema Name | Enter a default name for the Sybase schema, between double quotation marks. |
Advanced settings

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | tELTSybaseInput is intended for use with tELTSybaseMap. Note that the Output link to be used with these components must correspond strictly to the syntax of the table name. |

| Limitation | This component requires installation of its related jar files. |

Related scenarios

- Aggregating table columns and filtering on page 739
- Mapping date using using an Alias table on page 743
- Aggregating Snowflake data using context variables as table and connection names on page 719
tELTSybaseMap

Builds the SQL SELECT statement using the table schema(s) provided by one or more tELTSybaseInput components.

The three ELT Sybase components are closely related, in terms of their operating conditions. These components should be used to handle Sybase database table schemas to generate SQL statements, including clauses, which are to be executed in the database output table defined.

**tELTSybaseMap Standard properties**

These properties are used to configure tELTSybaseMap running in the Standard Job framework.

The Standard tELTSybaseMap component belongs to the ELT family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
</table>

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

</table>
Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>tELTSybaseOutput is intended for use with the tELTMysqlInput and tELTSybaseMap components. Note that the Output link to be used with these components must correspond strictly to the syntax of the table name.</th>
</tr>
</thead>
</table>
|            | **Note:**  
ELT components only handle schema information. They do not handle actual data flow. |

| Limitation | This component requires installation of its related jar files. |

Related scenarios

- Aggregating table columns and filtering on page 739
- Mapping date using using an Alias table on page 743
- Aggregating Snowflake data using context variables as table and connection names on page 719
tELTTeradataInput

Provides the Teradata table schema that will be used by the tELTTeradataMap component to generate the SQL SELECT statement.

The three ELT Teradata components are closely related, in terms of their operating conditions. These components should be used to handle Teradata database table schemas to generate SQL statements, including clauses, which are to be executed in the database output table defined.

tELTTeradataInput Standard properties

These properties are used to configure tELTTeradataInput running in the Standard Job framework. The Standard tELTTeradataInput component belongs to the ELT family. The component in this framework is available in all Talend products.

Basic settings

<table>
<thead>
<tr>
<th>Schema and Edit schema</th>
<th>A schema is a row description, that is to say, it defines the nature and number of fields to be processed. The schema is either built-in or remotely stored in the Repository. The Schema defined is then passed on to the ELT Mapper to be included to the Insert SQL statement. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available: • View schema: choose this option to view the schema only. • Change to built-in property: choose this option to change the schema to Built-in for local changes. • Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Built-in: The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide.</td>
<td></td>
</tr>
<tr>
<td>Repository: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide.</td>
<td></td>
</tr>
<tr>
<td>Default Table Name</td>
<td>Enter a default name for the table, between double quotation marks.</td>
</tr>
</tbody>
</table>

Advanced settings

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at component level. |
Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | tELTTeradataInput is to be used along with the tELTTeradataMap. Note that the Output link to be used with these components must correspond strictly to the syntax of the table name. Note: Note that the ELT components do not handle actual data flow but only schema information. |

Related scenarios

- Aggregating table columns and filtering on page 739
- Mapping date using an Alias table on page 743
- Aggregating Snowflake data using context variables as table and connection names on page 719
tELTTeradataMap

Builds the SQL SELECT statement using the table schema(s) provided by one or more tELTTeradataInput components.

The three ELT Teradata components are closely related, in terms of their operating conditions. These components should be used to handle Teradata database table schemas to generate SQL statements, including clauses, which are to be executed in the database output table defined.

tELTTeradataMap Standard properties

These properties are used to configure tELTTeradataMap running in the Standard Job framework. The Standard tELTTeradataMap component belongs to the ELT family. The component in this framework is available in all Talend products.

Basic settings

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Note:</strong> When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:</td>
<td></td>
</tr>
<tr>
<td>1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.</td>
<td></td>
</tr>
<tr>
<td>2. In the child level, use a dedicated connection component to read that registered database connection.</td>
<td></td>
</tr>
<tr>
<td>For an example about how to share a database connection across Job levels, see Talend Studio User Guide.</td>
<td></td>
</tr>
</tbody>
</table>

| ELT Teradata Map editor | The ELT Map editor allows you to define the output schema as well as build graphically the SQL statement to be executed. The column names of schema can be different from the column names in the database. |

<table>
<thead>
<tr>
<th>Style link</th>
<th>Select the way in which links are displayed.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Auto:</strong> By default, the links between the input and output schemas and the Web service parameters are in the form of curves.</td>
<td></td>
</tr>
<tr>
<td><strong>Bezier curve:</strong> Links between the schema and the Web service parameters are in the form of curve.</td>
<td></td>
</tr>
<tr>
<td><strong>Line:</strong> Links between the schema and the Web service parameters are in the form of straight lines.</td>
<td></td>
</tr>
<tr>
<td>This option slightly optimizes performance.</td>
<td></td>
</tr>
</tbody>
</table>
### Property type

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-in or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the Repository file where Properties are stored. The following fields are pre-filled in using fetched data.</td>
</tr>
</tbody>
</table>

### Host

- **Database server IP address**

### Database

- **Name of the database**

### Username and Password

- **DB user authentication data.**
  - To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

### Advanced settings

**Query band**

- Select this check box to use the Teradata Query Banding feature to add metadata to the query to be processed, such as the user running the query. This can help you, for example, identify the origin of this query.

  - Once selecting the check box, the **Query Band parameters** table is displayed, in which you need to enter the metadata information to be added. This information takes the form of key/value pairs, for example, *DpID* in the **Key** column and *Finance* in the **Value** column.

  - This check box actually generates the SET QUERY_BAND FOR SESSION statement with the key/value pairs declared in the **Query Band parameters** table. For further information about this statement, see [https://docs.teradata.com/search/all?query=End+logging+syntax](https://docs.teradata.com/search/all?query=End+logging+syntax).

  - This check box is not available when you have selected the **Using an existing connection** check box. In this situation, if you need to use the Query Band feature, set it in the **Advanced settings** tab of the Teradata connection component to be used.

**tStatCatcher Statistics**

- Select this check box to collect log data at the component level.

### Global Variables

**Global Variables**

- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

  - A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

  - To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.
For further information about variables, see Talend Studio User Guide.

Usage

Usage rule

`tELTTeradataMap` is used along with a `tELTTeradataInput` and `tELTTeradataOutput`. Note that the Output link to be used with these components must faithfully reflect the name of the tables.

Note:
The ELT components do not handle actual data flow but only schema information.

Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Mapping data using a subquery

This scenario describes a Job that maps the data from two input tables `PreferredSubject` and `CourseScore` to the output table `TotalScoreOfPreferredSubject` using a subquery.
The *PreferredSubject* table contains the student's preferred subject data. To reproduce this scenario, you can load the data to the table from a CSV file like the following. For how to load data to a Teradata table, see [Loading data into a Teradata database](#) on page 3868.

<table>
<thead>
<tr>
<th>SeqID</th>
<th>StuName</th>
<th>Subject</th>
<th>Detail</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Amanda</td>
<td>art</td>
<td>Amanda prefers art.</td>
</tr>
<tr>
<td>2</td>
<td>Ford</td>
<td>science</td>
<td>Ford prefers science.</td>
</tr>
<tr>
<td>3</td>
<td>Kate</td>
<td>art</td>
<td>Kate prefers art.</td>
</tr>
</tbody>
</table>

The *CourseScore* table contains the student's subject score data. To reproduce this scenario, you can load the data to the table from a CSV file like the following. For how to load data to a Teradata table, see [Loading data into a Teradata database](#) on page 3868.

<table>
<thead>
<tr>
<th>SeqID</th>
<th>StuName</th>
<th>Subject</th>
<th>Course</th>
<th>Score</th>
<th>Detail</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Amanda</td>
<td>science</td>
<td>math</td>
<td>85</td>
<td>science score</td>
</tr>
<tr>
<td>2</td>
<td>Amanda</td>
<td>science</td>
<td>physics</td>
<td>75</td>
<td>science score</td>
</tr>
<tr>
<td>3</td>
<td>Amanda</td>
<td>science</td>
<td>chemistry</td>
<td>80</td>
<td>science score</td>
</tr>
<tr>
<td>4</td>
<td>Amanda</td>
<td>art</td>
<td>chinese</td>
<td>85</td>
<td>art score</td>
</tr>
<tr>
<td>5</td>
<td>Amanda</td>
<td>art</td>
<td>history</td>
<td>95</td>
<td>art score</td>
</tr>
<tr>
<td>6</td>
<td>Amanda</td>
<td>art</td>
<td>geography</td>
<td>80</td>
<td>art score</td>
</tr>
<tr>
<td>7</td>
<td>Ford</td>
<td>science</td>
<td>math</td>
<td>95</td>
<td>science score</td>
</tr>
<tr>
<td>8</td>
<td>Ford</td>
<td>science</td>
<td>physics</td>
<td>85</td>
<td>science score</td>
</tr>
<tr>
<td>9</td>
<td>Ford</td>
<td>science</td>
<td>chemistry</td>
<td>80</td>
<td>science score</td>
</tr>
<tr>
<td>10</td>
<td>Ford</td>
<td>art</td>
<td>chinese</td>
<td>75</td>
<td>art score</td>
</tr>
<tr>
<td>11</td>
<td>Ford</td>
<td>art</td>
<td>history</td>
<td>80</td>
<td>art score</td>
</tr>
<tr>
<td>12</td>
<td>Ford</td>
<td>art</td>
<td>geography</td>
<td>85</td>
<td>art score</td>
</tr>
<tr>
<td>13</td>
<td>Kate</td>
<td>science</td>
<td>math</td>
<td>65</td>
<td>science score</td>
</tr>
<tr>
<td>14</td>
<td>Kate</td>
<td>science</td>
<td>physics</td>
<td>75</td>
<td>science score</td>
</tr>
<tr>
<td>15</td>
<td>Kate</td>
<td>science</td>
<td>chemistry</td>
<td>80</td>
<td>science score</td>
</tr>
<tr>
<td>16</td>
<td>Kate</td>
<td>art</td>
<td>chinese</td>
<td>85</td>
<td>art score</td>
</tr>
<tr>
<td>17</td>

<td>art</td>
<td>history</td>
<td>80</td>
<td>art score</td>
</tr>
<tr>
<td>18</td>
<td>Kate</td>
<td>art</td>
<td>geography</td>
<td>95</td>
<td>art score</td>
</tr>
</tbody>
</table>

Before the Job execution, there is no data in the output table *TotalScoreOfPreferredSubject*:

| SeqID | StuName | PreferredSubject | TotalScore |

**Dropping and renaming the components**

**Procedure**

1. Create a new Job and add the following components by typing their names in the design workspace or dropping them from the **Palette**: two *tELTTeradataInput* components, two *tELTTeradataMap* components, and one *tELTTeradataOutput* component.

2. Rename two *tELTTeradataInput* components to *PreferredSubject* and *CourseScore* respectively, two *tELTTeradataMap* components to *ELTSubqueryMap* and *ELTMap* respectively, and the *tELTTeradataOutput* component to *TotalScoreOfPreferredSubject*.

**Configuring the input components**

**Procedure**

1. Double-click *PreferredSubject* to open its **Basic settings** view.
2. In the **Default Table Name** field, enter an input table name. In this example, it is *PreferredSubject*.

3. Click the [...] button next to **Edit schema** to define the schema of the input table *PreferredSubject* in the schema editor.

   ![Schema of PreferredSubject](image)

   - Click the [+ button to add four columns, *SeqID* with the DB Type set to **INTEGER**, *StuName*, *Subject*, and *Detail* with the DB Type set to **VARCHAR**.
   - Click **OK** to validate these changes and close the schema editor.

4. Connect *PreferredSubject* to *ELTMap* using the **Link > PreferredSubject (Table)** link.

5. Double-click *CourseScore* to open its **Basic settings** view.

6. In the **Default Table Name** field, enter an input table name. In this example, it is *CourseScore*.

7. Click the [...] button next to **Edit schema** to define the schema of the input table *CourseScore* in the schema editor.
Click the [+ ] button to add six columns, _SeqID_ and _Score_ with the DB Type set to **INTEGER**, _StuName_, _Subject_, _Course_ and _Detail_ with the DB Type set to **VARCHAR**.

Click **OK** to validate these changes and close the schema editor.

8. Connect _CourseScore_ to _ELTSubqueryMap_ using the **Link > CourseScore (Table)** link.

**Configuring the output component**

**Procedure**

1. Double-click _TotalScoreOfPreferredSubject_ to open its **Basic settings** view.

2. In the **Default Table Name** field, enter an output table name. In this example, it is _TotalScoreOfPreferredSubject_.

3. Click the [...] button next to **Edit schema** to define the schema of the output table in the schema editor.
Click the [+] button to add four columns, `SeqID` and `TotalScore` with the DB Type set to `INTEGER`, `StuName` and `PreferredSubject` with the DB Type set to `VARCHAR`. Click **OK** to validate these changes and close the schema editor.

**Configuring data mapping to generate a subquery**

**Procedure**

1. Click **ELTSubqueryMap** to open its **Basic settings** view.

Note that you do not need to specify the Teradata database connection information in the **ELTSubqueryMap** component. The connection information will be specified in the **ELTMap** component.

2. Click the [...] button next to **ELT Teradata Map Editor** to open its map editor.
3. Add the input table CourseScore by clicking the [+ button in the upper left corner of the map editor and then selecting the relevant table name from the drop-down list in the pop-up dialog box.

4. Add an output table by clicking the [+ button in the upper right corner of the map editor and then entering the table name TotalScore in the corresponding field in the pop-up dialog box.

5. Drag StuName, Subject, and Score columns in the input table and then drop them to the output table.

6. Click the Add filter row button in the upper right corner of the output table and select Add an other(GROUP...) clause from the pop-up menu. Then in the Additional other clauses (GROUP/ ORDER BY...) field displayed, enter the clause GROUP BY CourseScore.StuName, CourseScore.Subject.

Add the aggregate function SUM for the column Score of the output table by changing the expression of this column to SUM(CourseScore.Score).

7. Click the Generated SQL Select query for “table1” output tab at the bottom of the map editor to display the corresponding generated SQL statement.

```
SELECT CourseScore.StuName, CourseScore.Subject, SUM(CourseScore.Score)
FROM CourseScore
GROUP BY CourseScore.StuName, CourseScore.Subject
```

This SQL query will appear as a subquery in the SQL query generated by the ELTMap component.

8. Click OK to validate these changes and close the map editor.

9. Connect ELTSubqueryMap to ELTMap using the Link > TotalScore (table1) link. Note that the link is renamed automatically to TotalScore (Table_ref) since the output table TotalScore here is a reference table.
Mapping the input and output schemas

Procedure

1. Right-click ELTMap, select Link > "New Output" (Table) from the contextual menu and click TotalScoreOfPreferredSubject. In the pop-up dialog box, click Yes to get the schema from the target component.

2. Click ELTMap to open its Basic settings view.

3. Fill in the Host, Database, Username, and Password fields with the Teradata database connection information.

4. Click the [...] button next to ELT Teradata Map Editor to open its map editor.

4. Add the input table PreferredSubject by clicking the [+] button in the upper left corner of the map editor and selecting the relevant table name from the drop-down list in the pop-up dialog box. Do the same to add another input table TotalScore.
5. Drag the StuName column in the input table PreferredSubject and drop it to the corresponding column in the input table TotalScore. Then select the Explicit join check box for the StuName column in the input table TotalScore. Do the same for the Subject column.

6. Drag the SeqID column in the input table PreferredSubject and drop it to the corresponding column in the output table. Do the same to drag the StuName and Subject columns in the input table PreferredSubject and the Score column in the input table TotalScore and drop them to the corresponding column in the output table.

7. Click the **Generated SQL Select query for "table2" output** tab at the bottom of the map editor to display the corresponding generated SQL statement.

The SQL query generated in the ELTSubqueryMap component appears as a subquery in the SQL query generated by this component. Alias will be automatically added for the selected columns in the subquery.

8. Click **OK** to validate these changes and close the map editor.

**Executing the Job**

**Procedure**

1. Press **Ctrl + S** to save the Job.
2. Press **F6** to run the Job.
The select statement is generated and the mapping data are written into the output table.

### Related scenarios

- [Mapping date using using an Alias table](#) on page 743
- [Aggregating Snowflake data using context variables as table and connection names](#) on page 719
**tELTTeradataOutput**

Performs the action (insert, update or delete) on data in the specified Teradata table through the SQL statement generated by the tELTTeradataMap component.

The three ELT Teradata components are closely related, in terms of their operating conditions. These components should be used to handle Teradata database table schemas to generate SQL statements, including clauses, which are to be executed in the database output table defined.

**tELTTeradataOutput Standard properties**

These properties are used to configure tELTTeradataOutput running in the Standard Job framework. The Standard tELTTeradataOutput component belongs to the ELT family.

The component in this framework is available in all Talend products.

**Basic settings**

| Action on data | On the data of the table defined, you can perform the following operation:  
|                | **Insert**: Add new entries to the table. If duplicates are found, Job stops.  
|                | **Update**: Updates entries in the table.  
|                | **Delete**: Deletes the entries which correspond to the entry flow. |

**Schema and Edit schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

<p>| Built-in | The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide. |
| Repository | The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide. |</p>
<table>
<thead>
<tr>
<th>Where clauses for (for UPDATE and DELETE only)</th>
<th>Enter a clause to filter the data to be updated or deleted during the update or delete operations.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Table Name</td>
<td>Enter a default name for the table, between double quotation marks. Note that the table must exist already. If it does not exist, you can use <code>tCreateTable</code> to create one first. For more information about <code>tCreateTable</code>, see <code>tCreateTable</code> on page 544.</td>
</tr>
<tr>
<td>Table name from connection name is variable</td>
<td>Select this check box when the name of the connection to this component is set to a variable, such as a context variable.</td>

</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics                        | Select this check box to gather the Job processing metadata at a Job level as well as at component level. |

**Global Variables**

| Global Variables                               | **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.  
**NB_LINE_INSERTED**: the number of rows inserted. This is an After variable and it returns an integer.  
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press *Ctrl + Space* to access the variable list and choose the variable to use from it.  
For further information about variables, see *Talend Studio User Guide*. |

**Usage**

| Usage rule                                     | `tELTTeradataOutput` is to be used along with the `tELTTeradataMap`. Note that the Output link to be used with |
these components must correspond strictly to the syntax of the table name.

**Note:**
Note that the ELT components do not handle actual data flow but only schema information.

| Limitation                                                                 | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center ([https://help.talend.com](https://help.talend.com)). |

**Related scenarios**

</tbody>
</table>

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>ELT Vertica Map Editor</th>
<th>The ELT Map editor allows you to define the output schema as well as build graphically the SQL statement to be executed. The column names of the schema can be different from the column names in the database.</th>

</thead>
</table>

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>tELTVerticaMap is used along with tELTVerticaInput and tELTVerticaOutput. Note that the Output link to be used with these components must correspond strictly to the syntax of the table name.</th>
</tr>
</thead>
</table>
Related scenarios

- Aggregating table columns and filtering on page 739
- Mapping date using using an Alias table on page 743
- Mapping data using a subquery on page 794, a related scenario using subquery
- Aggregating Snowflake data using context variables as table and connection names on page 719

Note:
The ELT components do not handle actual data flow but only schema information.
tELTVerticaOutput

Performs the action (insert, update or delete) on data in the specified Vertica table through the SQL statement generated by the tELTVerticaMap component.

The three ELT Vertica components are closely related, in terms of their operating conditions. These components should be used to handle Vertica database table schemas to generate SQL statements, including clauses, which are to be executed in the database output table defined.

tELTVerticaOutput Standard properties

These properties are used to configure tELTVerticaOutput running in the Standard Job framework. The Standard tELTVerticaOutput component belongs to the ELT family. The component in this framework is available in all Talend products.

Basic settings

<table>
<thead>
<tr>
<th>Action on data</th>
<th>On the data of the table defined, you can perform one of the following operations:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• <strong>Insert</strong>: Add new entries to the table. If duplicates are found, Job stops.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Update</strong>: Updates entries in the table.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Delete</strong>: Deletes entries which correspond to the entry flow.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Schema and Edit schema</th>
<th>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <code>line</code> when naming the fields.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Built-In</strong>: You create and store the schema locally for this component only.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
</tr>
<tr>
<td>Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:</td>
<td>• <strong>View schema</strong>: choose this option to view the schema only.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Change to built-in property</strong>: choose this option to change the schema to Built-in for local changes.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Update repository connection</strong>: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.</td>
</tr>
</tbody>
</table>

| Sync columns | Click this button to retrieve the schema from the previous component connected in the Job. |
### Where clauses (for UPDATE and DELETE only)

Enter a clause to filter the data to be updated or deleted during the update or delete operation.

This field is available only when **Update** or **Delete** is selected from the **Action on data** drop-down list.

### Default Table Name

Type in the default table name.

### Default Schema Name

Type in the default schema name.

### Table name from connection name is variable

Select this check box when the name of the connection to this component is set to a variable, such as a context variable.

### Use different table name

Select this check box to use a different output table name.

### Table name

Type in the output table name.

This field is available only when the **Use different table name** check box is selected.

### Advanced settings

**Direct**

Select this check box to write the data directly to disk, bypassing memory.

This check box is not visible when the **Set SQL Label** check box is selected.

**Set SQL Label**

Select this check box and specify the label that identifies the query. For more information, see [How to label queries for profiling](#).

This check box is not visible when the **Direct** check box is selected.

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

**Global Variables**

- **NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.
- **NB_LINE_INSERTED**: the number of rows inserted. This is an After variable and it returns an integer.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

tESBConsumer

Calls the defined method from the invoked Web service and returns the class as defined, based on the given parameters.

tESBConsumer Standard properties

These properties are used to configure tESBConsumer running in the Standard Job framework.

The Standard tESBConsumer component belongs to the ESB family.

The component in this framework is available in all Talend products.

Basic settings

<table>
<thead>
<tr>
<th>Service configuration</th>
<th>Description of Web service bindings and configuration. The <strong>Endpoint</strong> field gets filled in automatically upon completion of the service configuration.</th>
</tr>
</thead>
</table>
| **Input Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word **line** when naming the fields. Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
  • **View schema**: choose this option to view the schema only.  
  • **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
  • **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window. |
| **Built-in**: The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide. | |
| **Repository**: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide. | |
| **Response Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word **line** when naming the fields. Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
  • **View schema**: choose this option to view the schema only. |
| **Fault Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word 'line' when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Built-in**: The schema is created and stored locally for this component only. Related topic: see *Talend Studio User Guide*.

**Repository**: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see *Talend Studio User Guide*.

| **Use Service Registry** | This option is only available if you subscribed to Talend Enterprise ESB solutions.

Select this check box to enable the Service Registry. It provides dynamic endpoint lookup and allows services to be redirected based upon information retrieved from the registry. It works in runtime only.

Enter the authentication credentials in the **Username** and **Password** field.

If SAML token is registered in the service registry, you need to specify the client’s role in the **Role** field. You can also select the **Propagate Credentials** check box to make the call on behalf of an already authenticated user by propagating the existing credentials. You can enter the username and the password to authenticate via STS to propagate using username and password, or provide the alias, username.
Use Service Locator
Maintains the availability of the service to help meet demands and service level agreements (SLAs).
This option will not show if the Use Service Registry check box is selected.

Use Service Activity Monitor
Captures events and stores this information to facilitate in-depth analysis of service activity and track-and-trace of messages throughout a business transaction. This can be used to analyze service response times, identify traffic patterns, perform root cause analysis and more.
This option is disabled when the Use Service Registry check box is selected if you subscribed to Talend Enterprise ESB solutions.

Use Authentication
Select this check box to enable the authentication option. Select from Basic HTTP, HTTP Digest, Username Token, and SAML Token (ESB runtime only). Enter a username and a password in the corresponding fields as required. Authentication with Basic HTTP, HTTP Digest, and Username Token work in both the studio and runtime. Authentication with the SAML Token works in runtime only.
When SAML Token (ESB runtime only) is selected, you can either provide the user credentials to send the request or make the call on behalf of an already authenticated user by propagating the existing credentials. Select from:

- **Propagate using U/P**: Enter the username and the password in the corresponding fields to access the service.
- **Propagate using Certificate**: Enter the alias and the password used to authenticate against STS.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.
This option will not show if the Use Service Registry check box is selected.

Use Business Correlation
Select this check box to create a correlation ID in this component.
You can specify a correlation ID in the Correlation Value field. In this case the correlation ID will be passed on to the service it calls so that chained service calls will be grouped and the password to propagate using certificate. For more information, see the Use Authentication option. Select the Encryption/Signature body check box to enable XML Encryption/XML Signature. For more information, see the chapter about XKMS Service in the Talend ESB Infrastructure Services Configuration Guide.
In the Correlation Value field, specify a correlation ID or leave this field empty. For more information, see the Use Business Correlation option.
For more information about how to set up and use the Service Registry, see the Talend Administration Center User Guide and Talend ESB Infrastructure Services Configuration Guide.
under this correlation ID. If you leave this field empty, this value will be generated automatically at runtime.

When this option is enabled, tESBConsumer will also extract the correlation ID from the response header and store it in the component variable for further use in the flow.

This option will be enabled automatically when the **Use Service Registry** check box is selected.

**Use GZip Compress**

Select this check box to compress the incoming messages into GZip format before sending.

**Die on error**

Select this check box to kill the Job when an error occurs.

### Advanced settings

<table>
<thead>
<tr>
<th><strong>Log messages</strong></th>
<th>Select this check box to log the message exchange between the service provider and the consumer.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Service Locator Custom Properties</strong></td>
<td>This table appears when <strong>Use Service Locator</strong> is selected. You can add as many lines as needed in the table to customize the relevant properties. Enter the name and the value of each property between double quotation marks in the <strong>Property Name</strong> field and the <strong>Property Value</strong> field respectively.</td>
</tr>
<tr>
<td><strong>Service Activity Custom Properties</strong></td>
<td>This table appears when <strong>Use Service Activity Monitor</strong> is selected. You can add as many lines as needed in the table to customize the relevant properties. Enter the name and the value of each property between double quotation marks in the <strong>Property Name</strong> field and the <strong>Property Value</strong> field respectively.</td>
</tr>
</tbody>
</table>
| **Connection time out(second)** | Set a value in seconds for Web service connection time out. This option only works in the studio. To use it after the component is deployed in runtime:

1. Create a configuration file with the name `org.apache.cxf.http.conduits-<endpoint_name>.cfg` in the `<TalendRuntime Path>/container/etc/` folder.
2. Specify the `url` of the Web service and the `client.ConnectionTimeout` parameter in milliseconds in the configuration file. If you need to use the **Receive time out** option, specify the `client.ReceiveTimeout` in milliseconds too. The `url` can be a full endpoint address or a regular expression containing wild cards, for example:

   ```
   url = http://localhost:8040/*
   client.ConnectionTimeout=10000000
   client.ReceiveTimeout=20000000
   ```

| **Receive time out(second)** | Set a value in seconds for server answer. This option only works in the studio. For how to use it after the component is deployed in runtime, see the **Connection time out** option. |
### Disable Chunking
Select this check box to disable encoding the payload as chunks. In general, chunking will perform better as the streaming can take place directly. But sometimes the payload is truncated with chunking enabled. If you are getting strange errors when trying to interact with a service, try turning off chunking to see if that helps.

### Trust server with SSL/TrustStore file and TrustStore password
Select this check box to validate the server certificate to the client via an SSL protocol and fill in the corresponding fields:

- **TrustStore file**: Enter the path (including filename) to the certificate TrustStore file that contains the list of certificates that the client trusts.
- **TrustStore password**: Enter the password used to check the integrity of the TrustStore data.

### Use http proxy/Proxy host, Proxy port, Proxy user, and Proxy password
Select this check box if you are using a proxy server and fill in the necessary information.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

### HTTP Headers
Click [+] as many times as required to add the name-value pair(s) for HTTP headers to define the parameters of the requested HTTP operation.

### tStatCatcher Statistics
Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_LINE: the number of rows processed. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>CORRELATION_ID: the correlation ID by which chained service calls will be grouped. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td></td>
<td>HTTP_RESPONSE_CODE: HTTP response status code. This is an After variable and it returns an Integer.</td>
</tr>
<tr>
<td></td>
<td>HTTP_HEADERS: the set of HTTP headers from response. This is a Flow variable and it returns map object java.util.Map&lt;String, java.util.List&lt;?&gt;&gt;. Header name is represented by map key. Header values are represented by java.util.List&lt;?&gt;.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.</td>
</tr>
</tbody>
</table>
Usage

**Usage rule**

This component can be used as an intermediate component. It requires to be linked to an output component.

**Dynamic settings**

Click the [+] button to add a row in the table and fill the Code field with a context variable to turn on or off the Use Authentication or Use HTTP proxy option dynamically at runtime. You can add two rows in the table to set both options.

Once a dynamic parameter is defined, the corresponding option becomes highlighted and unusable in the Basic settings view or Advanced settings view.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

**Limitation**

A JDK is required for this component to operate.

Using tESBConsumer to retrieve the valid email

This scenario describes a Job that uses a tESBConsumer component to retrieve the valid email.

Dropping and linking the components

**Procedure**

1. Drop the following components from the Palette onto the design workspace: a tFixedFlowInput, a tESBConsumer, two tXMLMap, and two tLogRow components.
2. Right-click the tFixedFlowInput component, select Row > Main from the contextual menu and click the first tXMLMap component.
3. Right-click the tXMLMap component, select Row > *New Output* (Main) from the contextual menu and click the tESBConsumer component. Enter payload in the popup dialog box to name...
this row and accept the propagation that prompts you to get the schema from the tESBConsumer component.

4. Right-click the tESBConsumer component, select Row > Response from the contextual menu and click the second tXMLMap component.

5. Right-click the second tXMLMap component, select Row > "New Output" (Main) from the contextual menu and click the second tLogRow component. Enter response in the popup dialog box to name this row.

6. Right-click the tESBConsumer component again, select Row > Fault from the contextual menu and click the other tLogRow component.

**Configuring the components**

The tLogRow components will monitor the exchanges from the response and fault messages and does not need any configuration. Press Ctrl+S to save your Job.

**Configuring the tESBConsumer component**

**About this task**

In this scenario, a public web service which is available at http://www.webservicex.net/ValidateEmail.asmx will be called by the tESBConsumer component to return true or false for an email address. You can view the WSDL definition of the service at http://www.webservicex.net/ValidateEmail.asmx?WSDL for the service description.

**Procedure**

1. In the design workspace, double-click the tESBConsumer component to open its Basic settings view in the Component tab.

2. Click the three-dot button next to Service configuration.
3. In the dialog box that appears, type in: `http://www.webservicex.net/ValidateEmail.asmx?WSDL` in the **WSDL** field and click the refresh button to retrieve port name and operation name. In the **Port Name** list, select the port you want to use, `ValidateEmailSoap` in this example. Select the **Populate schema to repository on finish** to retrieve the schema from the WSDL definition, which will be used by the `tFixedFlowInput` component. This option is only available to users of Talend Studio with ESB. If you don't have this option, please ignore it. The schema can be created manually in the `tFixedFlowInput` component, which will be shown later.

Click **Finish** to validate your settings and close the dialog box.

4. Click the **Advanced settings** view in the **Component** tab.

5. Select the **Log messages** check box to show the exchange log in the execution console.

**Configuring the tFixedFlowInput component**

**Procedure**

1. Double-click the `tFixedFlowInput` component to open its **Basic settings** view in the **Component** tab.
2. For users of *Talend Studio* with ESB who have retrieved the schema from the service WSDL definition in the configuration of the tESBConsumer component, select **Repository** from the Schema list. Then click the [...] of the next field to show the Repository Content dialog box. Select the metadata under the IsValidEmail node to use it as the schema of the input message. Click **OK** to close the dialog box.

For users of *Talend Studio* without ESB, please go to the next step.
3. For users of *Talend Studio* without ESB, the schema need to be created manually. Select **Built-In** from the **Schema** list.

![Schema dialog box](image)

Click the three-dot button next to **Edit Schema**. In the schema dialog box, click the plus button to add a new line of **String** type and name it **Email**. Click **OK** to close the dialog box.

![Schema dialog box](image)

4. In the **Number of rows** field, set the number of rows as 1.
5. In the **Mode** area, select **Use Single Table** and input the following request in double quotation marks into the **Value** field:
   
   nomatter@gmail.com

### Configuring the tXMLMap component in the input flow

**About this task**

*Talend* data integration uses schemas based on rows and columns since it has roots in relational data warehouse integration. But SOAP messages uses the XML format. XML is hierarchical and supports richer structure than rows or columns. So we need the **tXMLMap** to convert from the relational row/column structure to the schema expected by the SOAP service.
Procedure

1. In the design workspace, double-click the **tXMLMap** component to open the **Map Editor**.
2. In the output table, right-click the root node and select **Rename** from the contextual menu. Enter **IsValidEmail** in the dialog box that appears.
3. Right-click the **IsValidEmail** node and select **Set A Namespace** from the contextual menu. Enter **http://www.webservicex.net** in the dialog box that appears.
4. Right-click the **IsValidEmail** node again and select **Create Sub-Element** from the contextual menu. Enter **Email** in the dialog box that appears.
5. Right-click the **Email** node and select **As loop element** from the contextual menu.
6. Click the **Email** node in the input table and drop it to the **Expression** column in the row of the **Email** node in the output table.
7. Click **OK** to validate the mapping and close the **Map Editor**.

**Configuring the tXMLMap component in the output flow**

**About this task**

The **tXMLMap** in the output flow will convert the response message from the XML format to the row/column structure.

Procedure

1. In the design workspace, double-click the **tXMLMap** component in the output flow to open the **Map Editor**.
2. In the input table, right-click the root node and select **Rename** from the contextual menu. Enter **IsValidEmailResponse** in the dialog box that appears.
3. Right-click the **IsValidEmailResponse** node and select **Set A Namespace** from the contextual menu. Enter **http://www.webservicex.net** in the dialog box that appears.
4. Right-click the `IsValidEmailResponse` node again and select **Create Sub-Element** from the contextual menu. Enter `IsValidEmailResult` in the dialog box that appears.

5. Right-click the `IsValidEmailResult` node and select **As loop element** from the contextual menu.

6. On the lower right part of the map editor, click `[+]` to add a row of `String` type to the output table and name it `response`.

7. Click the `IsValidEmailResult` node in the input table and drop it to the **Expression** column in the row of the `response` node in the output table.

8. Click **OK** to validate the mapping and close the **Map Editor**.

**Executing the Job**

Click the **Run** view to display it and click the **Run** button to launch the execution of your Job. You can also press **F6** to execute it. In the execution log you will see:
The email address nomatter@gmail.com is returned as false. The input and output SOAP messages in XML are also shown in the console.

**Using tESBCConsumer with custom SOAP Headers**

This scenario is similar to the previous one. It describes a Job that uses a tESBCConsumer component to retrieve a valid email address with custom SOAP headers in the request message.
Dropping and linking the components

Procedure

1. Drop the following components from the Palette onto the design workspace: a tESBConsumer, a tMap, two tFixedFlowInput, three tXMLMap, and two tLogRow.
2. Connect each of the tFixedFlowInput with a tXMLMap using the Row > Main connection.
3. Right-click the first tXMLMap, select Row > "New Output" (Main) from the contextual menu and click tMap. Enter payload in the popup dialog box to name this row. Repeat this operation to connect another tXMLMap to tMap and name the output row header.
4. Right-click the tMap component, select Row > "New Output" (Main) from the contextual menu and click the tESBConsumer component. Enter request in the popup dialog box to name this row and accept the propagation that prompts you to get the schema from the tESBConsumer component.
5. Right-click the tESBConsumer component, select Row > Response from the contextual menu and click the third tXMLMap component.
6. Right-click the third tXMLMap component, select Row > "New Output" (Main) from the contextual menu and click one of the tLogRow components. Enter response in the popup dialog box to name this row.
7. Right-click the tESBConsumer component again, select Row > Fault from the contextual menu and click the other tLogRow component.

Configuring the components

The tLogRow components will monitor the exchanges from the response and fault messages and does not need any configuration. Press Ctrl+S to save your Job.

Configuring the tESBConsumer component

About this task

In this scenario, a public web service which is available at http://www.webservicex.net/ValidateEmail.asmx will be called by the tESBConsumer component to returns true or false for an email address. You can view the WSDL definition of the service at http://www.webservicex.net/ValidateEmail.asmx?WSDL for the service description.
Procedure

1. In the design workspace, double-click the **tESBConsumer** component to open its **Basic settings** view in the **Component** tab.

2. Click the [...] button next to **Service configuration**.

3. In the dialog box that appears, type in: `http://www.webservicex.net/ValidateEmail.asmx?WSDL` in the **WSDL** field and click the refresh button to retrieve port name and operation name. In the **Port Name** list, select the port you want to use, **ValidateEmailSoap** in this example. Click **OK** to validate your settings and close the dialog box.

Select the **Populate schema to repository on finish** to retrieve the schema from the WSDL definition, which will be used by the **tFixedFlowInput** component. This option is only available to users of **Talend Studio** with ESB. If you don’t have this option, please ignore it. The schema can be created manually in the **tFixedFlowInput** component, which will be shown later.
Click **Finish** to validate your settings and close the dialog box.

4. In the **Advanced settings** view, select the **Log messages** check box to log the content of the messages.

![tESBConsumer_1](image)

### Configuring the tFixedFlowInput components

**Procedure**

1. Double-click the first **tFixedFlowInput** component to open its **Basic settings** view in the **Component** tab.

![tFixedFlowInput_1](image)

2. For users of **Talend Studio** with ESB who have retrieved the schema from the service WSDL definition in the configuration of the **tESBConsumer** component, select **Repository** from the **Schema** list. Then click the [...] of the next field to show the **Repository Content** dialog box. Select the metadata under the **IsValidEmail** node to use it as the schema of the input message. Click **OK** to close the dialog box.

For users of **Talend Studio** without ESB, please go to the next step.
3. For users of *Talend Studio* without ESB, the schema need to be created manually. Select **Built-In** from the **Schema** list.

Click the [...] button next to **Edit Schema**. In the schema dialog box, click the [+] button to add a new line of **String** type and name it **Email**. Click **OK** to close the dialog box.
4. In the **Number of rows** field, set the number of rows as 1.

5. In the **Mode** area, select **Use Single Table** and enter "nomatter@gmail.com" into the **Value** field, which is the payload of the request message.

6. Configure the second **tFixedFlowInput** as the first one, except for its schema.
   Add two rows of **String** type to the schema and name them **id** and **company** respectively.

Give the value *Hello world!* to **id** and *Talend to company*, which are the headers of the request message.
Configuring the tXMLMap components in the input flow

About this task

Talend data integration uses schemas based on rows and columns since it has roots in relational data warehouse integration. But SOAP messages uses the XML format. XML is hierarchical and supports richer structure than rows or columns. So we need the tXMLMap to convert from the relational row/column structure to the schema expected by the SOAP service.

Procedure

1. In the design workspace, double-click the first tXMLMap component to open the Map Editor.
2. In the output table, right-click the root node and select Rename from the contextual menu. Enter IsValidEmail in the dialog box that appears.
3. Right-click the IsValidEmail node and select Set A Namespace from the contextual menu. Enter http://www.webservicex.net in the dialog box that appears.
4. Right-click the IsValidEmail node again and select Create Sub-Element from the contextual menu. Enter Email in the dialog box that appears.
5. Right-click the Email node and select As loop element from the contextual menu.
6. Click the Email node in the input table and drop it to the Expression column in the row of the Email node in the output table.
7. Click OK to validate the mapping and close the Map Editor.
8. Configure the other tXMLMap in the same way. Add a row of Document type to the output table and name it header. Create two sub-elements to it, id and company. Map the id and the company nodes in the input table to the corresponding nodes in the output table.
Configuring the tMap component

Procedure

1. In the design workspace, double-click tMap to open the Map Editor.

2. On the lower right part of the map editor, click [+] to add two rows of Document type to the output table and name them payload and headers respectively.

3. Click the payload node in the input table and drop it to the Expression column in the row of the payload node in the output table.

4. Click the header node in the input table and drop it to the Expression column in the row of the headers node in the output table.

Configuring the tXMLMap component in the output flow

About this task

The tXMLMap in the output flow will convert the response message from the XML format to the row/column structure.

Procedure

1. In the design workspace, double-click the tXMLMap component in the output flow to open the Map Editor.

2. In the input table, right-click the root node and select Rename from the contextual menu. Enter IsValidEmailResponse in the dialog box that appears.

3. Right-click the IsValidEmailResponse node and select Set A Namespace from the contextual menu. Enter http://www.webservicex.net in the dialog box that appears.
4. Right-click the IsValidEmailResponse node again and select **Create Sub-Element** from the contextual menu. Enter IsValidEmailResult in the dialog box that appears.

5. Right-click the IsValidEmailResult node and select **As loop element** from the contextual menu.

6. On the lower right part of the map editor, click \([+]\) to add a row of **String** type to the output table and name it **response**.

7. Click the IsValidEmailResult node in the input table and drop it to the **Expression** column in the row of the **response** node in the output table.

8. Click **OK** to validate the mapping and close the **Map Editor**.

### Executing the Job

Click the **Run** view to display it and click the **Run** button to launch the execution of your Job. You can also press **F6** to execute it.
As shown in the execution log, the email address nomatter@gmail.com is returned as false. The input and output SOAP messages in XML is also shown in the console. The SOAP header is sent with the request to the service.
tESBProviderFault

Serves a Talend Job cycle result as a Fault message of the Web service in case of a request response communication style.

It acts as Fault message of the Web Service response at the end of a Talend Job cycle.

**tESBProviderFault Standard properties**

These properties are used to configure tESBProviderFault running in the Standard Job framework.

The Standard tESBProviderFault component belongs to the ESB family.

*This component is relevant only when used with one of the Talend solutions with ESB, as it should be used with the Service Repository node and the Data Service creation related wizard(s).*

**Basic settings**

<table>
<thead>
<tr>
<th>Schema and Edit schema</th>
<th>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:</th>
</tr>
</thead>
<tbody>
<tr>
<td>• View schema: choose this option to view the schema only.</td>
<td>• Change to built-in property: choose this option to change the schema to Built-in for local changes.</td>
</tr>
<tr>
<td>• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Built-in: The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide.</td>
</tr>
<tr>
<td></td>
<td>Repository: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide.</td>
</tr>
<tr>
<td>EBS service settings</td>
<td>Fault title: Value of the faultString column in the Fault message.</td>
</tr>
</tbody>
</table>

**Note:**

The Row > Fault flow of tESBConsumer has a pre-defined schema whose column, faultString, is filled up with the content of the field Fault title of tESBProviderFault.
Advanced settings

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

Global Variables

| Global Variables | NB_LINE: the number of rows processed. This is an After variable and it returns an integer. |
|                 | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. |
|                 | A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. |
|                 | To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. |
|                 | For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | This component should only be used with the tESBProviderRequest component. |
| Limitation | A JDK is required for this component to operate. |

Requesting airport names based on country codes

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

This scenario involves two Jobs, one as the data service provider and the other as data service consumer. The former listens to the requests from the consumer via tESBProviderRequest, matches the country code wrapped in the request against a MySQL database table that has the country code/airport pairs via tMap, and finally returns the correct airport name via tESBProviderResponse or if no matches are found, the error message via tESBProviderFault. The Consumer sends requests to the Provider and receives the airport information or error reminders via tESBConsumer.

Building the data service provider to publish a service

The data service airport has already been defined under the Services node of the Repository tree view. Its schema has three major elements as shown below:
For how to define a service in the Studio, see *Talend Studio User Guide*.

### Assigning a Job to the defined service

**Procedure**

1. Right-click `getAirportInformationByISOCountryCode` under the Web service `airport` and from the contextual menu, select **Assign Job**.

2. In the **Operation Choice** window, select **Create a new Job and Assign it to this Service Operation**.

3. Click **Next** to open the Job description window. The Job name `airportSoap_getAirportInformationByISOCountryCode` is automatically filled in.
4. Click **Finish** to create the Job and open it in the workspace. Three components are already available.

### Adding components to arrange the data flow

**Procedure**

1. Drop **tXMLMap** and **tMysqlInput** from the Palette to the workspace.
2. Link **tESBProviderRequest** to **tXMLMap** using a **Row > Main** connection.
3. Link **tMysqlInput** to **tXMLMap** using a **Row > Main** connection.
4. Link **tXMLMap** to **tESBProviderResponse** using a **Row > *New Output*(Main)** connection.
   - In the **new Output name** pop-up window, enter the output table name, *airport_response*.
   - Click **OK** in the pop-up window that asks whether to get the schema of the target component.
5. Link tXMLMap to tESBProviderFault using a Row > *New Output*(Main) connection. In the new Output name pop-up window, enter the output table name, fault_message. Click OK in the pop-up window that asks whether to get the schema of the target component.

Configuring how requests are processed

**Procedure**

1. Double-click tMysqlInput to display its Basic settings view.

2. Fill up the basic settings for the Mysql connection and database table. Click the [...] button to open the schema editor.
1. Click the [+ ] button to add two columns, id and name, with the type of string. Click OK to close the editor. Click Guess Query to retrieve the SQL query.

4. Double-click tXMLMap to open its mapper.

5. In the main : row1 table of the input flow side (left), right-click the column name payload and from the contextual menu, select Import from Repository. Then the Metadata wizard is opened.
Select the schema of the request message and click **OK** to validate this selection. In this example, the schema is `getAirportInformationByISOCountryCode`.

6. Do the same to import the hierarchical schemas for the response/fault messages (right). In this example, these schemas are `getAirportInformationByISOCountryCodeResponse` and `getAirportInformationByISOCountryCodeFault` respectively.

7. Then to create the join to the lookup data, drop the `CountryAbbrviation` node from the main flow onto the `id` column of the lookup flow.

8. On the lookup flow table, click the wrench icon on the upper right corner to open the setting panel.
   Set **Lookup Model** as **Reload at each row**, **Match Model** as **All matches** and **Join Model** as **Inner join**.

9. On the `airport_response` output flow table, click the wrench icon on the upper right corner to open the setting panel.
   Set the **All in one** option as **true**. This ensures that only one response is returned for each request if multiple airport matches are found in the database.

10. On the `fault_message` output flow table, click the wrench icon on the upper right corner to open the setting panel.
    Set the **Catch Lookup Inner Join Reject** option as **true** to monitor the mismatches between the country code in the request and the records in the database table. Once such a situation occurs, a fault message will be generated by **tESBConsumer** and outputted via its **Row > Fault** flow.
Note:
The Row > Fault flow of tESBConsumer has a predefined schema in which the faultString column is filled with the content of the field Fault title of tESBProviderFault.

11. Drop the name column in the lookup flow onto the Expression area next to the tns:getAirportInformationByISOCountryCodeResult node in the airport_response output flow.

Drop the tns:CountryAbbreviation node in the main flow onto the Expression area next to the tns:getAirportInformationByISOCountryCodeFaultString node in the fault_message output flow. This way, the incorrect country code in the request will be shown in the faultDetail column of the Row > Fault flow of tESBConsumer.

Click OK to close the editor and validate this configuration.

12. Double-click tESBProviderFault to display its Basic settings view:

13. In the field Fault title, enter the context variable context.fault_message.

For how to define context variables, see Talend Studio User Guide.

Publishing the service to listen to requests

Procedure

1. Press Ctrl+S to save the Job.

2. Press F6 to run this Job.

[statistics] connecting to socket on port 3875
[statistics] connected
[INFO ]: org.apache.cxf.service.factory.ReflectionServiceFactoryBean - Creating Service {http://airportsoap.sopra.ds}airport from WSDL.
E:/Talend/Talend-Studio-r116103-V5.4.1NE/workspace/PROJECT_20131029/services/airport_0.1.wsdl
[INFO ]: org.apache.cxf.endpoint.ServerImpl - Setting the server’s publish address to be http://localhost:8200/airport.service

Results

The data service is published and will listen to all the requests until you click the Kill button to stop it as by default, the Keep listening option of tESBProviderRequest is selected automatically.

Now is the time to configure the consumer Job that interacts with the data service.
Building the data service consumer to request the service

Built upon tESBConsumer, the consumer Job sends two requests that contain the country codes to the Web service for the relevant airport names. If wrong country code is wrapped in the request, the error message will be returned. The country codes and the MySQL database records are as follows:

<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
</tr>
</thead>
<tbody>
<tr>
<td>CH</td>
<td>Capital Airport</td>
</tr>
<tr>
<td>DE</td>
<td>Frankfurt Airport</td>
</tr>
<tr>
<td>FR</td>
<td>Roissy Airport</td>
</tr>
<tr>
<td>NULL</td>
<td>NULL</td>
</tr>
</tbody>
</table>

country_code.txt

1  CC
2  CN

Dropping and linking the components

Procedure

1. Drop a tFileInputDelimited, a tXMLMap, a tESBConsumer and two tLogRow from the Palette to the workspace.
2. Rename one tLogRow as response and the other as fault_message.
3. Link tFileInputDelimited to tXMLMap using a Row > Main connection.
4. Link tXMLMap to tESBConsumer using a Row > *New Output*(Main) connection.
   In the new Output name pop-up window, enter the output table name, for example request.
   Click OK in the pop-up window that asks whether to get the schema of the target component.
5. Link tESBConsumer to response using the Row > Response connection.
6. Link tESBConsumer to fault_message using the Row > Fault connection.

Configuring the components

Procedure

1. Double-click tFileInputDelimited to open its Basic settings view.
2. In the **File name/stream** field, enter the context variable for the file that has the country codes, `context.filepath`.

3. Click the [...] button to open the schema editor.

4. Click the [+] button to add a column, `country_code`, for example, with the type of string. Click **OK** to close the editor.

5. Double-click **tXMLMap** to open its Map editor.
6. In the request table of the output flow side, right-click the column name payload and from the contextual menu, select Import from Repository. Then the Metadata wizard is opened.

![Metadata wizard](image)

Select the schema of the request message and click OK to validate this selection. In this example, the schema is getAirportInformationByISOCountryCode.

7. Drop the country_code column in the main flow onto the Expression area next to the tns:CountryAbbreviation node in the request output flow.

Click OK to close the editor and validate this configuration.

8. Double-click tESBConsumer to open its service configuration wizard:
9. Click the **Browse...** button to select the desired WSDL file. The **Port name** and **Operation** are automatically filled up once the WSDL file is selected. Click **OK** to close the wizard.

10. Double-click **response** to open its **Basic settings** view:

11. Select **Vertical (each row is a key/value list)** and then **Print label** for a better view of the results. Do the same to the other **tLogRow, fault_message**.

**Executing the Job**

**Procedure**

1. Press **Ctrl + S** to save the Job.
2. Press **F6** to run this Job.
As shown above, two messages are returned, one giving the airport name that matches the country code `CN` and the other giving the error details caused by the country code `CC`.
tESBProviderRequest

Wraps Talend Job as web service. It waits for a request message from a consumer and passes it to the next component.

**tESBProviderRequest Standard properties**

These properties are used to configure tESBProviderRequest running in the Standard Job framework. The Standard tESBProviderRequest component belongs to the ESB family.

*This component is relevant only when used with one of the Talend solutions with ESB, as it should be used with the Service Repository node and the Data Service creation related wizard(s).*

**Basic settings**

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Either Built-in or Repository</th>
</tr>
</thead>
<tbody>
<tr>
<td>Built-in</td>
<td>No WSDL file is configured for the Job.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the desired web service from the Repository, to the granularity of the port name and operation.</td>
</tr>
</tbody>
</table>

**Schema and Edit schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

Click [Edit schema](#) to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

- **Built-in**: The schema is created and stored locally for this component only. Related topic: see [Talend Studio User Guide](#).
- **Repository**: The schema is created and stored in the Repository, hence can be reused. Related topic: see [Talend Studio User Guide](#).

**Keep listening**

Check this box when you want to ensure that the provider (and therefore Talend Job) will continue listening for requests after processing the first incoming request.
### Advanced settings

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Log messages (Studio only)</td>
<td>Select this check box to log the message exchange between the service provider and the consumer. This option works in the Studio only.</td>
</tr>
<tr>
<td>Response timeout, sec</td>
<td>Specify the time limit in seconds for sending response to the consumer. This parameter is necessary to avoid locking of message exchanges.</td>
</tr>
<tr>
<td>Request processing queue size</td>
<td>Specify the maximum number of received requests that can be processed in parallel by the components between tESBProviderRequest and tESBProviderResponse. Note that this parameter is different from the queueSize in the &lt;TalendRuntimePath&gt;/etc/org.apache.cxf.workqueues-default.cfg which defines pool configuration for incoming requests on CXF level.</td>
</tr>
<tr>
<td>Request processing timeout, sec</td>
<td>Specify the time limit in seconds for requests to be processed by the components between the tESBProviderRequest and the tESBProviderResponse.</td>
</tr>
<tr>
<td>tStatCatcher Statistics</td>
<td>Select this check box to gather the Job processing metadata at a Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

### Global Variables

<table>
<thead>
<tr>

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NB_LINE</td>
<td>the number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>CORRELATION_ID</td>
<td>the correlation ID by which chained service calls will be grouped. This is a Flow variable and it returns a string.</td>
</tr>
</tbody>
</table>
Usage

| Usage rule | This component covers the possibility that a Talend Job can be wrapped as a service, with the ability to input a request to a service into a Job and return the Job result as a service response.

The `tESBProviderResponse` component can both deliver the payload of a SOAP message and also access the HTTP and SOAP headers of a service.

The `tESBProviderRequest` component should be used with the `tESBProviderResponse` component to provide a Job result as a response, in case of a request-response communication style.

When the SAML Token or the Service Registry is enabled in the service runtime options and if the SAML Token exists in the request header, the `tESBProviderRequest` component will get and store the SAML Token in the component variable for further use in the flow.

The `tESBProviderRequest` component will get the Correlation Value in the request header if it exists and stored it in the component variable. When the Business Correlation or the Service Registry is enabled in the service runtime options, the Correlation Value will also be added to the response. In this case, `tESBProviderRequest` will create a Correlation Value if it does not exist.

Note that the Service Registry option is only available if you subscribed to Talend Enterprise ESB solutions. For more information about how to set the runtime options, see the corresponding section in the `Talend Studio User Guide`.

| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to turn on or off the Keep listening option dynamically at runtime.

When a dynamic parameter is defined, the corresponding Keep listening option in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

| Limitation | A JDK is required for this component to operate.

Sending a message without expecting a response

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

The Jobs, which are built upon the components under the ESB/Web Services family, act as the implementations of web services defined in the Services node of the Repository. They require the creation of and association with relevant services. For more information about services, see the related topics in the `Talend Studio User Guide`. 852
In this scenario, a provider Job and a consumer Job are needed. In the meantime, the related service should already exist in the **Services** node, with the WSDL URI being [http://127.0.0.1.8088/esb/provider/?WSDL](http://127.0.0.1.8088/esb/provider/?WSDL), the port name being **TEST_ProviderJobSoapBinding** and the operation being **invoke(anyType):anyType**.

The provider Job consists of a **tESBProviderRequest**, a **tXMLMap**, and two **tLogRow** components.

- Drop the following components from the **Palette** onto the design workspace: a **tESBProviderRequest**, a **tXMLMap**, and two **tLogRow**.
- Double-click **tESBProviderRequest_1** in the design workspace to display its **Component** view and set its **Basic settings**.

- Select **Repository** from the **Property Type** list and click the three-dot button to choose the service, to the granularity of port name and operation.

- Click **OK**.
- Click the three-dot button next to **Edit schema** to view the schema of **tESBProviderRequest_1**.
• Click OK.
• Connect **tESBProviderRequest_1** to **tLogRow_1**.
• Double-click **tLogRow_1** in the design workspace to display its Component view and set its Basic settings.

![Image of tLogRow_1 settings](image)

• Click the three-dot button next to **Edit schema**. and define the schema as follow.

![Image of tXMLMap_1 settings](image)

• Connect **tLogRow_1** to **tXMLMap_1**.
• Connect **tXMLMap_1** to **tLogRow_2** and name this row as **payload**.
• In the design workspace, double-click **tXMLMap_1** to open the Map Editor.
On the lower right part of the map editor, click the plus button to add one row to the payload table and name this row as payload.

In the Type column of this payload row, select Document as the data type. The corresponding XML root is added automatically to the top table on the right side which represents the output flow.

In the payload table, right-click root to open the contextual menu.

From the contextual menu, select Create Sub-Element and type in response in the popup dialog box.

Right-click the response node and select As loop element from the contextual menu.

Repeat this operation to create a sub-element request of the root node in the input table and set the request node as loop element.

Click the request node in the input table and drop it to the Expression column in the row of the response node in the output table.

Click OK to validate the mapping and close the map editor.

Double-click tLogRow_2 in the design workspace to display its Component view and set its Basic settings.
• Click the three-dot button next to **Edit Schema** and define the schema as follow.

![Schema of tLogRow_2](image)

• Save the Job.

The consumer Job consists of a **tFixedFlowInput**, a **tXMLMap**, a **tESBConsumer**, and two **tLogRow** components.

![Design workspace](image)

• Drop the following components from the **Palette** onto the design workspace: a **tFixedFlowInput**, a **tXMLMap**, a **tESBConsumer**, and two **tLogRow**.

• Double-click **tFixedFlowInput_1** in the design workspace to display its Component view and set its **Basic settings**.
- Edit the schema of the `tFixedFlowInput_1` component.

![Image of tFixedFlowInput_1 configuration](image)

- Click the plus button to add a new line of string type and name it `payloadString`.
- Click OK.
- In the **Number of rows** field, set the number of rows as 1.
- In the **Mode** area, select **Use Single Table** and input `world` in quotations into the Value field.
- Connect tFixedFlowInput_1 to tXMLMap_1.
- Connect tXMLMap_1 to tESBConsumer_1 and name this row as payload.
- In the design workspace, double-click tXMLMap_1 to open the Map Editor.
- In the output table, right-click the root node to open the contextual menu.
- From the contextual menu, select **Create Sub-Element** and type in `request` in the popup dialog box.
- Right-click the `request` node and select **As loop element** from the contextual menu.
- Click the `payloadstring` node in the input table and drop it to the Expression column in the row of the `request` node in the output table.
- Click OK to validate the mapping and close the Map Editor.
- Start the Provider Job. In the executing log you can see:

  ```
  ...
  web service [endpoint: http://127.0.0.1:8088/esb/provider] published
  ...
  ```

- In the tESBConsumer_1 Component view, set its Basic settings.

  ![tESBConsumer_1](image)

  - Click the three-dot button next to the Service Configuration to open the editor.
• In the WSDL field, type in: `http://127.0.0.1:8088/esb/provider?WSDL`.
• Click the Refresh button to retrieve port name and operation name.
• Click OK.
• In the Basic settings of the tESBConsumer, set the Input Schema as follow:

• Set the Response Schema as follow:

• Set the Fault Schema as follow:

• Connect tESBConsumer_1 to tLogRow_1 and tLogRow_2.
• In the design workspace, double-click the tLogRow_1 component to display its Component view and set its Basic settings.
- Click the three-dot button next to **Edit Schema** and define the schema as follow:

- In the Job Design, double-click **tLogRow_2** to display its **Component** view and set its **Basic settings**.

- Click the three-dot button next to **Edit Schema** and define the schema as follow.

- Save the Job.
- Run the provider Job. In the execution log you will see:

  INFO: Setting the server's publish address to be http://127.0.0.1:8088/esb/provider
  2011-04-21 14:14:36.793:INFO::jetty-7.2.2.v20101205
  2011-04-21 14:14:37.856:INFO::Started
  SelectChannelConnector@127.0.0.1:8088
  web service [endpoint: http://127.0.0.1:8088/esb/provider] published

- Run the consumer Job. In the execution log of the Job you will see:

```java
Starting job CallProvider at 14:15 21/04/2011.
[statistics] connecting to socket on port 3942

[tLogRow_1] payload: <?xml version="1.0" encoding="UTF-8"?>
  <request>world</request>
  ### world
[tLogRow_2] content: world
[tLogRow_3] payload: <?xml version="1.0" encoding="UTF-8"?>
  <response xmlns="http://talend.org/esb/service/job">Hello, world!</response>
[statistics] disconnected
Job ESBProvider2 ended at 14:16 21/04/2011. [exit code=0]
```
tESBProviderResponse

Serves a Talend Job cycle result as a response message.
It acts as a service provider response builder at the end of each Talend Job cycle.

tESBProviderResponse Standard properties

These properties are used to configure tESBProviderResponse running in the Standard Job framework.
The Standard tESBProviderResponse component belongs to the ESB family.

This component is relevant only when used with one of the Talend solutions with ESB, as it should be used with the Service Repository node and the Data Service creation related wizard(s).

Basic settings

| Schema and Edit schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.
Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:
• View schema: choose this option to view the schema only.
• Change to built-in property: choose this option to change the schema to Built-in for local changes.
• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.
Click Sync columns to retrieve the schema from the previous component connected in the Job. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Built-in: The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide.</td>
<td></td>
</tr>
<tr>
<td>Repository: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide.</td>
<td></td>
</tr>
</tbody>
</table>

Advanced settings

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |
Global Variables

**NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

Usage

**Usage rule**
The **tESBProviderResponse** component should only be used with the **tESBProviderRequest** component to provide a Job result as response for a web service provider, in case of a request-response communication style.

**Limitation**
A JDK is required for this component to operate.

Returning Hello world response

This scenario applies only to *Talend Open Studio for ESB*, *Talend Data Services Platform* and *Talend Data Fabric*.

The jobs, which are built upon the components under the ESB/Web Services family, act as the implementations of web services defined in the **Services** node of the **Repository**. They require the creation of and association with relevant services. For more information about services, see the related topics in the *Talend Studio User Guide*.

In this scenario, a provider Job and a consumer Job are needed. In the meantime, the related service should already exist in the **Services** node, with the WSDL URI being `http://127.0.0.1.8088/esb/provider/?WSDL`, the port name being **TEST_ProviderJobSoapBinding** and the operation being **invoke(anyType):anyType**.

The provider Job consists of a **tESBProviderRequest**, a **tESBProviderResponse**, a **tXMLMap**, and two **tLogRow** components.
• Drop the following components from the Palette onto the design workspace: a `tESBProviderRequest`, a `tESBProviderResponse`, a `tXMLMap`, and two `tLogRow`.

• In the design workspace, double-click `tESBProviderRequest_1` to display its Component view and set its Basic settings.

  • Select **Repository** from the Property Type list and click the three-dot button to choose the service, to the granularity of port name and operation.

  • Click OK.

  • Click the three-dot button next to Edit schema to view its schema.
• Connect `tESBProviderRequest_1` to `tLogRow_1`.
• Double-click `tLogRow_1` to display its Component view and set its Basic settings.

• Click the three-dot button next to Edit schema and define the schema as follow.

• Connect `tLogRow_1` to `tXMLMap_1`.
• Connect `tXMLMap_1` to `tLogRow_2` and name this row as `payload`.
• In the design workspace, double-click `tXMLMap_1` to open the Map Editor.
• On the lower right part of the map editor, click the plus button to add one row to the `payload` table and name this row as `payload`. 
• In the **Type** column of this *payload* row, select **Document** as the data type. The corresponding XML root is added automatically to the top table on the right side which represents the output flow.

• In the *payload* table, right-click **root** to open the contextual menu.

• From the contextual menu, select **Create Sub-Element** and type in *response* in the popup dialog box.

• Right-click the *response* node and select **As loop element** from the contextual menu.

• Repeat this operation to create a sub-element *request* of the *root* node in the input table and set the *request* node as loop element.

• Click the *request* node in the input table and drop it to the **Expression** column in the row of the *response* node in the output table.

• Click **OK** to validate the mapping and close the map editor.

• In the design workspace, double-click **tLogRow_2** to display its **Component** view and set its **Basic settings**.
• Click the three-dot button next to **Edit schema** and define the schema as follow.

![Schema of tLogRow_2](image1)

• Connect **tLogRow_2** to **tESBProviderResponse_1**.
• In the design workspace, double-click **tESBProviderResponse_1** to open its **Component** view and set its **Basic settings**.

![tESBProviderResponse_1](image2)

• Click the three-dot button next to **Edit schema** and define the schema as follow.

![Schema of tESBProviderResponse_1](image3)

• Save the provider Job.

The consumer Job consists of a **tFixedFlowInput**, a **tXMLMap**, a **tESBConsumer**, and two **tLogRow** components.
• Drop the following components from the Palette onto the design workspace: a `FixedFlowInput`, a `XMLMap`, a `ESBConsumer`, and two `LogRow`.

• Double-click `FixedFlowInput_1` in the design workspace to display its Component view and set its Basic settings.

• Click the three-dot button next to Edit schema.

• Click the plus button to add a new line of string type and name it `payloadString`.

• Click OK.
• In the **Number of rows** field, set the number of rows as 1.
• In the **Mode** area, select **Use Single Table** and input `world` in quotations into the **Value** field.
• Connect **tFixedFlowInput** to **tXMLMap**.
• Connect **tXMLMap** to **tESBConsumer** and name this row as `payload`.
• In the design workspace, double-click **tXMLMap_1** to open the **Map Editor**.
• In the **payload** table, right-click **root** to open the contextual menu.
• From the contextual menu, select **Create Sub-Element** and type in `request` in the popup dialog box.
• Right-click the `request` node and select **As loop element** from the contextual menu.
• Click the `payloadstring` node in the input table and drop it to the **Expression** column in the row of the `request` node in the output table.

![Map Editor](image)

- Click **OK** to validate the mapping and close the **Map Editor**.
- Start the Provider Job. In the executing log you can see:

```plaintext
... web service [endpoint: http://127.0.0.1:8088/esb/provider] published ...
```

- In the **tESBConsumer_1 Component** view, set its **Basic settings**.
Click the three-dot button next to the **Service Configuration** to open the editor.

- In the **WSDL** field, type in: `http://127.0.0.1:8088/esb/provider/?WSDL`
- Click the Refresh button to retrieve port name and operation name.
- Click **OK**.
- In the **Basic settings** of the tESBConsumer, set the **Input Schema** as follows:

```plaintext
invoke(anyType):anyType(string):string
```

- Set the **Response Schema** as follows:
• Set the **Fault Schema** as follows:

- Connect **tESBConsumer_1** to **tLogRow_1** and **tLogRow_2**.
- In the design workspace, double-click **tLogRow_1** to display its **Component** view and set its **Basic settings**.

- Click the three-dot button next to **Edit Schema** and define the schema as follow.

- In the Job Design, double-click **tLogRow_2** to display its **Component** view and set its **Basic settings**.
• Click the three-dot button next to **Edit Schema** and define the schema as follow:

![](image1)

• Save the consumer Job.
• Run the provider Job. In the execution log you will see:

```
2011-04-21 15:28:26.874:INFO::jetty-7.2.2.v20101205
SelectChannelConnector@127.0.0.1:8088
web service [endpoint: http://127.0.0.1:8088/esb/provider] published
```

• Run the consumer Job. In the execution log of the Job you will see:

```
Starting job CallProvider at 15:29 21/04/2011.
[statistics] connecting to socket on port 3690
[statistics] connected
TEST_ProviderJob
TEST_ProviderJobSoapBingding
invoke
[tLogRow_2] payload: <?xml version="1.0" encoding="UTF-8">?
<response xmlns="http://talend.org/esb/service/job">Hello, world!</response>
[statistics] disconnected
Job ConsumerJob ended at 15:29 21/04/2011. [exit code=0]
```

• In the provider's log you will see the trace log:
[tLogRow_1] payload: <?xml version="1.0" encoding="UTF-8"?>
<request>world</request>

## world

[tLogRow_2] content: world

[tLogRow_3] payload: <?xml version="1.0" encoding="UTF-8"?>
<response xmlns="http://talend.org/esb/service/job">Hello, world!</response>

[statistics] disconnected

Job ProviderJob ended at 15:29 21/04/2011. [exit code=0]
tEXABulkExec

Imports data into an EXASolution database table using the IMPORT command provided by the EXASolution database in a fast way.

The import will be cancelled after a configurable number of records fail to import. Erroneous records can be sent to a log table in the same database or to a local log file.

**tEXABulkExec Standard properties**

These properties are used to configure tEXABulkExec running in the Standard Job framework.

The Standard tEXABulkExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Use an existing connection</strong></td>
<td>Select this check box and from the list displayed select the relevant connection component to reuse the connection details you have already defined.</td>
</tr>
<tr>
<td><strong>Note:</strong></td>
<td>When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to: 1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection. 2. In the child level, use a dedicated connection component to read that registered database connection. For an example about how to share a database connection across Job levels, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>
| **Property Type** | Either Built-In or Repository.  
- **Built-In**: No property data stored centrally.  
- **Repository**: Select the repository file in which the properties are stored. The database connection fields that follow are completed automatically using the data retrieved. |
<p>| <strong>Host</strong> | Enter the host or host list of the EXASol database servers. EXASol can run in a cluster environment. The valid value can be a simple IP address (for example, 172.16.173.128), an IP range list (for example, 172.16.173.128..130 that represents three servers 172.16.173.128, 172.16.173.129, and 172.16.173.130), or a comma-separated host list (for example, server1,server2,server3) of the EXASolution database cluster. |
| <strong>Port</strong> | Enter the listening port number of the EXASolution database cluster. |</p>
<table>
<thead>
<tr>
<th>Schema</th>
<th>Enter the name of the schema you want to use.</th>
</tr>
</thead>
</table>
| **User and Password** | Enter the user authentication data to access the EXASolution database.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| **Table** | Enter the name of the table to be written.  
**Note:**  
Typically the table names are stored in upper case. If you need mixed case identifiers, you have to enter the name in double quotes. For example, "\TEST_data_LOAD". |
| **Action on table** | On the table defined, you can perform one of the following operations before running the import:  
- **None**: No operation is carried out.  
- **Drop and create table**: The table is removed and created again.  
- **Create table**: The table does not exist and gets created.  
- **Create table if not exists**: The table is created if it does not exist.  
- **Truncate table**: The table content is deleted. You do not have the possibility to rollback the operation. |
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.  
- **Built-In**: You create and store the schema locally for this component only.  
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.  
**Note:**  
The columns in the schema must be in the same order as they are in the CSV file. It is not necessary to fill all columns of the defined table unless the use case or table definition expects that. |
| | Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
- **View schema**: choose this option to view the schema only.  
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.  
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion. |
### Advanced settings

#### Additional JDBC Parameters
Specify additional connection properties for the database connection you are creating. The properties are separated by semicolon and each property is a key-value pair, for example, `encryption=1;clientname=Talend`.

This field is not available if the **Use an existing connection** check box is selected.

#### Column Formats
Specify the format for Date and numeric columns if the default can not be applied.

- **Column**: The cells in this column are automatically filled with the defined schema column names.
- **Has Thousand Delimiters**: Select this check box if the value of the corresponding numeric column (only for numeric column) in the file contains thousand separators.
- **Alternative Format**: Specify the necessary format as String value if a special format is expected. The necessary format will be created from the schema column length and precision. For more information about format models, see EXASolution User Manual.

#### Source table columns
If the source is a database, configure the mapping between the source columns and the target columns in this table. Specifically configuring the mapping is optional. If you set nothing here, it is assumed that the source table has the same structure as the target table.

- **Column**: The schema column in the target table.
- **Source column name**: The name of the column in the source table.

#### Column Separator
Enter the separator for the columns of a row in the local file.

#### Column Delimiter
Enter the delimiter that encapsulates the field content in the local file.

#### Row Separator
Enter the char used to separate the rows in the local file.

#### Null representation
Enter the string that represents a NULL value in the local file. If not specified, NULL values are represented as the empty string.

#### Skip rows
Enter the number of rows (for example, header or any other prefix rows) to be omitted.

#### Encoding
Enter the character set used in the local file. By default, it is UTF8.

#### Trim column values
Specify whether spaces are deleted at the border of CSV columns.

- **No trim**: no spaces are trimmed.
- **Trim**: spaces from both left and right sides are trimmed.
<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Trim only left</td>
<td>Spaces from only the left side are trimmed.</td>
</tr>
<tr>
<td>Trim only right</td>
<td>Spaces from only the right side are trimmed.</td>
</tr>
<tr>
<td>Default Date Format</td>
<td>Specify the format for datetime values. By default, it is YYYY-MM-DD.</td>
</tr>
<tr>
<td>Default Timestamp Format</td>
<td>Specify the timestamp format used. By default, it is YYYY-MM-DD HH24:MI:SS.FF3.</td>
</tr>
</tbody>
</table>
| Thousands Separator                          | Specify the character used to separate thousand groups in a numeric text value. In the numeric format, the character will be applied to the placeholder $G$. If the text values contain this char, you have to configure it also in the Column Formats table.  
Note that this setting affects the connection property NLS_NUMERIC_CHARACTERS that defines the decimal and group characters used for representing numbers. |
| Decimal Separator                            | Specify the character used to separate the integer part of a number from the fraction. In the numeric format, the character will be applied to the placeholder $D$.                                               
Note that this setting affects the connection property NLS_NUMERIC_CHARACTERS that defines the decimal and group characters used for representing numbers. |
| Minimal number errors to reject the transfer | Specify the maximum number of invalid rows allowed during the data loading process. For example, the value 2 means the loading process will stop if the third error occurs.                                      |
| Log Error Destination                        | Specify the location where error messages will be stored.                                                                                                                                              |
| No Logging                                   | Error messages will not be saved.                                                                                                                                                                       |
| Local Log File                               | Error messages will be stored in a specified local file.                                                                                                                                               |
| Local Error Log File                         | Specify the path to the local file that stores error messages.                                                                                                                                          |
| Add current timestamp to log file name       | Select this check box to add the current timestamp before the extension of the file name for identification reasons in case you use the same file multiple times.                                    |
| Logging Table                                | Error messages will be stored in a specified table. The table will be created if it does not exist.                                                                                                      |
| Error Log Table                              | Enter the name of the table that stores error messages.                                                                                                                                                 |
| Use current timestamp to build log table     | Select this check box to use the current timestamp to build the log table for identification reasons in case you use the same table multiple times.                                                          |
| Transfer files secure                        | Select this check box to transfer the file over HTTPS instead of HTTP.                                                                                                                                     |
| Test mode (no statements are executed)       | Select this check box to have the component running in test mode, where no statements are executed.                                                                                                       |
Use precision and length from schema

Select this check box to check column values that are of numeric types (that is, Double, Float, BigDecimal, Integer, Long, and Short) against the **Length** setting (which sets the number of integer digits) and the **Precision** setting (which sets the number of decimal digits) in the schema. Only the values with neither their number of integer digits nor number of decimal digits larger than the **Length** setting and the **Precision** setting are loaded.

For example, with Length set to 4 and Precision set to 3, the values 8888.8888 and 88888.88 will be dropped; the values 8888.88 and 888.888 will be loaded.

tStatCatcher Statistics

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Dynamic settings</th>
</tr>
</thead>
<tbody>
<tr>
<td>Click the [+] button to add a row in the table and fill the <strong>Code</strong> field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.</td>
</tr>
</tbody>
</table>
| The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic**
settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

## Settings for different sources of import data

The settings for this component change depending on the source of your import data.

The component handles data coming from any of the following sources:

- Local file
- Remote file
- EXASol database
- Oracle database
- JDBC-compliant database

### Local file

The local file is not transferred by uploading the file. Instead, the driver establishes a (secure) web service that sends the URL to the database, and the database retrieves the file from this local web service. Because the port of this service cannot be explicitly defined, this method requires a transparent network between the local Talend Job and the EXASolution database.

<table>
<thead>
<tr>
<th><strong>File name</strong></th>
<th>Specify the path to the local file to be imported.</th>
</tr>
</thead>
</table>

### Remote file

This method works with a file that is accessible on a server through the following protocols: SCP, SFTP, FTP, HTTP, or HTTPS.

<table>
<thead>
<tr>
<th><strong>Use predefined connection</strong></th>
<th>It is possible, via the SQL interface, to set up a named connection in the EXASolution database itself. Select this option if you want to use such a connection, and provide its name.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>To know what connections are available, look at the table SYS.EXA_DBA_CONNECTIONS in the database.</td>
</tr>
<tr>
<td></td>
<td>The connection must contain a URL with one of the following protocols: SCP, SFTP, FTP, HTTP, or HTTPS.</td>
</tr>
<tr>
<td></td>
<td>The URL must not contain the file name. The file name is always dynamic and must be provided by the component configuration.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Remote file server URL</strong></th>
<th>Specify the URL to the file server, without the file name itself.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>File name</strong></td>
<td>Specify the name of the file you want to fetch from the server.</td>
</tr>
<tr>
<td><strong>Query parameters</strong></td>
<td>If the web service depends on query parameters, specify them here.</td>
</tr>
<tr>
<td></td>
<td>For example, if you want to get a file from an HDFS file system via the web service, you need to add some additional parameters such as open=true.</td>
</tr>
</tbody>
</table>
**EXASol database**

An EXASolution database can also serve as a remote source for the data. The source can be a table or a specific query.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Use predefined connection</strong></td>
<td>It is possible, via the SQL interface, to set up a named connection in the EXASolution database itself. Select this option if you want to use such a connection, and provide its name. To know what connections are available, look at the table SYS.EXA_DBA_CONNECTIONS in the database. The username and password must be provided by the component and not as part of the predefined connection.</td>
</tr>
<tr>
<td><strong>EXASol database host</strong></td>
<td>Specify the host of the remote EXASolution database. This field can also be used to access a cluster.</td>
</tr>
<tr>
<td><strong>Use self defined query</strong></td>
<td>Select this check box if you want to use a specific query to get the data. This method is preferred if, for example, your data needs to be filtered (using a where condition), joined or converted.</td>
</tr>
<tr>
<td><strong>Source query</strong></td>
<td>If you want to use a specific query, enter the query in this field.</td>
</tr>
<tr>
<td><strong>Database or schema</strong></td>
<td>If you are not using a specific query, enter the schema name for the source table in this field.</td>
</tr>
<tr>
<td><strong>Source table</strong></td>
<td>If you are not using a specific query, enter the table name in this field. The mapping between the source table columns and the target table columns (schema columns) can be set in the advanced settings.</td>
</tr>
<tr>
<td><strong>Use user authentication</strong></td>
<td>Select this check box if you want to use Basic Authentication when connecting to the source database.</td>
</tr>
<tr>
<td><strong>Remote user and Remote users password</strong></td>
<td>Enter the user name and password needed to access the source database.</td>
</tr>
</tbody>
</table>

**Oracle database**

An Oracle database can also serve as a remote source for the data. Access to an Oracle database requires an Enterprise license for the EXASolution database and does not work with the free edition. The source can be a table or a specific query.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Use predefined connection</strong></td>
<td>It is possible, via the SQL interface, to set up a named connection in the EXASolution database itself. Select this option if you want to use such a connection, and provide its name. To know what connections are available, look at the table SYS.EXA_DBA_CONNECTIONS in the database. The username and password must be provided by the component and not as part of the predefined connection.</td>
</tr>
<tr>
<td><strong>Oracle database URL</strong></td>
<td>Specify the JDBC URL to the Oracle database.</td>
</tr>
</tbody>
</table>
**Use self defined query**
Select this check box if you want to use a specific query to get the data. This method is preferred if, for example, your data needs to be filtered (using a `where` condition), joined or converted.

**Source query**
If you want to use a specific query, enter the query in this field.

**Database or schema**
If you are not using a specific query, enter the schema name for the source table in this field.

**Source table**
If you are not using a specific query, enter the table name in this field. The mapping between the source table columns and the target table columns (schema columns) can be set in the advanced settings.

**Use user authentication**
Select this check box if you want to use Basic Authentication when connecting to the source database.

**Remote user and Remote users password**
Enter the user name and password needed to access the source database.

**JDBC-compliant database**
The free edition of the EXASolution database supports MySQL and PostgreSQL databases, and others are available in the Enterprise edition. The source can be table or a self defined query.

Nearly all enterprise-grade databases provide a JDBC interface.

**Use predefined connection**
It is possible, via the SQL interface, to set up a named connection in the EXASolution database itself. Select this option if you want to use such a connection, and provide its name.

To know what connections are available, look at the table `SYS.EXA_DBA_CONNECTIONS` in the database.

The username and password must be provided by the component and not as part of the predefined connection.

**JDBC database URL**
Specify the JDBC URL to the source database.

**Use self defined query**
Select this check box if you want to use a specific query to get the data. This method is preferred if, for example, your data needs to be filtered (using a `where` condition), joined or converted.

**Source query**
If you want to use a specific query, enter the query in this field.

**Database or schema**
If you are not using a specific query, enter the schema name for the source table in this field.

**Source table**
If you are not using a specific query, enter the table name in this field. The mapping between the source table columns and the target table columns (schema columns) can be set in the advanced settings.

**Use user authentication**
Select this check box if you want to use Basic Authentication when connecting to the source database.

**Remote user and Remote users password**
Enter the user name and password needed to access the source database.
Importing data into an EXASolution database table from a local CSV file

This scenario describes a Job that writes employee information into a CSV file, then loads the data from this local file into a newly created EXASolution database table using the tEXABulkExec component, and finally retrieves the data from the table and displays it on the console.

Dropping and linking the components

Procedure
1. Create a new Job and add the following components by typing their names in the design workspace or dropping them from the Palette: a tFixedFlowInput component, a tFileOutputDelimited component, a tEXABulkExec component, a tEXAInput component, and a tLogRow component.
2. Connect the tFixedFlowInput component to the tFileOutputDelimited component using a Row > Main connection.
3. Do the same to connect the tEXAInput component to the tLogRow component.
4. Connect the tFixedFlowInput component to the tEXABulkExec component using a Trigger > On Subjob Ok connection.
5. Do the same to connect the tEXABulkExec component to the tEXAInput component.

Configuring the components

Preparing the source data

Procedure
1. Double-click the tFixedFlowInput component to open its Basic settings view.
2. Click the [...] button next to **Edit schema** to open the **Schema** dialog box.

3. Click the [*] button to add six columns: **EmployeeID** of the **Integer** type, **EmployeeName**, **OrgTeam** and **JobTitle** of the **String** type, **OnboardDate** of the **Data** type with the *yyyy-MM-dd* date pattern, and **MonthSalary** of the **Double** type.

4. Click **OK** to close the dialog box and accept schema propagation to the next component.
5. In the **Mode** area, select **Use Inline Content (delimited file)** and enter the following employee data in the **Content** field.

```
12000;James;Dev Team;Developer;2008-01-01;15000.01
12001;Jimmy;Dev Team;Developer;2008-11-22;13000.11
12002;Herbert;QA Team;Tester;2008-05-12;12000.22
12003;Harry;Doc Team;Technical Writer;2009-03-10;12000.33
12004;Ronald;QA Team;Tester;2009-06-20;12500.44
12005;Mike;Dev Team;Developer;2009-10-15;14000.55
12006;Jack;QA Team;Tester;2009-03-25;13500.66
12007;Thomas;Dev Team;Developer;2010-02-20;16000.77
12008;Michael;Dev Team;Developer;2010-07-15;14000.88
12009;Peter;Doc Team;Technical Writer;2011-02-10;12500.99
```

6. Double-click the **tFileOutputDelimited** component to open its **Basic settings** view.

7. In the **File Name** field, specify the file into which the input data will be written. In this example, it is "E:/employee.csv".

8. Click **Advanced settings** to open the **Advanced settings** view of the **tFileOutputDelimited** component.

9. Select the **Advanced separator (for numbers)** check box and in the **Thousands separator** and **Decimal separator** fields displayed, specify the separators for thousands and decimal. In this example, the default values "," and "." are used.

---

**Loading the source data into a newly created EXASolution database table**

**Procedure**

1. Double-click the **tEXABulkExec** component to open its **Basic settings** view.
2. Fill in the Host, Port, Schema, User and Password fields with your EXASolution database connection details.

3. In the Table field, enter the name of the table into which the source data will be written. In this example, the target database table is named "employee" and it does not exist.

4. Select Create table from the Action on table list to create the specified table.

5. In the Source area, select Local file as the source for the input data, and then specify the file that contains the source data. In this example, it is "E:/employee.csv".

6. Click the [...] button next to Edit schema to open the Schema dialog box and define the schema, which should be the same as that of the tFixedSizeInput component. Then click OK to validate these changes and close the dialog box.

7. Click Advanced settings to open the Advanced settings view of the tEXABulkExec component.

8. In the Column Formats table, for the two numeric fields EmployeeID and MonthSalary, select the corresponding check boxes in the Has Thousand Delimiters column, and then define their format.
model strings in the corresponding fields of the Alternative Format column. In this example, "99G999" for EmployeeID and "99G999D99" for MonthSalary.

9. Make sure that the Thousands Separator and Decimal Separator fields have values identical to those of the tFileOutputDelimited component and keep the default settings for the other options.

Retrieving data from the EXASolution database table

Procedure

1. Double-click the tEXAInput component to open its Basic settings view.

2. Fill in the Host name, Port, Schema name, Username and Password fields with your EXASolution database connection details.

3. In the Table Name field, enter the name of the table from which the data will be retrieved. In this example, it is "employee".

4. Click the [...] button next to Edit schema to open the Schema dialog box and define the schema, which should be the same as that of the tFixedFlowInput component. Then click OK to close the dialog box and accept schema propagation to the next component.

5. Click the Guess Query button to fill the Query field with the following auto-generated SQL statement that will be executed on the specified table.

   ```sql
   SELECT employee.EmployeeID, 
         employee.EmployeeName, 
         employee.OrgTeam, 
         employee.JobTitle, 
         employee.OnboardingDate, 
         employee.MonthSalary
   FROM employee
   ```

6. Double-click the tLogRow component to open its Basic settings view.
7. In the **Mode** area, select the **Table (print values in cells of a table)** option for better readability of the output.

### Saving and executing the Job

**Procedure**

1. Press **Ctrl + S** to save the Job.
2. Press **F6** to execute the Job.

```
[statistics] connecting to socket on port 3680

```

[statistics] disconnected

As shown above, the employee data is written into the specified EXASolution database table and is then retrieved and displayed on the console.
**tEXAClose**

Closes an active connection to an EXASolution database instance to release the occupied resources.

### tEXAClose Standard properties

These properties are used to configure tEXAClose running in the Standard Job framework.

The Standard tEXAClose component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

#### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component List</td>
<td>Select the tEXAConnection component that opens the connection you need to close from the list.</td>
</tr>
</tbody>
</table>

#### Advanced settings

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

#### Global Variables

**Global Variables**

- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

  A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

  To fill up a field or expression with a variable, press `Ctrl + Space` to access the variable list and choose the variable to use from it.

  For further information about variables, see [Talend Studio User Guide](#).

#### Usage

**Usage rule**

This component is more commonly used with other EXASolution components, especially with the `tEXAConnection` and `tEXACommit` components.

**Dynamic settings**

Click the `[+]` button to add a row in the table and fill the **Code** field with a context variable to choose your database.
connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenario

No scenario is available for the Standard version of this component yet.
tEXACommit

Validates the data processed through the Job into the connected EXASolution database.

Using a unique connection, this component commits in one go a global transaction instead of doing that on every row or every batch and thus provides gain in performance.

**tEXACommit Standard properties**

These properties are used to configure tEXACommit running in the Standard Job framework.

The Standard tEXACommit component belongs to the Databases family.

The component in this framework is available in all Talend products.

*Note:* This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component List</td>
<td>Select the tEXAConnection component for which you want the commit action to be performed.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default and it allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection after the component has performed its task.</td>
</tr>
</tbody>
</table>

*Warning:* If you want to use a Row > Main connection to link tEXACommit to your Job, your data will be committed row by row. In this case, do not select the Close Connection check box or your connection will be closed before the end of your first row commit.

### Advanced settings

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

### Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. |

---

890
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is more commonly used with other EXASolution components, especially with the tEXAConnection and tEXARollback components.</th>
</tr>
</thead>
</table>

**Dynamic settings**

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

**Related scenario**

For a similar scenario using other database, see Inserting data in mother/daughter tables on page 2437.
tEXAConnection

Opens a connection to an EXASolution database instance that can then be reused by other EXASolution components.

**tEXAConnection Standard properties**

These properties are used to configure tEXAConnection running in the Standard Job framework.

The Standard tEXAConnection component belongs to the Databases and the ELT families.

The component in this framework is available in all Talend products.

*Note:* This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td><strong>Property Type</strong></td>
<td>Either <strong>Built-In</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-In</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the repository file in which the properties are stored. The database connection fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><strong>Host</strong></td>
<td>Enter the host or host list of the EXASol database servers. EXASol can run in a cluster environment. The valid value can be a simple IP address (for example, 172.16.173.128 ), an IP range list (for example, 172.16.173.128..130 that represents three servers 172.16.173.128, 172.16.173.129, and 172.16.173.130), or a comma-separated host list (for example, server1,server2,server3) of the EXASolution database cluster.</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Enter the listening port number of the EXASolution database cluster.</td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>Enter the name of the schema you want to use.</td>
</tr>
<tr>
<td><strong>Username</strong> and <strong>Password</strong></td>
<td>Enter the user authentication data to access the EXASolution database. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td><strong>Use or register a shared DB Connection</strong></td>
<td>Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the <strong>Shared DB Connection Name</strong> field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database</td>
</tr>
</tbody>
</table>
connection components from different Job levels that can be either parent or child.

This option is incompatible with the Use dynamic job and Use an independent process to run subjob options of the tRunJob component. Using a shared connection together with a tRunJob component with either of these two options enabled will cause your Job to fail.

### Advanced settings

| **Auto Commit** | Select this check box to commit any changes to the database automatically upon the transaction.

With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component.

Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component. |

| **Additional JDBC Parameters** | Specify additional connection properties for the database connection you are creating. The properties are separated by semicolon and each property is a key-value pair, for example, encryption=1;clientname=Talend.

This field is not available if the Use an existing connection check box is selected. |

| **tStatCatcher Statistics** | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

### Global Variables

| **Global Variables** | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide. |

| **Global Variables** | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide. |
Usage

| Usage rule | This component is more commonly used with other EXASolution components, especially with the tEXACommit and tEXARollback components. |

Related scenario

For a similar scenario using other database, see Inserting data in mother/daughter tables on page 2437.
tEXAInput

Retrieves data from an EXASolution database based on a query with a strictly defined order which corresponds to the schema definition, and passes the data to the next component.

**tEXAInput Standard properties**

These properties are used to configure tEXAInput running in the Standard Job framework.

The Standard tEXAInput component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td><strong>Property Type</strong></td>
<td>Either <strong>Built-In</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Built-In</strong>: No property data stored centrally.</td>

<tr>
<td></td>
<td>For more information about setting up and storing database connection parameters, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and from the list displayed select the relevant connection component to reuse the connection details you have already defined.

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.  
2. In the child level, use a dedicated connection component to read that registered database connection.  

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
| **Host name** | Enter the host or host list of the EXASol database servers. EXASol can run in a cluster environment. The valid value can be a simple IP address (for example, 172.16.173.128), an IP range list (for example, 172.16.173.128..130 that represents three servers 172.16.173.128, 172.16.173.129, and 172.16.173.130), or a comma-separated host list (for example, server1,server2,server3) of the EXASolution database cluster. |
| **Port** | Enter the listening port number of the EXASolution database cluster. |
| **Schema name** | Enter the name of the schema you want to use. |
| **Username and Password** | Enter the user authentication data to access the EXASolution database. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.  
- **Built-in**: You create and store the schema locally for this component only.  
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.  
  - Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
    - **View schema**: choose this option to view the schema only.  
    - **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
    - **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window. |
| **Table Name** | Enter the name of the table to be queried. |
| **Query Type and Query** | Enter the database query, paying particularly attention to the proper sequence of the fields in order to match the schema definition. |
| **Guess Query** | Click the button to generate the query that corresponds to the table schema in the **Query** field. |
| **Guess schema** | Click the button to retrieve the schema from the table. |

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>This component is usually used as a start component of a Job or subjob and it needs an output link.</td>
<td></td>
</tr>
<tr>
<td>Dynamic settings</td>
<td>Click the [+ ] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an</td>
</tr>
</tbody>
</table>
environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see [Reading data from databases through context-based dynamic connections](#) on page 2457 and [Reading data from different MySQL databases using dynamically loaded connection parameters](#) on page 491. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

### Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

### Related scenario

For a related scenario, see [Importing data into an EXASolution database table from a local CSV file](#) on page 882.

For similar scenarios using other databases, see:
tEXAOOutput

Writes, updates, modifies or deletes data in an EXASolution database by executing the action defined on the table and/or on the data in the table, based on the flow incoming from the preceding component.

tEXAOOutput Standard properties

These properties are used to configure tEXAOOutput running in the Standard Job framework.
The Standard tEXAOOutput component belongs to the Databases family.
The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
</table>
| Property Type | Either Built-In or Repository.  
- Built-In: No property data stored centrally.  
- Repository: Select the repository file in which the properties are stored. The database connection fields that follow are completed automatically using the data retrieved. |
| ![ ] | Click this icon to open a database connection wizard and store the database connection parameters you set in the component Basic settings view.  
For more information about setting up and storing database connection parameters, see Talend Studio User Guide. |

Use an existing connection

Select this check box and from the list displayed select the relevant connection component to reuse the connection details you have already defined.

Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:
1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
| Host | Enter the host or host list of the EXASol database servers. EXASol can run in a cluster environment. The valid value can be a simple IP address (for example, 172.16.173.128), an IP range list (for example, 172.16.173.128..130 that represents three servers 172.16.173.128, 172.16.173.129, and 172.16.173.130), or a comma-separated host list (for example, server1,server2,server3) of the EXASolution database cluster. |
| Port | Enter the listening port number of the EXASolution database cluster. |
| Schema name | Enter the name of the schema you want to use. |
| Username and Password | Enter the user authentication data to access the EXASolution database. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| Table | Enter the name of the table to be written. Note that only one table can be written at a time. |
| Action on table | On the table defined, you can perform one of the following operations:  
  • None: No operation is carried out.  
  • Drop and create table: The table is removed and created again.  
  • Create table: The table does not exist and gets created.  
  • Create table if does not exist: The table is created if it does not exist.  
  • Drop table if exists and create: The table is removed if it already exists and created again.  
  • Clear table: The table content is deleted.  
  • Truncate table: The table content is deleted. You don’t have the possibility to rollback the operation. |
| Action on data | On the data of the table defined, you can perform:  
  • Insert: Add new entries to the table. If duplicates are found, Job stops.  
  • Update: Make changes to existing entries  
  • Insert or update: Insert a new record. If the record with the given reference already exists, an update would be made.  
  • Update or insert: Update the record with the given reference. If the record does not exist, a new record would be inserted.  
  • Delete: Remove entries corresponding to the input flow. |
**Warning:**
You must specify at least one column as a primary key on which the Update and Delete operations are based. You can do that by clicking Edit Schema and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the Advanced settings view where you can simultaneously define primary keys for the update and delete operations. To do that: Select the Use field options check box and then in the Key in update column, select the check boxes next to the column name on which you want to base the update operation. Do the same in the Key in delete column for the deletion operation.

<table>
<thead>
<tr>
<th>Schema and Edit schema</th>
</tr>
</thead>
<tbody>
<tr>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td>• <strong>Built-In</strong>: You create and store the schema locally for this component only.</td>
</tr>
<tr>
<td>• <strong>Repository</strong>: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
</tr>
<tr>
<td>Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:</td>
</tr>
<tr>
<td>• <strong>View schema</strong>: choose this option to view the schema only.</td>
</tr>
<tr>
<td>• <strong>Change to built-in property</strong>: choose this option to change the schema to Built-in for local changes.</td>
</tr>
<tr>
<td>• <strong>Update repository connection</strong>: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.</td>
</tr>
<tr>
<td>When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.</td>
</tr>
<tr>
<td>You can find more details about how to verify default values in retrieved schema in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Die on error</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select the check box to stop the execution of the Job when an error occurs.</td>
</tr>
<tr>
<td>Clear the check box to skip any rows on error and complete the process for error-free rows. When errors are skipped, you can collect the rows on error using a Row &gt; Reject link.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Advanced settings</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Use commit control</strong></td>
</tr>
<tr>
<td>Select this box to display the Commit every field in which you can define the number of rows to be processed before committing.</td>
</tr>
</tbody>
</table>
### Additional JDBC parameters

Specify additional connection properties for the database connection you are creating. The properties are separated by semicolon and each property is a key-value pair, for example, `encryption=1;clientname=Talend`.

This field is not available if the **Use an existing connection** check box is selected.

### Additional Columns

This option is not offered if you create (with or without drop) the DB table. This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing.

- **Name**: Enter the name of the column to be modified or inserted.
- **SQL expression**: Enter the SQL expression to be executed to modify or insert data in the corresponding columns.
- **Position**: Select *Before*, *After* or *Replace*, depending on the action to be carried out on the reference column.
- **Reference column**: Type in a column of reference that can be used to place or replace the new or altered column.

### Use field options

Select this check box to customize a request for the corresponding column, particularly if multiple actions are being carried out on the data.

- **Key in update**: Select the check box for the corresponding column based on which the data is updated.
- **Key in delete**: Select the check box for the corresponding column based on which the data is deleted.
- **Updatable**: Select the check box if the data in the corresponding column can be updated.
- **Insertable**: Select the check box if the data in the corresponding column can be inserted.

### Enable debug mode

Select this check box to display each step of the process by which the data is written in the database.

### Use batch mode

Select this check box to activate the batch mode for data processing, and in the **Batch Size** field displayed enter the number of records to be processed in each batch.

### tStatCatcher Statistics

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE</strong></td>
<td>the number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_UPDATED</strong></td>
<td>the number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_INSERTED</strong></td>
<td>the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_DELETED</strong></td>
<td>the number of rows deleted. This is an After variable and it returns an integer.</td>
</tr>
</tbody>
</table>
**Usage**

**Usage rule**

This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible.

This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in an EXASolution database. It also allows you to create a reject flow using a Row > Rejects link to filter data in error. For a related scenario, see Retrieving data in error with a Reject link on page 2485.

**Dynamic settings**

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

**Limitation**

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

**NB_LINE_REJECTED**: the number of rows rejected. This is an After variable and it returns an integer.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.
Related scenario

For similar scenarios using other databases, see:

- Inserting a column and altering data using tMysqlOutput on page 2477.
tEXARollback

Cancels the transaction commit in the connected EXASolution database.
It allows you to roll back any changes made in the EXASolution database to prevent partial transaction commit if an error occurs.

tEXARollback Standard properties

These properties are used to configure tEXARollback running in the Standard Job framework.
The Standard tEXARollback component belongs to the Databases family.
The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component List</td>
<td>Select the tEXAConnection component for which you want the rollback action to be performed.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default and it allows you to close the database connection once the rollback is done. Clear this check box to continue to use the selected connection after the component has performed its task.</td>
</tr>
</tbody>
</table>

Advanced settings

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

For further information about variables, see Talend Studio User Guide.
Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is more commonly used with other EXASolution components, especially with the tEXAConnection and tEXACommit components.</th>
</tr>
</thead>
</table>

Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related Scenario

For a similar scenario using other database, see Rollback from inserting data in mother/daughter tables on page 2440.
tEXARow

Executes SQL queries on an EXASolution database.

Depending on the nature of the query and the database, tEXARow acts on the actual structure of the database, or indeed the data, although without modifying them. The Row suffix indicates that it is used to channel a flow in a Job although it does not produce any output data.

**tEXARow Standard properties**

These properties are used to configure tEXARow running in the Standard Job framework.

The Standard tEXARow component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
</table>
| Property Type | Either **Built-In** or **Repository**.  
  - **Built-In**: No property data stored centrally.  
  - **Repository**: Select the repository file in which the properties are stored. The database connection fields that follow are completed automatically using the data retrieved. |
| Use an existing connection | Select this check box and from the list displayed select the relevant connection component to reuse the connection details you have already defined.  
  
  **Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:  
  1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.  
  2. In the child level, use a dedicated connection component to read that registered database connection.  
  For an example about how to share a database connection across Job levels, see **Talend Studio User Guide**. |
| Host | Enter the host or host list of the EXASol database servers. EXASol can run in a cluster environment. The valid value can be a simple IP address (for example, 172.16.173.128), an IP range list (for example, 172.16.173.128..130). |
represents three servers 172.16.173.128, 172.16.173.129, and 172.16.173.130, or a comma-separated host list (for example, server1,server2,server3) of the EXASolution database cluster.

<table>
<thead>
<tr>
<th>Port</th>
<th>Enter the listening port number of the EXASolution database cluster.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Schema name</td>
<td>Enter the name of the schema you want to use.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>Enter the user authentication data to access the EXASolution database.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Schema and Edit schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <code>line</code> when naming the fields.</td>

<tr>
<td></td>
<td>• <strong>Repository</strong>: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
</tr>
<tr>
<td></td>
<td>Click <strong>Edit schema</strong> to make changes to the schema. If the current schema is of the <strong>Repository</strong> type, three options are available:</td>
</tr>
<tr>
<td></td>
<td>• <strong>View schema</strong>: choose this option to view the schema only.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Change to built-in property</strong>: choose this option to change the schema to <strong>Built-In</strong> for local changes.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Update repository connection</strong>: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the <strong>Repository Content</strong> window.</td>
</tr>
<tr>
<td>Table Name</td>
<td>Enter the name of the table to be processed.</td>
</tr>
<tr>
<td>Query Type</td>
<td>Either <strong>Built-In</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Built-In</strong>: Enter the query manually or with the help of the SQLBuilder.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Repository</strong>: Select the appropriate query from the Repository. The <strong>Query</strong> field is then completed automatically.</td>
</tr>
<tr>
<td>Guess Query</td>
<td>Click the <strong>Guess Query</strong> button to generate the query that corresponds to the table schema in the <strong>Query</strong> field.</td>
</tr>
<tr>
<td>Query</td>
<td>Enter the database query paying particularly attention to the proper sequence of the fields in order to match the schema definition.</td>
</tr>
</tbody>
</table>
**Advanced settings**

**Die on error**
Select the check box to stop the execution of the Job when an error occurs.
Clear the check box to skip any rows on error and complete the process for error-free rows. When errors are skipped, you can collect the rows on error using a **Row > Reject** link.

**Additional JDBC parameters**
Specify additional connection properties for the database connection you are creating. The properties are separated by semicolon and each property is a key-value pair, for example, `encryption=1;clientname=Talend`.
This field is not available if the **Use an existing connection** check box is selected.

**Propagate QUERY’s recordset**
Select this check box to insert the query results in one of the flow columns. Select the particular column from the **use column** list.

**Use PreparedStatement**
Select this check box to use prepared statements and in the **Set PreparedStatement Parameters** table displayed, add as many parameters as needed and set the following attributes for each parameter:
- **Parameter Index**: enter the index of the prepared statement parameter.
- **Parameter Type**: click in the cell and select the type of the parameter from the list.
- **Parameter Value**: enter the value of the parameter.

**Commit every**
Enter the number of rows to be included in each batch before the data is written. This option guarantees the quality of the transaction (although there is no rollback option) and improves performance.

**tStatCatcher Statistics**
Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

**Global Variables**

**Global Variables**

**QUERY**: the query statement being processed. This is a Flow variable and it returns a string.

**MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see **Talend Studio User Guide**.
Usage

</tr>
</tbody>
</table>
Global Variables

**NB_FILE**: the number of files processed. This is an After variable and it returns an integer.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

Usage

**Usage rule**

This component is typically used as a single component subjob but can also be used as an output or end object. eXist-db is an open source database management system built using XML technology. It stores XML data according to the XML data model and features efficient, index-based XQuery processing.

For further information about XQuery, see *XQuery*.

For further information about the XQuery update extension, see *XQuery update extension*.

**Limitation**

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

Related scenarios

No scenario is available for the Standard version of this component yet.
tEXistGet

Retrieves selected resources from a remote eXist database to a defined local directory.

**tEXistGet Standard properties**

These properties are used to configure tEXistGet running in the Standard Job framework.

The Standard tEXistGet component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Basic settings**

Retrieving resources from a remote eXist DB server

This is a single-component Job that retrieves data from a remote eXist DB server and download the data to a defined local directory.

This simple Job requires one component: tEXistGet.
Procedure

1. Drop the tEXistGet component from the Palette into the design workspace.
2. Double-click the tEXistGet component to open the Component view and define the properties in its Basic settings view.

3. Fill in the URI field with the URI of the eXist database you want to connect to. In this scenario, the URI is `xmldb:exist://192.168.0.165:8080/exist/xmlrpc`. Note that the URI used in this use case is for demonstration purposes only and is not an active address.
4. Fill in the Collection field with the path to the collection of interest on the database server, `/db/talend` in this scenario.
5. Fill in the Driver field with the driver for the XML database, `org.exist.xmldb.DatabaseImpl` in this scenario.
6. Fill in the Username and Password fields by typing in `admin` and `talend` respectively in this scenario.
7. Click the three-dot button next to the Local directory field to set a path for saving the XML file downloaded from the remote database server. In this scenario, set the path to your desktop, for example `C:/Documents and Settings/galano/Desktop/ExistGet`.
8. In the Files field, click the plus button to add a new line in the Filemask area, and fill it with a complete file name to retrieve data from a particular file on the server, or a filemask to retrieve data from a set of files. In this scenario, fill in `dictionary_en.xml`.
9. Save your Job and press F6 to execute it.
The XML file *dictionary_en.xml* is retrieved and downloaded to the defined local directory.
tEXistList

Lists the resources stored on a remote eXist database.

**tEXistList Standard properties**

These properties are used to configure tEXistList running in the Standard Job framework.

The Standard tEXistList component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>

</tbody>
</table>
Global Variables

**Global Variables**

**NB_FILE**: the number of files iterated upon. This is an After variable, and it returns an integer.

**CURRENT_FILE**: the current file name. This is a Flow variable and it returns a string.

**CURRENT_FILEPATH**: the current file path. This is a Flow variable and it returns a string.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](https://help.talend.com).

Usage

**Usage rule**

This component is typically used along with a [tEXistGet component](https://help.talend.com) to retrieve the files listed, for example. eXist-db is an open source database management system built using XML technology. It stores XML data according to the XML data model and features efficient, index-based XQuery processing.

For further information about XQuery, see [XQuery](https://help.talend.com).

For further information about the XQuery update extension, see [XQuery update extension](https://help.talend.com).

**Limitation**

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

Related scenario

For a related scenario, see [Listing and getting files/folders on an FTP directory](https://help.talend.com) on page 1222.
tEXistPut

Uploads specified files from a defined local directory to a remote eXist database.

tEXistPut Standard properties

These properties are used to configure tEXistPut running in the Standard Job framework.
The Standard tEXistPut component belongs to the Databases family.
The component in this framework is available in all Talend products.

Basic settings

| Use an existing connection/Component List | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level. |
| URI | URI of the database you want to connect to. |
| Collection | Enter a path to indicate where the resource is to be saved on the server. |
| Driver | This field is automatically populated with the standard driver. Note: Users can enter a different driver, depending on their needs. |
| Username and Password | User authentication information. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| Local directory | Path to the source location of the file(s). |
| Files | Click the plus button to add the lines you want to use as filters: Filemask: enter the filename or filemask using wildcharacters (*) or regular expressions. |

Advanced settings

| tStatCatcher Statistics | Select this check box to gather the job processing metadata at a job level as well as at each component level. |
## Global Variables

| Global Variables | **NB_FILE**: the number of files processed. This is an After variable and it returns an integer.  
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
For further information about variables, see *Talend Studio User Guide*. |

## Usage

| Usage rule | This component is typically used as a single component subJob but can also be used as an output or end object.  
eXist-db is an open source database management system built using XML technology. It stores XML data according to the XML data model and features efficient, index-based XQuery processing.

---

**Related scenarios**

No scenario is available for the Standard version of this component yet.
tExternalSortRow

Sorts input data based on one or several columns, by sort type and order, using an external sort application.

**tExternalSortRow Standard properties**

These properties are used to configure tExternalSortRow running in the Standard Job framework. The Standard tExternalSortRow component belongs to the Processing family. The component in this framework is available in all Talend products.

**Basic settings**

| **Schema and Edit Schema** | A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either Built-in or stored remotely in the Repository. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
  • View schema: choose this option to view the schema only.  
  • Change to built-in property: choose this option to change the schema to Built-in for local changes.  
  • Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. Click Sync columns to retrieve the schema from the previous component connected in the Job. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-in</strong></td>
<td>The schema will be created and stored locally for this component only. Related topic: see Talend Studio User Guide.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>The schema already exists and is stored in the Repository, hence can be reused in various projects and Job flowcharts. Related topic: see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>
| **File Name** | Name or path to the file to be processed and/or the variable to be used.  
For further information about how to define and use a variable in a Job, see Talend Studio User Guide. |
| **Field separator** | Character, string or regular expression to separate fields. |
| **External command “sort” path** | Enter the path to the external file containing the sorting algorithm to use. |
### Criteria

<table>
<thead>
<tr>
<th><strong>Criteria</strong></th>
<th>Click the plus button to add as many lines as required for the sort to be complete. By default the first column defined in your schema is selected.</th>
</tr>
</thead>
</table>

**Schema column**: Select the column label from your schema, which the sort will be based on. Note that the order is essential as it determines the sorting priority.

**Sort type**: Numerical and Alphabetical order are proposed. More sorting types to come.

**Order**: Ascending or descending order.

### Advanced settings

<table>
<thead>
<tr>
<th><strong>Maximum memory</strong></th>
<th>Type in the size of physical memory you want to allocate to sort processing.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Temporary directory</strong></td>
<td>Specify the temporary directory to process the sorting command.</td>
</tr>
<tr>
<td><strong>Set temporary input file directory</strong></td>
<td>Select the check box to activate the field in which you can specify the directory to handle your temporary input file.</td>
</tr>
<tr>
<td><strong>Add a dummy EOF line</strong></td>
<td>Select this check box when using the <code>tAggregateSortedRow</code> component.</td>
</tr>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to gather the Job processing metadata at the Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

### Global Variables

<table>
<thead>
<tr>
<th><strong>Global Variables</strong></th>
<th><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>NB_LINE</strong>: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see <em>Talend Studio User Guide</em>.</td>
</tr>
</tbody>
</table>

### Usage

| **Usage rule** | This component handles flow of data therefore it requires input and output, hence is defined as an intermediary step. |

---

**tExternalSortRow**
Related scenario

For related use case, see tSortRow on page 3540.
tExtractDelimitedFields

Generates multiple columns from a delimited string column.

**tExtractDelimitedFields Standard properties**

These properties are used to configure tExtractDelimitedFields running in the Standard Job framework.

The Standard tExtractDelimitedFields component belongs to the Processing family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Field to split</th>
<th>Select an incoming field from the Field to split list to split.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ignore NULL as the source data</td>
<td>Select this check box to ignore the Null value in the source data. Clear this check box to generate the Null records that correspond to the Null value in the source data.</td>
</tr>
<tr>
<td>Field separator</td>
<td>Enter character, string or regular expression to separate fields for the transferred data.</td>
</tr>
</tbody>
</table>

**Note:**

Since this component uses regex to split a field and the regex syntax uses special characters as operators, make sure to precede the regex operator you use as a field separator by a double backslash. For example, you have to use `\|` instead of `|`.

| Die on error | Clear the check box to skip any rows on error and complete the process for error-free rows. When errors are skipped, you can collect the rows on error using a Row > Reject link. |
| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available: |
| | • View schema: choose this option to view the schema only. |
| | • Change to built-in property: choose this option to change the schema to Built-in for local changes. |
| | • Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |
Click **Sync columns** to retrieve the schema from the previous component connected in the Job.

**Built-In:** You create and store the schema locally for this component only.

**Repository:** You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

### Advanced settings

<table>
<thead>
<tr>
<th><strong>Advanced separator (for number)</strong></th>
<th>Select this check box to change the separator used for numbers. By default, the thousands separator is a comma (,) and the decimal separator is a period (.).</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Trim column</strong></td>
<td>Select this check box to remove leading and trailing whitespace from all columns.</td>
</tr>
<tr>
<td><strong>Check each row structure against schema</strong></td>
<td>Select this check box to check whether the total number of columns in each row is consistent with the schema. If not consistent, an error message will be displayed on the console.</td>
</tr>
<tr>
<td><strong>Validate date</strong></td>
<td>Select this check box to check the date format strictly against the input schema.</td>
</tr>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to gather the processing metadata at the Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

### Global Variables

**Global Variables**

**ERROR_MESSAGE:** the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

**NB_LINE:** the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

**Usage rule**

This component handles flow of data therefore it requires input and output components. It allows you to extract data from a delimited field, using a **Row > Main** link, and enables you to create a reject flow filtering data which type does not match the defined type.
Extracting a delimited string column of a database table

This scenario describes a Job that writes data including a delimited string column into a MySQL database table and displays the data on the console, then extracts the delimited string column into multiple columns and displays the data after extraction on the console.

Adding and linking components

Procedure

1. Create a new Job and add the following components by typing their names in the design workspace or dropping them from the Palette: a tFixedFlowInput component, a tMysqlInput component, a tMysqlOutput component, a tExtractDelimitedFields component, two tLogRow components.

2. Link tFixedFlowInput to tMysqlOutput using a Row > Main connection.

3. Do the same to link tMysqlOutput to the first tLogRow, link tMysqlInput to tExtractDelimitedFields, link tExtractDelimitedFields to the second tLogRow.

4. Link tFixedFlowInput to tMysqlInput using a Trigger > On Subjob Ok connection.

Configuring the components

Populating data in a MySQL database table

Procedure

1. Double-click tFixedFlowInput to open its Basic settings view.
2. Click the [...] button next to *Edit schema* and in the pop-up window define the schema by adding three columns: *Id* of Integer type, and *Name* and *DelimitedField* of String type.

Click **OK** to close the schema editor and accept the propagation prompted by the pop-up dialog box.

3. In the *Mode* area, select *Use Inline Content(delimited file)*. Then in the *Content* field displayed, enter the data to write to the database. This input data includes a delimited string column. In this example, the input data is as follows:

1;Adam;32,Component Team,Developer
2;Bill;28,Component Team,Tester
3;Chris;30,Doc Team,Writer
4;David;35,Doc Team,Leader
5;Eddie;33,QA Team,Tester

4. Double-click **tMysqlOutput** to open its *Basic settings* view.
5. Fill the **Host**, **Port**, **Database**, **Username**, **Password** fields with the MySQL database connection information.

6. Fill the **Table** field with the name of the table to be written. In this example, it is *employee*.

7. Select **Drop table if exists and create** from the **Action on table** list.

8. Double-click the first **tLogRow** to open its **Basic settings** view.

In the **Mode** area, select **Table (print values in cells of a table)** for better readability of the result.

**Extracting the delimited string column in the database table into multiple columns**

**Procedure**

1. Double-click **tMysqlInput** to open its **Basic settings** view.
2. Fill the Host, Port, Database, Username, Password fields with the MySQL database connection information.

3. Click the [...] button next to Edit schema and in the pop-up window define the schema of the tMysqlInput component same as the schema of the tMysqlOutput component.

4. In the Table Name field, enter the name of the table into which the data was written. In this example, it is employee.

5. Click the Guess Query button to fill the Query field with the SQL query statement to be executed on the specified table. In this example, it is as follows:

```
SELECT `employee`.'Id',
     `employee`.'Name',
     `employee`.'DelimitedField'
FROM `employee`
```

6. Double-click tExtractDelimitedFields to open its Basic settings view.
7. In the **Field to split** list, select the delimited string column to be extracted. In this example, it is **DelimitedField**.

   In the **Field separator**, enter the separator used to separate the fields in the delimited string column. In this example, it is ",".

8. Click the [...] button next to **Edit schema** and in the pop-up window define the schema by adding five columns: **Id** of Integer type, and **Name**, **Age**, **Team**, **Title** of String type.

   In this example, the delimited string column **DelimitedField** is split into three columns **Age**, **Team** and **Title**, and the **Id** and **Name** columns are kept as well.

   ![Image of schema editor](image)

   Click **OK** to close the schema editor and accept the propagation prompted by the pop-up dialog box.

9. Double-click the second **tLogRow** to open its **Basic settings** view.

   ![Image of tLogRow settings](image)

   In the **Mode** area, select **Table (print values in cells of a table)** for better readability of the result.

**Saving and executing the Job**

**Procedure**

1. Press Ctrl + S to save the Job.

2. Execute the Job by pressing F6 or clicking **Run** on the Run tab.
As shown above, the primitive input data and the data after extraction are displayed on the console, and the delimited string column `DelimitedField` is extracted into three columns `Age`, `Team`, and `Title`.

<table>

</tbody>
</table>
**tExtractJSONFields**

Extracts the desired data from JSON fields based on the JSONPath or XPath query.

**tExtractJSONFields Standard properties**

These properties are used to configure tExtractJSONFields running in the Standard Job framework.

The Standard tExtractJSONFields component belongs to the Processing family.

The component in this framework is available in all Talend products.

### Basic settings

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-In or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Property type</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Built-In</strong>: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td><strong>Repository</strong>: Select the repository file where the properties are stored.</td>
<td></td>
</tr>
</tbody>
</table>

**Schema and Edit schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

- **Built-In**: You create and store the schema locally for this component only.
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

Click **Edit schema** to make changes to the schema. Note that if you make changes, the schema automatically becomes built-in.

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to `Built-in` for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Read By**

Select a way of extracting JSON data in the file.

- **JsonPath**: Extracts JSON data based on the JSONPath query. With this option selected, you need to select a JSONPath API version from the **API version** drop-down list. It is recommended to read data by JSONPath in order to gain better performance.
- **Xpath**: Extracts JSON data based on the XPath query.

**JSON field**

List of the JSON fields to be extracted.
| Loop Jasonpath query | Enter the path pointing to the node within the JSON field, on which the loop is based. 
Note if you have selected Xpath from the Read by drop-down list, the Loop Xpath query field is displayed instead. |
|----------------------|-------------------------------------------------------------------------------------------------|
| Mapping              | Complete this table to map the columns defined in the schema to the corresponding JSON nodes. 
- **Column**: The Column cells are automatically filled with the defined schema column names. 
- **Json query/JSONPath query**: Specify the JSONPath node that holds the desired data. For more information about JSONPath expressions, see http://goessner.net/articles/JsonPath/. 
  This column is available only when JsonPath is selected from the Read By list. 
- **XPath query**: Specify the XPath node that holds the desired data. 
  This column is available only when Xpath is selected from the Read By list. 
- **Get Nodes**: Select this check box to extract the JSON data of all the nodes or select the check box next to a specific node to extract the data of that node. 
  This column is available only when Xpath is selected from the Read By list. 
- **Is Array**: Select this check box when the JSON field to be extracted is an array instead of an object. 
  This column is available only when Xpath is selected from the Read By list. |
| Die on error         | Select the check box to stop the execution of the Job when an error occurs. 
Select the check box to skip any rows on error and complete the process for error-free rows. When errors are skipped, you can collect the rows on error using a Row > Reject link. |
| Advanced settings    | Select the encoding from the list or select Custom and define it manually. This field is compulsory for database data handling. The supported encodings depend on the JVM that you are using. For more information, see https://docs.oracle.com. |
| Use the loop node as root | Select this check box to use the loop node as the root for querying the file. 
The loop node is set in the Loop Json query text frame in the Basic Settings view. If this option is checked, only the child elements of the loop node are available for querying; otherwise, both the parent elements and the child elements of the loop node can be queried. You can specify a parent element through JSON path syntax. 
This check box is available only when JsonPath is selected in the Read By drop-down list of the Basic settings view. |
tStatCatcher Statistics

Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NB_LINE</td>
<td>The number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>ERROR_MESSAGE</td>
<td>The error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is selected.</td>
</tr>
</tbody>
</table>

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>This component is an intermediate component. It needs an input and an output components.</td>
<td></td>
</tr>
</tbody>
</table>

Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

Retrieving error messages while extracting data from JSON fields

In this scenario, tWriteJSONField wraps the incoming data into JSON fields, data of which is then extracted by tExtractJSONFields. Meanwhile, the error messages generated due to extraction failure, which include the concerned JSON fields and errors, are retrieved via a Row > Reject link.

Linking the components

Procedure

1. Drop the following components from the Palette onto the design workspace: tFixedFlowInput, tWriteJSONField, tExtractJSONFields, and tLogRow (X2). The two tLogRow components are renamed as data_extracted and reject_info.
2. Link tFixedFlowInput and tWriteJSONField using a Row > Main connection.
3. Link tWriteJSONField and tExtractJSONFields using a Row > Main connection.
4. Link tExtractJSONFields and data_extracted using a Row > Main connection.
5. Link tExtractJSONFields and reject_info using a Row > Reject connection.
Configuring the components

Setting up the tFixedFlowInput

Procedure

1. Double-click `tFixedFlowInput` to display its **Basic settings** view.

2. Click **Edit schema** to open the schema editor.
Click the [+] button to add three columns, namely firstname, lastname and dept, with the type of string.

Click OK to close the editor.

3. Select Use Inline Content and enter the data below in the Content box:

```
Andrew;Wallace;Doc
John;Smith;R&D
Christian;Dior;Sales
```

**Setting up the tWriteJSONField**

**Procedure**

1. Click tWriteJSONField to display its Basic settings view.

2. Click Configure JSON Tree to open the XML tree editor.

   The schema of tFixedFlowInput appears in the Linker source panel.

3. In the Linker target panel, click the default rootTag and type in staff, which is the root node of the JSON field to be generated.

4. Right-click staff and select Add Sub-element from the context menu.

5. In the pop-up box, enter the sub-node name, namely firstname.
Repeat the steps to add two more sub-nodes, namely lastname and dept.

6. Right-click firstname and select Set As Loop Element from the context menu.

7. Drop firstname from the Linker source panel to its counterpart in the Linker target panel.
   In the pop-up dialog box, select Add linker to target node.

   Click OK to close the dialog box.

8. Repeat the steps to link the two other items.
   Click OK to close the XML tree editor.

9. Click Edit schema to open the schema editor.

   Click the [+] button in the right panel to add one column, namely staff, which will hold the JSON data generated.
   Click OK to close the editor.
Setting up the tExtractJSONFields

Procedure

1. Double-click tExtractJSONFields to display its Basic settings view.

2. Click Edit schema to open the schema editor.

3. Click the [+ ] button in the right panel to add three columns, namely firstname, lastname and dept, which will hold the data of their counterpart nodes in the JSON field staff.
   Click OK to close the editor.

4. In the pop-up Propagate box, click Yes to propagate the schema to the subsequent components.
5. In the Loop XPath query field, enter "/staff", which is the root node of the JSON data.
6. In the Mapping area, type in the node name of the JSON data under the XPath query part. The data of those nodes will be extracted and passed to their counterpart columns defined in the output schema.
7. Specifically, define the XPath query "firstname" for the column firstname, "lastname" for the column lastname, and "" for the column dept. Note that "" is not a valid XPath query and will lead to execution errors.

**Setting up the tLogRow components**

**Procedure**

1. Double-click **data_extracted** to display its Basic settings view.

   ![Basic settings view](image)

   - Select **Table (print values in cells of a table)** for a better display of the results.
   - Perform the same setup on the other **tLogRow** component, namely **reject_info**.

**Executing the Job**

**Procedure**

1. Press **Ctrl + S** to save the Job.
2. Click **F6** to execute the Job.

   ```
<table>
<thead>
<tr>
<th>firstname</th>
<th>lastname</th>
<th>dept</th>
<th>errorJSONField</th>
<th>errorCode</th>
<th>errorMessage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Andrew</td>
<td>Wallace</td>
<td>null</td>
<td>null</td>
<td>[null]</td>
<td>[null]</td>
</tr>
<tr>
<td>John</td>
<td>Smith</td>
<td>null</td>
<td>null</td>
<td>[null]</td>
<td>[null]</td>
</tr>
<tr>
<td>Christian</td>
<td>Dior</td>
<td>null</td>
<td>null</td>
<td>[null]</td>
<td>[null]</td>
</tr>
</tbody>
</table>
  ```

As shown above, the reject row offers such details as the data extracted, the JSON fields whose data is not extracted and the cause of the extraction failure.

**Collecting data from your favorite online social network**

In this scenario, **tFileInputJSON** retrieves the friends node from a JSON file that contains the data of a Facebook user and **tExtractJSONFields** extracts the data from the friends node for flat data output.
Linking the components

Procedure

1. Drop the following components from the Palette onto the design workspace: tFileInputJSON, tExtractJSONFields and tLogRow.
2. Link tFileInputJSON and tExtractJSONFields using a Row > Main connection.
3. Link tExtractJSONFields and tLogRow using a Row > Main connection.

Configuring the components

Procedure

1. Double-click tFileInputJSON to display its Basic settings view.
   ![Basic settings view]

2. Click Edit schema to open the schema editor.
   ![Schema editor view]
Click the [+] button to add one column, namely friends, of the String type.
Click OK to close the editor.

3. Click the [...] button to browse for the JSON file, facebook.json in this case:

```
{
  "user": {
    "id": "9999912398",
    "name": "Kelly Clarkson",
    "friends": [
      {
        "name": "Tom Cruise",
        "id": "55555555555555",
        "likes": {
          "data": [
            {
              "category": "Movie",
              "name": "The Shawshank Redemption",
              "id": "103636093053996",
              "created_time": "2012-11-20T15:52:07+0000"
            },
            {
              "category": "Community",
              "name": "Positivertribution",
              "id": "471389562899413",
              "created_time": "2012-12-16T21:13:26+0000"
            }
          ]
        }
      },
      {
        "name": "Tom Hanks",
        "id": "88888888888888",
        "likes": {
          "data": [
            {
              "category": "Journalist",
              "name": "Janelle Wang",
              "id": "136009823148851",
              "created_time": "2013-01-01T08:22:17+0000"
            },
            {
              "category": "Tv show",
              "name": "Now With Alex Wagner",
              "id": "305948749433410",
              "created_time": "2012-11-20T06:14:10+0000"
            }
          ]
        }
      }
    ]
  }
}
```

4. Clear the Read by XPath check box.
   In the Mapping table, enter the JSONPath query ".user.friends[*]" next to the friends column, retrieving the entire friends node from the source file.

5. Double-click tExtractJSONFields to display its Basic settings view.
6. Click **Edit schema** to open the schema editor.

7. Click the [+] button in the right panel to add five columns, namely *id*, *name*, *like_id*, *like_name* and *like_category*, which will hold the data of relevant nodes in the JSON field *friends*. Click **OK** to close the editor.

8. In the pop-up **Propagate** box, click **Yes** to propagate the schema to the subsequent components.

9. In the **Loop XPath query** field, enter “/likes/data”.
10. In the **Mapping** area, type in the queries of the JSON nodes in the **XPath query** column. The data of those nodes will be extracted and passed to their counterpart columns defined in the output schema.

11. Specifically, define the XPath query ".//id" (querying the "friends/id" node) for the column **id**, ".//name" (querying the "friends/name" node) for the column **name**, "id" for the column **like_id**, "name" for the column **like_name**, and "category" for the column **like_category**.

12. Double-click **tLogRow** to display its **Basic settings** view.

```
<table>
<thead>
<tr>
<th>data_extracted(tLogRow_1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Basic settings</td>
</tr>
<tr>
<td>Advanced settings</td>
</tr>
<tr>
<td>Dynamic settings</td>
</tr>
<tr>
<td>View</td>
</tr>
<tr>
<td>Documentation</td>
</tr>
<tr>
<td>Validation Rules</td>
</tr>
</tbody>
</table>
```

13. Select **Table (print values in cells of a table)** for a better display of the results.

**Executing the Job**

**Procedure**

1. Press **Ctrl + S** to save the Job.
2. Click **F6** to execute the Job.

```
<table>
<thead>
<tr>
<th>tLogRow_1</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
</tr>
<tr>
<td>----</td>
</tr>
<tr>
<td>5555555555555555</td>
</tr>
<tr>
<td>5555555555555555</td>
</tr>
<tr>
<td>8888888888888888</td>
</tr>
<tr>
<td>8888888888888888</td>
</tr>
</tbody>
</table>
```

As shown above, the friends data of the Facebook user Kelly Clarkson is extracted correctly.

**Extracting data from a JSON file through looping**

This scenario describes a Job that extracts data from a JSON file through multiple loops and displays the data on the console.
The following lists the content of the JSON file, sample.json.

```json
{
    "Guid": "a2hdge9-5517-4e12-b9j6-887ft29e1711",
    "Transactions": [
        {
            "TransactionId": 1,
            "Products": [
                {
                    "ProductId": "A1",
                    "Packs": [
                        {
                            "Quantity": 20,
                            "Price": 40.00,
                            "Due_Date": "2019/03/01"
                        }
                    ]
                }
            ]
        },
        {
            "TransactionId": 2,
            "Products": [
                {
                    "ProductId": "B1",
                    "Packs": [
                        {
                            "Quantity": 1,
                            "Price": 15.00,
                            "Due_Date": "2019/01/01"
                        },
                        {
                            "Quantity": 21,
                            "Price": 315.00,
                            "Due_Date": "2019/02/14"
                        }
                    ]
                }
            ]
        },
        {
            "TransactionId": 3,
            "Products": [
                {
                    "ProductId": "C1",
                    "Packs": [
                        {
                            "Quantity": 2,
                            "Price": 5.00,
                            "Due_Date": "2019/02/19"
                        },
                        {
                            "Quantity": 3,
                            "Price": 7.50,
                            "Due_Date": "2019/05/21"
                        }
                    ]
                }
            ]
        }
    ]
}
```

This Job extracts the values of the following elements.

- Guid
- TransactionId
- ProductId
- Quantity
- Price
- Due-Date
Establishing tExtractJSONFields looping Job

Procedure

1. Create a Job and add a tFileInputJSON component, three tExtractJsonFields components, and a tLogRow component.
2. Connect the components using Row > Main connections.

Configuring tExtractJSONFields looping input

About this task

This task assumes that you know the structure of the JSON file.

Procedure

1. In the Basic settings view of the tFileInputJSON component, select JsonPath from the Read By drop-down list.
2. In the filename field, specify the input JSON file, sample.json in this example.
3. In the schema editor, add two columns, Guid (type String) and Transactions (type Object).
4. Click Yes in the subsequent dialog box to propagate the schema to the next component. The columns just added appear in the Mapping table of the Basic settings view.

5. In the Basic settings view, enter "$" in the Loop Json query text box to loop the elements within the root elements.

6. In the Json query column of the Mapping table, enter the following Json query expressions in double quotation marks.
   - $\.Guid to extract the value of the Guid element;
   - $\.Transactions to extract the content of the Transactions element.

**Configuring the tExtractJSONFields components for looping**

**Procedure**

1. In the schema editor of the first tExtractJSONFields component, add the following columns in the output table.
   - Guid, type String;
   - TransactionId, type Integer;
   - Products, type Object

2. Close the schema editor and click Yes in the subsequent dialog box to propagate the schema to the next component. The columns just added appear in the Mapping table of the Basic settings view.

3. Set the other options in the Basic settings view as follows.
The settings loop all the elements within the Transactions element and extract the values of the TransactionId and the Products elements.

4. In the schema editor of the second tExtractJSONFields component, add the following columns in the output table.
   - Guid, type String;
   - TransactionId, type Integer;
   - ProductId, type String;
   - Packs, type Object

5. Close the schema editor and click Yes in the subsequent dialog box to propagate the schema to the next component.

The columns just added appear in the Mapping table of the Basic settings view.

6. Set the other options in the Basic settings view as follows.
   - JSON field: Products;
   - Loop Jsonpath query: "*" (in double quotation marks);
   - Guid: empty, for receiving the Guid value from the previous component;
   - TransactionId: empty, for receiving the TransactionId from the previous component;
   - ProductId: "ProductId" (in double quotation marks);
   - Packs: "Packs" (in double quotation marks);
   - Others: unchanged

   The settings in the above figure loop all the elements within the Products element and extract the values of the ProductId and the Packs elements.

7. In the schema editor of the third tExtractJSONFields component, add the following columns in the output table.

---

- Price, type Float;
- Due_Date, type Date

8. Close the schema editor and click Yes in the subsequent dialog box to propagate the schema to the next component.
   The columns just added appear in the Mapping table of the Basic settings view.

9. Set the other options in the Basic settings view as follows.
   - JSON field: Packs;
   - Loop Jsonpath query: "*" (in double quotation marks);
   - Guid: empty, for receiving the Guid value from the previous component;
   - TransactionId: empty, for receiving the TransactionId value from the previous component;
   - ProductId: empty, for receiving the ProductId value from the previous component;
   - Quantity: "Quantity" (in double quotation marks);
   - Price: "Price" (in double quotation marks);
   - Due_Date: "Due_Date" (in double quotation marks);
   - Others: unchanged

The settings in the above figure loop all the elements within the Packs element and extract the values of the Quantity, the Price, and the Due_Date elements.

Setting the display for tExtractJSONFields values

Procedure
1. Open the Basic settings view of the tLogRow component.

![tLogRow_1]

2. Select the preferred option in the Mode section.

Executing tExtractJSONFields loop Job

Procedure
1. Press Ctrl+S to save the Job.
2. Press F6 to execute the Job. The following figure shows the result.
The values of the Guid element, the TransactionId element, the ProductId element, the Quantity element, the Price element, and the Due_date element are extracted from the source JSON file and displayed.
**tExtractPositionalFields**

Extracts data and generates multiple columns from a formatted string using positional fields.
tExtractPositionalFields generates multiple columns from one column using positional fields.

**tExtractPositionalFields Standard properties**

These properties are used to configure tExtractPositionalFields running in the Standard Job framework.
The Standard tExtractPositionalFields component belongs to the Processing family.
The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Field</th>
<th>Select an incoming field from the <strong>Field</strong> list to extract.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ignore NULL as the source data</td>
<td>Select this check box to ignore the Null value in the source data. Clear this check box to generate the Null records that correspond to the Null value in the source data.</td>
</tr>
</tbody>
</table>
| Customize | Select this check box to customize the data format of the positional file and define the table columns:  
  **Column**: Select the column you want to customize.  
  **Size**: Enter the column size.  
  **Padding char**: Type in between inverted commas the padding character used, in order for it to be removed from the field. A space by default.  
  **Alignment**: Select the appropriate alignment parameter. |
| Pattern | Enter the pattern to use as basis for the extraction. A pattern is length values separated by commas, interpreted as a string between quotes. Make sure the values entered in this fields are consistent with the schema defined. |
| Die on error | Clear the check box to skip any rows on error and complete the process for error-free rows. When errors are skipped, you can collect the rows on error using a **Row > Reject** link. |
| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.  
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
  - **View schema**: choose this option to view the schema only.  
  - **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes. |
• **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

Click **Sync columns** to retrieve the schema from the previous component connected in the Job.

<table>
<thead>
<tr>
<th>Built-In</th>
<th>You create and store the schema locally for this component only.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Repository</strong></td>
<td>You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
</tr>
</tbody>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th>Advanced separator (for number)</th>
<th>Select this check box to change the separator used for numbers. By default, the thousands separator is a comma (,) and the decimal separator is a period (·).</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Trim Column</strong></td>
<td>Select this check box to remove leading and trailing whitespace from all columns.</td>
</tr>
<tr>
<td><strong>Check each row structure against schema</strong></td>
<td>Select this check box to check whether the total number of columns in each row is consistent with the schema. If not consistent, an error message will be displayed on the console.</td>
</tr>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to gather the processing metadata at the Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

**Global Variables**

**Global Variables**

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

**NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.

The **NB_LINE** variable is not available to the Map/Reduce version.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see **Talend Studio User Guide**.
Usage

This component handles flow of data therefore it requires input and output components. It allows you to extract data from a delimited field, using a Row > Main link, and enables you to create a reject flow filtering data which type does not match the defined type.

Related scenario

For a related scenario, see Extracting name, domain and TLD from e-mail addresses on page 960.
tExtractRegexFields

Extracts data and generates multiple columns from a formatted string using regex matching.

**tExtractRegexFields Standard properties**

These properties are used to configure tExtractRegexFields running in the Standard Job framework.

The Standard tExtractRegexFields component belongs to the Data Quality and the Processing families.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Field to split</th>
<th>Select an incoming field from the Field to split list to split.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Regex</td>
<td>Enter a regular expression according to the programming language you are using.</td>
</tr>
</tbody>
</table>
| Schema and Edit Schema  | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
  • View schema: choose this option to view the schema only.  
  • Change to built-in property: choose this option to change the schema to Built-in for local changes.  
  • Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.  
  Click Sync columns to retrieve the schema from the previous component connected in the Job. |
|                         | **Warning:** Make sure that the output schema does not contain any column with the same name as the input column to be split. Otherwise, the regular expression will not work as expected. |
| Built-In                | You create and store the schema locally for this component only. |
| Repository              | You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. |
Advanced settings

Die on error | Select the check box to stop the execution of the Job when an error occurs.
Clear the check box to skip any rows on error and complete the process for error-free rows. When errors are skipped, you can collect the rows on error using a Row > Reject link.

Check each row structure against schema | Select this check box to check whether the total number of columns in each row is consistent with the schema. If not consistent, an error message will be displayed on the console.

tStatCatcher Statistics | Select this check box to gather the processing metadata at the Job level as well as at each component level.

Global Variables

Global Variables
ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.
For further information about variables, see Talend Studio User Guide.

Usage

Usage rule
This component handles flow of data therefore it requires input and output components. It allows you to extract data from a delimited field, using a Row > Main link, and enables you to create a reject flow filtering data which type does not match the defined type.

Extracting name, domain and TLD from e-mail addresses

This scenario describes a three-component Job where tExtractRegexFields is used to specify a regular expression that corresponds to one column in the input data, email. The tExtractRegexFields component is used to perform the actual regular expression matching. This regular expression includes field identifiers for user name, domain name and Top-Level Domain (TLD) name portions in each e-mail address. If the given e-mail address is valid, the name, domain and TLD are extracted and displayed on the console in three separate columns. Data in the other two input columns, id and age is extracted and routed to destination as well.
Setting up the Job

Procedure

1. Drop the following components from the Palette onto the design workspace: tFileInputDelimited, tExtractRegexFields, and tLogRow.

2. Connect tFileInputDelimited to tExtractRegexFields using a Row > Main link, and do the same to connect tExtractRegexFields to tLogRow.

Configuring the components

Procedure

1. Double-click the tFileInputDelimited component to open its Basic settings view in the Component tab.

2. Click the [...] button next to the File name/Stream field to browse to the file where you want to extract information from.

   The input file used in this scenario is called test4. It is a text file that holds three columns: id, email, and age.

   
   id;email;age
   1;anna@yahoo.net;24
   2;diana@sohu.com;31
   3;fiona@gmail.org;20

   For more information, see tFileInputDelimited on page 1008.

3. Click Edit schema to define the data structure of this input file.

4. Double-click the tExtractRegexFields component to open its Basic settings view.
5. Select the column to split from the **Field to split** list: *email* in this scenario.

6. Enter the regular expression you want to use to perform data matching in the **Regex** panel. In this scenario, the regular expression "([a-z]*)@([a-z]*)\.( [a-z]*)" is used to match the three parts of an email address: user name, domain name and TLD name.

7. Click **Edit schema** to open the **Schema of tExtractRegexFields** dialog box, and click the plus button to add five columns for the output schema.

In this scenario, we want to split the input *email* column into three columns in the output flow, *name*, *domain*, and *tld*. The two other input columns will be extracted as they are.

8. Double-click the **tLogRow** component to open its **Component** view.

9. In the **Mode** area, select **Table (print values in cells of a table)**.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl+S** to save your Job.

2. Execute the Job by pressing **F6** or clicking **Run** on the **Run** tab.
Results

The `tExtractRegexFields` component matches all given e-mail addresses with the defined regular expression and extracts the name, domain, and TLD names and displays them on the console in three separate columns. The two other columns, `id` and `age`, are extracted as they are.
tExtractXMLField

Reads the XML structured data from an XML field and sends the data as defined in the schema to the following component.

**tExtractXMLField Standard properties**

These properties are used to configure tExtractXMLField running in the Standard Job framework. The Standard tExtractXMLField component belongs to the Processing and the XML families. The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-In or Repository. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• View schema: choose this option to view the schema only.</td>
</tr>
<tr>
<td></td>
<td>• Change to built-in property: choose this option to change the schema to Built-In for local changes.</td>
</tr>
<tr>
<td></td>
<td>• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.</td>
</tr>
<tr>
<td></td>
<td>Built-In: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file where the properties are stored.</td>
</tr>
<tr>
<td></td>
<td>When this file is selected, the fields that follow are pre-filled in using fetched data.</td>
</tr>
<tr>
<td>Schema type</td>
<td>Built-In: You create and store the schema locally for this component only.</td>
</tr>
<tr>
<td></td>
<td>Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
</tr>
<tr>
<td>XML field</td>
<td>Name of the XML field to be processed.</td>
</tr>
<tr>
<td></td>
<td>Related topic: see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Loop XPath query</td>
<td>Node of the XML tree, which the loop is based on.</td>
</tr>
</tbody>
</table>
### Mapping

**Column**: reflects the schema as defined by the Schema type field.

**XPath Query**: Enter the fields to be extracted from the structured input.

**Get nodes**: Select this check box to recuperate the XML content of all current nodes specified in the XPath query list or select the check box next to specific XML nodes to recuperate only the content of the selected nodes.

### Limit

Maximum number of rows to be processed. If Limit is 0, no rows are read or processed.

### Die on error

Select the check box to stop the execution of the Job when an error occurs.

Clear the check box to skip any rows on error and complete the process for error-free rows. When errors are skipped, you can collect the rows on error using a Row > Reject link.

## Advanced settings

### Ignore the namespaces

Select this check box to ignore namespaces when reading and extracting the XML data.

### tStatCatcher Statistics

Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

## Global Variables

### Global Variables

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

**NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

## Usage

### Usage rule

This component is an intermediate component. It needs an input and an output components.
Extracting XML data from a field in a database table

This three-component scenario allows to read the XML structure included in the fields of a database table and then extracts the data.

Procedure

1. Drop the following components from the Palette onto the design workspace: tMysqlInput, tExtractXMLField, and tFileOutputDelimited.
   Connect the three components using Main links.

2. Double-click tMysqlInput to display its Basic settings view and define its properties.
   - Property Type: Repository
   - Use an existing connection
   - Host: "localhost"
   - Database: "test"
   - Username: "root"
   - Scheme: DB (MYSQL):localDBMS
   - Panel: DB (MYSQL):localDBMS - customerdetails
   - Table Name: "customerdetails"
   - Query Type: Built-In
   - Query: 
     ```sql
     SELECT customerdetails.CustomerDetails
     FROM customerdetails
     ```

3. If you have already stored the input schema in the Repository tree view, select Repository first from the Property Type list and then from the Schema list to display the Repository Content dialog box where you can select the relevant metadata.
   For more information about storing schema metadata in the Repository tree view, see Talend Studio User Guide.

   If you have not stored the input schema locally, select Built-in in the Property Type and Schema fields and enter the database connection and the data structure information manually. For more information about tMysqlInput properties, see tMysqlInput on page 2448.

4. In the Table Name field, enter the name of the table holding the XML data, customerdetails in this example.
   Click Guess Query to display the query corresponding to your schema.

5. Double-click tExtractXMLField to display its Basic settings view and define its properties.
6. Click **Sync columns** to retrieve the schema from the preceding component. You can click the three-dot button next to **Edit schema** to view/modify the schema.

   The **Column** field in the **Mapping** table will be automatically populated with the defined schema.

7. In the **Xml field** list, select the column from which you want to extract the XML data. In this example, the field holding the XML data is called **CustomerDetails**.

   In the **Loop XPath query** field, enter the node of the XML tree on which to loop to retrieve data. In the **Xpath query** column, enter between inverted commas the node of the XML field holding the data you want to extract, **CustomerName** in this example.

8. Double-click **tFileOutputDelimited** to display its **Basic settings** view and define its properties.

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Use Output Stream</th>
<th>File Name</th>
<th>Row Separator</th>
<th>Append</th>
<th>Include Header</th>
<th>Compress as zip file</th>
</tr>
</thead>
<tbody>
<tr>
<td>Built-In</td>
<td></td>
<td>&quot;D:/04_Jobs/CustomerNames.csv&quot;</td>
<td>&quot;n&quot;</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

9. In the **File Name** field, define or browse to the path of the output file you want to write the extracted data in.

   Click **Sync columns** to retrieve the schema from the preceding component. If needed, click the three-dot button next to **Edit schema** to view the schema.

10. Save your Job and click **F6** to execute it.
tExtractXMLField read and extracted the clients names under the node CustomerName of the CustomerDetails field of the defined database table.

Extracting correct and erroneous data from an XML field in a delimited file

This scenario describes a four-component Job that reads an XML structure from a delimited file, outputs the main data and rejects the erroneous data.

Procedure

1. Drop the following components from the Palette to the design workspace: tFileInputDelimited, tExtractXMLField, tFileOutputDelimited and tLogRow.
   Connect the first three components using Row Main links.
   Connect tExtractXMLField to tLogRow using a Row Reject link.

2. Double-click tFileInputDelimited to open its Basic settings view and define the component properties.
3. Select **Built-in** in the **Schema** list and fill in the file metadata manually in the corresponding fields.

Click the three-dot button next to **Edit schema** to display a dialog box where you can define the structure of your data.

Click the plus button to add as many columns as needed to your data structure. In this example, we have one column in the schema: **xmlStr**.

Click **OK** to validate your changes and close the dialog box.

**Note:**

If you have already stored the schema in the **Metadata** folder under **File delimited**, select **Repository** from the **Schema** list and click the three-dot button next to the field to display the **Repository Content** dialog box where you can select the relevant schema from the list. Click **Ok** to close the dialog box and have the fields automatically filled in with the schema metadata.

For more information about storing schema metadata in the Repository tree view, see **Talend Studio User Guide**.

4. In the **File Name** field, click the three-dot button and browse to the input delimited file you want to process, **CustomerDetails_Error** in this example.

This delimited file holds a number of simple XML lines separated by double carriage return.

Set the row and field separators used in the input file in the corresponding fields, double carriage return for the first and nothing for the second in this example.

If needed, set **Header**, **Footer** and **Limit**. None is used in this example.

5. In the design workspace, double-click **tExtractXMLField** to display its **Basic settings** view and define the component properties.
6. Click **Sync columns** to retrieve the schema from the preceding component. You can click the three-dot button next to **Edit schema** to view/modify the schema. The **Column** field in the **Mapping** table will be automatically populated with the defined schema.

7. In the **Xml field** list, select the column from which you want to extract the XML data. In this example, the field holding the XML data is called *xmlStr*.

   In the **Loop XPath query** field, enter the node of the XML tree on which to loop to retrieve data.

8. In the design workspace, double-click **tFileOutputDelimited** to open its **Basic settings** view and display the component properties.

9. In the **File Name** field, define or browse to the output file you want to write the correct data in, *CustomerNames_right.csv* in this example.

   Click **Sync columns** to retrieve the schema of the preceding component. You can click the three-dot button next to **Edit schema** to view/modify the schema.

10. In the design workspace, double-click **tLogRow** to display its **Basic settings** view and define the component properties.

    Click **Sync Columns** to retrieve the schema of the preceding component. For more information on this component, see **tLogRow** on page 1956.

11. Save your Job and press **F6** to execute it.
Results

[statistics] connecting to socket on port 3845

[statistics] disconnected
Job A ended at 14.22 05/11/2009. [exit code=0]

tExtractXMLField reads and extracts in the output delimited file, CustomerNames_right, the client information for which the XML structure is correct, and displays as well erroneous data on the console of the Run view.
tFileArchive

Creates a new zip, gzip, or tar.gz archive file from one or more files or folders. The archive file can be compressed using different compression method.

**tFileArchive Standard properties**

These properties are used to configure tFileArchive running in the Standard Job framework.
The Standard tFileArchive component belongs to the File family.
The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Directory</strong></td>
<td>Specify the directory that contains the files to be added to the archive file. This field is available when zip or tar.gz is selected from the archive format list. Warning: Use absolute path (instead of relative path) for this field to avoid possible errors.</td>
</tr>
<tr>
<td><strong>Subdirectories</strong></td>
<td>Select this check box if you want to add the files in the subdirectories to the archive file. This field is available only when zip is selected from the archive format list.</td>
</tr>
<tr>
<td><strong>Source File</strong></td>
<td>Specify the path to the file that you want to add to the archive file. This field is available only when gzip is selected from the archive format list.</td>
</tr>
<tr>
<td><strong>Archive file</strong></td>
<td>Specify the path to the archive file to be created. Warning: Use absolute path (instead of relative path) for this field to avoid possible errors.</td>
</tr>
<tr>
<td><strong>Create directory if does not exist</strong></td>
<td>Select this check box to create the destination folder if it does not exist.</td>
</tr>
<tr>
<td><strong>Archive format</strong></td>
<td>Select an archive file format from the list: zip, gzip, or tar.gz.</td>
</tr>
<tr>
<td><strong>Compress level</strong></td>
<td>Select the compression level you want to apply.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Best</strong>: the compression quality will be optimum, but the compression time will be long.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Normal</strong>: the compression quality and time will be average.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Fast (no compression)</strong>: the compression will be fast, but the quality will be lower.</td>
</tr>
<tr>
<td><strong>All files</strong></td>
<td>Select this check box if all files in the specified directory will be added to the archive file. Clear it to specify the file(s) you want to add to the archive file in the Files table.</td>
</tr>
</tbody>
</table>
### Filemask

**Filemask:** type in the file name or the file mask using a special character or a regular expression.

This check box is available when zip or tar.gz is selected from the *Archive format* list.

### Encoding

Select an encoding type from the list or select CUSTOM and define it manually. This field is compulsory for DB data handling.

This list is available when zip is selected from the *Archive format* list.

### Overwrite Existing Archive

This check box is selected by default. This allows you to save an archive by replacing the existing one. But if you clear the check box, an error is reported, the replacement fails and the new archive cannot be saved.

**Note:**

When the replacement fails, the Job runs.

### Encrypt files

Select this check box if you want the archive file to be password protected.

**Encrypt method:** select an encrypt method from the list, Java Encrypt, Zip4j AES, or Zip4j STANDARD.

**AES Key Strength:** select a key strength for the Zip4j AES method, either AES 128 or AES 256.

**Enter Password:** enter the encryption password.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

This check box is available only when zip is selected from the *Archive format* list. With this check box selected, the compressed archive file can be decompressed only by the tFileUnarchive component and not by a common archiver. For more information about tFileUnarchive, see tFileUnarchive on page 1161.

### ZIP64 mode

This option allows for archives with the .zip64 extension to be created, with three modes available:

- **ASNEEDED:** archives with the .zip64 extension will be automatically created based on the file size.
- **ALWAYS:** archives with the .zip64 extension will be created, no matter what size the file may be.
- **NEVER:** no archives with the .zip64 extension will be created, no matter what size the file may be.

Note that if the file size or the total size of the archive exceeds 4GB or there are more than 65536 files inside the archive, you need to set the mode to **ALWAYS**.

### Advanced settings

#### Use sync flush

Select this check box to flush the compressor before flushing the output stream. Clear this check box to flush only the output stream.
This check box is available when gzip or tar.gz is selected from the Archive format list.

| tStatCatcher Statistics | Select this check box to gather the processing metadata at the Job level as well as at each component level. |

**Global Variables**

| Global Variables | 
|------------------|---|

**ARCHIVE_FILEPATH**: the path to the archive file. This is an After variable and it returns a string.

**ARCHIVE_FILENAME**: the name of the archive file. This is an After variable and it returns a string.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

**Usage**

| Usage rule | This component must be used as a standalone component. |

**Connections**

Outgoing links (from this component to another):

**Row**: Main; Reject; Iterate.

**Trigger**: On Subjob Ok; On Subjob Error; Run if; On Component Ok; On Component Error.

Incoming links (from one component to this one):

**Row**: Main; Reject; Iterate.

**Trigger**: Run if; On Subjob Ok; On Subjob Error; On component Ok; On Component Error; Synchronize; Parallelize.

For further information regarding connections, see Talend Studio User Guide.

**Zipping files using a tFileArchive**

This scenario creates a Job with a unique component. It aims at zipping files and recording them in the selected directory.
Procedure

1. Drop the tFileArchive component from the Palette onto the workspace.
2. Double-click it to display its Component view.

3. In the Directory field, click the [...] button, browse your directory and select the directory or the file you want to compress.
4. Select the Subdirectories check box if you want to include the subfolders and their files in the archive.
5. Then, set the Archive file field, by filling the destination path and the name of your archive file.
6. Select the Create directory if not exists check box if you do not have a destination directory yet and you want to create it.
7. In the Compress level list, select the compression level you want to apply to your archive. In this example, we use the normal level.
8. Clear the All Files check box if you only want to zip specific files.

Filemask

**"R55"**

Encoding

ISO-8859-15

Overwrite Existing Archive

Encrypt files

ZIP64 mode

ASNEEDED
9. Add a row in the table by clicking the [+ ] button and click the name which appears. Between two star symbols (ie. "RG"), type part of the name of the file that you want to compress.

10. Press F6 to execute your Job.

Results
The tFileArchive has compressed the selected file(s) and created the folder in the selected directory.
tFileCompare

Comes next to file and provides comparison data based on a read-only schema.

**tFileCompare Standard properties**

These properties are used to configure tFileCompare running in the Standard Job framework.

The Standard tFileCompare component belongs to the File family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Schema and Edit Schema</th>
<th>A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema of this component is read-only.</th>
</tr>
</thead>
<tbody>
<tr>
<td>File to compare</td>
<td>Filepath to the file to be checked. <strong>Warning:</strong> Use absolute path (instead of relative path) for this field to avoid possible errors.</td>
</tr>
<tr>
<td>Reference file</td>
<td>Filepath to the file, the comparison is based on. <strong>Warning:</strong> Use absolute path (instead of relative path) for this field to avoid possible errors.</td>
</tr>
<tr>
<td>If differences are detected, display and If no difference detected, display</td>
<td>Type in a message to be displayed in the Run console based on the result of the comparison.</td>
</tr>
<tr>
<td>Print to console</td>
<td>Select this check box to display the message.</td>
</tr>
</tbody>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th>Encoding</th>
<th>Select the encoding from the list or select Custom and define it manually. This field is compulsory for DB data handling.</th>
</tr>
</thead>
<tbody>
<tr>
<td>tStatCatcher Statistics</td>
<td>Select this check box to gather the Job processing metadata at a Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th><strong>DIFFERENCE:</strong> the result of the comparison. This is a Flow variable and it returns a boolean. <strong>ERROR_MESSAGE:</strong> the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</th>
</tr>
</thead>
</table>
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule

This component can be used as standalone component but it is usually linked to an output component to gather the log data.

Connections

Outgoing links (from this component to another):
- **Row**: Main.
- **Trigger**: On Subjob Ok; On Subjob Error; Run if; On Component Ok; On Component Error.

Incoming links (from one component to this one):
- **Row**: Main; Reject; Iterate.
- **Trigger**: Run if; On Subjob Ok; On Subjob Error; On component Ok; On Component Error; Synchronize; Paralle lize.

For further information regarding connections, see Talend Studio User Guide.

Comparing unzipped files

This scenario describes a Job unarchiving a file and comparing it to a reference file to make sure it did not change. The output of the comparison is stored into a delimited file and a message displays in the console.

Procedure

Procedure

1. Drag and drop the following components: tFileUnarchive, tFileCompare, and tFileOutputDelimited.
2. Link the tFileUnarchive to the tFileCompare with Iterate connection.
3. Connect the tFileCompare to the output component, using a Main row link.
4. In the tFileUnarchive component Basic settings, fill in the path to the archive to unzip.
5. In the Extraction Directory field, fill in the destination folder for the unarchived file.
6. In the **tFileCompare Basic settings**, set the **File to compare**. Press Ctrl+Space bar to display the list of global variables. Select \$_globals[tFileUnarchive_1]{CURRENT_FILEPATH} or "((String)globalMap.get("tFileUnarchive_1_Current_FILEPATH"))" according to the language you work with, to fetch the file path from the **tFileUnarchive** component.

7. And set the **Reference file** to base the comparison on it.

8. In the messages fields, set the messages you want to see if the files differ or if the files are identical, for example: "[job : \$_globals\{job_name\}] Files differ".

9. Select the **Print to Console** check box, for the message defined to display at the end of the execution.

10. The schema is read-only and contains standard information data. Click **Edit schema** to have a look to it.

11. Then set the output component as usual with semi-colon as data separators.

12. Save your Job and press **F6** to run it.

```
Starting job CompareFiles at 14:11 19/06/2007
[Job CompareFiles] Files differ
Job CompareFiles ended at 14:11 19/06/2007. [exit code=0]
```

The message set is displayed to the console and the output shows the schema information data.
File Compare

C:\Input\Accounts\Sunnyvale_accounts_new.xls;C:\Input/Sunnyvale_accounts.csv;
2007-06-19 14:11:38;compare=files;FileCompare_1;1;[Job compare=files] Files differ
**tFileCopy**

Copies a source file or folder into a target directory.

**tFileCopy Standard properties**

These properties are used to configure tFileCopy running in the Standard Job framework.

The Standard tFileCopy component belongs to the File family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>

| | Trigger: Run if; On Subjob Ok; On Subjob Error; On component Ok; On Component Error; Synchronize; Parallelize. |
| | For further information regarding connections, see Talend Studio User Guide. |

Restoring files from bin

This scenario describes a Job that iterates on a list of files in a directory, copies each file to a defined target directory, and then removes the copied files from the source directory.
Procedure

1. Create a new Job and add a tFileList component and a tFileCopy component by typing their names in the design workspace or dropping them from the Palette.
2. Connect tFileList to tFileCopy using a Row > Iterate link.
3. Double-click tFileList to open its Basic settings view.

   ![tFileList](image)

4. In the Directory field, browse to or type in the directory to iterated upon.
5. Double-click tFileCopy to open its Basic settings view.

   ![tFileCopy](image)

6. In the File Name field, press Ctrl+Space to access the global variable list and select the tFileList_1.CURRENT_FILEPATH variable from the list to fill the field with (String)globalMap.get("tFileList_1.CURRENT_FILEPATH").
7. In the Destination directory field, browse to or type in the directory to copy each file to.
8. Select the Remove source file check box to get rid of the files that have been copied.
9. Press Ctrl+S to save your Job and press F6 to execute it.
All the files in the defined source directory are copied to the destination directory and are removed from the source directory.
tFileDelete

Deletes files from a given directory.

### tFileDelete Standard properties

These properties are used to configure tFileDelete running in the Standard Job framework.

The Standard tFileDelete component belongs to the File family.

The component in this framework is available in all Talend products.

#### Basic settings

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>File Name</strong></td>
<td>Path to the file to be deleted. This field is hidden when you select the Delete folder check box or the Delete file or folder check box. <strong>Warning:</strong> Use absolute path (instead of relative path) for this field to avoid possible errors.</td>
</tr>
<tr>
<td><strong>Directory</strong></td>
<td>Path to the folder to be deleted. This field is available only when you select the Delete folder check box.</td>
</tr>
<tr>
<td><strong>File or directory to delete</strong></td>
<td>Enter the path to the file or to the folder you want to delete. This field is available only when you select the Delete file or folder check box.</td>
</tr>
<tr>
<td><strong>Fail on error</strong></td>
<td>Select this check box to prevent the main Job from being executed if an error occurs, for example, if the file to be deleted does not exist.</td>
</tr>
<tr>
<td><strong>Delete Folder</strong></td>
<td>Select this check box to display the Directory field, where you can indicate the path the folder to be deleted.</td>
</tr>
<tr>
<td><strong>Delete file or folder</strong></td>
<td>Select this check box to display the File or directory to delete field, where you can indicate the path to the file or to the folder you want to delete.</td>
</tr>
</tbody>
</table>

#### Advanced settings

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to gather the Job processing metadata at a Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

#### Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DELETE_PATH</td>
<td>the path to the deleted file or folder. This is an After variable and it returns a string.</td>
</tr>
<tr>
<td>CURRENT_STATUS</td>
<td>the execution result of the component. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td>ERROR_MESSAGE</td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the</td>
</tr>
</tbody>
</table>
Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component can be used as standalone component.</th>
</tr>
</thead>
</table>

Connections

Outgoing links (from this component to another):
- **Row**: Main.
- **Trigger**: On Subjob Ok; On Subjob Error; Run if; On Component Ok; On Component Error.

Incoming links (from one component to this one):
- **Row**: Main; Reject; Iterate.
- **Trigger**: Run if; On Subjob Ok; On Subjob Error; On component Ok; On Component Error; Synchronize; Parallelize.

For further information regarding connections, see Talend Studio User Guide.

Deleting files

This very simple scenario describes a Job deleting files from a given directory.

Procedure

1. Drop the following components: **tFileList, tFileDelete, tJava** from the Palette to the design workspace.
2. In the **tFileList Basic settings**, set the directory to loop on in the **Directory** field.

![tFileList_1](image1)

**Directory**: `C:/output/bin`

**Filemask**: `*.txt`

**Case Sensitive**: No
3. The filemask is "*.txt" and no case check is to carry out.

4. In the **tFileDelete** Basic settings panel, set the **File Name** field in order for the current file in selection in the **tFileList** component be deleted. This delete all files contained in the directory, as specified earlier.

5. Press **Ctrl+Space bar** to access the list of global variables. In Java, the relevant variable to collect the current file is: `(String)globalMap.get("tFileList_1_CURRENT_FILEPATH")`.

6. Then in the **tJava** component, define the message to be displayed in the standard output (Run console). In this Java use case, type in the Code field, the following script: `System.out.println( ((String)globalMap.get("tFileList_1_CURRENT_FILE"))
+ " has been deleted!");`

7. Then save your Job and press **F6** to run it.

<table>
<thead>
<tr>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>16.txt has been deleted!</td>
</tr>
<tr>
<td>15.txt has been deleted!</td>
</tr>
<tr>
<td>14.txt has been deleted!</td>
</tr>
<tr>
<td>13.txt has been deleted!</td>
</tr>
<tr>
<td>12.txt has been deleted!</td>
</tr>
<tr>
<td>11.txt has been deleted!</td>
</tr>
<tr>
<td>10.txt has been deleted!</td>
</tr>
<tr>
<td>09.txt has been deleted!</td>
</tr>
<tr>
<td>08.txt has been deleted!</td>
</tr>
<tr>
<td>07.txt has been deleted!</td>
</tr>
<tr>
<td>06.txt has been deleted!</td>
</tr>
<tr>
<td>05.txt has been deleted!</td>
</tr>
<tr>
<td>04.txt has been deleted!</td>
</tr>
<tr>
<td>03.txt has been deleted!</td>
</tr>
<tr>
<td>02.txt has been deleted!</td>
</tr>
<tr>
<td>01.txt has been deleted!</td>
</tr>
</tbody>
</table>

| Job FileDelete ended at 18:29 20/06/2007  [exit code=0] |

**Results**

The message set in the **tJava** component displays in the log, for each file that has been deleted through the **tFileDelete** component.
tFileExist

Checks if a file exists or not.

**tFileExist Standard properties**

These properties are used to configure tFileExist running in the Standard Job framework.

The Standard tFileExist component belongs to the File family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>File Name</th>
<th>Path to the file you want to check if it exists or not.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Warning: Use absolute path instead of relative path for this field to avoid possible errors.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>EXIST: the result of whether a specified file exists. This is a Flow variable and it returns a boolean.</th>

Checking for the presence of a file and creating it if it does not exist

This scenario describes a simple Job that: checks if a given file exists, displays a graphical message to confirm that the file does not exist, reads the input data in another given file and writes it in an output delimited file.

A dialog box appears to confirm that the file does not exists.

Click OK to close the dialog box and continue the Job execution process. The missing file, file1 in this scenario, got written in a delimited file in the defined place.

Dropping and linking the components

Procedure

1. Drop the following components from the Palette onto the design workspace: tFileExist, tFileInputDelimited, tFileOutputDelimited, and tMsgBox.
2. Connect tFileExist to tFileInputDelimited using an OnSubjobOk and to tMsgBox using a Run If link.

3. Connect tFileInputDelimited to tFileOutputDelimit using a Row Main link.

Configuring the components

Procedure

1. In the design workspace, select tFileExist and click the Component tab to define its basic settings.
2. In the **File name** field, enter the file path or browse to the file you want to check if it exists or not.

3. In the design workspace, select **tFileInputDelimited** and click the **Component** tab to define its basic settings.

4. Browse to the input file you want to read to fill out the **File Name** field.

**Warning:**

If the path of the file contains some accented characters, you will get an error message when executing your Job.

5. Set the row and field separators in their corresponding fields.

6. Set the header, footer and number of processed rows as needed. In this scenario, there is one header in our table.

7. Set **Schema** to **Built-in** and click the **Edit schema** button to define the data to pass on to the **tFileOutputDelimited** component. Define the data present in the file to read, file2 in this scenario. For more information about schema types, see [Talend Studio User Guide](#).

The schema in file2 consists of five columns: **Num, Ref, Price, Quant, and tax**.

8. In the design workspace, select the **tFileOutputDelimited** component.

9. Click the **Component** tab to define the basic settings of **tFileOutputDelimited**.
10. Set property type to **Built-in**.

11. In the **File name** field, press **Ctrl+Space** to access the variable list and select the global variable `FILENAME`.

12. Set the row and field separators in their corresponding fields.

13. Select the **Include Header** check box as file2 in this scenario includes a header.

14. Set **Schema** to **Built-in** and click **Sync columns** to synchronize the output file schema (file1) with the input file schema (file2).

15. In the design workspace, select the **tMsgBox** component.

16. Click the **Component** tab to define the basic settings of **tMsgBox**.

17. Click the **If** link to display its properties in the **Basic settings** view.

18. In the **Condition** panel, press **Ctrl+Space** to access the variable list and select the global variable `EXISTS`. Type an exclamation mark before the variable to negate the meaning of the variable.
Saving and executing the Job

Procedure

1. Press **Ctrl+S** to save your Job.
2. Press **F6** or click the **Run** button in the **Run** tab to execute it.
tFileFetch

Retrieves a file through the given protocol (HTTP, HTTPS, FTP, or SMB).

**tFileFetch Standard properties**

These properties are used to configure tFileFetch running in the Standard Job framework.

The Standard tFileFetch component belongs to the Internet family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Protocol</td>
<td>Select the protocol you want to use from the list and fill in the corresponding fields: http, https, ftp, smb. The properties differ slightly depending on the type of protocol selected. The additional fields are defined in this table, after the basic settings.</td>
</tr>
<tr>
<td>URI</td>
<td>Type in the URI of the site from which the file is to be fetched.</td>
</tr>
<tr>
<td>Use cache to save resource</td>
<td>Select this check box to save the data in the cache. This option allows you to process the file data flow (in streaming mode) without saving it on your drive. This is faster and improves performance.</td>
</tr>
<tr>
<td>Domain</td>
<td>Enter the Microsoft server domain name. Available for the smb protocol.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>Enter the authentication information required to access the server.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. Available for the smb protocol.</td>
</tr>
<tr>
<td>Destination Directory</td>
<td>Browse to the destination folder where the file fetched is to be placed.</td>
</tr>
<tr>
<td>Destination Filename</td>
<td>Enter a new name for the file fetched. If the Upload file option on the Advanced settings view is selected, the upload response will be saved in this file.</td>
</tr>
<tr>
<td>Create full path according to URI</td>
<td>It allows you to reproduce the URI directory path. To save the file at the root of your destination directory, clear the check box. Available for the http, https and ftp protocols.</td>
</tr>
<tr>
<td>Add header</td>
<td>Select this check box if you want to add one or more HTTP request headers as fetch conditions. In the Headers table, enter the name(s) of the HTTP header parameter(s) in the</td>
</tr>
</tbody>
</table>
**POST method**

This check box is selected by default. It allows you to use the POST method. In the Parameters table, enter the name of the variable(s) in the Name field and the corresponding value in the Value field.

Clear the check box if you want to use the GET method.

Available for the http and https protocols.

---

**Die on error**

Clear this check box to skip the rows in error and to complete the process for the error free rows

Available for the http, https and ftp protocols.

---

**Read Cookie**

Select this check box for tFileFetch to load a web authentication cookie.

Available for the http, https, ftp and smb protocols.

---

**Save Cookie**

Select this check box to save the web page authentication cookie. This means you will not have to log on to the same web site in the future.

Available for the http, https, ftp and smb protocols.

---

**Cookie file**

Type in the full path to the file which you want to use to save the cookie or click [...] and browse to the desired file to save the cookie.

Available for the http, https, ftp and smb protocols.

---

**Cookie policy**

Choose a cookie policy from this drop-down list. Four options are available, BROWSER_COMPATIBILITY, DEFAULT, NETSCAPE and RFC_2109.

Available for the http, https, ftp and smb protocols.

---

**Single cookie header**

Check this box to put all cookies into one request header for maximum compatibility among different servers.

Available for the http, https, ftp and smb protocols.

---

### Advanced settings

**tStatCatcher Statistics**

Select this check box to collect the log data at each component level.

**Timeout**

Enter the number of milliseconds after which the protocol connection should close.

Available for the http and https protocols.

**Print response to console**

Select this check box to print the server response in the console.

Available for the http and https protocols.

**Upload file**

Select this check box to upload one or more files to the server. Then in the Files table displayed, click the [+] button to add the file(s) to upload and define the following parameters for each file:
**FileFetch**

- **Name**: the new name of the file after being uploaded, between double quotation marks.
- **File**: the full path of the file to upload, e.g. '\D:\filefetch.txt'.
- **Content-Type**: the content type of the file to upload. The default value is 'application/octet-stream'.
- **Charset**: the character set of the file to upload. The default value is 'ISO-8859-1'.

Available for the **http** and **https** protocols, with the **POST method** option in the **Basic settings** view selected.

With this option selected, the upload response will be saved in the file specified in the **Destination filename** field in the **Basic settings** view.

---

**Enable proxy server**

Select this check box if you are connecting via a proxy and complete the fields which follow with the relevant information.

Available for the **http**, **https** and **ftp** protocols.

---

**Enable NTLM Credentials**

Select this check box if you are using an NTLM authentication protocol.

**Domain**: The client domain name.

**Host**: The client's IP address.

Available for the **http** and **https** protocols.

---

**Need authentication**

Select this check box and enter the username and password in the relevant fields, if they are required to access the protocol.

Available for the **http** and **https** protocols.

---

**Support redirection**

Select this check box to repeat the redirection request until redirection is successful and the file can be retrieved.

Available for the **http**, **https** and **ftp** protocols.

---

**Global Variables**

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

**INPUT_STREAM**: the content of the file being fetched. This is a Flow variable and it returns an InputStream.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*. 
Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>Limitation</th>
</tr>
</thead>
<tbody>
<tr>
<td>This component is generally used as a start component to feed the input flow of a Job and is often</td>
<td>Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>

</tr>
</tbody>
</table>

Fetching data through HTTP

This scenario describes a three-component Job which retrieves a file from an HTTP website, reads data from the fetched file and displays the data on the console.

Dropping and linking components

Procedure

1. Drop a tFileFetch, a tFileInputDelimited and a tLogRow onto your design workspace.
2. Link tFileFetch to tFileInputDelimited using a Trigger > On Subjob Ok or On Component Ok connection.
3. Link tFileInputDelimited to tLogRow using a Row > Main connection.
## Configuring the components

### Procedure

1. Double-click **tFileFetch** to open its **Basic settings** view.

   ![tFileFetch](image)

   - **Protocol**: http
   - **URI**: "http://talendforge.org/file_fetch.txt"
   - **Use resource cache**
   - **Destination directory**: D:/Output
   - **Destination filename**: new.txt
   - **Add header**: False
   - **POST method**: False
   - **Die on error**: False
   - **Save cookies**: False

2. Select the protocol you want to use from the list. Here, **http** is selected.

3. In the **URI** field, type in the URI where the file to be fetched can be retrieved from. You can paste the URI directly in your browser to view the data in the file.

4. In the **Destination directory** field, browse to the folder where the fetched file is to be stored. In this example, it is D:/Output.

5. In the **Destination filename** field, type in a new name for the file if you want it to be changed. In this example, **new.txt**.

6. If needed, select the **Add header** check box and define one or more HTTP request headers as fetch conditions. For example, to fetch the file only if it has been modified since 19:43:31 GMT, October 29, 1994, fill in the **Name** and **Value** fields with "If-Modified-Since" and "Sat, 29 Oct 1994 19:43:31 GMT" respectively in the **Headers** table. For details about HTTP request header definitions, see **Header Field Definitions**.

7. Double-click **tFileInputDelimited** to open its **Basic settings** view.

   ![tFileInputDelimited](image)

   - **Property Type**: Built-In
   - **File name/Stream**: D:/Output/new.txt
   - **Row separator**: \n
8. In the **File name** field, type in the full path to the fetched file which had been stored locally.
9. Click the [...] button next to Edit schema to open the Schema dialog box. In this example, add one column output to store the data from the fetched file.

10. Leave other settings as they are.

Saving and executing the Job

Procedure
1. Press Ctrl+S to save your Job.
2. Press F6 or click Run on the Run tab to execute the Job.

Starting job test at 17:14 10/01/2014.

[statistics] connecting to socket on port 3656
[statistics] connected
Well done
[statistics] disconnected
Job test ended at 17:14 10/01/2014. [exit code=0]

The data of the fetched file is displayed on the console.

Reusing stored cookie to fetch files through HTTP

This scenario describes a two-component Job which logs in a given HTTP website and then using cookie stored in a user-defined local directory, fetches data from this website.
Dropping and linking components

Procedure
1. Drop two `tFileFetch` components onto your design workspace.
2. Link the two components as subJobs using a `Trigger > On Subjob Ok` connection.

Configuring the components

Configuring the first subJob

Procedure
1. Double click `tFileFetch_1` to open its component view.
2. Select the protocol you want to use from the Protocol list. Here, we use the https protocol.

3. In the URI field, type in the URI through which you can log in the website and fetch the web page accordingly. In this example, the URI is https://www.codeproject.com/script/Membership/LogOn.aspx?download=true.

4. In the Destination directory field, browse to the folder where the fetched web page is to be stored. This folder will be created on the fly if it does not exist. In this example, type in D:/download.

5. In the Destination Filename field, type in a new name for the file if you want it to be changed. In this example, codeproject.html.

6. Under the Parameters table, click the plus button to add two rows and fill in the credentials for accessing the desired website.

   In the Name column, type in a new name respectively for the two rows. In this example, they are Email and Password, which are required by the website you are logging in.

   In the Value column, type in the authentication information.

7. Select the Save cookie check box.

8. In the Cookie file field, type in the full path to the file which you want to use to save the cookie. In this example, it is D:/download/cookie.

9. Click Advanced settings to open its view.

10. Select the Support redirection check box so that the redirection request will be repeated until the redirection is successful.

Configuring the second subJob

Procedure

1. Double-click tFileFetch_2 to open its Component view.
2. From the **Protocol** list, select **http**.

3. In the **URI** field, type in the address from which you fetch the files of your interest. In this example, the address is `http://www.codeproject.com/script/articles/download.aspx?file=/KB/DLL/File_List_Downloader/FLD02June2011_Source.zip&rp=http://www.codeproject.com/Articles/203991/File-List-Downloader`.

4. In the **Destination directory** field, type in the directory or browse to the folder where you want to store the fetched files. This folder can be automatically created if it does not exist yet during the execution process. In this example, type in `D:/download`.

5. In the **Destination Filename** field, type in a new name for the file if you want it to be changed. In this example, `source.zip`.

6. Clear the **POST method** check box to deactivate the **Parameters** table.

7. Select the **Read cookie** check box.

8. In the **Cookie file** field, browse to the file which is used to save the cookie. In this example, it is `D:/download/cookie`.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl+S** to save your Job.

2. Press **F6** or click **Run** on the **Run** tab to execute the Job.

Then, go to the local directory `D:/download` to check the downloaded file.
Related scenario

For an example of transferring data in streaming mode, see Reading data from a remote file in streaming mode on page 1013
tFileInputARFF

Reads an ARFF file row by row to split them up into fields and then sends the fields as defined in the schema to the next component.

**tFileInputARFF Standard properties**

These properties are used to configure tFileInputARFF running in the Standard Job framework. The Standard tFileInputARFF component belongs to the File family. The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-in or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file where the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Click this icon to open a connection wizard and store the Excel file connection parameters you set in the component’s Basic settings view. For more information about setting up and storing file connection parameters, see Talend Studio User Guide.</td>
<td></td>
</tr>
<tr>
<td>File Name</td>
<td>Name and path of the ARFF file and/or variable to be processed. For further information about how to define and use a variable in a Job, see Talend Studio User Guide.</td>
</tr>
<tr>
<td></td>
<td>Warning: Use absolute path (instead of relative path) for this field to avoid possible errors.</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either Built-in or stored remotely in the Repository. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:</td>
</tr>
<tr>
<td></td>
<td>View schema: choose this option to view the schema only.</td>
</tr>
<tr>
<td></td>
<td>Change to built-in property: choose this option to change the schema to Built-in for local changes.</td>
</tr>
<tr>
<td></td>
<td>Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.</td>
</tr>
</tbody>
</table>
### Advanced settings

**Encoding**
- Select the encoding type from the list or select **Custom** and define it manually. This field is compulsory for DB data handling.

**tStatCatcher Statistics**
- Select this check box to gather the processing metadata at the Job level as well as at each component level.

### Global Variables

**Global Variables**
- **NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](https://help.talend.com).

### Usage

**Usage rule**
- Use this component to read a file and separate the fields with the specified separator.

**Limitation**
- Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

### Displaying the content of a ARFF file

This scenario describes a two-component Job in which the rows of an ARFF file are read, the delimited data is selected and the output is displayed in the **Run** view.
An ARFF file looks like the following:

```arff
@relation vote
@attribute 'handicapped-infants' { 'n', 'y'}
@attribute 'water-project-cost-sharing' { 'n', 'y'}
@attribute 'adoption-of-the-budget-resolution' { 'n', 'y'}
@attribute 'physician-fee-freeze' { 'n', 'y'}
@attribute 'el-salvador-aid' { 'n', 'y'}
@attribute 'religious-groups-in-schools' { 'n', 'y'}
@attribute 'anti-satellite-test-ban' { 'n', 'y'}
@attribute 'aid-to-nicaraguan-contras' { 'n', 'y'}
@attribute 'mx-missile' { 'n', 'y'}
@attribute 'immigration' { 'n', 'y'}
@attribute 'synfuels-corporation-cutback' { 'n', 'y'}
@attribute 'education-spending' { 'n', 'y'}
@attribute 'superfund-right-to-sue' { 'n', 'y'}
@attribute 'crime' { 'n', 'y'}
@attribute 'duty-free-exports' { 'n', 'y'}
@attribute 'export-administration-act-south-africa' { 'n', 'y'}
@attribute 'Class' { 'democrat', 'republican'}
@data
'n','y','n','y','y','y','y','n','n','n','y','?','y','y','y','n','n','y','republican' 'n','n','n','y','y','y','y','y','n','n','n','n','n','n','n','n','?','republican' 'n','?','y','y','y','n','n','n','n','n','n','n',' democrat'
```

It is generally made of two parts. The first part describes the data structure, that is to say the rows which begin by @attribute and the second part comprises the raw data, which follows the expression @data.

### Dropping and linking components

**Procedure**

1. Drop the `tFileInputARFF` component from the Palette onto the workspace.
2. In the same way, drop the `tLogRow` component.
3. Right-click the `tFileInputARFF` and select Row > Main in the menu. Then, drag the link to the `tLogRow`, and click it. The link is created and appears.

### Configuring the components

**Procedure**

1. Double-click the `tFileInputARFF`.
2. In the Component view, in the File Name field, browse your directory in order to select your .arff file.
3. In the Schema field, select Built-In.
4. Click the [...] button next to Edit schema to add column descriptions corresponding to the file to be read.
5. Click on the button as many times as required to create the number of columns required, according to the source file. Name the columns as follows.

6. For every column, the Nullable check box is selected by default. Leave the check boxes selected, for all of the columns.

7. Click OK.

8. In the workspace, double-click the tLogRow to display its Component view.
9. Click the [...] button next to Edit schema to check that the schema has been propagated. If not, click the Sync columns button.

**Saving and executing the Job**

**Procedure**

1. Press Ctrl+S to save your Job.
2. Press F6 to execute your Job.

The console displays the data contained in the ARFF file, delimited using a vertical line (the default separator).
tFileInputDelimited

Reads a delimited file row by row to split them up into fields and then sends the fields as defined in the schema to the next component.

**tFileInputDelimited Standard properties**

These properties are used to configure tFileInputDelimited running in the Standard Job framework. The Standard tFileInputDelimited component belongs to the File family. The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-In or Repository.</th>
<th>Built-In: No property data stored centrally.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Repository:</td>
<td>Select the repository file where the properties are stored.</td>
<td></td>
</tr>
</tbody>
</table>

**File Name/Stream**

- **File name**: Name and path of the file to be processed.
- **Stream**: The data flow to be processed. The data must be added to the flow in order for tFileInputDelimited to fetch these data via the corresponding representative variable.
  
  This variable could be already pre-defined in your Studio or provided by the context or the components you are using along with this component; otherwise, you could define it manually and use it according to the design of your Job, for example, using tJava or tJavaFlex.

  In order to avoid the inconvenience of hand writing, you could select the variable of interest from the auto-completion list (Ctrl+Space) to fill the current field on condition that this variable has been properly defined.

  **Warning**: Use absolute path (instead of relative path) for this field to avoid possible errors.

  Related topic to the available variables: see Talend Studio User Guide

- **Row separator**: The separator used to identify the end of a row.

- **Field separator**: Enter character, string or regular expression to separate fields for the transferred data.

- **CSV options**: Select this check box to specify the following CSV parameters:
  - **Escape char**: enter the escape character between double quotation marks.
  - **Text enclosure**: enter the enclosure character (only one character) between double quotation marks. For example, """" needs to be entered when double quotation marks (") are used as the enclosure character.
It is recommended to use standard escape character, that is "\". Otherwise, you should set the same character for **Escape char** and **Text enclosure**. For example, if the escape character is set to "\", the text enclosure can be set to any other character. On the other hand, if the escape character is set to other character rather than "\", the text enclosure can be set to any other characters. However, the escape character will be changed to the same character as the text enclosure. For instance, if the escape character is set to "#" and the text enclosure is set to "@", the escape character will be changed to "@", not "#".

<table>
<thead>
<tr>
<th>Header</th>
<th>Enter the number of rows to be skipped in the beginning of file.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Footer</td>
<td>Number of rows to be skipped at the end of the file.</td>
</tr>
<tr>
<td>Limit</td>
<td>Maximum number of rows to be processed. If Limit = 0, no row is read or processed.</td>
</tr>
</tbody>
</table>
| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word *line* when naming the fields. Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
  • **View schema**: choose this option to view the schema only.  
  • **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
  • **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.  
  Note that if the input value of any non-nullable primitive field is null, the row of data including that field will be rejected. |
| **Built-In**: You create and store the schema locally for this component only. |
| **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. |
| **Skip empty rows** | Select this check box to skip the empty rows. |
| **Uncompress as zip file** | Select this check box to uncompress the input file. |
| **Die on error** | Select the check box to stop the execution of the Job when an error occurs.  
  Clear the check box to skip any rows on error and complete the process for error-free rows. When errors are skipped, you can collect the rows on error using a **Row > Reject** link. |
To catch the `FileNotFoundException`, you also need to select this check box.

**Advanced settings**

<table>
<thead>
<tr>
<th>Advanced separator (for numbers)</th>
<th>Select this check box to change the separator used for numbers. By default, the thousands separator is a comma (,) and the decimal separator is a period (.)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Extract lines at random</td>
<td>Select this check box to set the number of lines to be extracted randomly.</td>
</tr>
<tr>
<td>Encoding</td>
<td>Select the encoding from the list or select Custom and define it manually. This field is compulsory for database data handling. The supported encodings depend on the JVM that you are using. For more information, see <a href="https://docs.oracle.com">https://docs.oracle.com</a>.</td>
</tr>
<tr>
<td>Trim all column</td>
<td>Select this check box to remove the leading and trailing whitespaces from all columns. When this check box is cleared, the Check column to trim table is displayed, which lets you select particular columns to trim.</td>
</tr>
<tr>
<td>Check each row structure against schema</td>
<td>Select this check box to check whether the total number of columns in each row is consistent with the schema. If not consistent, an error message will be displayed on the console.</td>
</tr>
<tr>
<td>Check date</td>
<td>Select this check box to check the date format strictly against the input schema.</td>
</tr>
<tr>
<td>Check columns to trim</td>
<td>This table is filled automatically with the schema being used. Select the check box(es) corresponding to the column(s) to be trimmed.</td>
</tr>
<tr>
<td>Split row before field</td>
<td>Select this check box to split rows before splitting fields.</td>
</tr>
</tbody>
</table>
| Permit hexadecimal (0xNNN) or octal (0NNNN) for numeric types | Select this check box if any of your numeric types (long, integer, short, or byte type), will be parsed from a hexadecimal or octal string.  
In the table that displays, select the check box next to the column or columns of interest to transform the input string of each selected column to the type defined in the schema.  
Select the Permit hexadecimal or octal check box to select all the columns.  
This table appears only when the Permit hexadecimal (0xNNN) or octal (0NNNN) for numeric types check box is selected. |
| tStatCatcher Statistics | Select this check box to gather the processing metadata at the Job level as well as at each component level. |

**Global Variables**

| Global Variables | **NB_LINE**: the number of rows processed. This is an After variable and it returns an integer. |
ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule

Use this component to read a file and separate fields contained in this file using a defined separator. It allows you to create a data flow using a Row > Main link or via a Row > Reject link in which case the data is filtered by data that does not correspond to the type defined. For further information, please see Procedure on page 968.

Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

Reading data from a Delimited file and display the output

The following scenario creates a two-component Job, which aims at reading each row of a file, selecting delimited data and displaying the output in the Run log console.

Dropping and linking components

Procedure

1. Drop a tFileInputDelimited component and a tLogRow component from the Palette to the design workspace.
2. Right-click on the tFileInputDelimited component and select Row > Main. Then drag it onto the tLogRow component and release when the plug symbol shows up.
Configuring the components

Procedure

1. Select the tFileInputDelimited component again, and define its Basic settings:

2. Fill in a path to the file in the File Name field. This field is mandatory.

   Warning: If the path of the file contains some accented characters, you will get an error message when executing your Job.

3. Define the Row separator allowing to identify the end of a row. Then define the Field separator used to delimit fields in a row.

4. In this scenario, the header and footer limits are not set. And the Limit number of processed rows is set on 50.

5. Set the Schema as either a local (Built-in) or a remotely managed (Repository) to define the data to pass on to the tLogRow component.

6. You can load and/or edit the schema via the Edit Schema function. Related topics: see Talend Studio User Guide.

7. Enter the encoding standard the input file is encoded in. This setting is meant to ensure encoding consistency throughout all input and output files.

8. Select the tLogRow and define the Field separator to use for the output display. Related topic: tLogRow on page 1956.

9. Select the Print schema column name in front of each value check box to retrieve the column labels in the output displayed.

Saving and executing the Job

Procedure

1. Press Ctrl+S to save your Job.

2. Go to Run tab, and click on Run to execute the Job.

   The file is read row by row and the extracted fields are displayed on the Run log as defined in both components Basic settings.
The Log sums up all parameters in a header followed by the result of the Job.

## Reading data from a remote file in streaming mode

This scenario describes a four component Job used to fetch data from a voluminous file almost as soon as it has been read. The data is displayed in the **Run** view. The advantage of this technique is that you do not have to wait for the entire file to be downloaded, before viewing the data.

### Dropping and linking components

**Procedure**

1. Drop the following components onto the workspace: **tFileFetch**, **tSleep**, **tFileInputDelimited**, and **tLogRow**.

2. Connect **tSleep** and **tFileInputDelimited** using a **Trigger > OnComponentOk** link and connect **tFileInputDelimited** to **tLogRow** using a **Row > Main** link.

### Configuring the components

**Procedure**

1. Double-click **tFileFetch** to display the **Basic settings** tab in the **Component** view and set the properties.
2. From the **Protocol** list, select the appropriate protocol to access the server on which your data is stored.

3. In the **URI** field, enter the URI required to access the server on which your file is stored.

4. Select the **Use cache to save the resource** check box to add your file data to the cache memory. This option allows you to use the streaming mode to transfer the data.

5. In the workspace, click **tSleep** to display the **Basic settings** tab in the **Component** view and set the properties.
   
   By default, **tSleep**'s **Pause** field is set to 1 second. Do not change this setting. It pauses the second Job in order to give the first Job, containing **tFileFetch**, the time to read the file data.

6. In the workspace, double-click **tFileInputDelimited** to display its **Basic settings** tab in the **Component** view and set the properties.

7. In the **File name/Stream** field:
   
   - Delete the default content.
   - Press **Ctrl+Space** to view the variables available for this component.
   - Select **tFileFetch_1_INPUT_STREAM** from the auto-completion list, to add the following variable to the **Filename** field: `((java.io.InputStream)globalMap.get("tFileFetch_1_INPUT_STREAM"))`. 
8. From the **Schema** list, select **Built-in** and click [...] next to the **Edit schema** field to describe the structure of the file that you want to fetch. The *US_Employees* file is composed of six columns: ID, Employee, Age, Address, State, EntryDate.

Click [+] to add the six columns and set them as indicated in the above screenshot. Click **OK**.

![Schema of tFileInputDelimited_1](image)

9. In the workspace, double-click **tLogRow** to display its **Basic settings** in the **Component** view and click **Sync Columns** to ensure that the schema structure is properly retrieved from the preceding component.

**Configuring Job execution and executing the Job**

**Procedure**

1. Click the **Job** tab and then on the **Extra** view.

![tFileInputDelimited 0.1](image)

2. Select the **Multi thread execution** check box in order to run the two Jobs at the same time. Bear in mind that the second Job has a one second delay according to the properties set in **tSleep**. This option allows you to fetch the data almost as soon as it is read by **tFileFetch**, thanks to the **tFileDelimited** component.

3. Save the Job and press **F6** to run it.
The data is displayed in the console as almost as soon as it is read.
## tFileInputExcel

Reads an Excel file row by row to split them up into fields using regular expressions and then sends the fields as defined in the schema to the next component.

### tFileInputExcel Standard properties

These properties are used to configure tFileInputExcel running in the Standard Job framework.

The Standard tFileInputExcel component belongs to the File family.

The component in this framework is available in all Talend products.

#### Basic settings

<table>
<thead>
<tr>
<th>Property type</th>
<th>Built-in: No property data stored centrally.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Repository: Select the repository file where the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
<td></td>
</tr>
</tbody>
</table>

Click this icon to open a connection wizard and store the Excel file connection parameters you set in the component Basic settings view.

For more information about setting up and storing file connection parameters, see Talend Studio User Guide.

Select this check box to read the .xlsx file of Excel 2007.

**File Name/Stream**

**File name**: Name of the file and/or the variable to be processed.

**Stream**: Data flow to be processed. The data must be added to the flow in order to be collected by tFileInputExcel via the `INPUT_STREAM` variable in the auto-completion list (`Ctrl + Space`).

For further information about how to define and use a variable in a Job, see Talend Studio User Guide.

**Warning**: Use absolute path (instead of relative path) for this field to avoid possible errors.

Select this check box to process all sheets of the Excel file.

**Sheet list**

Click the plus button to add as many lines as needed to the list of the excel sheets to be processed:

**Sheet (name or position)**: enter the name or position of the excel sheet to be processed.

**Use Regex**: select this check box if you want to use a regular expression to filter the sheets to process.

Enter the number of rows to be skipped in the beginning of file.
<table>
<thead>
<tr>
<th><strong>Footer</strong></th>
<th>Number of records to be skipped at the end of the file.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Limit</strong></td>
<td>Maximum number of lines to be processed.</td>
</tr>
<tr>
<td><strong>Affect each sheet(header&amp;footer)</strong></td>
<td>Select this check box if you want to apply the parameters set in the Header and Footer fields to all excel sheets to be processed.</td>
</tr>
</tbody>
</table>

**Note:** This option is only available when you select Memory-consuming (User mode) from the Generation mode drop-down list in the Advanced settings view.

<table>
<thead>
<tr>
<th><strong>Die on error</strong></th>
<th>Select this check box to stop the execution of the Job when an error occurs. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can collect the rows on error using a Row &gt; Reject link.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>First column and Last column</strong></td>
<td>Define the range of the columns to be processed through setting the first and last columns in the First column and Last column fields respectively.</td>
</tr>
</tbody>
</table>

| **Schema and Edit Schema** | A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either Built-in or stored remotely in the Repository. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
  - View schema: choose this option to view the schema only.  
  - Change to built-in property: choose this option to change the schema to Built-in for local changes.  
  - Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-in</strong></td>
<td>The schema will be created and stored locally for this component only. Related topic: see Talend Studio User Guide.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>The schema already exists and is stored in the Repository, hence can be reused in various projects and Job flowcharts. Related topic: see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

### Advanced settings

<table>
<thead>
<tr>
<th><strong>Advanced separator</strong></th>
<th>Select this check box to change the used data separators.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Trim all columns</strong></td>
<td>Select this check box to remove the leading and trailing whitespaces from all columns. When this check box is cleared, the Check column to trim table is displayed, which lets you select particular columns to trim.</td>
</tr>
<tr>
<td><strong>Check column to trim</strong></td>
<td>This table is filled automatically with the schema being used. Select the check box(es) corresponding to the column(s) to be trimmed.</td>
</tr>
<tr>
<td>--------------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| **Convert date column to string** | Available when Read excel2007 file format (xlsx) is selected in the Basic settings view.  
Select this check box to show the table **Check need convert date column**. Here you can parse the string columns that contain date values based on the given date pattern.  
**Column**: all the columns available in the schema of the source .xlsx file.  
**Convert**: select this check box to choose all the columns for conversion (only if they are all of the string type). You can also select the individual check box next to each column for conversion.  
**Date pattern**: set the date format here. |
| **Encoding** | Select the encoding from the list or select **Custom** and define it manually. This field is compulsory for DB data handling. |
| **Read real values for numbers** | Select this check box to read numbers in real values. This check box becomes unavailable when you select Read excel2007 file format (xlsx) in the Basic settings view. |
| **Stop reading on encountering empty rows** | Select this check box to ignore the empty line encountered and, if there are any, the lines that follow this empty line. This check box becomes unavailable when you select Read excel2007 file format (xlsx) in the Basic settings view. |
| **Generation mode** | Available when Read excel2007 file format (xlsx) is selected in the Basic settings view. Select the mode used to read the Excel 2007 file.  
- **Less memory consumed for large excel(Event mode)**: used for large file. This is a memory-saving mode to read the Excel 2007 file as a flow. With this mode selected, the data will be extracted with the format symbol, for example, the percent symbol % and the currency symbol $. Moreover, the Include phonetic runs check box is selected by default to allow you to use phonetic strings at index.  
- **Memory-consuming (User mode)**: used for small file. It needs much memory. With this mode selected, the pure data without the format symbol will be extracted. |
| **Don't validate the cells** | Select this check box to in order not to validate data. This check box becomes unavailable when you select Read excel2007 file format (xlsx) in the Basic settings view. |
| **Ignore the warning** | Select this check box to ignore all warnings generated to indicate errors in the Excel file. This check box becomes unavailable when you select Read excel2007 file format (xlsx) in the Basic settings view. |
| **tStatCatcher Statistics** | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

</tbody>
</table>

Usage

| Usage rule | Use this component to read an Excel file and to output the data separately depending on the schemas identified in the file. You can use a Row > Reject link to filter the data which doesn’t correspond to the type defined. For an example of how to use these two links, see Procedure on page 968. |

Limitation

| Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |

Related scenarios

No scenario is available for the Standard version of this component yet.
tFileInputFullRow

Reads a file row by row and sends complete rows of data as defined in the schema to the next component via a Row link.

**tFileInputFullRow Standard properties**

These properties are used to configure tFileInputFullRow running in the Standard Job framework. The Standard tFileInputFullRow component belongs to the File family. The component in this framework is available in all Talend products.

**Basic settings**

| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:
| | • View schema: choose this option to view the schema only.
| | • Change to built-in property: choose this option to change the schema to Built-in for local changes.
| | • Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |
| Built-In | You create and store the schema locally for this component only. |
| Repository | You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. |
| File Name | Specify the path to the file to be processed. **Warning:** Use absolute path (instead of relative path) for this field to avoid possible errors. |
| Row separator | The separator used to identify the end of a row. |
| Header | Enter the number of rows to be skipped in the beginning of file. |
| Footer | Enter the number of rows to be skipped at the end of the file. |
Limit | Enter the maximum number of rows to be processed. If the value is set to 0, no row is read or processed.
---|---
Skip empty rows | Select this check box to skip the empty rows.

**Advanced settings**

**Encoding** | Select the encoding from the list or select Custom and define it manually. This field is compulsory for database data handling. The supported encodings depend on the JVM that you are using. For more information, see [https://docs.oracle.com](https://docs.oracle.com).

**Extract lines at random** | Select this check box to set the number of lines to be extracted randomly.

**tStatCatcher Statistics** | Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

**Global Variables**

**Global Variables**

**NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](https://docs.oracle.com).

**Usage**

**Usage rule** | Use this component to read full rows in delimited files that can get very large.

### Reading full rows in a delimited file

The following scenario creates a two-component Job that aims at reading complete rows in the delimited file `states.csv` and displaying the rows on the console.

The content of the file `states.csv` that holds ten rows of data is as follows:

```
StateID;StateName
1;Alabama
2;Alaska
3;Arizona
4;Arkansas
```

1022
Reading full rows in a delimited file

Procedure

1. Create a new Job and add a `tFileInputFullRow` component and a `tLogRow` component by typing their names in the design workspace or dropping them from the Palette.

2. Link the `tFileInputFullRow` component to the `tLogRow` component using a Row > Main connection.

3. Double-click the `tFileInputFullRow` component to open its Basic settings view on the Component tab.

4. Click the [...] button next to Edit schema to view the data to be passed onto the `tLogRow` component. Note that the schema is read-only and it consists of only one column *line*.

5. In the File Name field, browse to or enter the path to the file to be processed. In this scenario, it is `E:/states.csv`.

6. In the Row Separator field, enter the separator used to identify the end of a row. In this example, it is the default value 

---

5;California
6;Colorado
7;Connecticut
8;Delaware
9;Florida
10;Georgia
7. In the **Header** field, enter 1 to skip the header row at the beginning of the file.

8. Double-click the **tLogRow** component to open its **Basic settings** view on the **Component** tab.

   ![tLogRow component](image)

<table>

<td></td>
</tr>
<tr>
<td></td>
<td><strong>Table</strong> (print values in cells of a table)</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>Vertical</strong> (each row is a key/value list)</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

   In the **Mode** area, select **Table (print values in cells of a table)** for better readability of the result.

9. Press **Ctrl+S** to save your Job and then **F6** to execute it.

```
[statistics] connecting to socket on port 3617
[statistics] connected
    =========
    line
    =========
1: Alabama
2: Alaska
3: Arizona
4: Arkansas
5: California
6: Colorado
7: Connecticut
8: Delaware
9: Florida
10: Georgia

[statistics] disconnected
```

As shown above, ten rows of data in the delimited file `states.csv` are read one by one, ignoring field separators, and the complete rows of data are displayed on the console.

To extract fields from rows, you must use **tExtractDelimitedFields**, **tExtractPositionalFields**, or **tExtractRegexFields**. For more information, see **tExtractDelimitedFields** on page 930, **tExtractPositionalFields** on page 956 and **tExtractRegexFields** on page 959.
tFileInputJSON

Extracts JSON data from a file and transfers the data to a file, a database table, etc.

tFileInputJSON Standard properties

These properties are used to configure tFileInputJSON running in the Standard Job framework.
The Standard tFileInputJSON component belongs to the Internet and the File families.
The component in this framework is available in all Talend products.

Basic settings

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Either Built-In or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Built-In</strong>: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: Select the repository file where the properties are stored.</td>
</tr>
</tbody>
</table>

Schema and Edit schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

- **Built-In**: You create and store the schema locally for this component only.
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

Click **Edit schema** to make changes to the schema. Note that if you make changes, the schema automatically becomes built-in.

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

Read By

Select a way of extracting JSON data in the file.

- **JsonPath**: Extracts JSON data based on the JSONPath query. With this option selected, you need to select a JSONPath API version from the **API version** drop-down list. It is recommended to read data by JSONPath in order to gain better performance.
- **Xpath**: Extracts JSON data based on the XPath query.
- **JsonPath without loop**: Extracts JSON data based on the JSONPath query without setting a loop node.
<table>

</tbody>
</table>

**Usage**

| Usage rule | This component is a start component of a Job and always needs an output link. |

**Extracting JSON data from a file using JSONPath without setting a loop node**

This scenario describes a two-component Job that extracts data from the JSON file Store.json by specifying the complete JSON path for each node of interest and displays the flat data extracted on the console.
The JSON file Store.json contains information about a department store and the content of the file is as follows:

```json
{"store": {
    "name": "Sunshine Department Store",
    "address": "Wangfujing Street",
    "goods": {
        "book": [
            {
                "category": "Reference",
                "title": "Sayings of the Century",
                "author": "Nigel Rees",
                "price": 8.88
            },
            {
                "category": "Fiction",
                "title": "Sword of Honour",
                "author": "Evelyn Waugh",
                "price": 12.66
            }
        ],
        "bicycle": {
            "type": "GIANT OCR2600",
            "color": "White",
            "price": 276
        }
    }
}}
```

In the following example, we will extract the store name, the store address, and the bicycle information from this file.

**Adding and linking the components**

**Procedure**

1. Create a new Job and add a `tFileInputJSON` component and a `tLogRow` component by typing their names in the design workspace or dropping them from the Palette.
2. Link the `tFileInputJSON` component to the `tLogRow` component using a `Row > Main` connection.

**Configuring the components**

**Procedure**

1. Double-click the `tFileInputJSON` component to open its Basic settings view.
2. Select **JsonPath without loop** from the **Read By** drop-down list. With this option, you need to specify the complete JSON path for each node of interest in the **JSONPath query** fields of the **Mapping** table.

3. Click the [...] button next to **Edit schema** to open the schema editor.

4. Click the [+] button to add five columns, *store_name*, *store_address*, *bicycle_type*, and *bicycle_color* of **String** type, and *bicycle_price* of **Double** type.

   Click **OK** to close the schema editor. In the pop-up dialog box, click **Yes** to propagate the schema to the subsequent component.

5. In the **Filename** field, specify the path to the JSON file that contains the data to be extracted. In this example, it is “E:/Store.json”.

6. In the **Mapping** table, the **Column** fields are automatically filled with the schema columns you have defined.

   In the **JSONPath query** fields, enter the JSONPath query expressions between double quotation marks to specify the nodes that hold the desired data.
• For the columns store_name and store_address, enter the JSONPath query expressions "$.store.name" and "$.store.address" relative to the nodes name and address respectively.

• For the columns bicycle_type, bicycle_color, and bicycle_price, enter the JSONPath query expressions "$.store.goods.bicycle.type", "$.store.goods.bicycle.color", and "$.store.goods.bicycle.price" relative to the child nodes type, color, and price of the bicycle node respectively.

7. Double-click the tLogRow component to display its Basic settings view.

8. In the Mode area, select Table (print values in cells of a table) for better readability of the result.

**Executing the Job**

**Procedure**

1. Press Ctrl+S to save the Job.

2. Press F6 to execute the Job.

As shown above, the store name, the store address, and the bicycle information are extracted from the source JSON data and displayed in a flat table on the console.

**Extracting JSON data from a file using JSONPath**

Based on Extracting JSON data from a file using JSONPath without setting a loop node on page 1027, this scenario extracts data under the book array of the JSON file Store.json by specifying a loop node and the relative JSON path for each node of interest, and then displays the flat data extracted on the console.

**Procedure**

1. In the Studio, open the Job used in Extracting JSON data from a file using JSONPath without setting a loop node on page 1027 to display it in the design workspace.
2. Double-click the `tFileInputJSON` component to open its **Basic settings** view.

![Basic settings](image)

3. Select **JsonPath** from the **Read By** drop-down list.

4. In the **Loop Json query** field, enter the JSONPath query expression between double quotation marks to specify the node on which the loop is based. In this example, it is `"$.store.goods.book[*]"`.

5. Click the `[...]` button next to **Edit schema** to open the schema editor.

![Schema editor](image)

Select the five columns added previously and click the `x` button to remove all of them.

Click the `[+]` button to add four columns, `book_title`, `book_category`, and `book_author` of **String** type, and `book_price` of **Double** type.

Click **OK** to close the schema editor. In the pop-up dialog box, click **Yes** to propagate the schema to the subsequent component.

6. In the **Json query** fields of the **Mapping** table, enter the JSONPath query expressions between double quotation marks to specify the nodes that hold the desired data. In this example, enter the JSONPath query expressions `"title"`, `"category"`, `"author"`, and `"price"` relative to the four child nodes of the `book` node respectively.

7. Press **Ctrl+S** to save the Job.
8. Press **F6** to execute the Job.

As shown above, the book information is extracted from the source JSON data and displayed in a flat table on the console.

### Extracting JSON data from a file using XPath

Based on Extracting JSON data from a file using JSONPath without setting a loop node on page 1027, this scenario extracts the store name and the book information from the JSON file `Store.json` using XPath queries and displays the flat data extracted on the console.

#### Procedure

**Procedure**

1. In the Studio, open the Job used in Extracting JSON data from a file using JSONPath without setting a loop node on page 1027 to display it in the design workspace.
2. Double-click the **tFileInputJSON** component to open its **Basic settings** view.

3. Select **XPath** from the **Read By** drop-down list.
4. Click the **[...]** button next to **Edit schema** to open the schema editor.
Select the five columns added previously and click the x button to remove all of them.
Click the [+] button to add five columns, store_name, book_title, book_category, and book_author of String type, and book_price of Double type.
Click OK to close the schema editor. In the pop-up dialog box, click Yes to propagate the schema to the subsequent component.

5. In the Loop XPath query field, enter the XPath query expression between double quotation marks to specify the node on which the loop is based. In this example, it is "/store/goods/book".

6. In the XPath query fields of the Mapping table, enter the XPath query expressions between double quotation marks to specify the nodes that hold the desired data.
   - For the column store_name, enter the XPath query "../../name" relative to the name node.

7. Press Ctrl+S to save the Job.
8. Press F6 to execute the Job.

As shown above, the store name and the book information are extracted from the source JSON data and displayed in a flat table on the console.

Extracting JSON data from a URL

In this scenario, tFileInputJSON retrieves data of the friends node from the JSON file facebook.json on the Web that contains the data of a Facebook user and tExtractJSONFields extracts the data from the friends node for flat data output.
The JSON file `facebook.json` is deployed on the Tomcat server, specifically, located in the folder `<tomcat path>/webapps/docs`, and the content of the file is as follows:

```json
{"user": {
    "id": "9999912398",
    "name": "Kelly Clarkson",
    "friends": [
        {
            "name": "Tom Cruise",
            "id": "55555555555555",
            "likes": {
                "data": [
                    {
                        "category": "Movie",
                        "name": "The Shawshank Redemption",
                        "id": "103636093053996",
                        "created_time": "2012-11-20T15:52:07+0000"
                    },
                    {
                        "category": "Community",
                        "name": "Positiveretribution",
                        "id": "471389562899413",
                        "created_time": "2012-12-16T21:13:26+0000"
                    }
                ]
            }
        },
        {
            "name": "Tom Hanks",
            "id": "88888888888888",
            "likes": {
                "data": [
                    {
                        "category": "Journalist",
                        "name": "Janelle Wang",
                        "id": "136009823148851",
                        "created_time": "2013-01-01T08:22:17+0000"
                    },
                    {
                        "category": "Tv show",
                        "name": "Now With Alex Wagner",
                        "id": "305948749433410",
                        "created_time": "2012-11-20T06:14:10+0000"
                    }
                ]
            }
        }
    ]
}}
```

**Adding and linking the components**

**Procedure**

1. Create a new Job and add a `tFileInputJSON` component, a `tExtractJSONFields` component, and two `tLogRow` components by typing their names in the design workspace or dropping them from the Palette.

2. Link the `tFileInputJSON` component to the first `tLogRow` component using a Row > Main connection.

3. Link the first `tLogRow` component to the `tExtractJSONFields` component using a Row > Main connection.
4. Link the `tExtractJSONFields` component to the second `tLogRow` component using a Row > Main connection.

**Configuring the components**

**Procedure**

1. Double-click the `tFileInputJSON` component to open its Basic settings view.

2. Select JsonPath without loop from the Read By drop-down list. Then select the Use Url check box and in the URL field displayed enter the URL of the file facebook.json from which the data will be retrieved. In this example, it is http://localhost:8080/docs/facebook.json.

3. Click the [...] button next to Edit schema and in the Schema dialog box define the schema by adding one column friends of String type.

   ![Schema dialog box](image)

   Click OK to close the dialog box and accept the propagation prompted by the pop-up dialog box.

4. In the Mapping table, enter the JSONPath query ".user.friends[*]" next to the friends column to retrieve the entire friends node from the source file.

5. Double-click `tExtractJSONFields` to open its Basic settings view.
6. Select **XPath** from the **Read By** drop-down list.

7. In the **Loop XPath query** field, enter the XPath expression between double quotation marks to specify the node on which the loop is based. In this example, it is "/likes/data".

8. Click the [...] button next to **Edit schema** and in the **Schema** dialog box define the schema by adding five columns of **String** type, id, name, like_id, like_name, and like_category, which will hold the data of relevant nodes under the JSON field **friends**.

   ![Schema of tExtractJSONFields_1](image)

   Click **OK** to close the dialog box and accept the propagation prompted by the pop-up dialog box.

9. In the **XPath query** fields of the **Mapping** table, type in the XPath query expressions between double quotation marks to specify the JSON nodes that hold the desired data. In this example:

   - "./id" (querying the "/friends/id" node) for the column **id**,
   - "./name" (querying the "/friends/name" node) for the column **name**,
   - "id" for the column **like_id**,
   - "name" for the column **like_name**, and
   - "category" for the column **like_category**.

10. Double-click the second **tLogRow** component to open its **Basic settings** view.
In the Mode area, select **Table (print values in cells of a table)** for better readability of the result.

### Executing the Job

**Procedure**

1. Press **Ctrl + S** to save the Job.
2. Click **F6** to execute the Job.

As shown above, the friends data in the JSON file specified using the URL is extracted and then the data from the node `friends` is extracted and displayed in a flat table.
tFileInputLDIF

Reads an LDIF file row by row to split them up into fields and sends the fields as defined in the schema to the next component using a Row connection.

**tFileInputLDIF Standard properties**

These properties are used to configure tFileInputLDIF running in the Standard Job framework.

The Standard tFileInputLDIF component belongs to the File family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-in or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file where the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

**File Name**

Name of the file and/or variable to be processed.

For further information about how to define and use a variable in a Job, see Talend Studio User Guide.

*Warning:* Use absolute path (instead of relative path) for this field to avoid possible errors.

**add operation as prefix when the entry is modify type**

Select this check box to display the operation mode.

**Value separator**

Type in the separator required for parsing data in the given file. By default, the separator used is ",".

**Die on error**

Select this check box to stop the execution of the Job when an error occurs. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can collect the rows on error using a Row > Reject link.

**Schema and Edit schema**

A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either Built-in or stored remotely in the Repository.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion.
Advanced settings

**Encoding**
Select the encoding type from the list or select **Custom** and define it manually. This field is compulsory for DB data handling.

**Use field options (for Base64 decode checked)**
Select this check box to specify the Base64-encoded columns of the input flow. Once selected, this check box activates the **Decode Base64 encoding values** table to enable you to precise the columns to be decoded from Base64.

**Note:**
The data type of the columns to be handled by this check box is **byte** that you define in the input schema editor.

**tStatCatcher Statistics**
Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

Global Variables

**Global Variables**

- **NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

Usage

**Usage rule**
Use this component to read full rows in a voluminous LDIF file. This component enables you to create a data flow, using a **Row > Main** link, and to create a reject flow with a **Row > Reject** link filtering the data which type does not match the defined type. For an example of usage, see *Procedure* on page 1089 from *tFileInputXML*.

**Limitation**
Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can
Related scenario

For a related scenario, see Writing data from a database table into an LDIF file on page 1126.
# tFileInputMail

Reads the standard key data of a given MIME or MSG email file.

## tFileInputMail Standard properties

These properties are used to configure tFileInputMail running in the Standard Job framework.

The Standard tFileInputMail component belongs to the File family.

The component in this framework is available in all Talend products.

### Basic settings

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>File Name</strong></td>
<td>Specify the email file to read and extract data from.</td>
</tr>
<tr>
<td><strong>Warning:</strong> Use absolute path (instead of relative path) for this field to avoid possible errors.</td>
<td></td>
</tr>
<tr>
<td><strong>Schema and Edit Schema</strong></td>
<td>A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either <strong>Built-in</strong> or stored remotely in the <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Warning:</strong> Use absolute path (instead of relative path) for this field to avoid possible errors.</td>
<td></td>
</tr>
<tr>
<td><strong>Mail type</strong></td>
<td>Select a type of email from the drop-down list, either <strong>MIME</strong> or <strong>MSG</strong>.</td>
</tr>
<tr>
<td><strong>Attachment export directory</strong></td>
<td>Specify the directory to which you want to export email attachments.</td>
</tr>
<tr>
<td><strong>Warning:</strong> Use absolute path (instead of relative path) for this field to avoid possible errors.</td>
<td></td>
</tr>
</tbody>
</table>

**Built-in**: The schema will be created and stored locally for this component only. Related topic: see Talend Studio User Guide.

**Repository**: The schema already exists and is stored in the Repository, hence can be reused in various projects and Job flowcharts. Related topic: see Talend Studio User Guide.

**Warning:** Use absolute path (instead of relative path) for this field to avoid possible errors.
### Mail parts

Specify the header fields to extract from the MIME email file specified in the **File Name** field.

- **Column:** The Column cells are automatically filled with the column names defined in the schema.
- **Mail part:** Type in the names of the header fields or body parts to be extracted from the email file in double quotation marks. Refer to [https://tools.ietf.org/html/rfc4021](https://tools.ietf.org/html/rfc4021) for a list of MIME mail header fields.
- **Multi value:** Select this check box to allow multiple field values.
- **Separator:** Enter a character as the separators for multiple field values.

This table appears only when **MIME** is selected from the **Mail type** drop-down list.

<table>
<thead>
<tr>
<th>MSG Mail parts</th>
<th>Specify what to extract from the defined MSG email file for each schema column.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• <strong>Column:</strong> The Column cells are automatically filled with the column name defined in the schema.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Mail part:</strong> Click each cell and then select an email part to be extracted.</td>
</tr>
<tr>
<td></td>
<td>This table appears only when <strong>MSG</strong> is selected from the <strong>Mail type</strong> drop-down list.</td>
</tr>
</tbody>
</table>

### Die on error

Select this check box to stop the execution of the Job when an error occurs. Clear the check box to skip the row on error and complete the process for error-free rows.

### Advanced settings

- **tStatCatcher Statistics**

  Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

| Global Variables | **EXPORTED_FILE_PATH:** the directory to export mail attachment. This is a Flow variable and it returns a string. **ERROR_MESSAGE:** the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see *Talend Studio User Guide*. |
Usage

| Usage rule | This component handles flow of data therefore it requires output. It is defined as an intermediary step. |

Extracting key fields from an email

This Java scenario describes a two-component Job that extracts some key standard fields and displays the values on the Run console.

Procedure

1. Drop a tFileInputMail and a tLogRow component from the Palette to the design workspace.
2. Connect the two components together using a Main Row link.
3. Double-click tFileInputMail to display its Basic settings view and define the component properties.

4. Click the three-dot button next to the File Name field and browse to the mail file to be processed.
5. Set schema type to Built-in and click the three-dot button next to Edit schema to open a dialog box where you can define the schema including all columns you want to retrieve on your output.
6. Click the plus button in the dialog box to add as many columns as you want to include in the output flow. In this example, the schema has four columns: Date, Author, Object and Status.
7. Once the schema is defined, click OK to close the dialog box and propagate the schema into the Mail parts table.
8. Click the three-dot button next to Attachment export directory and browse to the directory in which you want to export email attachments, if any.
9. In the **Mail part** column of the **Mail parts** table, type in the actual header or body standard keys that will be used to retrieve the values to be displayed.

10. Select the **Multi Value** check box next to any of the standard keys if more than one value for the relative standard key is present in the input file.

11. If needed, define a separator for the different values of the relative standard key in the **Separator** field.

12. Double-click **tLogRow** to display its **Basic settings** view and define the component properties in order for the values to be separated by a carriage return. On Windows OS, type in ‘\n’ between double quotes.

13. Save your Job and press **F6** to execute it and display the output flow on the console.

Starting job **tFileInputMail** at 11:48 06/11/2009

</table>

The Multi Schema Editor

The Multi Schema Editor enables you to:

- set the path to the source file,

  **Warning:** Use absolute path (instead of relative path) for this field to avoid possible errors.

- define the source file properties,
- define data structure for each of the output schemas.

When you define data structure for each of the output schemas in the Multi Schema Editor, column names in the different data structures automatically appear in the input schema lists of the components that come after tFileInputMSDelimited. However, you can still define data structures directly in the Basic settings view of each of these components.

The Multi Schema Editor also helps to declare the schema that should act as the source schema (primary key) from the incoming data to insure its unicity. The editor uses this mapping to associate all schemas processed in the delimited file to the source schema in the same file.

The editor opens with the first column, that usually holds the record type indicator, selected by default. However, once the editor is open, you can select the check box of any of the schema columns to define it as a primary key.

The below figure illustrates an example of the Multi Schema Editor.
For detailed information about the usage of the **Multi Schema Editor**, see [Reading a multi structure delimited file](#) on page 1047.

### Reading a multi structure delimited file

The following scenario creates a Java Job which aims at reading three schemas in a delimited file and displaying their data structure on the **Run Job** console.

The delimited file processed in this example looks like the following:

```plaintext
<table>
<thead>
<tr>
<th>Column 0</th>
<th>Column 1</th>
<th>Column 2</th>
<th>Column 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>01</td>
<td>SOFT MUSIC ALBUM</td>
<td>RICHARDSON</td>
<td>15/12/2005</td>
</tr>
<tr>
<td>02</td>
<td>We Danced</td>
<td></td>
<td></td>
</tr>
<tr>
<td>02</td>
<td>She's Everything</td>
<td></td>
<td></td>
</tr>
<tr>
<td>02</td>
<td>Once in a Lifetime Love</td>
<td></td>
<td></td>
</tr>
<tr>
<td>03</td>
<td>National Library</td>
<td></td>
<td></td>
</tr>
<tr>
<td>01</td>
<td>COUNTRY MUSIC ALBUM</td>
<td>WHITE</td>
<td>02/01/2006</td>
</tr>
<tr>
<td>02</td>
<td>Fall Into Me</td>
<td></td>
<td></td>
</tr>
<tr>
<td>02</td>
<td>Another Try</td>
<td></td>
<td></td>
</tr>
<tr>
<td>02</td>
<td>Something About Her</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

For detailed information about the usage of the **Multi Schema Editor**, see [Reading a multi structure delimited file](#) on page 1047.
Dropping and linking components

Procedure

1. Drop a tFileInputMSDelimited component and three tLogRow components from the Palette onto the design workspace.

2. In the design workspace, right-click tFileInputMSDelimited and connect it to tLogRow1, tLogRow2, and tLogRow3 using the row_A_1, row_B_1, and row_C_1 links respectively.

Configuring the components

Procedure

1. Double-click tFileInputMSDelimited to open the Multi Schema Editor.
2. Click **Browse...** next to the **File name** field to locate the multi schema delimited file you need to process.

3. In the **File Settings** area:
   - Select from the list the encoding type the source file is encoded in. This setting is meant to ensure encoding consistency throughout all input and output files.
   - Select the field and row separators used in the source file.

   **Note:**
   Select the **Use Multiple Separator** check box and define the fields that follow accordingly if different field separators are used to separate schemas in the source file.

A preview of the source file data displays automatically in the **Preview** panel.
Note:

Column 0 that usually holds the record type indicator is selected by default. However, you can select the check box of any of the other columns to define it as a primary key.

4. Click Fetch Codes to the right of the Preview panel to list the type of schema and records you have in the source file. In this scenario, the source file has three schema types (A, B, C).
Click each schema type in the Fetch Codes panel to display its data structure below the Preview panel.

5. Click in the name cells and set column names for each of the selected schema.
In this scenario, column names read as the following:
- Schema A: Type, DiscName, Author, Date,
- Schema B: Type, SongName,
- Schema C: Type, LibraryName.

You need now to set the primary key from the incoming data to insure its unicity (DiscName in this scenario). To do that:

6. In the Fetch Codes panel, select the schema holding the column you want to set as the primary key (schema A in this scenario) to display its data structure.

7. Click in the Key cell that corresponds to the DiscName column and select the check box that appears.

8. Click anywhere in the editor and the false in the Key cell will become true.

You need now to declare the parent schema by which you want to group the other "children" schemas (DiscName in this scenario). To do that:

9. In the Fetch Codes panel, select schema B and click the right arrow button to move it to the right. Then, do the same with schema C.

Note:
The Cardinality field is not compulsory. It helps you to define the number (or range) of fields in "children" schemas attached to the parent schema. However, if you set the wrong number or range and try to execute the Job, an error message will display.

10. In the Multi Schema Editor, click OK to validate all the changes you did and close the editor.

The three defined schemas along with the corresponding record types and field separators display automatically in the Basic settings view of tFileInputMSDelimited.
The three schemas you defined in the Multi Schema Editor are automatically passed to the three tLogRow components.

11. If needed, click the Edit schema button in the Basic settings view of each of the tLogRow components to view the input and output data structures you defined in the Multi Schema Editor or to modify them.

Saving and executing the Job

Procedure

1. Press Ctrl+S to save your Job.
2. Press F6 or click Run on the Run tab to execute the Job.

The multi schema delimited file is read row by row and the extracted fields are displayed on the Run Job console as defined in the [Multi Schema Editor].
Starting job pivot at 10:32 18/01/2010.

01|SOFT MUSIC ALBUM|RICHARDSON|15/12/2005
02|We Danced|SOFT MUSIC ALBUM
02|She's Everything|SOFT MUSIC ALBUM
02|Once in a Lifetime Love|SOFT MUSIC ALBUM
03|National Library|SOFT MUSIC ALBUM
01|COUNTRY MUSIC ALBUM|WHITE|02/01/2006
02|Fall Into Me|COUNTRY MUSIC ALBUM
02|Another Try|COUNTRY MUSIC ALBUM
02|Something About Her|COUNTRY MUSIC ALBUM

Job pivot ended at 10:33 18/01/2010. [exit code=0]
tFileInputMSPositional

Reads the data structures (schemas) of a multi-structured positional file and sends the fields as defined in the different schemas to the next components using Row connections.

**tFileInputMSPositional Standard properties**

These properties are used to configure tFileInputMSPositional running in the Standard Job framework. The Standard tFileInputMSPositional component belongs to the File family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-in or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file where the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>File Name</td>
<td>Name of the file and/or the variable to be processed. For further information about how to define and use a variable in a Job, see Talend Studio User Guide.</td>
</tr>
<tr>
<td></td>
<td><strong>Warning:</strong> Use absolute path (instead of relative path) for this field to avoid possible errors.</td>
</tr>
<tr>
<td>Row separator</td>
<td>String (ex: \n on Unix) to distinguish rows.</td>
</tr>
<tr>
<td>Header Field Position</td>
<td>Start-end position of the schema identifier.</td>
</tr>
<tr>
<td>Records</td>
<td><strong>Schema:</strong> define as many schemas as needed. <strong>Header value:</strong> value in the row that identifies a schema. <strong>Pattern:</strong> string which represents the length of each column of the schema, separated by commas. Make sure the values defined in this field are relevant with the defined schema. <strong>Reject incorrect row size:</strong> select the check boxes of the schemas where to reject incorrect row size. <strong>Parent row:</strong> Select the parent row from the drop-down list. By default, it is &lt;Empty&gt;. <strong>Parent key column:</strong> Type in the parent key column name. If the parent row is not &lt;Empty&gt;, this field must be filled with a column name of the parent row schema. <strong>Key column:</strong> Type in the key column name.</td>
</tr>
<tr>
<td>Skip from header</td>
<td>Number of rows to be skipped in the beginning of file.</td>
</tr>
<tr>
<td>Skip from footer</td>
<td>Number of rows to be skipped at the end of the file.</td>
</tr>
</tbody>
</table>
Limit | Maximum number of rows to be processed. If Limit = 0, no row is read or processed.
---|---
Die on parse error | Let the component die if an parsing error occurs.
Die on unknown header type | Length values separated by commas, interpreted as a string between quotes. Make sure the values entered in this fields are consistent with the schema defined.

**Advanced settings**

| Process long rows (needed for processing rows longer than 100,000 characters wide) | Select this check box to process long rows (this is necessary to process rows longer than 100 000 characters).
---|---
Advanced separator (for numbers) | Select this check box to modify the separators used for numbers:
- **Thousands separator**: define separators for thousands.
- **Decimal separator**: define separators for decimals.
Trim all column | Select this check box to remove leading and trailing whitespaces from defined columns.
Validate date | Select this check box to check the date format strictly against the input schema.
Encoding | Select the encoding type from the list or select **Custom** and define it manually. This field is compulsory for DB data handling.
tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

**Global Variables**

| Global Variables | **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is a Flow variable and it returns an integer.
---|---
| | **NB_LINE_REJECTED**: the number of rows rejected. This is a Flow variable and it returns an integer.
| | **NB_LINE_UNKNOWN_HEADER_TYPES**: the number of rows with unknown header type. This is a Flow variable and it returns an integer.
| | **NB_LINE_PARSE_ERRORS**: the number of rows with parse errors. This is a Flow variable and it returns an integer.
| | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.
Usage

Usage rule

Use this component to read a multi schemas positional file and separate fields using a position separator value. You can also create a rejection flow using a **Row > Reject** link to filter the data which does not correspond to the type defined. For an example of how to use these two links, see **Procedure** on page 968.

Reading data from a positional file

The following scenario reads data from a positional file, which contains two schemas. The positional file is shown below:

```plaintext
schema_1 (car_owner): schema_id; car_make; owner; age
schema_2 (car-insurance): schema_id; car_owner; age; car_insurance
1 bmw  John  45
1 bench Mike  30
2 John  45 yes
2 Mike  50 No
```

Dropping the components

**Procedure**

1. Drop one **tFileInputMSPositional** and two **tLogRow** from the **Palette** to the design workspace.
2. Rename the two **tLogRow** components as **car_owner** and **car_insurance**.

![Diagram](https://via.placeholder.com/150)

Configuring the components

**Procedure**

1. Double-click the **tFileInputMSPositional** component to show its **Basic settings** view and define its properties.
2. In the **File name/Stream** field, type in the path to the input file. Also, you can click the [...] button to browse and choose the file.

3. In the **Header Field Position** field, enter the start-end position for the schema identifier in the input file, 0-1 in this case as the first character in each row is the schema identifier.

4. Click the [+•] button twice to added two rows in the **Records** table.

5. Click the cell under the **Schema** column to show the [...] button. Click the [...] button to show the schema naming box.

6. Enter the schema name and click **OK**. The schema name appears in the cell and the schema editor opens.
7. Define the schema `car_owner`, which has four columns: `schema_id`, `car_make`, `owner` and `age`.

8. Repeat the steps to define the schema `car_insurance`, which has four columns: `schema_id`, `car_owner`, `age` and `car_insurance`.

9. Connect `tFileInputMSPositional` to the `car_owner` component with the `Row > car_owner` link, and the `car_insurance` component with the `Row > car_insurance` link.

10. In the `Header value` column, type in the schema identifier value for the schema, 1 for the schema `car_owner` and 2 for the schema `car_insurance` in this case.

11. In the `Pattern` column, type in the length of each field in the schema, the number of characters, number, etc in each field, 1,8,10,3 for the schema `car_owner` and 1,10,3,3 for the schema `car_insurance` in this case.

12. In the `Skip from header` field, type in the number of beginning rows to skip, 2 in this case as the two rows in the beginning just describes the two schemas, instead of the values.

13. Choose `Table (print values in cells of a table)` in the `Mode` area of the components `car_owner` and `car_insurance`.

**Executing the Job**

**Procedure**

1. Press `Ctrl+S` to save the Job.

2. Press `F6` or click `Run` on the `Run` tab to execute the Job.
The file is read row by row based on the length values defined in the **Pattern** field and output in two tables with different schemas.

<table>
<thead>
<tr>
<th>scheme_id</th>
<th>car_owner</th>
<th>age</th>

</tbody>
</table>
**tFileInputMSXML**

Reads the data structures (schemas) of a multi-structured XML file and sends the fields as defined in the different schemas to the next components using Row connections.

### tFileInputMSXML Standard properties

These properties are used to configure tFileInputMSXML running in the Standard Job framework. The Standard tFileInputMSXML component belongs to the File and the XML families. The component in this framework is available in all Talend products.

#### Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>File Name</strong></td>
<td>Name of the file and/or the variable to be processed. For further information about how to define and use a variable in a Job, see <a href="#">Talend Studio User Guide</a>.</td>
</tr>
<tr>
<td><strong>Root XPath query</strong></td>
<td>The root of the XML tree, which the query is based on.</td>
</tr>
<tr>
<td><strong>Enable XPath in column &quot;Schema XPath loop&quot; but lose the order</strong></td>
<td>Select this check box if you want to define a XPath path in the <strong>Schema XPath loop</strong> field of the <strong>Outputs</strong> table while not keeping the order of the data shown in the source XML file. <strong>Warning:</strong> This option takes effect only if you select the Dom4j generation mode in the <strong>Advanced settings</strong> view.</td>
</tr>
<tr>
<td><strong>Outputs</strong></td>
<td><strong>Schema:</strong> Define as many schemas as needed. <strong>Schema XPath loop:</strong> Enter the node of the XML tree or XPath path which the loop is based on. <strong>XPath Queries:</strong> Enter the fields to be extracted from the structured input. <strong>Create empty row:</strong> Select this check box if you want to create empty rows for the empty field(s) in the schema.</td>
</tr>
<tr>
<td><strong>Die on error</strong></td>
<td>Select this check box to stop the execution of the Job when an error occurs. Clear the check box to skip the row on error and complete the process for error-free rows.</td>
</tr>
</tbody>
</table>

#### Advanced settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Trim all column</strong></td>
<td>Select this check box to remove leading and trailing whitespaces from defined columns.</td>
</tr>
<tr>
<td><strong>Validate date</strong></td>
<td>Select this check box to check the date format strictly against the input schema.</td>
</tr>
</tbody>
</table>
Ignore DTD file | Select this check box to ignore the DTD file indicated in the XML file being processed.
---|---
Generation mode | Select the appropriate generation mode according to your memory availability. The available modes are:
• Slow and memory-consuming (Dom4j)
Note: This option allows you to use dom4j to process the XML files of high complexity.
• Fast with low memory consumption (SAX)
Encoding | Select the encoding type from the list or select CUSTOM and define it manually. This field is compulsory for DB data handling.
tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

Global Variables

Global Variables | NB_LINE: the number of rows processed. This is an After variable and it returns an integer.
ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.
For further information about variables, see Talend Studio User Guide.

Reading a multi-structure XML file

The following scenario describes a Job which reads a multi-structure XML file, extracts the desired fields and displays them on the console.

Designing the Job

Procedure

1. Drop a tFileInputMSXML component from the Palette onto the design workspace and double-click the component to open its Basic settings view in the Component tab.
2. Browse to the XML file you want to process. In this example, it is `D:/Input/multischema_xml.xml`, which contains the following data:

```
<root>
  <toy>Cat</toy>
  <record>We Belong Together</record>
  <book>As You Like It</book>
  <book>All's Well That Ends Well</book>
  <record>When You Believe</record>
  <toy>Dog</toy>
</root>
```

3. In the **Root XPath query** field, enter the root of the XML tree, which the query will be based on. In this example, it is `/root`.

4. Select the **Enable XPath in column “Schema XPath loop” but lose the order** check box. In this example, to extract the desired fields, you need to define a XPath path in the **Schema XPath loop** field in the **Outputs** table for each output flow while not keeping the order of the data shown in the source XML file.

5. Click the plus button to add lines in the **Outputs** table where you can define the output schemas, `record` and `book` in this example.

6. In the **Outputs** table, click in the **Schema** cell and then click a three-dot button to display a dialog box where you can define the schema name.

   Enter a name for the output schema and click **OK** to close the dialog box.

```
<root>
  <toy>Cat</toy>
  <record>We Belong Together</record>
  <book>As You Like It</book>
  <book>All's Well That Ends Well</book>
  <record>When You Believe</record>
  <toy>Dog</toy>
</root>
```

7. The **tFileInputMSXML** schema editor appears.

   Define the schema according to your need.
8. Do the same to define the output schema *record*.

9. In the **Schema XPath loop** cell, enter the node of the XML tree, which the loop is based on. In this example, enter `/book` and `/record` respectively.

10. In the **XPath Queries** cell, enter the fields to be extracted from the structured XML input. In this example, enter the XPath query ".".

11. In the design workspace, drop two **tLogRow** components from the **Palette** and connect **tFileInputMSXML** to **tLogRow1** and **tLogRow2** using the **book** and **record** links respectively. Rename the two **tLogRow** components as **book** and **record** respectively.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl+S** to save your Job.

2. Execute the Job by pressing **F6** or clicking **Run** on the **Run** tab.

The multi-structure XML file is read row by row and the extracted fields are displayed on the console. The first two fields are for the **book** schema, and the last two fields are for the **record** schema.
Starting job check at 17:58 07/05/2014.

[statistics] connecting to socket on port 3985
[statistics] connected
As You Like It
All's Well That Ends Well
We Belong Together
When You Believe
[statistics] disconnected
Job check ended at 17:58 07/05/2014. [exit code]
tFileInputPositional

Reads a positional file row by row to split them up into fields based on a given pattern and then sends the fields as defined in the schema to the next component.

**tFileInputPositional Standard properties**

These properties are used to configure tFileInputPositional running in the Standard Job framework. The Standard tFileInputPositional component belongs to the File family. The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-In or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Built-In</strong>: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: Select the repository file where the properties are stored.</td>
</tr>
</tbody>
</table>

**File Name/Stream**

- **File name**: Name and path of the file to be processed.
- **Stream**: The data flow to be processed. The data must be added to the flow in order for tFileInputPositional to fetch these data via the corresponding representative variable.

This variable could be already pre-defined in your Studio or provided by the context or the components you are using along with this component, for example, the `INPUT_STREAM` variable of tFileFetch; otherwise, you could define it manually and use it according to the design of your Job, for example, using tJava or tJavaFlex.

In order to avoid the inconvenience of hand writing, you could select the variable of interest from the auto-completion list (Ctrl+Space) to fill the current field on condition that this variable has been properly defined.

**Warning**: Use absolute path (instead of relative path) for this field to avoid possible errors.

Related topic to the available variables: see Talend Studio User Guide.

Related scenario to the input stream, see Reading data from a remote file in streaming mode on page 1013.

**Row separator**

The separator used to identify the end of a row.

**Use byte length as the cardinality**

Select this check box to enable the support of double-byte character to this component. JDK 1.6 is required for this feature.

**Customize**

Select this check box to customize the data format of the positional file and define the table columns:

- **Column**: Select the column you want to customize.
- **Size**: Enter the column size.
| **Padding char**: Enter, between double quotation marks, the padding character you need to remove from the field. A space by default. |
| **Alignment**: Select the appropriate alignment parameter. |

| **Pattern** | Length values separated by commas, interpreted as a string between quotes. Make sure the values entered in this field are consistent with the schema defined. |

| **Pattern Units** | The unit of the length values specified in the Pattern field. |
|                    | **Bytes**: With this option selected, the length values in the Pattern field should be the count of bytes that represent symbols in original encoding of the input file. |
|                    | **Symbols**: With this option selected, the length values in the Pattern field should be the count of regular symbols, not including surrogate pairs. |
|                    | **Symbols (including rare)**: With this option selected, the length values in the Pattern field should be the count of symbols, including rare symbols such as surrogate pairs, and each surrogate pair counts as a single symbol. Considering the performance factor, it is not recommended to use this option when your input data consists of only regular symbols. |

| **Skip empty rows** | Select this check box to skip the empty rows. |
| **Uncompress as zip file** | Select this check box to uncompress the input file. |
| **Die on error** | Select the check box to stop the execution of the Job when an error occurs. Clear the check box to skip any rows on error and complete the process for error-free rows. When errors are skipped, you can collect the rows on error using a Row > Reject link. |
| **Header** | Enter the number of rows to be skipped in the beginning of file. |
| **Footer** | Number of rows to be skipped at the end of the file. |
| **Limit** | Maximum number of rows to be processed. If Limit = 0, no row is read or processed. |

| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available: |
|                           | **View schema**: choose this option to view the schema only. |
|                           | **Change to built-in property**: choose this option to change the schema to Built-in for local changes. |
|                           | **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon |
This component must work with `tSetDynamicSchema` to leverage the dynamic schema feature.

### Advanced settings

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>

</thead>
<tbody>
<tr>
<td>NB_LINE</td>
<td>the number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>ERROR_MESSAGE</td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press <code>Ctrl + Space</code> to access the variable list and choose the variable to use from it. For further information about variables, see <a href="https://docs.oracle.com">Talend Studio User Guide</a>.</td>
</tr>
</tbody>
</table>
Usage

| Usage rule | Use this component to read a file and separate fields using a position separator value. You can also create a rejection flow using a Row > Reject link to filter the data which does not correspond to the type defined. For an example of how to use these two links, see Procedure on page 968. |

Reading a Positional file and saving filtered results to XML

The following scenario describes a two-component Job, which aims at reading data from an input file that contains contract numbers, customer references, and insurance numbers as shown below, and outputting the selected data (according to the data position) into an XML file.

<table>
<thead>
<tr>
<th>Contract</th>
<th>CustomerRef</th>
<th>InsuranceNr</th>
</tr>
</thead>
<tbody>
<tr>
<td>00001</td>
<td>B200</td>
<td>50330</td>
</tr>
<tr>
<td>00001</td>
<td>B201</td>
<td>50331</td>
</tr>
<tr>
<td>00002</td>
<td>B202</td>
<td>50332</td>
</tr>
<tr>
<td>00002</td>
<td>B203</td>
<td>50333</td>
</tr>
</tbody>
</table>

Dropping and linking components

About this task

Procedure

1. Drop a `tFileInputPositional` component from the Palette to the design workspace.
2. Drop a `tFileOutputXML` component as well. This file is meant to receive the references in a structured way.
3. Right-click the `tFileInputPositional` component and select Row > Main. Then drag it onto the `tFileOutputXML` component and release when the plug symbol shows up.

Configuring data input

Procedure

1. Double-click the `tFileInputPositional` component to show its Basic settings view and define its properties.
2. Define the Job Property type if needed. For this scenario, we use the built-in Property type. As opposed to the Repository, this means that the Property type is set for this station only.

3. Fill in a path to the input file in the **File Name** field. This field is mandatory.

4. Define the **Row separator** identifying the end of a row if needed, by default, a carriage return.

5. If required, select the **Use byte length as the cardinality** check box to enable the support of double-byte character.

6. Define the **Pattern** to delimit fields in a row. The pattern is a series of length values corresponding to the values of your input files. The values should be entered between quotes, and separated by a comma. Make sure the values you enter match the schema defined.

7. Fill in the **Header**, **Footer** and **Limit** fields according to your input file structure and your need. In this scenario, we only need to skip the first row when reading the input file. To do this, fill the **Header** field with 1 and leave the other fields as they are.

8. Next to **Schema**, select **Repository** if the input schema is stored in the Repository. In this use case, we use a **Built-In** input schema to define the data to pass on to the tFileOutputXML component.

9. You can load and/or edit the schema via the **Edit Schema** function. For this schema, define three columns, respectively **Contract**, **CustomerRef** and **InsuranceNr** matching the structure of the input file. Then, click **OK** to close the **Schema** dialog box and propagate the changes.
Configuring data output

Procedure

1. Double-click tFileOutputXML to show its Basic settings view.

   ![Basic settings view](contracts_ref_xml.png)

   - File Name: C:\Outputs\ContractsRef.xml*
   - Row tag: ContractRef
   - Schema: Built-In

2. Enter the XML output file path.

3. Define the row tag that will wrap each row of data, in this use case ContractRef.

4. Click the three-dot button next to Edit schema to view the data structure, and click Sync columns to retrieve the data structure from the input component if needed.

5. Switch to the Advanced settings tab view to define other settings for the XML output.

   ![Advanced settings view](contracts_list.png)

   - Tag: "ContractsList"

6. Click the plus button to add a line in the Root tags table, and enter a root tag (or more) to wrap the XML output structure, in this case ContractsList.

7. Define parameters in the Output format table if needed. For example, select the As attribute check box for a column if you want to use its name and value as an attribute for the parent XML element, clear the Use schema column name check box for a column to reuse the column label from the input schema as the tag label. In this use case, we keep all the default output format settings as they are.

8. To group output rows according to the contract number, select the Use dynamic grouping check box, add a line in the Group by table, select Contract from the Column list field, and enter an attribute for it in the Attribute label field.
9. Leave all the other parameters as they are.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl+S** to save your Job to ensure that all the configured parameters take effect.
2. Press **F6** or click **Run** on the Run tab to execute the Job.

The file is read row by row based on the length values defined in the Pattern field and output as an XML file as defined in the output settings. You can open it using any standard XML editor.

```xml
<ContractsList>
  <Contract Nr="00001">
    <ContractRef>
      <CustomerRef>8200</CustomerRef>
      <InsuranceNr>50330</InsuranceNr>
    </ContractRef>
    <ContractRef>
      <CustomerRef>0201</CustomerRef>
      <InsuranceNr>50331</InsuranceNr>
    </ContractRef>
  </Contract>
  <Contract Nr="00002">
    <ContractRef>
      <CustomerRef>8202</CustomerRef>
      <InsuranceNr>50332</InsuranceNr>
    </ContractRef>
    <ContractRef>
      <CustomerRef>8203</CustomerRef>
      <InsuranceNr>50333</InsuranceNr>
    </ContractRef>
  </Contract>
</ContractsList>
```
**tFileInputProperties**

Reads a text file row by row and separates the fields according to the model key = value.

**tFileInputProperties Standard properties**

These properties are used to configure tFileInputProperties running in the Standard Job framework.

The Standard tFileInputProperties component belongs to the File family.

The component in this framework is available in all Talend products.

### Basic settings

Usage

| Usage rule | Use this component to read a text file and separate data according to the structure key = value. |

Reading and matching the keys and the values of different .properties files and outputting the results in a glossary

This four-component Job reads two .properties files, one in French and the other in English. The data in the two input files is mapped to output a glossary matching the English and French terms.

The two input files used in this scenario hold localization strings for the tMysqlInput component in Talend Studio.
The glossary displays on the console listing three columns holding: the key name in the first column, the English term in the second, and the corresponding French term in the third.

**Dropping and linking the components**

**Procedure**

1. Drop the following components from the Palette onto the design workspace: `tFileInputProperties` (x2), `tMap`, and `tLogRow`.

2. Connect the component together using Row > Main links. The second properties file, `FR`, is used as a lookup flow.

![Diagram showing component connections](image)

**Configuring the components**

**Procedure**

1. Double-click the first `tFileInputProperties` component to open its Basic settings view and define its properties.
2. In the **File Format** field, select your file format.
3. In the **File Name** field, click the three-dot button and browse to the input `.properties` file you want to use.
4. Do the same with the second tFileInputProperties and browse to the French `.properties` file this time.
5. Double-click the tMap component to open the tMap editor.
6. Select all columns from the English_terms table and drop them to the output table. Select the key column from the English_terms table and drop it to the key column in the French_terms table.

7. In the glossary table in the lower right corner of the tMap editor, rename the value field to EN because it will hold the values of the English file.

8. Click the plus button to add a line to the glossary table and rename it to FR.

9. In the Length field, set the maximum length to 255.

10. In the upper left corner of the tMap editor, select the value column in the English_terms table and drop it to the FR column in the French_terms table. When done, click OK to validate your changes and close the map editor and propagate the changes to the next component.

**Saving and executing the Job**

**Procedure**

1. Press Ctrl+S to save your Job.
2. Press F6 or click the Run button from the Run tab to execute it.
Starting job tFileInputProperties at 15:25 29/05/2009

</table>
tFileInputRaw

Reads all data in a raw file and sends it to a single output column for subsequent processing by another component.

**tFileInputRaw Standard properties**

These properties are used to configure tFileInputRaw running in the Standard Job framework.

The Standard tFileInputRaw component belongs to the File family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Schema and Edit Schema</th>
<th>A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either <strong>Built-in</strong> or stored remotely in the <strong>Repository</strong>. Click Edit schema to make changes to the schema. If the current schema is of the <strong>Repository</strong> type, three options are available:</th>
</tr>
</thead>
<tbody>
<tr>
<td>• View schema: choose this option to view the schema only.</td>
<td><strong>Built-in</strong>: No property data stored centrally.</td>
</tr>
<tr>
<td>• Change to built-in property: choose this option to change the schema to <strong>Built-in</strong> for local changes.</td>
<td><strong>Repository</strong>: Select the repository file where the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select <strong>No</strong> upon completion and choose this schema metadata again in the <strong>Repository Content</strong> window.</td>
<td><strong>Filename</strong> The path of the input file to be processed, which you can enter manually between double quotes or browse and select by clicking the [...] button. <strong>Warning</strong>: Use absolute path (instead of relative path) for this field to avoid possible errors.</td>
</tr>
<tr>
<td>Mode</td>
<td><strong>Read the file as a string</strong>: The content of the file is read as a string. <strong>Read the file as a bytes array</strong>: The content of the file is read as a bytes array. <strong>Stream the file</strong>: As soon as the first character is entered in the source file, it is read immediately.</td>
</tr>
</tbody>
</table>
If you are using the Read the file as a string mode, select the encoding type from the list or select Custom and define it manually.

Select this check box to stop the execution of the Job when an error occurs. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can collect the rows on error using a Row > Reject link.

To catch the FileNotFoundException, you also need to select this check box.

Select this check box to gather the processing metadata at the Job level as well as at each component level.

FILENAME_PATH: the path of the input file. This is an After variable and it returns a string.

ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Use this component to provide input data for Jobs that require a single column of data or that require a whole file to be read as a single column.

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

For a related use case, see:

• Uploading files to Dropbox on page 655
tFileInputRegex

Reads a file row by row to split them up into fields using regular expressions and sends the fields as defined in the schema to the next component.

Powerful feature which can replace number of other components of the File family. Requires some advanced knowledge on regular expression syntax.

tFileInputRegex Standard properties

These properties are used to configure tFileInputRegex running in the Standard Job framework.
The Standard tFileInputRegex component belongs to the File family.
The component in this framework is available in all Talend products.

Basic settings

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-In or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Built-In: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file where the properties are stored.</td>
</tr>
</tbody>
</table>

**File Name/Stream**

- **File name**: Name of the file and/or the variable to be processed
- **Stream**: Data flow to be processed. The data must be added to the flow so that it can be collected by the tFileInputRegex via the INPUT_STREAM variable in the autocompletion list (Ctrl+Space)

For further information about how to define and use a variable in a Job, see Talend Studio User Guide.

**Warning:** Use absolute path (instead of relative path) for this field to avoid possible errors.

**Row separator**

The separator used to identify the end of a row.

**Regex**

Type in your Java regular expression including the subpattern matching the fields to be extracted. This field can contain multiple lines.

**Note:** Antislashes need to be doubled in regexp

**Warning:**

- The regular expression needs to be in double quotes.
- To extract all the desired strings, make sure the regular expression contains the corresponding subpatterns that match the strings. Also, each subpattern in the regular expression needs to be in a pair of brackets.
<table>
<thead>
<tr>
<th><strong>Header</strong></th>
<th>Enter the number of rows to be skipped in the beginning of file.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Footer</strong></td>
<td>Number of rows to be skipped at the end of the file.</td>
</tr>
<tr>
<td><strong>Limit</strong></td>
<td>Maximum number of rows to be processed. If Limit = 0, no row is read or processed.</td>
</tr>
<tr>
<td><strong>Ignore error message for the unmatched record</strong></td>
<td>Select this check box to avoid outputting error messages for records that do not match the specified regex. This check box is cleared by default.</td>
</tr>
</tbody>
</table>

### Schema and Edit Schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No upon completion** and choose this schema metadata again in the **Repository Content** window.

**Built-In**: You create and store the schema locally for this component only.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

### Skip empty rows

Select this check box to skip the empty rows.

### Die on error

Select the check box to stop the execution of the Job when an error occurs.

Clear the check box to skip any rows on error and complete the process for error-free rows. When errors are skipped, you can collect the rows on error using a **Row > Reject** link.

### Advanced settings

<table>
<thead>
<tr>
<th><strong>Encoding</strong></th>
<th>Select the encoding from the list or select <strong>Custom</strong> and define it manually. This field is compulsory for database data handling. The supported encodings depend on the JVM that you are using. For more information, see <a href="https://docs.oracle.com">https://docs.oracle.com</a>. In the Map/Reduce version of <strong>tFileInputRegex</strong>, you need to select the <strong>Custom encoding</strong> check box to display this list.</th>
</tr>
</thead>
</table>
Global Variables

| Global Variables | NB_LINE: the number of rows processed. This is an After variable and it returns an integer.  
     | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  
     | A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
     | To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.  
     | For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | Use this component to read a file and separate fields contained in this file according to the defined Regex. You can also create a rejection flow using a Row > Reject link to filter the data which doesn’t correspond to the type defined. For an example of how to use these two links, see Procedure on page 968. |

Regex to Positional file

The following scenario creates a two-component Job, reading data from an Input file using regular expression and outputting delimited data into a positional file.

Dropping and linking the components

**Procedure**

1. Drop a tFileInputRegex component from the Palette to the design workspace.
2. Drop a tFileOutputPositional component the same way.
3. Right-click on the tFileInputRegex component and select Row > Main. Drag this main row link onto the tFileOutputPositional component and release when the plug symbol displays.
Configuring the components

Procedure

1. Select the \texttt{tFileInputRegex} again so the Component view shows up, and define the properties:

   
   \begin{table}[h]
   \centering
   \begin{tabular}{|c|c|}
   \hline
   Property & Value \\
   \hline
   Property Type & Built-In \\
   File name/Stream & "D:/Input/Apache.log" \\
   Row Separator & "\n" \\
   Regex & \textbackslash{\textbackslash r}\{a-zA-Z\}\{3\}\textbackslash s\{0-9\}\{2\}\textbackslash s\{0-9\}\{2\}\textbackslash s\{0-9\}\{2\}\}.* \\
   Header & 0 \\
   Footer & 0 \\
   Limit & 0 \\
   Skip empty rows & \\
   Die on error & \\
   Edit schema & \\
   \hline
   \end{tabular}
   \caption{Component properties for \texttt{tFileInputRegex}.}
   \end{table}

2. The Job is built-in for this scenario. Hence, the Properties are set for this station only.
3. Fill in a path to the file in File Name field. This field is mandatory.
4. Define the Row separator identifying the end of a row.
5. Then define the Regular expression in order to delimit fields of a row, which are to be passed on to the next component. You can type in a regular expression using Java code, and on multiple lines if needed.

   \textbf{Warning:}

   \begin{quote}
   Regex syntax requires double quotes.
   \end{quote}

6. In this expression, make sure you include all subpatterns matching the fields to be extracted.
7. In this scenario, ignore the header, footer and limit fields.
8. Select a local (Built-in) Schema to define the data to pass on to the tFileOutputPositional component.
9. You can load or create the schema through the Edit Schema function.
10. Then define the second component properties:
11. Enter the Positional file output path.

12. Enter the **Encoding** standard, the output file is encoded in. Note that, for the time being, the encoding consistency verification is not supported.

13. Select the **Schema** type. Click on **Sync columns** to automatically synchronize the schema with the Input file schema.

### Saving and executing the Job

**Procedure**

1. Press Ctrl+S to save your Job.

2. Now go to the Run tab, and click on Run to execute the Job.

   The file is read row by row and split up into fields based on the **Regular Expression** definition. You can open it using any standard file editor.
tFileInputXML

Reads an XML structured file row by row to split them up into fields and sends the fields as defined in the schema to the next component.

### tFileInputXML Standard properties

These properties are used to configure tFileInputXML running in the Standard Job framework.

The Standard tFileInputXML component belongs to the File and the XML families.

The component in this framework is available in all Talend products.

#### Basic settings

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-In or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Built-In: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file where the properties are stored.</td>
</tr>
</tbody>
</table>

#### Schema and Edit Schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-In for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

- **Built-In**: You create and store the schema locally for this component only.
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

#### File name/Stream

- **File name**: Name and path of the file to be processed.
- **Stream**: The data flow to be processed. The data must be added to the flow in order for tFileInputXML to fetch these data via the corresponding representative variable.

**Warning**: Use absolute path (instead of relative path) for this field to avoid possible errors.
This variable could be already pre-defined in your Studio or provided by the context or the components you are using along with this component, for example, the `INPUT_STREAM` variable of `tFileFetch`; otherwise, you could define it manually and use it according to the design of your Job, for example, using `tJava` or `tJavaFlex`.

In order to avoid the inconvenience of hand writing, you could select the variable of interest from the auto-completion list (`Ctrl+Space`) to fill the current field on condition that this variable has been properly defined.

Related topic to the available variables: see *Talend Studio User Guide*. Related scenario to the input stream, see *Reading data from a remote file in streaming mode* on page 1013.

<table>
<thead>
<tr>
<th>Loop XPath query</th>
<th>Node of the tree, which the loop is based on.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Mapping</strong></td>
<td><strong>Column</strong>: Columns to map. They reflect the schema as defined in the Schema type field. <strong>XPath Query</strong>: Enter the fields to be extracted from the structured input. <strong>Get nodes</strong>: Select this check box to recuperate the XML content of all current nodes specified in the XPath query list, or select the check box next to specific XML nodes to recuperate only the content of the selected nodes. These nodes are important when the output flow from this component needs to use the XML structure, for example, the Document data type. For further information about the Document type, see <em>Talend Studio User Guide</em>.</td>
</tr>
<tr>
<td><strong>Limit</strong></td>
<td>Maximum number of rows to be processed. If Limit = 0, no row is read nor processed. If -1, all rows are read or processed.</td>
</tr>
<tr>
<td><strong>Die on error</strong></td>
<td>Select the check box to stop the execution of the Job when an error occurs. Clear the check box to skip any rows on error and complete the process for error-free rows. When errors are skipped, you can collect the rows on error using a Row &gt; Reject link.</td>
</tr>
</tbody>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th>Ignore DTD file</th>
<th>Select this check box to ignore the DTD file indicated in the XML file being processed.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Advanced separator (for number)</strong></td>
<td>Select this check box to change the separator used for numbers. By default, the thousands separator is a comma (,) and the decimal separator is a period (.).</td>
</tr>
</tbody>
</table>
### tFileInputXML

**Thousands separator**: define the separators to use for thousands.

**Decimal separator**: define the separators to use for decimals.

<table>
<thead>
<tr>
<th>Ignore the namespaces</th>
<th>Select this check box to ignore name spaces.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Generate a temporary file</strong>: click the three-dot button to browse to the XML temporary file and set its path in the field.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Use Separator for mode Xerces</th>
<th>Select this check box if you want to separate concatenated children node values.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Note</strong>:</td>
<td>This field can only be used if the selected <strong>Generation mode</strong> is Xerces.</td>
</tr>
</tbody>
</table>

The following field displays:

**Field separator**: Define the delimiter to be used to separate the children node values.

| Encoding | Select the encoding from the list or select **Custom** and define it manually. This field is compulsory for database data handling. The supported encodings depend on the JVM that you are using. For more information, see [https://docs.oracle.com](https://docs.oracle.com). |

<table>
<thead>
<tr>
<th>Generation mode</th>
<th>From the drop-down list select the generation mode for the XML file, according to the memory available and the desired speed:</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Note</strong>:</td>
<td>This option allows you to use dom4j to process the XML files of high complexity.</td>
</tr>
</tbody>
</table>

- **Slow and memory-consuming (Dom4j)**

- **Memory-consuming (Xerces)**

- **Fast with low memory consumption (SAX)**

| Validate date | Select this check box to check the date format strictly against the input schema. |

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>NB_LINE</strong>: the number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule

tFileInputXML is for use as an entry component. It allows you to create a flow of XML data using a Row > Main link. You can also create a rejection flow using a Row > Reject link to filter the data which doesn’t correspond to the type defined. For an example of how to use these two links, see Procedure on page 968.

Reading and extracting data from an XML structure

This scenario describes a basic Job that reads a defined XML directory and extracts specific information and outputs it on the Run console via a tLogRow component.

Procedure

Procedure

1. Drop tFileInputXML and tLogRow from the Palette to the design workspace.
2. Connect both components together using a Main Row link.
3. Double-click tFileInputXML to open its Basic settings view and define the component properties.

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Repository</th>
<th>Repository</th>
<th>StreetFinder</th>
<th>*</th>
<th>Edit schema</th>
</tr>
</thead>
<tbody>
<tr>
<td>Schema Type</td>
<td>Repository</td>
<td>Repository</td>
<td>StreetFinder</td>
<td>*</td>
<td>Edit schema</td>
</tr>
<tr>
<td>Filename</td>
<td>'C:\Input\areas.xml'</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Loop XPath query</td>
<td>'areas/area/street'</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Mapping column/XPath query</td>
<td>Column</td>
<td>XPath query</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>City</td>
<td>'./@city'</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>District</td>
<td>'@district'</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Street</td>
<td>'.'</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Limit

Encoding

'ISO-8859-15' *
4. As the street dir file used as input file has been previously defined in the Metadata area, select **Repository** as **Property type**. This way, the properties are automatically leveraged and the rest of the properties fields are filled in (apart from Schema). For more information regarding the metadata creation wizards, see *Talend Studio* User Guide.

5. Select the same way the relevant schema in the Repository metadata list. **Edit schema** if you want to make any change to the schema loaded.

6. The **Filename** shows the structured file to be used as input.

7. In **Loop XPath query**, change if needed the node of the structure where the loop is based.

8. On the **Mapping** table, fill the fields to be extracted and displayed in the output.

9. If the file size is consequent, fill in a **Limit** of rows to be read.

10. Enter the encoding if needed then double-click on **tLogRow** to define the separator character.

11. Save your Job and press **F6** to execute it.

**Results**

```
Starting job XMLStreetFinder at 12:42 05/01/2007.
Paris|2eme arrondissement|Rue de la Paix
Paris|8eme arrondissement|Champs Elysees
New York City|Manhattan|Madison avenue
New York City|Brooklyn|Washington heights
Job XMLStreetFinder ended at 12:42 05/01/2007. fexit ccok
```

The fields defined in the input properties are extracted from the XML structure and displayed on the console.

**Extracting erroneous XML data via a reject flow**

This Java scenario describes a three-component Job that reads an XML file and:

1. first, returns correct XML data in an output XML file,
2. and second, displays on the console erroneous XML data which type does not correspond to the defined one in the schema.

**Procedure**

**Procedure**

1. Drop the following components from the **Palette** to the design workspace: **tFileInputXML**, **tFileOutputXML** and **tLogRow**.

   Right-click **tFileInputXML** and select **Row > Main** in the contextual menu and then click **tFileOutputXML** to connect the components together.

   Right-click **tFileInputXML** and select **Row > Reject** in the contextual menu and then click **tLogRow** to connect the components together using a reject link.
2. Double-click `tFileInputXML` to display the **Basic settings** view and define the component properties.

3. In the **Property Type** list, select **Repository** and click the three-dot button next to the field to display the **Repository Content** dialog box where you can select the metadata relative to the input file if you have already stored it in the `File xml` node under the Metadata folder of the Repository tree view. The fields that follow are automatically filled with the fetched data. If not, select **Built-in** and fill in the fields that follow manually.

   For more information about storing schema metadata in the Repository tree view, see *Talend Studio User Guide*.

4. In the **Schema Type** list, select **Repository** and click the three-dot button to open the dialog box where you can select the schema that describe the structure of the input file if you have already stored it in the Repository tree view. If not, select **Built-in** and click the three-dot button next to **Edit schema** to open a dialog box where you can define the schema manually.
The schema in this example consists of five columns: id, CustomerName, CustomerAddress, idState and id2.

5. Click the three-dot button next to the **Filename** field and browse to the XML file you want to process.

6. In the **Loop XPath query**, enter between inverted commas the path of the XML node on which to loop in order to retrieve data.

   In the **Mapping** table, **Column** is automatically populated with the defined schema.

   In the **XPath query** column, enter between inverted commas the node of the XML file that holds the data you want to extract from the corresponding column.

7. In the **Limit** field, enter the number of lines to be processed, the first 10 lines in this example.

8. Double-click **tFileOutputXML** to display its **Basic settings** view and define the component properties.

9. Click the three-dot button next to the **File Name** field and browse to the output XML file you want to collect data in, *customer_data.xml* in this example.

   In the **Row tag** field, enter between inverted commas the name you want to give to the tag that will hold the recuperated data.

   Click **Edit schema** to display the schema dialog box and make sure that the schema matches that of the preceding component. If not, click **Sync columns** to retrieve the schema from the preceding component.

10. Double-click **tLogRow** to display its **Basic settings** view and define the component properties.

    Click **Edit schema** to open the schema dialog box and make sure that the schema matches that of the preceding component. If not, click **Sync columns** to retrieve the schema of the preceding component.
In the **Mode** area, select the **Vertical** option.

11. Save your Job and press **F6** to execute it.

**Results**

*Starting job tFileInputXML at 14:34 06/11/2009.*

```
<table>
<thead>
<tr>
<th>key</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>null</td>
</tr>
<tr>
<td>CustomerName</td>
<td>null</td>
</tr>
<tr>
<td>CustomerAddress</td>
<td>null</td>
</tr>
<tr>
<td>idState</td>
<td>null</td>
</tr>
<tr>
<td>id2</td>
<td>null</td>
</tr>
<tr>
<td>errorCode</td>
<td>null</td>
</tr>
<tr>
<td>errorMessage</td>
<td>For input string: &quot;ab&quot; - line: 1</td>
</tr>
</tbody>
</table>
```

```
<table>
<thead>
<tr>
<th>key</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>9</td>
</tr>
<tr>
<td>CustomerName</td>
<td>Childress Child Day Care</td>
</tr>
<tr>
<td>CustomerAddress</td>
<td>788 Tennyson Ave.</td>
</tr>
<tr>
<td>idState</td>
<td>12</td>
</tr>
<tr>
<td>id2</td>
<td>null</td>
</tr>
<tr>
<td>errorCode</td>
<td>null</td>
</tr>
<tr>
<td>errorMessage</td>
<td>For input string: &quot;cd&quot; - line: 8</td>
</tr>
</tbody>
</table>
```

*Job tFileInputXML ended at 14:35 06/11/2009. [exit code=0]*

The output file `customer_data.xml` holding the correct XML data is created in the defined path and erroneous XML data is displayed on the console of the **Run** view.
tFileList

Iterates a set of files or folders in a given directory based on a filemask pattern.

**Note:** This component iterates over every file in a directory, including system file, hidden file, zero-byte file, and so on, as long as the file meets the conditions set in the **Files** field.

**tFileList Standard properties**

These properties are used to configure tFileList running in the Standard Job framework.

The Standard tFileList component belongs to the File and the Orchestration families.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Directory</td>
<td>Path to the directory where the files are stored.</td>
</tr>
<tr>
<td></td>
<td><strong>Warning:</strong> Use absolute path (instead of relative path) for this field to avoid possible errors.</td>
</tr>
<tr>
<td>FileList Type</td>
<td>Select the type of input you want to iterate on from the list:</td>
</tr>
<tr>
<td></td>
<td><strong>Files</strong> if the input is a set of files,</td>
</tr>
<tr>
<td></td>
<td><strong>Directories</strong> if the input is a set of directories,</td>
</tr>
<tr>
<td></td>
<td><strong>Both</strong> if the input is a set of the above two types.</td>
</tr>
<tr>
<td>Include subdirectories</td>
<td>Select this check box if the selected input source type includes sub-directories.</td>
</tr>
<tr>
<td>Case Sensitive</td>
<td>Set the case mode from the list to either create or not create case sensitive filter on filenames.</td>
</tr>
<tr>
<td>Generate Error if no file found</td>
<td>Select this check box to generate an error message if no files or directories are found.</td>
</tr>
<tr>
<td>Use Glob Expressions as Filemask</td>
<td>This check box is selected by default. It filters the results using a Global Expression (Glob Expressions).</td>
</tr>
<tr>
<td>Files</td>
<td>Click the plus button to add as many filter lines as needed:</td>
</tr>
<tr>
<td></td>
<td><strong>Filemask</strong>: in the added filter lines, type in a filename or a filemask using special characters or regular expressions.</td>
</tr>
<tr>
<td>Order by</td>
<td>The folders are listed first of all, then the files. You can choose to prioritise the folder and file order either:</td>
</tr>
<tr>
<td></td>
<td><strong>By default</strong>: alphabetical order, by folder then file;</td>
</tr>
<tr>
<td></td>
<td><strong>By file name</strong>: alphabetical order or reverse alphabetical order;</td>
</tr>
<tr>
<td></td>
<td><strong>By file size</strong>: smallest to largest or largest to smallest;</td>
</tr>
<tr>
<td></td>
<td><strong>By modified date</strong>: most recent to least recent or least recent to most recent.</td>
</tr>
</tbody>
</table>
Note:
If ordering by file name, in the event of identical file names then modified date takes precedence. If ordering by file size, in the event of identical file sizes then file name takes precedence. If ordering by modified date, in the event of identical dates then file name takes precedence.

| Order action | Select a sort order by clicking one of the following radio buttons:
|              | ASC: ascending order;
|              | DESC: descending order; |

**Advanced settings**

| Use Exclude Filemask | Select this check box to enable Exclude Filemask field to exclude filtering condition based on file type:
|                      | **Exclude Filemask**: Fill in the field with file types to be excluded from the Filemasks in the Basic settings view. |
|                      | **Note:** File types in this field should be quoted with double quotation marks and separated by comma. |

| Format file path to slash(/) style(useful on Windows) | Select this check box to format the file path to slash(/) style which is useful on Windows. |

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

**Global Variables**

| Global Variables | **CURRENT_FILE**: the current file name. This is a Flow variable and it returns a string. |
|                 | **CURRENT_FILEPATH**: the current file path. This is a Flow variable and it returns a string. |
|                 | **CURRENT_FILEEXTENSION**: the extension of the current file. This is a Flow variable and it returns a string. |
|                 | **CURRENT_FILEDIRECTORY**: the current file directory. This is a Flow variable and it returns a string. |
|                 | **NB_FILE**: the number of files iterated upon so far. This is a Flow variable and it returns an integer. |
|                 | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. |
|                 | A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. |
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>tFileList provides a list of files or folders from a defined directory on which it iterates</th>
</tr>
</thead>
</table>

Connections

Outgoing links (from this component to another):
- Row: Iterate
- Trigger: On Subjob Ok; On Subjob Error; Run if; On Component Ok; On Component Error.

Incoming links (from one component to this one):
- Row: Iterate.
- Trigger: Run if; On Subjob Ok; On Subjob Error; On component Ok; On Component Error; Synchronize; Parallelize.

For further information regarding connections, see Talend Studio User Guide.

Iterating on a file directory

The following scenario creates a three-component Job, which aims at listing files from a defined directory, reading each file by iteration, selecting delimited data and displaying the output in the Run log console.

Dropping and linking the components

Procedure
1. Drop the following components from the Palette to the design workspace: tFileList, tFileInputDelimited, and tLogRow.
2. Right-click the tFileList component, and pull an Iterate connection to the tFileInputDelimited component. Then pull a Main row from the tFileInputDelimited to the tLogRow component.

Configuring the components

Procedure
1. Double-click tFileList to display its Basic settings view and define its properties.
2. Browse to the **Directory** that holds the files you want to process. To display the path on the Job itself, use the label (**DIRECTORY**) that shows up when you put the pointer anywhere in the **Directory** field. Type in this label in the **Label Format** field you can find if you click the **View** tab in the **Basic settings** view.

3. In the **Basic settings** view and from the **FileList Type** list, select the source type you want to process, **Files** in this example.

4. In the **Case sensitive** list, select a case mode, **Yes** in this example to create case sensitive filter on file names.

5. Keep the **Use Glob Expressions as Filemask** check box selected if you want to use global expressions to filter files, and define a file mask in the **Filemask** field.

6. Double-click **tFileInputDelimited** to display its **Basic settings** view and set its properties.

7. Enter the **File Name** field using a variable containing the current filename path, as you filled in the **Basic settings** of **tFileList**. Press **Ctrl+Space bar** to access the autocomplete list of variables, and select the global variable **((String)globalMap.get("tFileList_1_CURRENT_FILEPATH")).** This way, all files in the input directory can be processed.

8. Fill in all other fields as detailed in the **tFileInputDelimited** section. Related topic: **tFileInputDelimited** on page 1008.

9. Select the last component, **tLogRow**, to display its **Basic settings** view and fill in the separator to be used to distinguish field content displayed on the console. Related topic: **tLogRow** on page 1956.
Executing the Job

Press Ctrl + S to save your Job, and press F6 to run it.

**Starting job test at 17:18 21/09/2009.**

**Job test ended at 17:16 21/09/2009. (Exit code=0)**

The Job iterates on the defined directory, and reads all included files. Then delimited data is passed on to the last component which displays it on the console.

**Finding duplicate files between two folders**

This scenario describes a Job that iterates on files in two folders, transforms the iteration results to data flows to obtain a list of filenames, and then picks up all duplicates from the list and shows them on the Run console, as a preparation step before merging the two folders, for example.
Dropping and linking the components

Procedure

1. From the Palette, drop two tFileList components, two tIterateToFlow components, two tFileOutputDelimited components, a tFileInputDelimited component, a tUniqRow component, and a tLogRow component onto the design workspace.

2. Link the first tFileList component to the first tIterateToFlow component using a Row > Iterate connection, and the connect the first tIterateToFlow component to the first tFileOutputDelimited component using a Row > Main connection to form the first subJob.

3. Link the second tFileList component to the second tIterateToFlow component using a Row > Iterate connection, and the connect the second tIterateToFlow component to the second tFileOutputDelimited component using a Row > Main connection to form the second subJob.

4. Link the tFileInputDelimited to the tUniqRow component using a Row > Main connection, and the tUniqRow component to the tLogRow component using a Row > Duplicates connection to form the third subJob.

5. Link the three subJobs using Trigger > On Subjob Ok connections so that they will be triggered one after another, and label the components to better identify their roles in the Job.

Configuring the components

Procedure

1. In the Basic settings view of the first tFileList component, fill the Directory field with the path to the first folder you want to read filenames from, E:/DataFiles/DI/images in this example, and leave the other settings as they are.
2. Double-click the first `tIterateToFlow` component to show its **Basic settings** view.

3. Double-click the [...] button next to **Edit schema** to open the **Schema** dialog box and define the schema of the text file the next component will write filenames to. When done, click **OK** to close the dialog box and propagate the schema to the next component.

   In this example, the schema contains only one column: *Filename*. 
4. In **Value** field of the **Mapping** table, press **Ctrl+Space** to access the autocomplete list of variables, and select the global variable `((String)globalMap.get("tFileList_1_CURRENT_FILE"))` to read the name of each file in the input directory, which will be put into a data flow to pass to the next component.

5. In the **Basic settings** view of the first **tFileOutputDelimited** component, fill the **File Name** field with the path of the text file that will store the filenames from the incoming flow, `D:/temp/tempdata.csv` in this example. This completes the configuration of the first subjob.

6. Repeat the steps above to complete the configuration of the second subjob, but:
   - fill the **Directory** field in the **Basic settings** view of the second **tFileList** component with the other folder you want to read filenames from, `E:/DataFiles/DQ/images` in this example.
   - select the **Append** check box in the **Basic settings** view of the second **tFileOutputDelimited** component so that the filenames previously written to the text file will not be overwritten.

7. In the **Basic settings** view of the **tFileInputDelimited** component, fill the **File name/Stream** field with the path of the text file that stores the list of filenames, `D:/temp/tempdata.csv` in this example, and define the file schema, which contains only one column in this example, **Filename**.
8. In the Basic settings view of the tUniqRow component, select the Key attribute check box for the only column, Filename in this example.

9. In the Basic settings view of the tLogRow component, select the Table (print values in cells of a table) option for better display effect.

**Executing the Job**

**Procedure**

1. Press Ctrl+S to save your Job.
2. Click Run or press F6 to run the Job.

   All the duplicate files between the selected folders are displayed on the console.
Results

For other scenarios using **tFileList**, see **tFileCopy** on page 981.
tFileOutputARFF

Writes an ARFF file that holds data organized according to the defined schema.

**tFileOutputARFF Standard properties**

These properties are used to configure tFileOutputARFF running in the Standard Job framework.
The Standard tFileOutputARFF component belongs to the File family.
The component in this framework is available in all Talend products.

### Basic settings

<table>
<thead>
<tr>
<th>Property type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-in</strong>: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: Select the repository file where the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td></td>
<td>Click this icon to open a connection wizard and store the Excel file connection parameters you set in the component Basic settings view. For more information about setting up and storing file connection parameters, see Talend Studio User Guide.</td>
</tr>
<tr>
<td>File name</td>
<td>Name or path to the output file and/or the variable to be used. For further information about how to define and use a variable in a Job, see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Attribute Define</td>
<td>Displays the schema you defined in the Edit schema dialog box. <strong>Column</strong>: Name of the column. <strong>Type</strong>: Data type. <strong>Pattern</strong>: Enter the data model (pattern), if necessary.</td>
</tr>
<tr>
<td>Relation</td>
<td>Enter the name of the relation.</td>
</tr>
<tr>
<td>Append</td>
<td>Select this check box to add the new rows at the end of the file.</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either Built-in or stored remotely in the Repository. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:</td>
</tr>
</tbody>
</table>
- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

**Built-in**: You can create the schema and store it locally for this component. Related topic: see *Talend Studio User Guide*.

**Repository**: You have already created and stored the schema in the Repository. You can reuse it in various projects and Job flowcharts. Related topic: see *Talend Studio User Guide*.

**Create directory if not exists**: This check box is selected by default. It creates a directory to hold the output table if it does not exist.

### Advanced settings

**Don’t generate empty file** Select this check box if you do not want to generate empty files.

**tStatCatcher Statistics** Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

### Global Variables

**Global Variables**

**NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press *Ctrl + Space* to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

**Usage rule** Use this component along with a *Row* link to collect data from another component and to re-write the data to an ARFF file.
Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your HDFS connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access files in different HDFS systems or different distributions, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Connections

Outgoing links (from this component to another):
Row: Main.
Trigger: On Subjob Ok; On Subjob Error; Run if.

Incoming links (from one component to this one):
Row: Main; Reject; Iterate.
Trigger: On Subjob Ok; On Subjob Error; Run if; On Component Ok; On Component Error; Synchronize; Parallelize.

For further information regarding connections, see Talend Studio User Guide.

Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

Related scenario

For tFileOutputARFF related scenario, see Displaying the content of a ARFF file on page 1004.
tFileOutputDelimited

Outputs the input data to a delimited file according to the defined schema.

**tFileOutputDelimited Standard properties**

These properties are used to configure tFileOutputDelimited running in the Standard Job framework. The Standard tFileOutputDelimited component belongs to the File family. The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-In or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Built-In: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file where the properties are stored.</td>
</tr>
</tbody>
</table>

**Use Output Stream**

Select this check box process the data flow of interest. Once you have selected it, the Output Stream field displays and you can type in the data flow of interest.

The data flow to be processed must be added to the flow in order for this component to fetch these data via the corresponding representative variable.

This variable could be already pre-defined in your Studio or provided by the context or the components you are using along with this component; otherwise, you could define it manually and use it according to the design of your Job, for example, using tJava or tJavaFlex.

In order to avoid the inconvenience of hand writing, you could select the variable of interest from the auto-completion list (Ctrl+Space) to fill the current field on condition that this variable has been properly defined.

For further information about how to use a stream, see Reading data from a remote file in streaming mode on page 1013.

**File name**

Name or path to the output file and/or the variable to be used.

This field becomes unavailable once you have selected the Use Output Stream check box.

For further information about how to define and use a variable in a Job, see Talend Studio User Guide.

**Warning:** Use absolute path (instead of relative path) for this field to avoid possible errors.

**Row Separator**

The separator used to identify the end of a row.

**Field Separator**

Enter character, string or regular expression to separate fields for the transferred data.
Append
Select this check box to add the new rows at the end of the file.

Include Header
Select this check box to include the column header to the file.

Compress as zip file
Select this check box to compress the output file in zip format.

Schema and Edit schema
A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word "line" when naming the fields.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

Built-In: You create and store the schema locally for this component only.

Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

Sync columns
Click to synchronize the output file schema with the input file schema. The Sync function only displays once the Row connection is linked with the output component.

Advanced settings

Advanced separator (for numbers)
Select this check box to change the separator used for numbers. By default, the thousands separator is a comma (,) and the decimal separator is a period (.).

- **Thousands separator**: define separators for thousands.
- **Decimal separator**: define separators for decimals.

CSV options
Select this check box to specify the following CSV parameters:

- **Escape char**: enter the escape character between double quotation marks.
- **Text enclosure**: enter the enclosure character (only one character) between double quotation marks. For example, "" needs to be entered when double quotation marks (") are used as the enclosure character.

It is recommended to use standard escape character, that is \\.

Otherwise, you should set the same character for
**Create directory if not exists**
This check box is selected by default. It creates the directory that holds the output delimited file, if it does not already exist.

**Split output in several files**
In case of very big output files, select this check box to divide the output delimited file into several files.
**Rows in each output file:** set the number of lines in each of the output files.

**Custom the flush buffer size**
Select this check box to define the number of lines to write before emptying the buffer.
**Row Number:** set the number of lines to write.

**Output in row mode**
Select this check box to ensure atomicity of the flush so that each row of data can remain consistent as a set and incomplete rows of data are never written to a file.
This check box is mostly useful when using this component in the multi-thread situation.

**Encoding**
Select the encoding from the list or select Custom and define it manually. This field is compulsory for database data handling. The supported encodings depend on the JVM that you are using. For more information, see https://docs.oracle.com.

**Don't generate empty file**
Select this check box if you do not want to generate empty files.

**Throw an error if the file already exist**
Select this check box to throw an exception if the output file specified in the File Name field on the Basic settings view already exists.
Clear this check box to overwrite the existing file.

**tStatCatcher Statistics**
Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

---

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE</strong>: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.</td>
<td></td>
</tr>
<tr>
<td><strong>FILE_NAME</strong>: the name of the file being processed. This is a Flow variable and it returns a string.</td>
<td></td>
</tr>
<tr>
<td><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</td>
<td></td>
</tr>
</tbody>
</table>
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

You can find more details about how to install external modules in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
</tbody>
</table>

Writing data in a delimited file

This scenario describes a three-component Job that extracts certain data from a file holding information about clients, customers, and then writes the extracted data in a delimited file.

In the following example, we have already stored the input schema under the Metadata node in the Repository tree view. For more information about storing schema metadata in the Repository, see Talend Studio User Guide.

Dropping and linking components

Procedure

1. In the Repository tree view, expand Metadata and File delimited in succession and then browse to your input schema, customers, and drop it on the design workspace. A dialog box displays where you can select the component type you want to use.
2. Click **tFileInputDelimited** and then **OK** to close the dialog box. A **tFileInputDelimited** component holding the name of your input schema appears on the design workspace.

3. Drop a **tMap** component and a **tFileOutputDelimited** component from the **Palette** to the design workspace.

4. Link the components together using **Row > Main** connections.

### Configuring the components

#### Configuring the input component

**Procedure**

1. Double-click **tFileInputDelimited** to open its **Basic settings** view. All its property fields are automatically filled in because you defined your input file locally.

   ![Image](image.png)

   2. If you do not define your input file locally in the **Repository** tree view, fill in the details manually after selecting **Built-in** in the **Property type** list.

   3. Click the [...] button next to the **File Name** field and browse to the input file, *customer.csv* in this example.

   ![Image](image.png)
Warning:
If the path of the file contains some accented characters, you will get an error message when executing your Job.

4. In the Row Separators and Field Separators fields, enter respectively "\n" and ";" as line and field separators.

5. If needed, set the number of lines used as header and the number of lines used as footer in the corresponding fields and then set a limit for the number of processed rows.

In this example, Header is set to 6 while Footer and Limit are not set.

6. In the Schema field, schema is automatically set to Repository and your schema is already defined since you have stored your input file locally for this example. Otherwise, select Built-in and click the [...] button next to Edit Schema to open the Schema dialog box where you can define the input schema, and then click OK to close the dialog box.

Configuring the mapping component

Procedure

1. In the design workspace, double-click tMap to open its editor.
2. In the tMap editor, click on top of the panel to the right to open the Add a new output table dialog box.

![Add a new output table dialog box](image)

3. Enter a name for the table you want to create, row2 in this example.
4. Click OK to validate your changes and close the dialog box.
5. In the table to the left, row1, select the first three lines (Id, CustomerName and CustomerAddress) and drop them to the table to the right.

6. In the Schema editor view situated in the lower left corner of the tMap editor, change the type of RegisterTime to String in the table to the right.

<table>
<thead>
<tr>
<th>Column</th>
<th>Key</th>
<th>Type</th>
<th>Nullable</th>
<th>Date Pattern</th>
<th>Length</th>
<th>Precision</th>
<th>Default</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>idState</td>
<td></td>
<td>int</td>
<td></td>
<td></td>
<td>2</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>id2</td>
<td></td>
<td>int</td>
<td></td>
<td></td>
<td>2</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>RegTime</td>
<td></td>
<td>String</td>
<td></td>
<td></td>
<td>30</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>RegisterTime</td>
<td></td>
<td>String</td>
<td></td>
<td></td>
<td>30</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Sum1</td>
<td></td>
<td>Float</td>
<td></td>
<td></td>
<td>10</td>
<td>5</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Sum2</td>
<td></td>
<td>Float</td>
<td></td>
<td></td>
<td>10</td>
<td>5</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

7. Click OK to save your changes and close the editor.

Configuring the output component

Procedure

1. In the design workspace, double-click tFileOutputDelimited to open its Basic settings view and define the component properties.

![tFileOutputDelimited Basic settings](image)

2. In the Property Type field, set the type to Built-in and fill in the fields that follow manually.
3. Click the [...] button next to the File Name field and browse to the output file you want to write data in, customerselection.txt in this example.
4. In the Row Separator and Field Separator fields, set "\n" and ";" respectively as row and field separators.
5. Select the **Include Header** check box if you want to output columns headers as well.

6. Click **Edit schema** to open the schema dialog box and verify if the recuperated schema corresponds to the input schema. If not, click **Sync Columns** to recuperate the schema from the preceding component.

### Saving and executing the Job

**Procedure**

1. Press **Ctrl+S** to save your Job.
2. Press **F6** or click **Run** on the **Run** tab to execute the Job.

```
customersselection.txt
```

```
1 id;CustomerName;CustomerAddress
2 1;Griffith Paving and Sealcoating;talend@apress91
3 2;Bill's Dive Shop;511 Maple Ave. Apt. 1B
4 3;Childress Child Day Care;662 Lyons Circle
5 4;Facelift Kitchen and Bath;unknown
6 5;Terrinno & Son Auto and Truck;770 Exmoor Rd.
7 6;Kermit the Pet Shop;1060 Parkside Ln.
8 7;Tub's Furniture Store;307 Old Trail Rd.
9 8;Tootle & Hyerson Ltd;610 Sheridan rd.
10 9;Childress Child Day Care;788 Tennyson Ave.
11 10;Elle Hypnosis and Therapy Cent;2032 Northbrook Ct.
```

The three specified columns *Id, CustomerName* and *CustomerAddress* are output in the defined output file.

### Utilizing Output Stream to save filtered data to a local file

Based on the preceding scenario, this scenario saves the filtered data to a local file using output stream.

![Diagram](image_url)

### Dropping and linking components

**Procedure**

1. Drop **tJava** from the **Palette** to the design workspace.
2. Connect **tJava** to **tFileInputDelimited** using a **Trigger > On Subjob OK** connection.
Configuring the components

Procedure

1. Double-click **tJava** to open its **Basic settings** view.

   ![tJava Basic settings](image1)

   - Code:
     ```
     new java.io.File("C:/myFolder").mkdirs();
     globalMap.put("out_file", new java.io.FileOutputStream("C:/myFolder/customerselection.txt",false));
     ```

   **Note:**
   In this scenario, the command we use in the **Code** area of **tJava** will create a new folder `C:/myFolder` where the output file `customerselection.txt` will be saved. You can customize the command in accordance with actual practice.

2. In the **Code** area, type in the following command:

   ```
   new java.io.File("C:/myFolder").mkdirs();
   globalMap.put("out_file", new java.io.FileOutputStream("C:/myFolder/customerselection.txt",false));
   ```

3. Double-click **tFileOutputDelimited** to open its **Basic settings** view.

   ![tFileOutputDelimited Basic settings](image2)

   - **Property Type**: Built-In
     - **Use Output Stream**
     - **Output Stream**: `(java.io.OutputStream)globalMap.get("out_file")`
     - **Row Separator**: "\n"
     - **Field Separator**: "\n",
     - **Include Header**: Yes
     - **Compress as zip file**: No
     - **Schema**: Built-In
     - **Edit schema**: Edit schema
     - **Sync columns**: Sync columns

4. Select **Use Output Stream** check box to enable the **Output Stream** field in which you can define the output stream using command.

   Fill in the **Output Stream** field with following command:

   ```
   (java.io.OutputStream)globalMap.get("out_file")
   ```

   **Note:**
   You can customize the command in the **Output Stream** field by pressing **CTRL+SPACE** to select built-in command from the list or type in the command into the field manually in accordance with actual practice. In this scenario, the command we use in the **Output Stream** field will call the `java.io.OutputStream` class to output the filtered data stream to a local file which is defined in the **Code** area of **tJava** in this scenario.

5. Click **Sync columns** to retrieve the schema defined in the preceding component.
6. Leave rest of the components as they were in the previous scenario.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl+S** to save your Job.

2. Press **F6** or click **Run** on the **Run** tab to execute the Job.

   The three specified columns *Id, CustomerName* and *CustomerAddress* are output in the defined output file.

<table>
<thead>

**tFileOutputExcel**

Writes an MS Excel file with separated data values according to a defined schema.

**tFileOutputExcel Standard properties**

These properties are used to configure tFileOutputExcel running in the Standard Job framework.

The Standard tFileOutputExcel component belongs to the File family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Write excel 2007 file format (xlsx)</strong></td>
<td>Select this check box to write the processed data into the .xlsx format of Excel 2007.</td>
</tr>
<tr>
<td><strong>Use Output Stream</strong></td>
<td>Select this check box process the data flow of interest. Once you have selected it, the Output Stream field displays and you can type in the data flow of interest. The data flow to be processed must be added to the flow in order for this component to fetch these data via the corresponding representative variable. This variable could be already pre-defined in your Studio or provided by the context or the components you are using along with this component; otherwise, you could define it manually and use it according to the design of your Job, for example, using tJava or tJavaFlex. In order to avoid the inconvenience of writing manually, you could select the variable of interest from the auto-completion list (Ctrl+Space) to fill the current field on condition that this variable has been properly defined. For further information about how to use a stream, see Reading data from a remote file in streaming mode on page 1013.</td>
</tr>
<tr>
<td><strong>File name</strong></td>
<td>Name or path to the output file. This field becomes unavailable once you have selected the Use Output Stream check box. For further information about how to define and use a variable in a Job, see Talend Studio User Guide. <strong>Warning:</strong> Use absolute path (instead of relative path) for this field to avoid possible errors.</td>
</tr>
<tr>
<td><strong>Sheet name</strong></td>
<td>Name of the xsl sheet.</td>
</tr>
<tr>
<td><strong>Include header</strong></td>
<td>Select this check box to include a header row to the output file.</td>
</tr>
<tr>
<td><strong>Append existing file</strong></td>
<td>Select this check box to add the new lines at the end of the file. <strong>Append existing sheet:</strong> Select this check box to add the new lines at the end of the Excel sheet.</td>
</tr>
</tbody>
</table>
### Is absolute Y pos.

Select this check box to add information in specified cells:

**First cell X**: cell position on the X-axis (X-coordinate or Abcissa).

**First cell Y**: cell position on the Y-axis (Y-coordinate).

**Keep existing cell format**: select this check box to retain the original layout and format of the cell you want to write into.

### Font

Select in the list the font you want to use.

### Define all columns auto size

Select this check box if you want the size of all your columns to be defined automatically. Otherwise, select the **Auto size** check boxes next to the column names you want their size to be defined automatically.

### Schema and Edit Schema

A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either **Built-in** or stored remotely in the **Repository**.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No upon completion** and choose this schema metadata again in the **Repository Content** window.

**Built-in**: The schema will be created and stored locally for this component only. Related topic: see *Talend Studio User Guide*.

**Repository**: The schema already exists and is stored in the Repository, hence can be reused in various projects and Job designs. Related topic: see *Talend Studio User Guide*.

### Advanced settings

<table>
<thead>
<tr>
<th>Create directory if not exists</th>
<th>This check box is selected by default. This option creates the directory that will hold the output files if it does not already exist.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Custom the flush buffer size</td>
<td>Available when <strong>Write excel2007 file format (xlsx)</strong> is selected in the <strong>Basic settings</strong> view. Select this check box to set the maximum number of rows in the <strong>Row number</strong> field that are allowed in the buffer.</td>
</tr>
<tr>
<td><strong>Advanced separator (for numbers)</strong></td>
<td>Select this check box to modify the separators you want to use for numbers: <strong>Thousands separator</strong>: define separators for thousands.</td>
</tr>
</tbody>
</table>
### Decimal separator

Define separators for decimals.

### Encoding

Select the encoding type from the list or select Custom and define it manually. This field is compulsory for DB data handling.

### Don’t generate empty file

Select the check box to avoid the generation of an empty file.

### Recalculate formula

Select this check box if you need to recalculate formula(s) in the specified Excel file.

This check box appears only when you select all these three check boxes: Write excel2007 file format(xlsx), Append existing file, and Append existing sheet.

### tStatCatcher Statistics

Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

### Global Variables

**NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

### Usage

**Usage rule**

Use this component to write an MS Excel file with data passed on from other components using a Row link.

**Dynamic settings**

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your HDFS connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access files in different HDFS systems or different distributions, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.
For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

| Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |

**Related scenario**

For `tFileOutputExcel` related scenario, see `tSugarCRMInput` on page 3742;

For scenario about the usage of **Use Output Stream** check box, see Utilizing Output Stream to save filtered data to a local file on page 1113.
tFileOutputJSON

Receives data and rewrites it in a JSON structured data block in an output file.

**tFileOutputJSON Standard properties**

These properties are used to configure tFileOutputJSON running in the Standard Job framework.

The Standard tFileOutputJSON component belongs to the File family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th><strong>File Name</strong></th>
<th>Name and path of the output file.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Warning:</strong></td>
<td>Use absolute path (instead of relative path) for this field to avoid possible errors.</td>
</tr>
</tbody>
</table>

| **Generate an array json** | Select this check box to generate an array JSON file. |

| **Name of data block** | Enter a name for the data block to be written, between double quotation marks.  
This field disappears when the Generate an array json check box is selected. |

| **Schema** and **Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.  
Click **Edit schema** to make changes to the schema. If the current schema is of the Repository type, three options are available:  
• **View schema**: choose this option to view the schema only.  
• **Change to built-in property**: choose this option to change the schema to Built-in for local changes.  
• **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No upon completion** and choose this schema metadata again in the Repository Content window. |

| **Built-In**: | You create and store the schema locally for this component only. |

| **Repository**: | You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. |

| **Sync columns** | Click to synchronize the output file schema with the input file schema. The Sync function only displays once the Row connection is linked with the Output component. |
Advanced settings

<th>Use this component to rewrite received data in a JSON structured output file.</th>
</tr>
</thead>
</table>

Writing a JSON structured file

This is a 2 component scenario in which a tRowGenerator component generates random data which a tFileOutputJSON component then writes to a JSON structured output file.

Procedure

1. Drop a tRowGenerator and a tFileOutputJSON component onto the workspace from the Palette.
2. Link the components using a Row > Main connection.
3. Double click tRowGenerator to define its Basic Settings properties in the Component view.
4. Click [...] next to **Edit Schema** to display the corresponding dialog box and define the schema.

<table>
<thead>
<tr>
<th>Column</th>
<th>Key</th>
<th>Type</th>
<th>Null</th>
<th>Date P</th>
<th>L...</th>
<th>P...</th>
<th>D...</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td></td>
<td>String</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>age</td>
<td></td>
<td>Integer</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>birthplace</td>
<td></td>
<td>String</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

5. Click [+] to add the number of columns desired.
6. Under **Columns** type in the column names.
7. Under **Type**, select the data type from the list.
8. Click **OK** to close the dialog box.
9. Click [+] next to **RowGenerator Editor** to open the corresponding dialog box.
10. Under **Functions**, select pre-defined functions for the columns, if required, or select [...] to set customized function parameters in the **Function parameters** tab.

11. Enter the number of rows to be generated in the corresponding field.

12. Click **OK** to close the dialog box.

13. Click **tFileOutputJSON** to set its **Basic Settings** properties in the **Component** view.

14. Click [...] to browse to where you want the output JSON file to be generated and enter the file name.

15. Enter a name for the data block to be generated in the corresponding field, between double quotation marks.

16. Select **Built-In** as the **Schema** type.

17. Click **Sync Columns** to retrieve the schema from the preceding component.

18. Press **F6** to run the Job.

```json
{
    "person": [
        {
            "birthplace": "Manchester",
            "age": 43,
            "name": "Carter"
        },
        {
            "birthplace": "Liverpool",
            "age": 39,
            "name": "Clinton"
        },
        {
            "birthplace": "London",
            "age": 53,
            "name": "Taylor"
        }
    ]
}
```

**Results**

The data from the input schema is written in a JSON structured data block in the output file.
tFileOutputLDIF

Writes or modifies an LDIF file with data separated in respective entries based on the schema defined, or else deletes content from an LDIF file.

tFileOutputLDIF outputs data to an LDIF type of file which can then be loaded into an LDAP directory.

**tFileOutputLDIF Standard properties**

These properties are used to configure tFileOutputLDIF running in the Standard Job framework.
The Standard tFileOutputLDIF component belongs to the File family.
The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>File Name</th>
<th>Specify the path to the LDIF output file.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Warning:</strong></td>
<td>Use absolute path (instead of relative path) for this field to avoid possible errors.</td>
</tr>
</tbody>
</table>

| Wrap | Specify the number of characters at which the line will be wrapped. |

<table>
<thead>
<tr>
<th>Change type</th>
<th>Select a changetype that defines the operation you want to perform on the entries in the output LDIF file.</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Add</td>
<td>the LDAP operation for adding the entry.</td>
</tr>
<tr>
<td>• Modify</td>
<td>the LDAP operation for modifying the entry.</td>
</tr>
<tr>
<td>• Delete</td>
<td>the LDAP operation for deleting the entry.</td>
</tr>
<tr>
<td>• Modrdn</td>
<td>the LDAP operation for modifying an entry’s RDN (Relative Distinguished Name).</td>
</tr>
<tr>
<td>• Default</td>
<td>the default LDAP operation.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Multi-Values / Modify Detail</th>
<th>Specify the attributes for multi-value fields when Add or Default is selected from the Change type list or provide the detailed modification information when Modify is selected from the Change type list.</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Column</td>
<td>The Column cells are automatically filled with the defined schema column names.</td>
</tr>
<tr>
<td>• Operation</td>
<td>Select an operation to be performed on the corresponding field. This column is available only when Modify is selected from the Change type list.</td>
</tr>
<tr>
<td>• MultiValue</td>
<td>Select the check box if the corresponding field is a multi-value field.</td>
</tr>
<tr>
<td>• Separator</td>
<td>Specify the value separator in the corresponding multi-value field.</td>
</tr>
<tr>
<td>• Binary</td>
<td>Select the check box if the corresponding field represents binary data.</td>
</tr>
<tr>
<td>• Base64</td>
<td>Select the check box if the corresponding field should be base-64 encoded. The base-64 encoded data in the LDIF file is represented by the :: symbol.</td>
</tr>
</tbody>
</table>

This table is available only when Add, Modify, or Default is selected from the Change type list.
A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the jobs upon completion. If you just want to propagate the changes to the current job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Built-In**: You create and store the schema locally for this component only.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and job designs.

**Sync columns**
Click to synchronize the output file schema with the input file schema. The Sync function only displays once the Row connection is linked with the Output component.

**Append**
Select this check box to add the new rows at the end of the file.

### Advanced settings

<table>
<thead>
<tr>
<th>Enforce safe base 64 conversion</th>
<th>Select this check box to enable the safe base-64 encoding. For more detailed information about the safe base-64 encoding, see <a href="https://www.ietf.org/rfc/rfc2849.txt">https://www.ietf.org/rfc/rfc2849.txt</a>.</th>
</tr>

You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |

Writing data from a database table into an LDIF file

This scenario describes a Job that loads data into a database table, and then extracts the data from the table and writing the data into a new LDIF file.
Adding and linking components

Procedure

1. Create a new Job and add the following components by typing their names in the design workspace or dropping them from the Palette: a `tFixedFlowInput` component, a `tMysqlOutput` component, a `tMysqlInput` component, and a `tFileOutputLDIF` component.

2. Link `tFixedFlowInput` to `tMysqlOutput` using a Row > Main connection.

3. Link `tMysqlInput` to `tFileOutputLDIF` using a Row > Main connection.

4. Link `tFixedFlowInput` to `tMysqlInput` using a Trigger > On Subjob Ok connection.

Configuring the components

Loading data into a database table

Procedure

1. Double-click `tFixedFlowInput` to open its Basic settings view.

   ![Schema settings](image)

   - Click the [...] button next to Edit schema and in the pop-up window define the schema by adding four columns: `dn`, `id_owners`, `registration`, and `make`, all of String type.
3. Click **OK** to close the schema editor and accept the propagation prompted by the pop-up dialog box.

4. In the **Mode** area, select **Use Inline Content (delimited file)**, and then in the **Content** field displayed, enter the following input data:

```
24;24;5382 KC 94;Volkswagen 32;32;9591 0E 79;Honda 35;35;3129 VH 61;Volkswagen
```

5. Double-click **tMysqlOutput** to open its **Basic settings** view.

7. In the **Table** field, enter the name of the table into which the data will be written. In this example, it is `ldifdata`.

8. Select **Drop table if exists and create** from the **Action on table** drop-down list.
Extracting data from the database table and writing it into an LDIF file

Procedure

1. Double-click tMysqlInput to open its Basic settings view.

2. Fill in the Host, Port, Database, Username, and Password fields with your MySQL database connection details.

3. Click the [...] button next to Edit schema and in the pop-up window define the schema by adding four columns: dn, id_owners, registration, and make, all of String type.

4. In the Table Name field, enter the name of the table from which the data will be read. In this example, it is ldifdata.

5. Click the Guess Query button to fill in the Query field with the auto-generated query.

6. Double-click tFileOutputLDIF to open its Basic settings view.

7. In the File Name field, browse to or enter the path to the LDIF file to be generated. In this example, it is E:/out.ldif.
8. Select the operation Add from the Change type list.
9. Click the Sync columns button to retrieve the schema from the preceding component.

**Saving and executing the Job**

**Procedure**

1. Press Ctrl+S to save your Job.
2. Press F6 or click Run on the Run tab to execute the Job.

The LDIF file created contains the data from the database table and the change type for the entries is set to add.
**tFileOutputMSDelimited**

Creates a complex multi-structured delimited file, using data structures (schemas) coming from several incoming Row flows.

**tFileOutputMSDelimited Standard properties**

These properties are used to configure tFileOutputMSDelimited running in the Standard Job framework.

The Standard tFileOutputMSDelimited component belongs to the File family.

The component in this framework is available in all Talend products.

### Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>File Name</strong></td>
<td>Name and path to the file to be created and/or the variable to be used.</td>
</tr>
<tr>
<td></td>
<td>For further information about how to define and use a variable in a Job, see Talend Studio User Guide.</td>
</tr>
<tr>
<td></td>
<td><strong>Warning:</strong> Use absolute path (instead of relative path) for this field to avoid possible errors.</td>
</tr>
<tr>
<td><strong>Row Separator</strong></td>
<td>String (ex: <code>\n</code> on Unix) to distinguish rows.</td>
</tr>
<tr>
<td><strong>Field Separator</strong></td>
<td>Character, string or regular expression to separate fields.</td>
</tr>
<tr>
<td><strong>Use Multi Field Separators</strong></td>
<td>Select this check box to set a different field separator for each of the schemas using the <strong>Field separator</strong> field in the <strong>Schemas</strong> area.</td>
</tr>
<tr>
<td><strong>Schemas</strong></td>
<td>The table gets automatically populated by schemas coming from the various incoming rows connected to tFileOutputMSDelimited. Fill out the dependency between the various schemas:</td>
</tr>
<tr>
<td></td>
<td><strong>Parent row:</strong> Type in the parent flow name (based on the Row name transferring the data).</td>
</tr>
<tr>
<td></td>
<td><strong>Parent key column:</strong> Type in the key column of the parent row.</td>
</tr>
<tr>
<td></td>
<td><strong>Key column:</strong> Type in the key column for the selected row.</td>
</tr>
</tbody>
</table>

### Advanced settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Advanced separator (for numbers)</strong></td>
<td>Select this check box to modify the separators used for numbers:</td>
</tr>
<tr>
<td></td>
<td><strong>Thousands separator:</strong> define separators for thousands.</td>
</tr>
<tr>
<td></td>
<td><strong>Decimal separator:</strong> define separators for decimals.</td>
</tr>
<tr>
<td><strong>CSV options</strong></td>
<td>Select this check box to take into account all parameters specific to CSV files, in particular <strong>Escape char</strong> and <strong>Text enclosure</strong> parameters.</td>
</tr>
</tbody>
</table>
**Create directory if not exists**
This check box is selected by default. It creates the directory that holds the output delimited file, if it does not already exist.

**Encoding**
Select the encoding from the list or select **Custom** and define it manually. This field is compulsory for DB data handling.

**Don't generate empty file**
Select this check box if you do not want to generate empty files.

**tStatCatcher Statistics**
Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

### Global Variables

**Global Variables**

**NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an **After** variable and it returns an integer.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an **After** variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an **After** variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](https://help.talend.com).

### Usage

**Usage rule**
Use this component to write a multi-schema delimited file and separate fields using a field separator value.

**Limitation**
Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

### Related scenarios

No scenario is available for the Standard version of this component yet.
tFileOutputMSPositional

Creates a complex multi-structured file, using data structures (schemas) coming from several incoming Row flows.

**tFileOutputMSPositional Standard properties**

These properties are used to configure tFileOutputMSPositional running in the Standard Job framework.

The Standard tFileOutputMSPositional component belongs to the File family.

The component in this framework is available in all Talend products.

### Basic settings

<table>
<thead>
<tr>
<th><strong>File Name</strong></th>
<th>Name and path to the file to be created and/or variable to be used. For further information about how to define and use a variable in a Job, see <em>Talend Studio User Guide.</em></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Row separator</strong></td>
<td>String (ex: <code>\n</code> on Unix) to distinguish rows.</td>
</tr>
</tbody>
</table>
| **Schemas** | The table gets automatically populated by schemas coming from the various incoming rows connected to tFileOutputMSPositional. Fill out the dependency between the various schemas:  
- **Parent row:** Type in the parent flow name (based on the Row name transferring the data).  
- **Parent key column:** Type in the key column of the parent row  
- **Key column:** Type in the key column for the selected row  
- **Pattern:** Type in the pattern that positions the fields separator for each incoming row.  
- **Padding char:** Type in the padding character to be used  
- **Alignment:** Select the relevant alignment parameter |

### Advanced settings

| **Advanced separator (for numbers)** | Select this check box to modify the separators used for numbers:  
- **Thousands separator:** define separators for thousands.  
- **Decimal separator:** define separators for decimals. |
| **Create directory if not exists** | This check box is selected by default. It creates the directory that holds the output delimited file, if it does not already exist. |
### Encoding
Select the encoding from the list or select Custom and define it manually. This field is compulsory for DB data handling.

### tStatCatcher Statistics
Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_LINE: the number of rows read by an input component or transferred to an output component. This is a Flow variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>NB_LINE_REJECTED: the number of rows rejected. This is a Flow variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>NB_LINE_UNKNOWN_HEADER_TYPES: the number of rows with unknown header type. This is a Flow variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>NB_LINE_PARSE_ERRORS: the number of rows with parse errors. This is a Flow variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

### Usage

| Usage rule | Use this component to write a multi-schema positional file and separate fields using a position separator value. |

### Related scenarios

No scenario is available for the Standard version of this component yet.
tFileOutputMSXML

Creates a complex multi-structured XML file, using data structures (schemas) coming from several incoming Row flows.

**tFileOutputMSXML Standard properties**

These properties are used to configure tFileOutputMSXML running in the Standard Job framework. The Standard tFileOutputMSXML component belongs to the File family.

The component in this framework is available in all Talend products.

### Basic settings

<table>
<thead>
<tr>
<th>File Name</th>
<th>Name and path to the file to be created and or the variable to be used. For further information about how to define and use a variable in a Job, see Talend Studio User Guide.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Warning:</strong></td>
<td>Use absolute path (instead of relative path) for this field to avoid possible errors.</td>
</tr>
<tr>
<td>Configure XML tree</td>
<td>Opens the dedicated interface to help you set the XML mapping. For details about the interface, see Defining the MultiSchema XML tree on page 1136.</td>
</tr>
</tbody>
</table>

### Advanced settings

<table>
<thead>
<tr>
<th>Create directory only if not exists</th>
<th>This check box is selected by default. It creates the directory that holds the output delimited file, if it does not already exist.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Advanced separator (for numbers)</td>
<td>Select this check box to modify the separators used for numbers:&lt;br&gt;&lt;br&gt;<strong>Thousands separator:</strong> define separators for thousands.&lt;br&gt;<strong>Decimal separator:</strong> define separators for decimals.</td>
</tr>
<tr>
<td>Encoding</td>
<td>Select the encoding from the list or select Custom and define it manually. This field is compulsory for DB data handling.</td>
</tr>
<tr>
<td>Don't generate empty file</td>
<td>Select this check box if you do not want to generate empty files.</td>
</tr>
<tr>
<td>Trim the whitespace characters</td>
<td>Select this check box to remove leading and trailing whitespace from the columns.</td>
</tr>
<tr>
<td>Escape text</td>
<td>Select this check box to escape special characters.</td>
</tr>
<tr>
<td>tStatCatcher Statistics</td>
<td>Select this check box to gather the Job processing metadata at a Job level as well as at each component level.</td>
</tr>
</tbody>
</table>
Global Variables

**NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press `Ctrl + Space` to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

---

**Defining the MultiSchema XML tree**

Double-click on the `tFileOutputMSXML` component to open the dedicated interface or click on the three-dot button on the **Basic settings** vertical tab of the **Component** tab.

To the left of the mapping interface, under **Linker source**, the drop-down list includes all the input schemas that should be added to the multi-schema output XML file (only if more than one input flow is connected to the `tFileOutputMSXML` component).

And under **Schema List**, are listed all columns retrieved from the input data flow in selection.
To the right of the interface, are expected all XML structures you want to create in the output XML file.

You can create manually or easily import the XML structures. Then map the input schema columns onto each element of the XML tree, respectively for each of the input schemas in selection under Linker source.

**Importing the XML tree**

The easiest and most common way to fill out the XML tree panel, is to import a well-formed XML file.

**Procedure**

1. Rename the root tag that displays by default on the XML tree panel, by clicking on it once.
2. Right-click on the root tag to display the contextual menu.
3. On the menu, select **Import XML tree**.
4. Browse to the file to import and click **OK**.
   - You can import an XML tree from files in XML, XSD and DTD formats.
   - When importing an XML tree structure from an XSD file, you can choose an element as the root of your XML tree.

   The XML Tree column is hence automatically filled out with the correct elements.
5. If you need to add or remove an element or sub-elements, right-click the relevant element of the tree to display the contextual menu.
6. Select **Delete** to remove the selection from the tree or select the relevant option among: **Add sub-element**, **Add attribute**, **Add namespace** to enrich the tree.

**Creating the XML tree manually**

If you don’t have any XML structure defined as yet, you can create it manually.

**Procedure**

1. Rename the root tag that displays by default on the XML tree panel, by clicking on it once.
2. Right-click on the root tag to display the contextual menu.
3. On the menu, select Add sub-element to create the first element of the structure.
4. If you need to add an attribute or a child element to any element or remove any element, right-click the left of the corresponding element name to display the contextual menu.
5. Right-click to the left of the element name to display the contextual menu.
6. On the menu, select the relevant option among: **Add sub-element**, **Add attribute**, **Add namespace** or **Delete**.

**Mapping XML data from multiple schema sources**

Once your XML tree is ready, select the first input schema that you want to map.

You can map each input column with the relevant XML tree element or sub-element to fill out the Related Column.
**Procedure**

1. Click on one of the *Schema column name*.
2. Drag it onto the relevant sub-element to the right.
3. Release the mouse button to implement the actual mapping.

4. If you need to disconnect any mapping on any element of the XML tree, select the element and right-click to the left of the element name to display the contextual menu.
5. Select **Disconnect link**.
   The light blue link disappears.

**Defining the node status**

Defining the XML tree and mapping the data is not sufficient. You also need to define the loop elements for each of the source in selection and if required the group element.

**Define a loop element**

The loop element allows you to define the iterating object. Generally the Loop element is also the row generator.

**About this task**

To define an element as loop element:

**Procedure**

1. Select the relevant element on the XML tree.
2. Right-click to the left of the element name to display the contextual menu.
3. Select **Set as Loop Element**.

**Results**

The **Node Status** column shows the newly added status.

There can only be one loop element at a time.
Define a group element

The group element is optional, it represents a constant element where the groupby operation can be performed. A group element can be defined only if a loop element was defined before.

About this task

When using a group element, the rows should sorted, in order to be able to group by the selected node.

To define an element as group element:

Procedure

1. Select the relevant element on the XML tree.
2. Right-click to the left of the element name to display the contextual menu.
3. Select Set as Group Element.

Results

The Node Status column shows the newly added status and any group status required are automatically defined, if needed.

Click OK once the mapping is complete to validate the definition and continue the job configuration where needed.

Related scenarios

No scenario is available for the Standard version of this component yet.
**tFileOutputPositional**

Writes a file row by row according to the length and the format of the fields or columns in a row.

**tFileOutputPositional Standard properties**

These properties are used to configure tFileOutputPositional running in the Standard Job framework. The Standard tFileOutputPositional component belongs to the File family. The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-In or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Built-In: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file where the properties are stored.</td>
</tr>
</tbody>
</table>

**Use Output Stream**

Select this check box process the data flow of interest. Once you have selected it, the **Output Stream** field displays and you can type in the data flow of interest.

The data flow to be processed must be added to the flow in order for this component to fetch these data via the corresponding representative variable.

This variable could be already pre-defined in your Studio or provided by the context or the components you are using along with this component; otherwise, you could define it manually and use it according to the design of your Job, for example, using tJava or tJavaFlex.

In order to avoid the inconvenience of hand writing, you could select the variable of interest from the auto-completion list (Ctrl+Space) to fill the current field on condition that this variable has been properly defined.

For further information about how to use a stream, see Reading data from a remote file in streaming mode on page 1013.

**File Name**

Name or path to the file to be processed and or the variable to be used.

This field becomes unavailable once you have selected the **Use Output Stream** check box.

For further information about how to define and use a variable in a Job, see Talend Studio User Guide.

**Schema and Edit Schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

**Warning:** Use absolute path (instead of relative path) for this field to avoid possible errors.
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

| **Built-In**: You create and store the schema locally for this component only. |
| **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. |

**Row separator**

The separator used to identify the end of a row.

**Append**

Select this check box to add the new rows at the end of the file.

**Include header**

Select this check box to include the column header to the file.

**Compress as zip file**

Select this check box to compress the output file in zip format.

**Formats**

Customize the positional file data format and fill in the columns in the Formats table.

**Column**: Select the column you want to customize.

**Size**: Enter the column size.

**Padding char**: Type in between quotes the padding characters used. A space by default.

**Alignment**: Select the appropriate alignment parameter.

**Keep**: If the data in the column or in the field are too long, select the part you want to keep.

**Advanced settings**

**Advanced separator (for numbers)**

Select this check box to change the separator used for numbers. By default, the thousands separator is a comma (,) and the decimal separator is a period (.

**Thousands separator**: define separators for thousands.

**Decimal separator**: define separators for decimals.

**Use byte length as the cardinality**

Select this check box to add support of double-byte character to this component. JDK 1.6 is required for this feature.
<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create directory if not exists</td>
<td>This check box is selected by default. It creates a directory to hold the output table if it does not exist.</td>
</tr>
<tr>
<td>Custom the flush buffer size</td>
<td>Select this check box to define the number of lines to write before emptying the buffer. <strong>Row Number</strong>: set the number of lines to write.</td>
</tr>
<tr>
<td>Output in row mode</td>
<td>Writes in row mode.</td>
</tr>
<tr>
<td>Encoding</td>
<td>Select the encoding from the list or select Custom and define it manually. This field is compulsory for database data handling. The supported encodings depend on the JVM that you are using. For more information, see <a href="https://docs.oracle.com">https://docs.oracle.com</a>.</td>
</tr>
<tr>
<td>Don’t generate empty file</td>
<td>Select this check box if you do not want to generate empty files.</td>
</tr>
<tr>
<td>tStatCatcher Statistics</td>
<td>Select this check box to gather the Job processing metadata at a Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

### Global Variables

- **Global Variables**
  - **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.
  - **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.
  - A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.
  - To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.
  - For further information about variables, see *Talend Studio User Guide*.

### Usage

- **Usage rule**
  - Use this component to read a file and separate the fields using the specified separator.
- **Dynamic settings**
  - Click the [+ ] button to add a row in the table and fill the **Code** field with a context variable to choose your HDFS connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access files in different HDFS systems or different distributions, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of *Talend Studio*.
  - The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the Basic
settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

**Related scenario**

For a related scenario, see Regex to Positional file on page 1082.

For scenario about the usage of Use Output Stream check box, see Utilizing Output Stream to save filtered data to a local file on page 1113.
**tFileOutputProperties**

 Writes a configuration file, of the type .ini or .properties, containing text data organized according to the model key = value.

**tFileOutputProperties Standard properties**

These properties are used to configure tFileOutputProperties running in the Standard Job framework. The Standard tFileOutputProperties component belongs to the File family. The component in this framework is available in all Talend products.

**Basic settings**

| Schema and Edit Schema | A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either **Built-in** or stored remotely in the **Repository**.
For this component, the schema is read-only. It is made of two column, **Key** and **Value**, corresponding to the parameter name and the parameter value to be copied. |
<table>
<thead>

Usage

| Usage rule | Use this component to write files where data is organized according to the structure key = value. |

Related scenarios

For a related scenario, see Reading and matching the keys and the values of different .properties files and outputting the results in a glossary on page 1073 of tFileInputProperties on page 1072.
**tFileOutputRaw**

Provides data coming from another component, in the form of a single column of output data.

**tFileOutputRaw Standard properties**

These properties are used to configure tFileOutputRaw running in the Standard Job framework.

The Standard tFileOutputRaw component belongs to the File family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Schema and Edit Schema</th>
</tr>
</thead>
</table>
| **A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either Built-in or stored remotely in the Repository.**  
Click **Edit schema** to make changes to the schema. If the current schema is of the Repository type, three options are available:  
- **View schema**: choose this option to view the schema only.  
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.  
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the Repository Content window. |

| Built-in | No property data stored centrally. |
| Repository | Select the repository file where the properties are stored. The fields that follow are completed automatically using the data retrieved. |

**Filename**

The name of and path to the output file to be processed, which you can enter manually between double quotes or browse and select by clicking the [...] button.

**Warning:** Use absolute path (instead of relative path) for this field to avoid possible errors.

**Encoding**

If the output is a string, select the encoding type from the list or select Custom and define it manually.

**Die on error**

Select this check box to stop the execution of the Job when an error occurs. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can collect the rows on error using a Row > Reject link.

To catch the FileNotFoundException, you also need to select this check box.
### Advanced settings

| tStatCatcher Statistics | Select this check box to gather the processing metadata at the Job level as well as at each component level. |

</tbody>
</table>

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Use this component to write an XML file with data passed on from other components using a Row link.</strong></td>
<td></td>
</tr>
</tbody>
</table>

### Related scenarios

For related scenarios using **tFileOutputXML**, see [Reading a Positional file and saving filtered results to XML](#) on page 1068 and [Using a SOAP message from an XML file to get country name information and saving the information to an XML file](#) on page 3529.
tFileProperties

Creates a single row flow that displays the main properties of the processed file.

### tFileProperties Standard properties

These properties are used to configure tFileProperties running in the Standard Job framework.

The Standard tFileProperties component belongs to the File family.

The component in this framework is available in all Talend products.

#### Basic settings

| Schema and Edit schema | A schema is a row description, it defines the fields to be processed and passed on to the next component. The schema of this component is read-only. It describes the main properties of the specified file. You can click the [...] button next to Edit schema to view the predefined schema which contains the following fields:
|  | • abs_path: the absolute path of the file.
|  | • dirname: the directory of the file.
|  | • basename: the name of the file.
|  | • mode_string: the access mode of the file, r and w for read and write permissions respectively.
|  | • size: the file size in bytes.
|  | • mtime: the timestamp indicating when the file was last modified, in milliseconds that have elapsed since the Unix epoch (00:00:00 UTC, Jan 1, 1970).
|  | • mtime_string: the date and time the file was last modified.
| File | Name or path to the file to be processed and/or the variable to be used.
|  | For further information about how to define and use a variable in a Job, see Talend Studio User Guide.

**Warning:** Use absolute path (instead of relative path) for this field to avoid possible errors.

| Calculate MD5 Hash | Select this check box to check the MD5 of the downloaded file.

#### Advanced settings

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

#### Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the
Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl** + **Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

---

### Usage

#### Usage rule

This component can be used as standalone component.

#### Connections

Outgoing links (from this component to another):

- **Row**: Main; Iterate.
- **Trigger**: On Subjob Ok; On Subjob Error; Run If; On Component Ok; On Component Error.

Incoming links (from one component to this one):

- **Row**: Iterate.
- **Trigger**: Run If; On Subjob Ok; On Subjob Error; On component Ok; On Component Error; Synchronize; Paralize.

For further information regarding connections, see *Talend Studio User Guide*.

---

### Displaying the properties of a processed file

This Java scenario describes a very simple Job that displays the properties of the specified file.

#### Procedure

1. Drop a **{tFileProperties} component** and a **{tLogRow} component** from the **Palette** onto the design workspace.
2. Right-click on **tFileProperties** and connect it to **tLogRow** using a **Main Row** link.
3. In the design workspace, select **tFileProperties**.
4. Click the **Component** tab to define the basic settings of **tFileProperties**.
5. Set **Schema** type to **Built-In**.

6. If desired, click the **Edit schema** button to see the read-only columns.

7. In the **File** field, enter the file path or browse to the file you want to display the properties for.

8. In the design workspace, select **tLogRow** and click the **Component** tab to define its basic settings. For more information, see **tLogRow** on page 1956.

9. Press **F6** to execute the Job.

```
<table>
<thead>
<tr>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>#1. tLogRow_1</td>
</tr>
<tr>
<td>key</td>
</tr>
<tr>
<td>abs_path</td>
</tr>
<tr>
<td>dirname</td>
</tr>
<tr>
<td>basename</td>
</tr>
<tr>
<td>mtime</td>
</tr>
<tr>
<td>size</td>
</tr>
</tbody>
</table>
```

**Results**

The properties of the defined file are displayed on the console.
tFileRowCount

Opens a file and reads it row by row in order to determine the number of rows inside.

**tFileRowCount Standard properties**

These properties are used to configure tFileRowCount running in the Standard Job framework.
The Standard tFileRowCount component belongs to the File family.
The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>File Name</td>
<td>Name or path to the file to be processed and/or the variable to be used.</td>
</tr>
<tr>
<td></td>
<td>For further information about how to define and use a variable in a Job, see Talend Studio User Guide.</td>
</tr>
<tr>
<td></td>
<td><strong>Warning:</strong> Use absolute path (instead of relative path) for this field to avoid possible errors.</td>
</tr>
<tr>
<td>Row separator</td>
<td>String (ex: &quot;\n&quot; on Unix) to distinguish rows in the output file.</td>
</tr>
<tr>
<td>Ignore empty rows</td>
<td>Select this check box to ignore the empty rows while the component is counting the rows in the file.</td>
</tr>
<tr>
<td>Encoding</td>
<td>Select the encoding type from the list or select <strong>Custom</strong> and define it manually. This field is compulsory for DB data handling.</td>
</tr>
</tbody>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tStatCatcher Statistics</td>
<td>Select this check box to gather the processing metadata at the Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

**Global Variables**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Global Variables</td>
<td><strong>COUNT:</strong> the number of rows in a file. This is a Flow variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td><strong>ERROR_MESSAGE:</strong> the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press <strong>Ctrl + Space</strong> to access the variable list and choose the variable to use from it.</td>
</tr>
</tbody>
</table>
For further information about variables, see *Talend Studio User Guide.*

### Usage

| Usage rule | tFileRowCount is a standalone component, it must be used with a [OnSubjobOk](#) connection to [tJava](#). |

### Connections

**Outgoing links (from this component to another):**

- **Row:** Main; Iterate.
- **Trigger:** On Subjob Ok; On Subjob Error; Run if; On Component Ok; On Component Error.

**Incoming links (from one component to this one):**

- **Row:** Main; Reject; Iterate.
- **Trigger:** On Subjob Ok; On Subjob Error; Run if; On component Ok; On Component Error; Synchronize; Parallel.

For further information regarding connections, see *Talend Studio User Guide.*

### Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

---

**Writing a file to MySQL if the number of its records matches a reference value**

In this scenario, **tFileRowCount** counts the number of records in a .txt file, which is compared against a reference value through **tJava**. Once the two values match, the .txt file will be written to a MySQL table.

The .txt file has two records:

```
1;andy
2;mike
```

### Linking the components

**Procedure**

1. Drop **tFileRowCount**, **tJava**, **tFileInputDelimited**, and **tMysqlOutput** from the **Palette** onto the design workspace.
2. Link **tFileRowCount** to **tJava** using an **OnSubjobOk** trigger.
3. Link **tJava** to **tFileInputDelimited** using a **Run if** trigger.
4. Link **tFileInputDelimited** to **tMysqlOutput** using a **Row > Main** connection.
Configuring the components

Procedure

1. Double-click **tFileRowCount** to open its **Basic settings** view.

   ![tFileRowCount](image)

   **Basic settings**
   - **File Name**: D:/staff.txt
   - **Row Separator**: 
   - **Ignore empty rows**: checked

2. In the **File Name** field, type in the full path of the .txt file. You can also click the [...] button to browse for this file.

   Select the **Ignore empty rows** check box.

3. Double-click **tJava** to open its **Basic settings** view.

   ![tJava](image)

   **Basic settings**
   - **Code**

   ```java
   System.out.println(globalMap.get("tFileRowCount_1_COUNT"));
   ```

4. Click the **if** trigger connection to open its **Basic settings** view.

   ![If](image)

   **Basic settings**
   - **Condition**: 

   ```java
   ((Integer)globalMap.get("tFileRowCount_1_COUNT")) == 2
   ```
In the **Condition** box, enter the statement to judge if the number of rows is 2:

```java
((Integer)globalMap.get("tFileRowCount_1_COUNT"))==2
```

This **if** trigger means that if the row count equals 2, the rows of the .txt file will be written to MySQL.

5. Double-click **tFileInputDelimited** to open its **Basic settings** view.

   ![Basic settings](image)

   In the **File name/Stream** field, type in the full path of the .txt file. You can also click the `[...]` button to browse for this file.

6. Click the **Edit schema** button open the schema editor.

   ![Schema editor](image)

   7. Click the `[+]` button to add two columns, namely **id** and **name**, respectively of the **integer** and **string** type.

   8. Click the **Yes** button in the pop-up box to propagate the schema setup to the following component.
9. Double-click **tMysqlOutput** open its **Basic settings** view.

10. In the **Host** and **Port** fields, enter the connection details.
    In the **Database** field, enter the database name.
    In the **Username** and **Password** fields, enter the authentication details.
    In the **Table** field, enter the table name, for instance "staff".

11. In the **Action on table** list, select **Create table if not exists**.
    In the **Action on data** list, select **Insert**.

### Executing the Job

**Procedure**

1. Press **Ctrl+S** to save the Job.
2. Press **F6** to run the Job.

```
Starting job tFileRowCount at 10:35 27/08/2013.
[statistics] connecting to socket on port 3610
[statistics] connected
[statistics] disconnected
Job tFileRowCount ended at 10:35 27/08/2013. [exit code=0]
```

As shown above, the Job has been executed successfully and the number of rows in the .txt file has been printed out.

3. Go to the MySQL GUI and open the table **staff**.

As shown above, the table has been created with the two records inserted.
tFileTouch

Creates an empty file or, if the specified file already exists, updates its date of modification and of last access while keeping the contents unchanged.

**tFileTouch Standard properties**

These properties are used to configure tFileTouch running in the Standard Job framework.
The Standard tFileTouch component belongs to the File family.
The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>File Name</th>
<th>Path and name of the file to be created and/or the variable to be used.</th>
</tr>
</thead>
</table>

**Warning:** Use absolute path (instead of relative path) for this field to avoid possible errors.

Create directory if not exists

This check box is selected by default. It creates a directory to hold the output table if it does not exist.

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the processing metadata at the Job level as well as at each component level. |

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th><strong>ERROR_MESSAGE:</strong> the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press <strong>Ctrl + Space</strong> to access the variable list and choose the variable to use from it.</td>
</tr>
</tbody>
</table>

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component can be used as a standalone component.</th>
</tr>
</thead>
</table>

**Connections**

Outgoing links (from this component to another): Row: Main.
**tFileTouch**

**Trigger**: On Subjob Ok; On Subjob Error; Run if; On Component Ok; On Component Error.

Incoming links (from one component to this one):

**Row**: Main; Reject; Iterate.

**Trigger**: Run if; On Subjob Ok; On Subjob Error; On component Ok; On Component Error; Synchronize; Parallelize.

For further information regarding connections, see [Talend Studio User Guide](https://docs.talend.com).

---

**Related scenarios**

No scenario is available for the Standard version of this component yet.
tFileUnarchive

Decompresses an archive file for further processing, in one of the following formats: *.tar.gz, *.tgz, *.tar, *.gz and *.zip.

**tFileUnarchive Standard properties**

These properties are used to configure tFileUnarchive running in the Standard Job framework.

The Standard tFileUnarchive component belongs to the File family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Archive file</td>
<td>File path to the archive.</td>
</tr>
<tr>
<td><strong>Warning:</strong> Use absolute path (instead of relative path) for this field to avoid possible errors.</td>
<td></td>
</tr>
<tr>
<td>Extraction Directory</td>
<td>Folder where the unzipped file(s) will be put.</td>
</tr>
<tr>
<td><strong>Warning:</strong> Use absolute path (instead of relative path) for this field to avoid possible errors.</td>
<td></td>
</tr>
<tr>
<td>Use archive file name as root directory</td>
<td>Select this check box to create a folder named as the archive, if it does not exist, under the specified directory and extract the zipped file(s) to that folder.</td>
</tr>
<tr>
<td>Check the integrity before unzip</td>
<td>Select this check box to run an integrity check before unzipping the archive.</td>
</tr>
<tr>
<td>Extract file paths</td>
<td>Select this check box to reproduce the file path structure zipped in the archive.</td>
</tr>
<tr>
<td>Need a password</td>
<td>Select this check box and provide the correct decrypt method and password if the archive to be unzipped is password protected. Note that the encrypted archive must be one created by the tFileArchive component; otherwise you will see error messages or get nothing extracted even if no error message is displayed.</td>
</tr>
<tr>
<td><strong>Decrypt method:</strong> select the decrypt method from the list, either Java Decrypt or Zip4j Decrypt.</td>
<td></td>
</tr>
<tr>
<td><strong>Enter the password:</strong> enter the decryption password.</td>
<td></td>
</tr>
<tr>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
<td></td>
</tr>
</tbody>
</table>

</tbody>
</table>
Global Variables

**CURRENT_FILE**: the current file name. This is a Flow variable and it returns a string.

**CURRENT_FILEPATH**: the current file path. This is a Flow variable and it returns a string.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see **Talend Studio User Guide**.

Usage

**Usage rule**

This component can be used as a standalone component but it can also be used within a Job as a Start component using an **Iterate** link.

**Connections**

Outgoing links (from this component to another):

- **Row**: Iterate.
- **Trigger**: On Subjob Ok; On Subjob Error; Run if; On Component Ok; On Component Error.

Incoming links (from one component to this one):

- **Row**: Iterate.
- **Trigger**: Run if; On Subjob Ok; On Subjob Error; On component Ok; On Component Error; Synchronize; Parallelize.

For further information regarding connections, see **Talend Studio User Guide**.

**Limitation**

**Warning:**

Related scenario

For **tFileUnarchive** related scenario, see **tFileCompare** on page 977.
tFilterColumns

Homogenizes schemas either by ordering the columns, removing unwanted columns or adding new columns.

### tFilterColumns Standard properties

These properties are used to configure tFilterColumns running in the Standard Job framework.

The Standard tFilterColumns component belongs to the Processing family.

The component in this framework is available in all Talend products.

#### Basic settings

<table>
<thead>
<tr>
<th>Schema and Edit Schema</th>
<th>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:</th>
</tr>
</thead>
<tbody>
<tr>
<td>• View schema: choose this option to view the schema only.</td>
<td></td>
</tr>
<tr>
<td>• Change to built-in property: choose this option to change the schema to Built-in for local changes.</td>
<td></td>
</tr>
<tr>
<td>• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. Click Sync columns to retrieve the schema from the previous component in the Job.</td>
<td></td>
</tr>
<tr>
<td>Built-In: You create and store the schema locally for this component only.</td>
<td></td>
</tr>
<tr>
<td>Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
<td></td>
</tr>
</tbody>
</table>

#### Advanced settings

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

#### Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the |
**Die on error** check box is cleared, if the component has this check box.

**NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

---

**Usage**

| Usage rule | This component is not startable (green background) and it requires an output component. |

---

**Related Scenario**

For more information regarding the **tFilterColumns** component in use, see *Multiple replacements and column filtering* on page 3117.
tFilterRow

Filters input rows by setting one or more conditions on the selected columns.

tFilterRow Standard properties

These properties are used to configure tFilterRow running in the Standard Job framework.
The Standard tFilterRow component belongs to the Processing family.
The component in this framework is available in all Talend products.

Basic settings

| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.
The schema of this component is built-in only. |
|------------------------|--------------------------------------------------------------------------------------------------|
| Logical operator used to combine conditions | Select a logical operator to combine simple conditions and to combine the filter results of both modes if any advanced conditions are defined.

**And**: returns the boolean value of true if all conditions are true; otherwise false. For each two conditions combined using a logical AND, the second condition is evaluated only if the first condition is evaluated to be true.

**Or**: returns the boolean value of true if any condition is true; otherwise false. For each two conditions combined using a logical OR, the second condition is evaluated only if the first condition is evaluated to be false. |
| Conditions | Click the plus button to add as many simple conditions as needed. Based on the logical operator selected, the conditions are evaluated one after the other in sequential order for each row. When evaluated, each condition returns the boolean value of true or false.

**Input column**: Select the column of the schema the function is to be operated on

**Function**: Select the function on the list

**Operator**: Select the operator to bind the input column with the value

**Value**: Type in the filtered value, between quotes if needed. |
| Use advanced mode | Select this check box when the operations you want to perform cannot be carried out through the standard functions offered, for example, different logical operations in the same component. In the text field, type in the regular expression as required.

If multiple advanced conditions are defined, use a logical operator between two conditions:

**&&**: (logical AND): returns the boolean value of true if both conditions are true; otherwise false. The second condition is evaluated only if the first condition is evaluated to be true. |
|| (logical OR): returns the boolean value of true if either condition is true; otherwise false. The second condition is evaluated only if the first condition is evaluated to be false.

### Advanced settings

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>NB_LINE: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>NB_LINE_OK: the number of rows matching the filter. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>NB_LINE_REJECTED: the number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td></td>
<td>For further information about variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

### Usage

| Usage rule | This component is not startable (green background) and it requires an output component. |

### Filtering a list of names using simple conditions

The following scenario shows a Job that uses simple conditions to filter a list of records. This scenario will output two tables: the first will list all male persons with a last name shorter than nine characters and aged between 10 and 80 years; the second will list all rejected records. An error message for each rejected record will display in the same table to explain why such a record has been rejected.
Dropping and linking components

Procedure

1. Drop `tFixedFlowInput`, `tFilterRow` and `tLogRow` from the Palette onto the design workspace.
2. Connect the `tFixedFlowInput` to the `tFilterRow`, using a Row > Main link. Then, connect the `tFilterRow` to the `tLogRow`, using a Row > Filter link.
3. Drop `tLogRow` from the Palette onto the design workspace and rename it as `reject`. Then, connect the `tFilterRow` to the `reject`, using a Row > Reject link.
4. Label the components to better identify their roles in the Job.

Configuring the components

Procedure

1. Double-click `tFixedFlowInput` to display its Basic settings view and define its properties.
2. Click the [...] button next to Edit schema to define the schema for the input data. In this example, the schema is made of the following four columns: `LastName` (type String), `Gender` (type String), `Age` (type Integer) and `City` (type String).

When done, click OK to validate the schema setting and close the dialog box. A new dialog box opens and asks you if you want to propagate the schema. Click Yes.
3. Set the row and field separators in the corresponding fields if needed. In this example, use the default settings for both, namely the row separator is a carriage return and the field separator is a semi-colon.

4. Select the Use Inline Content(delimited file) option in the Mode area and type in the input data in the Content field.

```
Van Buren;M;73;Chicago
Adams;M;40;Albany
Jefferson;F;66;New York
Adams;M;9;Albany
Jefferson;M;30;Chicago
Carter;F;26;Chicago
Harrison;M;40;New York
Roosevelt;F;15;Chicago
Monroe;M;8;Boston
Arthur;M;20;Albany
Pierce;M;18;New York
Quincy;F;83;Albany
McKinley;M;70;Boston
Coolidge;M;4;Chicago
Monroe;M;60;Chicago
```

5. Double-click tFilterRow to display its Basic settings view and define its properties.
6. In the **Conditions** table, add four conditions and fill in the filtering parameters.

   - From the **InputColumn** list field of the first row, select **LastName**, from the **Function** list field, select **Length**, from the **Operator** list field, select **Lower than**, and in the **Value** column, type in 9 to limit the length of last names to nine characters.
   - From the **InputColumn** list field of the second row, select **Gender**, from the **Operator** list field, select **Equals**, and in the **Value** column, type in "M" in double quotes to filter records of male persons.

   **Warning:**
   In the **Value** field, you must type in your values between double quotes for all types of values, except for integer values, which do not need quotes.

   - From the **InputColumn** list field of the third row, select **Age**, from the **Operator** list field, select **Greater than**, and in the **Value** column, type in 10 to set the lower limit to 10 years.
   - From the **InputColumn** list field of the fourth row, select **Age**, from the **Operator** list field, select **Lower than**, and in the **Value** column, type in 80 to set the upper limit to 80 years.

7. To combine the conditions, select **And** as that only those records that meet all the defined conditions are accepted.

8. In the **Basic settings** of **tLogRow** components, select **Table (print values in cells of a table)** in the **Mode** area.

**Executing the Job**

**Procedure**

Save your Job and press **F6** to execute it.

As shown above, the first table lists the records of male persons aged between 10 and 80 years, whose last names are made up of less than nine characters, and the second table lists all the records that do not match the filter conditions. Each rejected record has a corresponding error message that explains the reason of rejection.
Filtering a list of names through different logical operations

Based on the previous scenario, this scenario further filters the input data so that only those records of people from New York and Chicago are accepted. Without changing the filter settings defined in the previous scenario, advanced conditions are added in this scenario to enable both logical AND and logical OR operations in the same tFilterRow component.

Procedure

1. Double-click the tFilterRow component to show its Basic settings view.

2. Select the Use advanced mode check box, and type in the following expression in the text field:

   ```java
   input_row.City.equals("Chicago") || input_row.City.equals("New York")
   ```

   This defines two conditions on the City column of the input data to filter records that contain the cities of Chicago and New York, and uses a logical OR to combine the two conditions so that records satisfying either condition will be accepted.

3. Press Ctrl+S to save the Job and press F6 to execute it.
As shown above, the result list of the previous scenario has been further filtered, and only the records containing the cities of New York and Chicago are accepted.
tFirebirdClose

Closes a transaction with a Firebird database.

**tFirebirdClose Standard properties**

These properties are used to configure tFirebirdClose running in the Standard Job framework.

The Standard tFirebirdClose component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tFirebirdConnection component in the list if more than one connection are planned for the current Job.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is to be used along with Firebird components, especially with tFirebirdConnection and tFirebirdCommit. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |
Related scenarios

No scenario is available for the Standard version of this component yet.
**tFirebirdCommit**

Commits a global transaction instead of doing so on every row or every batch, thus providing a gain in performance.

**tFirebirdCommit Standard properties**

These properties are used to configure tFirebirdCommit running in the Standard Job framework. The Standard tFirebirdCommit component belongs to the Databases family. The component in this framework is available in all Talend products.

*Note:* This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tFirebirdConnection component in the list if more than one connection are planned for the current Job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

*Warning:* If you want to use a Row > Main connection to link tFirebirdCommit to your Job, your data will be committed row by row. In this case, do not select the Close connection check box or your connection will be closed before the end of your first row commit.

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is more commonly used with other tFirebird components, especially with the tFirebirdConnection and tFirebirdRollback components.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic settings</td>
<td>Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an</td>
</tr>
</tbody>
</table>
environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenario

For tFirebirdCommit related scenario, see Inserting data in mother/daughter tables on page 2437
tFirebirdConnection

Opens a connection to the specified database that can then be reused in the subsequent subjob or subjobs.

**tFirebirdConnection Standard properties**

These properties are used to configure tFirebirdConnection running in the Standard Job framework.

The Standard tFirebirdConnection component belongs to the Databases and the ELT families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Host name</td>
<td>Database server IP address.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Use or register a shared DB Connection</td>
<td>Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the Shared DB Connection Name field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child. This option is incompatible with the Use dynamic job and Use an independent process to run subjob options of the tRunJob component. Using a shared connection together with a tRunJob component with either of these two options enabled will cause your Job to fail.</td>
</tr>
</tbody>
</table>
## Advanced settings

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Auto Commit</td>
<td>Select this check box to commit any changes to the database automatically upon the transaction. With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component. Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component.</td>
</tr>
<tr>
<td>tStatCatcher Statistics</td>
<td>Select this check box to gather the job processing metadata at a Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

## Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is more commonly used with other tFirebird* components, especially with the <strong>tFirebirdCommit</strong> and <strong>tFirebirdRollback</strong> components.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limitation</td>
<td>Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
</tbody>
</table>

## Related scenarios

For **tFirebirdConnection** related scenario, see **tMysqlConnection** on page 2436
tFirebirdInput

Executes a database query on a Firebird database with a strictly defined order which must correspond to the schema definition then passes on the field list to the next component via a Main row link.

**tFirebirdInput Standard properties**

These properties are used to configure tFirebirdInput running in the Standard Job framework.

The Standard tFirebirdInput component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-in:</strong> No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository:</strong> Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td>Host</td>
<td>Database server IP address</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of the DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database</td>
</tr>
</tbody>
</table>

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
### Username and Password

DB user authentication data.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

### Schema and Edit schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

#### Built-In

You create and store the schema locally for this component only.

#### Repository

You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

### Query type and Query

Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.

### Advanced Settings

<table>
<thead>
<tr>
<th>Trim all the String/Char columns</th>
<th>Select this check box to remove leading and trailing whitespace from all the String/Char columns.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Trim column</td>
<td>Remove leading and trailing whitespace from defined columns.</td>
</tr>
<tr>
<td>tStat Catcher Statistics</td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_LINE: the number of rows processed. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>QUERY: the query statement being processed. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the</td>
</tr>
</tbody>
</table>
Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component covers all possible SQL queries for FireBird databases.</th>
</tr>
</thead>
</table>

**Dynamic settings**

Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>Limitation</th>
<th>Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</th>
</tr>
</thead>
</table>

**Related scenarios**

For related topics, see:

See also related topic: Reading data from different MySQL databases using dynamically loaded connection parameters on page 491.
tFirebirdOutput

Executes the action defined on the table in a Firebird database and/or on the data contained in the table, based on the flow incoming from the preceding component in the Job.
tFirebirdOutput writes, updates, makes changes or suppresses entries in a database.

tFirebirdOutput Standard properties

These properties are used to configure tFirebirdOutput running in the Standard Job framework.
The Standard tFirebirdOutput component belongs to the Databases family.
The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td>Host</td>
<td>Database server IP address</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database</td>
</tr>
<tr>
<td>----------</td>
<td>---------------------</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Table</td>
<td>Name of the table to be written. Note that only one table can be written at a time</td>
</tr>
<tr>
<td>Action on table</td>
<td>On the table defined, you can perform one of the following operations: <strong>None</strong>: No operation is carried out. <strong>Drop and create a table</strong>: The table is removed and created again. <strong>Create a table</strong>: The table does not exist and gets created. <strong>Create a table if not exists</strong>: The table is created if it does not exist. <strong>Drop a table if exists and create</strong>: The table is removed if it already exists and created again. <strong>Clear a table</strong>: The table content is deleted.</td>
</tr>
<tr>
<td>Action on data</td>
<td>On the data of the table defined, you can perform: <strong>Insert</strong>: Add new entries to the table. If duplicates are found, Job stops. <strong>Update</strong>: Make changes to existing entries. <strong>Insert or update</strong>: Insert a new record. If the record with the given reference already exists, an update would be made. <strong>Update or insert</strong>: Update the record with the given reference. If the record does not exist, a new record would be inserted. <strong>Delete</strong>: Remove entries corresponding to the input flow. <strong>Warning</strong>: You must specify at least one column as a primary key on which the <strong>Update</strong> and <strong>Delete</strong> operations are based. You can do that by clicking <strong>Edit Schema</strong> and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the <strong>Advanced settings</strong> view where you can simultaneously define primary keys for the update and delete operations. To do that: Select the <strong>Use field options</strong> check box and then in the <strong>Key in update</strong> column, select the check boxes next to the column name on which you want to base the update operation. Do the same in the <strong>Key in delete</strong> column for the deletion operation.</td>
</tr>
<tr>
<td>Schema and Edit schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <strong>line</strong> when naming the fields. <strong>Built-In</strong>: You create and store the schema locally for this component only.</td>
</tr>
</tbody>
</table>
Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- View schema: choose this option to view the schema only.
- Change to built-in property: choose this option to change the schema to Built-in for local changes.
- Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

Die on error

This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a Row > Rejects link.

Advanced settings

Commit every

Enter the number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and, above all, better performance at execution.

Additional Columns

This option is not offered if you create (with or without drop) the DB table. This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing.

Name: Type in the name of the schema column to be altered or inserted as new column

SQL expression: Type in the SQL statement to be executed in order to alter or insert the relevant column data.

Position: Select Before, Replace or After following the action to be performed on the reference column.

Reference column: Type in a column of reference that the tDBOutput can use to place or replace the new or altered column.
### Use field options
- **Enable debug mode**: Select this check box to display each step during processing entries in a database.
- **Support null in "SQL WHERE" statement**: Select this check box if you want to deal with the Null values contained in a DB table. 
  
  **Note:**
  Make sure the Nullable check box is selected for the corresponding columns in the schema.
- **Use Batch**: Select this check box to activate the batch mode for data processing.
  
  **Note:**
  This check box is available only when you have selected the Insert, Update, or Delete option in the Action on data option.
- **Batch Size**: Specify the number of records to be processed in each batch.
  This field appears only when the Use batch mode check box is selected.
- **tStat Catcher Statistics**: Select this check box to collect log data at the component level.

### Global Variables
**Global Variables**
- **NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.
- **NB_LINE_UPDATED**: the number of rows updated. This is an After variable and it returns an integer.
- **NB_LINE_INSERTED**: the number of rows inserted. This is an After variable and it returns an integer.
- **NB_LINE_DELETED**: the number of rows deleted. This is an After variable and it returns an integer.
- **NB_LINE_REJECTED**: the number of rows rejected. This is an After variable and it returns an integer.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.
For further information about variables, see *Talend Studio User Guide*.

## Usage

### Usage rule

This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible.

This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in a Firebird database. It also allows you to create a reject flow using a **Row > Rejects** link to filter data in error. For an example of **tMySqlOutput** in use, see *Retrieving data in error with a Reject link* on page 2485.

### Dynamic settings

Click the `[+]` button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see *Reading data from databases through context-based dynamic connections* on page 2457 and *Reading data from different MySQL databases using dynamically loaded connection parameters* on page 491. For more information on **Dynamic settings** and context variables, see *Talend Studio User Guide*.

### Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

## Related scenarios

For related topics, see:

- Inserting a column and altering data using **tMysqlOutput** on page 2477.
**tFirebirdRollback**

Cancels the transaction committed in the connected Firebird database.

**tFirebirdRollback Standard properties**

These properties are used to configure tFirebirdRollback running in the Standard Job framework.

The Standard tFirebirdRollback component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
