| Usage rule | This component can be used as a single-component subjob or used with other components. This component is particularly useful when used with tSCPGet to get multiple files in a directory given that tSCPGet does not support wildcarding. |

Related scenario

For a related scenario using a different protocol, see Listing and getting files/folders on an FTP directory on page 1222.
tSCPGet

Copies files from the defined SCP server.
tSCPGet transfers defined files via an SCP connection over a fully encrypted channel.

**tSCPGet Standard properties**

These properties are used to configure tSCPGet running in the Standard Job framework.
The Standard tSCPGet component belongs to the Internet family.
The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>SCP IP address.</td>

<tr>
<td>Attachments</td>
<td>Specify the file(s) attached and sent along with the email message. Click the [+] button to add as many rows as needed and set the value of the following columns for each row:</td>
</tr>
<tr>
<td>Other Headers</td>
<td>Click the plus button to add as many lines as needed where you can type the Key and the corresponding Value of any header information that does not belong to the standard header.</td>
</tr>
<tr>
<td>SMTP Host and Port</td>
<td>IP address of SMTP server used to send emails.</td>
</tr>
</tbody>
</table>
### SSL Support
- Select this check box to authenticate the server at the client side via an SSL protocol.

### STARTTLS Support
- Select this check box to authenticate the server at the client side via a STARTTLS protocol.

### Importance
- Select in the list the priority level of your messages.

### Need authentication / Username and Password
- Select this check box and enter a username and a password in the corresponding fields if this is necessary to access the service.
- To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

### Die on error
- This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows.

## Advanced settings

<table>
<thead>
<tr>
<th><strong>MIME subtype from the 'text' MIME type</strong></th>
<th>Select in the list the structural form for the text of the message.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Encoding type</strong></td>
<td>Select the encoding from the list or select Custom and define it manually.</td>
</tr>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to gather the Job processing metadata at a Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

## Global Variables

**Global Variables**

- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

  A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

  To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

  For further information about variables, see *Talend Studio User Guide*.

## Usage

**Usage rule**

- This component is typically used as one subJob but can also be used as output or end object. It can be connected to other components with either **Row** or **Iterate** links.
Sedning an email on error

This scenario creates a three-component Job which sends an email to defined recipients when an error occurs.

- Drop the following components from your Palette to the design workspace: **tFileInputDelimited, tFileOutputXML, tSendMail**.
- Define **tFileInputDelimited** properties. Related topic: **tFileInputDelimited** on page 1008.
- Right-click on the **tFileInputDelimited** component and select *Row > Main*. Then drag it onto the **tFileOutputXML** component and release when the plug symbol shows up.
- Define **tFileOutputXML** properties.
- Drag a **Run on Error** link from **tFileDelimited** to **tSendMail** component.
- Define the **tSendMail** component properties:
  - Enter the recipient and sender email addresses, as well as the email subject.
  - Enter a message containing the error code produced using the corresponding global variable. Access the list of variables by pressing **Ctrl+Space**.
  - Add attachments and extra header information if any. Type in the SMTP information.
In this scenario, the file containing data to be transferred to XML output cannot be found. tSendmail runs on this error and sends a notification email to the defined recipient.
tServerAlive

Validates the status of the connection to a specified host.

tServerAlive checks whether the connection to a specified host is up or down, which is indicated by the boolean value returned by the global variable SERVER_ALIVE_RESULT.

**tServerAlive Standard properties**

These properties are used to configure tServerAlive running in the Standard Job framework.

The Standard tServerAlive component belongs to the Misc family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Select either Ping or Telnet from the drop-down list of protocols.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>IP address or host name of the remote server to be checked.</td>
</tr>
<tr>
<td>Timeout Interval (in seconds)</td>
<td>Enter the timeout interval in seconds. If the target host is reached within this time, the component's global variable SERVER_ALIVE_RESULT will be set to true, otherwise false.</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of the Telnet server. Available when Telnet is selected from the Protocol drop-down list.</td>
</tr>
</tbody>
</table>

**Advanced settings**

- **tStatCatcher Statistics**
  - Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

**Global Variables**

- **SERVER_ALIVE_RESULT**: the status of the connection to a remote host. This is an After variable and it returns a boolean.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.
Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is generally used as a one-component subjob.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limitation</td>
<td></td>
</tr>
</tbody>
</table>

Validating the status of the connection to a remote host

In this scenario, tServerAlive is used to ping a remote host and the value of its global variable SERVER_ALIVE_RESULT is extracted to show the connection status.

Dropping and linking components

Procedure

1. Drop the following components from the Palette onto the design workspace: tServerAlive, tFixedFlowInput, and tLogRow.
2. Connect tServerAlive to tFixedFlowInput using a Trigger > On Subjob Ok connection.
3. Connect tFixedFlowInput to tLogRow using a Row > Main connection.

Configuring the components

Procedure

1. Double-click tServerAlive to open its Basic settings view.
2. In the Protocol drop-down list, select Ping.
3. In the Host field, enter the IP address of the remote server to ping.
4. In the **Timeout Interval** field, enter the timeout interval in seconds.

5. Double-click **tFixedFlowInput** to open its **Basic settings** view.

6. Click the [...] button next to **Edit schema** to open the schema editor.

7. Click the [+] button to add one column, namely **status**, of the boolean type.
   Click **OK** to validate the schema and close the editor.
   In the dialog box that appears, click **Yes** to propagate the changes to the subsequent component.

8. In the **Values** table, press the Ctrl + Space keys in the **Value** field to select **tServerAlive_1_SERVER_ALIVE_RESULT** from the variable list.
9. Double-click **tLogRow** to open its **Basic settings** view.

10. Select **Table (print values in cells of a table)** for a better display of the results.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl+S** to save your Job.
2. Press **F6** to execute the Job.

```
[statistics] connecting to socket on port 3516
[statistics] connected

---
<table>
<thead>
<tr>
<th>tLogRow_1</th>
</tr>
</thead>
<tbody>
<tr>
<td>status</td>
</tr>
<tr>
<td>true</td>
</tr>
</tbody>
</table>
```

**Results**

As shown above, the remote server is pingable.
tServiceNowConnection

Opens a connection to a ServiceNow instance that can then be reused by other ServiceNow components.

**tServiceNowConnection Standard properties**

These properties are used to configure tServiceNowConnection running in the Standard Job framework.

The Standard tServiceNowConnection component belongs to the Business and the Cloud families.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>URL</th>
<th>Enter the URL of the ServiceNow instance to be connected.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Username and Password</td>
<td>Enter the user authentication data to connect to the ServiceNow instance. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global Variables**

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

**Usage**

| Usage rule | This component is more commonly used with other ServiceNow components. |
Related scenario

No scenario is available for the Standard version of this component yet.
**tServiceNowInput**

Accesses ServiceNow and retrieves data from it.

tServiceNowInput retrieves data from ServiceNow according to the specified conditions.

**tServiceNowInput Standard properties**

These properties are used to configure tServiceNowInput running in the Standard Job framework.
The Standard tServiceNowInput component belongs to the Business and the Cloud families.
The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Use Existing Connection</th>
<th>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Note:</strong> When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to: 1. In the parent level, register the database connection to be shared in the <strong>Basic settings</strong> view of the connection component which creates that very database connection. 2. In the child level, use a dedicated connection component to read that registered database connection. For an example about how to share a database connection across Job levels, see <a href="https://www.talend.com">Talend Studio User Guide</a>.</td>
<td></td>
</tr>
</tbody>
</table>

| URL | Enter the URL of the ServiceNow instance to be connected. |

<table>
<thead>
<tr>
<th>Username and Password</th>
<th>Enter the user authentication data to connect to the ServiceNow instance.</th>
</tr>
</thead>
<tbody>
<tr>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
<td></td>
</tr>
</tbody>
</table>

| Table | Select the name of the table from which the data will be retrieved or select **Use Custom Table** and in the **Custom Table Name** field displayed enter the table name. |

<table>
<thead>
<tr>
<th>Schema and Edit schema</th>
<th>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <code>line</code> when naming the fields.</th>
</tr>
</thead>
<tbody>
<tr>
<td>• <strong>Built-In:</strong> You create and store the schema locally for this component only.</td>
<td></td>
</tr>
</tbody>
</table>
Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

Conditions

Specify search conditions to retrieve only the data that matches the criteria by clicking the [+] button to add as many conditions as needed and then setting the following parameters for each condition:

- **Input column**: click in the cell and select the column of the input schema on which the search condition is to be set.
- **Operator**: click in the cell and select an operator for the search condition.
- **Value**: enter the value for the corresponding column for the search condition.

Advanced settings

Trim all columns

Select this check box to remove the leading and trailing whitespaces from all columns.

Limit

Enter the maximum number of records to be retrieved.

tStatCatcher Statistics

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

Global Variables

**NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.
Usage

Usage rule
This component is usually used as a start component in a Talend flow and it requires an output component.

Dynamic settings
Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenario
No scenario is available for the Standard version of this component yet.
tServiceNowOutput

Performs the defined action on the data on ServiceNow.
tServiceNowOutput inserts or updates data on ServiceNow.

**tServiceNowOutput Standard properties**

These properties are used to configure tServiceNowOutput running in the Standard Job framework.
The Standard tServiceNowOutput component belongs to the Business and the Cloud families.
The component in this framework is available in all Talend products.

**Basic settings**

</table>
component. When you create a Spark Job, avoid the reserved word LINE when naming the fields.

- **Built-In**: You create and store the schema locally for this component only.
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-In** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

### Advanced settings

<table>
<thead>
<tr>
<th><strong>Enable payload debug mode</strong></th>
<th>Select this check box to enable the payload debug mode and logging for the payload of the request message.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Enable response debug mode</strong></td>
<td>Select this check box to enable the response debug mode and logging for the response message from the log server.</td>
</tr>
</tbody>
</table>

| **tStatCatcher Statistics** | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

### Global Variables

**Global Variables**

- **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.
- **NB_LINE_INSERTED**: the number of rows inserted. This is an After variable and it returns an integer.
- **NB_LINE_UPDATED**: the number of rows updated. This is an After variable and it returns an integer.
- **NB_LINE_REJECTED**: the number of rows rejected. This is an After variable and it returns an integer.
- **PAYLOAD**: the payload of the JSON request message. This is a Flow variable and it returns an object.
- **RESPONSE**: the response message from the log server. This is a Flow variable and it returns an object.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is usually used as an end component in a Talend flow and it requires an input component.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic settings</td>
<td>Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

Related scenario

No scenario is available for the Standard version of this component yet.
**tSetEnv**

Adds variables temporarily to system environment during the execution of a Job.

tSetEnv creates variables and execute a Job script through communicating the information about the newly created variables between subJobs. After job execution, the newly created variables are deleted.

### tSetEnv Standard properties

These properties are used to configure tSetEnv running in the Standard Job framework.

The Standard tSetEnv component belongs to the System family.

The component in this framework is available in all Talend products.

#### Basic settings

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Click the plus button to add the variables needed for the job. <strong>name</strong>: Enter the syntax for the new variable. <strong>value</strong>: Enter a parameter value according to the context. <strong>append</strong>: Select this check box to add the new variable at the end.</th>
</tr>
</thead>
</table>

#### Advanced settings

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
<th>Select this check box to gather the processing metadata at the Job level as well as at each component level.</th>

</thead>
</table>

Modifying a variable during a Job execution

The following scenario is made of two Jobs parent and child. With the tSetEnv component, you can transfer and modify in a child Job a value created in a parent Job. As part of this Job, the tMsgBox components allow you to display, for information purposes only, that a variable is properly set, via an info-box.

To modify the value of the parent Job by using a variable set in the tSetEnv component, do as described in the following sections:

Drop and link components

Procedure

1. Create a first Job named parentJob: right-click on the Job Design node of the Repository, and choose Create a Job.
2. From the Palette, drop a tSetEnv component, two tMsgBox components, and one tRunJob component onto the design workspace.
3. Connect the tSetEnv component to a first tMsgBox component with a OnSubjobOk link : right-click on the start component, select Trigger, then OnSubjobOk. Then click on the end component you want to connect.
4. Connect the first tMsgBox component to the tRunJob with a OnSubjobOk link.
5. Then connect the tRunJob component to the second tMsgBox with a OnSubjobOk link.
7. From the Palette, drop a tSetEnv component onto the design workspace.
8. Connect the tSetEnv component to the tMsgBox with a OnSubjobOk link: right-click on the start component, select Trigger, then OnSubjobOk. Then click on the end component you want to connect.
Results

Set the components

About this task

In this example, the value set in the parent Job is transferred to the child Job. There, it is modified and adopts the value of the child Job, and then transferred to the parent Job again.

Procedure

1. In parentJob, select the tSetEnv component and click the Component tab. Add a variable row by clicking the [+] button to set the initial value of the variable. Type Variable_1 in the Name field, and Parent job value in the Value field.

2. Select the first tMsgBox component, and click the Component tab. In the Message field, type the message displayed in the info-box which confirms that your variable has properly been taken into account. For example: "Parent:"+System.getProperty("Variable_1") displays the variable set in the tSetEnv component (here Parent job value).

3. Select the second tMsgBox component, and click the Component tab. In the Message field, type the "Parent:"+System.getProperty("Variable_1") line again. It makes the variable set in the child Job appear.

4. Select the tRunJob component and click the Component tab. In the Job field, type the name of your child Job, here ChildJob. This will run the child Job when you run the parent Job.

5. Now double-click the tRunJob component to open the child Job ChildJob.
6. Select the `tSetEnv` component, and click the **Component** tab. Add a variable row by clicking the `[+]` button to set the initial value of the variable. Type `Variable_1` in the **Name** field, and `Child job value` in the **Value** field.

7. Select the `tMsgBox` component and click the **Component** tab. In the **Message** field, type the message displayed in the info-box which confirms that your variable has properly been taken into account. For example: "Son:"+System.getProperty("Variable_1") displays the variable set in the `tSetEnv` component (here `Child job value`).

8. Save your Job, go back to `parentJob`, then run the Job by pressing **F6**.

**Run the Job**

Three info-boxes are displayed one after the other:

- **Parent**: `Parent job value`: parent Job's value is `Parent job value`.
- **Child**: `Child job value`: Child Job's value is `Child job value`.
- **Parent**: `Child job value`: parent Job's value was modified by the variable set in the `tSetEnv` of the child Job, then transferred again to the parent Job. parent Job's value is now the one set in the child Job.
**tSetGlobalVar**

Facilitates the process of defining global variables.
tSetGlobalVar allows you to define and set global variables in GUI.

**tSetGlobalVar Standard properties**

These properties are used to configure tSetGlobalVar running in the Standard Job framework.
The Standard tSetGlobalVar component belongs to the Custom Code family.
The component in this framework is available in all Talend products.

**Basic settings**

| Variables | This table contains two columns.  
**Key**: Name of the variable to be called in the code.  
**Value**: Value assigned to this variable. |
|-----------|--------------------------------------------------------------------------------------------------|

**Advanced settings**

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
<th>Select this check box to gather the Job processing metadata at a Job level as well as at each component level.</th>

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is generally used as a one-component subjob.</th>
</tr>
</thead>
</table>

| Limitation | Knowledge of Java language is required. |
Printing out the content of a global variable

This scenario is a simple Job that prints out the value of a global variable defined in the `tSetGlobalVar` component.

Setting up the Job

Procedure

1. Drop the following components from the Palette onto the design workspace: `tSetGlobalVar` and `tJava`.
2. Connect the `tSetGlobalVar` component to the `tJava` component using a `Trigger > OnSubjobOk` connection.

Configuring the tSetGlobalVar component

Procedure

1. Double-click the `tSetGlobalVar` component to display its Basic settings view.

<table>
<thead>
<tr>
<th>Variables</th>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>“K1”</td>
<td>“20”</td>
</tr>
</tbody>
</table>

2. Click the plus button to add a line in the Variables table, and fill the Key and Value fields with `K1` and 20 respectively.
3. Then double-click the `tJava` component to display its Basic settings view.

```java
String foo = "bar";
String K1;
String Result = "The value is:";
Result = Result + globalMap.get("K1");
System.out.println(Result);
```
4. In the **Code** area, type in the following lines:

```java
String foo = "bar";
String K1;
String Result = "The value is:";

Result = Result + globalMap.get("K1");
System.out.println(Result);
```

In this use case, we use the `Result` variable. To access the global variable list, press **Ctrl + Space** bar on your keyboard and select the relevant global parameter.

**Job execution**

Save your Job and press **F6** to execute it.

The content of global variable `K1` is displayed on the console.

```
Starting job SetGlobalVar at 16:22 25/02/2011
[statistics] connecting to socket on port 3489
[statistics] connected
The value is:20
Job SetGlobalVar ended at 16:22 25/02/2011.
[exit code=0]
```
tSetKerberosConfiguration

Sets the relevant information for Kerberos authentication.

tSetKerberosConfiguration is designed to configure Kerberos authentication for enhanced security of network communications.

For more information on the Kerberos protocol, go to http://www.kerberos.org.

**tSetKerberosConfiguration Standard properties**

These properties are used to configure tSetKerberosConfiguration running in the Standard Job framework.

The Standard tSetKerberosConfiguration component belongs to the Internet family.

The component in this framework is available in all Talend products.

### Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>KDC Server</td>
<td>Address of the Key Distribution Center (KDC) server.</td>
</tr>
<tr>
<td>Realm</td>
<td>Name of the Kerberos realm.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>Kerberos authentication credentials.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field,</td>
</tr>
<tr>
<td></td>
<td>and then in the pop-up dialog box enter the password between double quotes</td>
</tr>

Related scenarios

No scenario is available for the Standard version of this component yet.
tSetKeystore

Sets the authentication data type between **PKCS 12** and **JKS**.

*tSetKeystore* submits authentication data of a truststore with or without keystore to validation for the SSL connection.

### tSetKeystore Standard properties

These properties are used to configure *tSetKeystore* running in the Standard Job framework.

The Standard tSetKeystore component belongs to the Internet family.

The component in this framework is available in all **Talend products**.

#### Basic settings

<table>
<thead>
<tr>
<th><strong>TrustStore type</strong></th>
<th>Select the type of the TrustStore to be used. It may be <strong>PKCS 12</strong> or <strong>JKS</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>TrustStore file</strong></td>
<td>Type in the path, or browse to the certificate TrustStore file (including filename) that contains the list of certificates that the client trusts.</td>
</tr>
<tr>
<td><strong>TrustStore password</strong></td>
<td>Type in the password used to check the integrity of the TrustStore data.</td>
</tr>
<tr>
<td><strong>Need Client authentication</strong></td>
<td>Select this check box to validate the keystore data. Once doing so, you need complete three fields:</td>
</tr>
<tr>
<td></td>
<td>- <strong>KeyStore type</strong>: select the type of the keystore to be used. It may be <strong>PKCS 12</strong> or <strong>JKS</strong>.</td>
</tr>
<tr>
<td></td>
<td>- <strong>KeyStore file</strong>: type in the path, or browse to the file (including filename) containing the keystore data.</td>
</tr>
<tr>
<td></td>
<td>- <strong>KeyStore password</strong>: type in the password for this keystore.</td>
</tr>
<tr>
<td><strong>Check server identity</strong></td>
<td>Select this check box to make the Job verify the match between the hostname of the URL and the hostname of the server. If they mismatch, the verification mechanism asks whether this connection should be allowed.</td>
</tr>
</tbody>
</table>

#### Advanced settings

| **tStatCatcher Statistics** | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

#### Global Variables

| **Global Variables** | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. |

---

3464
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is used standalone.</th>
</tr>
</thead>
</table>

### Connections

Outgoing links (from this component to another):

**Trigger**: Run if, On Subjob Ok, On Subjob Error, On Component Ok; On Component Error.

Incoming links (from one component to this one):

**Trigger**: Run if, On Subjob Ok, On Component Ok, On Component Error.

For further information regarding connections, see *Talend Studio User Guide*.

### Limitation

n/a.

### Extracting customer information from a private WSDL file

This scenario describes a three-component Job that connects to a private WSDL file in order to extract customer information.

The WSDL file used in this Job accesses the corresponding web service under the SSL protocol. For this purpose, the most relative code in this file reads as follows:

```xml
<wswl:port name="CustomerServiceHttpSoap11Endpoint"
    binding="ns:CustomerServiceSoap11Binding">
</wswl:port>
```

Accordingly, we enter the following code in the *server.xml* file of Tomcat:

```xml
<Connector port="8443" protocol="HTTP/1.1" SSLEnabled="true"
    maxThreads="150" scheme="https" secure="true"
    clientAuth="true" sslProtocol="TLS"
    keystoreFile="D:/server.keystore" keystorePass="password"
    keystoreType="JKS"
    truststoreFile="D:/server.p12" truststorePass="password"
    truststoreType="PKCS12"/>
```

So we need keystore files to connect to this WSDL file. To replicate this Job, proceed as follows:

- Drop the following components from the **Palette** onto the design workspace: **tSetKeystore**, **tWebService**, and **tLogRow**.
Right-click **tSetKeystore** to open its contextual menu.

In this menu, select **Trigger > On Subjob Ok** to connect this component to **tWebService**.

Right-click **tWebService** to open its contextual menu.

In this menu, select **Row > Main** to connect this component to **tLogRow**.

Double-click **tSetKeystore** to open its **Basic settings** view and define the component properties.

In the **TrustStore type** field, select **PKCS12** from the drop-down list.

In the **TrustStore file** field, browse to the corresponding truststore file. Here, it is `server.p12`.

In the **TrustStore password** field, type in the password for this truststore file. In this example, it is `password`.

Select the **Need Client authentication** check box to activate the keystore configuration fields.

In the **KeyStore type** field, select **JKS** from the drop-down list.

In the **KeyStore file** field, browse to the corresponding keystore file. Here, it is `server.keystore`.

Double-click **tWebService** to open the component editor, or select the component in the design workspace and in the **Basic settings** view, click the three-dot button next to **Service configuration**.
In the **WSDL** field, browse to the private WSDL file to be used. In this example, it is `CustomerService.wsdl`.

Click the refresh button next to the **WSDL** field to retrieve the WSDL description and display it in the fields that follow.

In the **Port Name** list, select the port you want to use, `CustomerServiceHttpSoap11Endpoint` in this example.

In the **Operation** list, select the service you want to use. In this example the selected service is `getCustomer(parameters):Customer`.

Click **Next** to open a new view in the editor.

In the panel to the right of the **Input mapping** view, the input parameter of the service displays automatically. However, you can add other parameters if you select `[+] parameters` and then click the plus button on top to display the **Parameter Tree** dialog box where you can select any of the listed parameters.
The Web service in this example has only one input parameter, ID.

- In the Expression column of the parameters.ID row, type in the customer ID of your interest between quotation marks. In this example, it is A00001.
- Click Next to open a new view in the editor.

In the Element list to the left of the view, the output parameter of the web service displays automatically. However, you can add other parameters if you select [+ parameters] and then click the plus button on top to display the Parameter Tree dialog box where you can select any of the parameters listed.

The Web service in this example has four output parameter: return.address, return.email, return.name and return.phone.

You now need to create a connection between the output parameter of the defined Web service and the schema of the output component. To do so:

- In the panel to the right of the view, click the three-dot button next to Edit Schema to open a dialog box in which you can define the output schema.

In the schema editing dialog box, click the plus button to add four columns to the output schema. Click in each column and type in the new names, Name, Phone, Email and Address in this example. This will retrieve the customer information of your interest.
• Click **OK** to validate your changes and to close the schema editing dialog box.
• In the **Element** list to the right of the editor, drag each parameter to the field that corresponds to the column you have defined in the schema editing dialog box.

**Note:**
If available, use the **Auto map!** button, located at the bottom left of the interface, to carry out the mapping operation automatically.

• Click **OK** to validate your changes and to close the editor.
• In the design workspace, double-click **tLogRow** to open its **Basic settings** view and define its properties.
• Click **Sync columns** to retrieve the schema from the preceding component.
• Save your **Job** and press **F6** to execute it.

The information of the customer with ID **A00001** is returned and displayed in the console of *Talend Studio*.

```
<table>
<thead>
<tr>
<th>name</th>
<th>phone</th>
<th>email</th>
<th>address</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rose Gonzalez</td>
<td>(512) 757-9000</td>
<td><a href="mailto:rose@edge.com">rose@edge.com</a></td>
<td>313 Constitution Place Austin, TX 78767 USA</td>
</tr>
</tbody>
</table>
```

[statistics] disconnected

</tr>
</tbody>
</table>

**Schema and Edit Schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

**Built-In:** You create and store the schema locally for this component only.

**Repository:** You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

If the Snowflake data type to be handled is VARIANT, OBJECT or ARRAY, while defining the schema in the component, select `String` for the corresponding data in the Type column of the schema editor wizard.

Click `Edit schema` to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema:** choose this option to view the schema only.
- **Change to built-in property:** choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection:** choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

Note that if the input value of any non-nullable primitive field is null, the row of data including that field will be rejected.

**Table Action**

Select the action to be carried out on the table.

- **NONE:** No operation made to the table.
- **DROP_CREATE:** Remove the table and create it again.
- **CREATE:** Create a new table.
- **CREATE_IF_NOT_EXISTS:** Create the specified table if it does not exist.
- **DROP_IF_EXISTS_AND_CREATE:** Remove the table if it already exists and create again.
- **CLEAR:** Delete the table content.
### Output Action
Select the operation to insert, delete, update or merge data in the Snowflake table. By now user should already define a Snowflake table.

- **TRUNCATE**: Delete all the rows in the table and release the file space back to the operating system.
- **INSERT**: Insert new records in a Snowflake table.
- **UPDATE**: Update existing records in a Snowflake table.
- **UPSERT**: Create new records and update existing records. In the **Upsert Key Column** field displayed, specify the key column to be used as the join key for the upsert operation.
- **DELETE**: Remove records from a Snowflake table.

### Storage
Select the type of storage where you copy data from:

- **Internal**: Select an internal storage to load data. User needs to specify credentials in order to connect to the default Snowflake storage specified in **Stage Folder**.
- **S3**: Select an Amazon S3 bucket to load data.
- **Azure**: Select an Azure container to load data.

### Stage Folder
Specify the path to the default Snowflake stage. This field is available only when **Internal** is selected from the **Storage** drop-down list.

### Region
Specify the region where the S3 bucket locates. This field is available only when **S3** is selected from the **Storage** drop-down list.

### Access Key and Secret Key
Enter the authentication information required to connect to the Amazon S3 bucket to be used. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings. This field is available only when **S3** is selected from the **Storage** drop-down list.

### Bucket
Enter the name of the bucket to be used to load data. This bucket must exist. This field appears when you select **S3** from the **Storage** drop-down list.

### Folder
Enter the directory in which you want to store data in this given bucket. This directory is created if it does not exist at runtime. This field is available only when **S3** is selected from the **Storage** drop-down list.

### Protocol
Select the protocol used to create Azure connection. This field is available only when **Azure** is selected from the **Storage** drop-down list.

### Account Name
Enter the name of the Azure storage account you need to access.
### SnowflakeBulkExec

<table>

</thead>
</table>
| **Use Custom Snowflake Region**   | Select this check box to use the customized Snowflake region.  
  - **Region ID**: enter, within double quotation marks, a region ID, for example eu-west-1 or east-us-2.azure. For more information on Snowflake Region ID, see https://docs.snowflake.net/manuals/user-guide/intro-regions.html#region-ids-in-account-urls. |
| **Login Timeout**                 | Specify how long to wait for a response when connecting to Snowflake before returning an error.                                                                                                                                                                                                                                         |
| **Tracing**                       | Select the log level for the Snowflake JDBC driver. If enabled, a standard Java log is generated.                                                                                                                                                                                                                                      |
| **Role**                          | Enter, within double quotation marks, the default access control role to use to initiate the Snowflake session.  
  This role must already exist and has been granted to the user ID you are using to connect to Snowflake. If this field is left empty, the PUBLIC role is automatically granted. For further information about the Snowflake access control model, see Snowflake documentation at Understanding the Access Control Model. |
| **Allow Snowflake to convert columns and tables to uppercase** | Select this check box to convert lowercase in the defined table name and schema column names to uppercase. Note that unquoted identifiers should match the Snowflake Identifier Syntax.  
  If you deselect the check box, all identifiers are automatically quoted.  
  This property is not available when you select the Manual Query check box. |
For more information on the Snowflake Identifier Syntax, refer to Identifier Syntax.

</tbody>
</table>
tSnowflakeBulkExec

**ERROR_MESSAGE**
The error message generated by the component when an error occurs. This is an After variable and it returns a string.

### Usage

| Usage rule | This component is an end component of a data flow in your Job. It receives data from other components through the Row > Main link. |

### Loading data in a Snowflake table using custom stage path

This scenario describes a Job that loads data into a Snowflake table via the internal Snowflake stage configured using the Custom Stage Path property.

The input data contains several records:

| #Name  
|--------  
| Bill  
| Franklin  
| Jimmy |

Then, the input data is inserted into a Snowflake table and the path to the internal Snowflake stage is customized in the Advanced settings of tSnowflakeOutputBulk and tSnowflakeBulkExec.

Finally, the input data is outputted from the tSnowflake table to the console.

### Creating a Job for loading data using custom stage path

Create a Job to open a connection to access a Snowflake database, then create a Snowflake table and several records and insert these records into the table via the internal Snowflake stage configured using the Custom Stage Path property, and finally get and display the records on the console.
Procedure

1. Create a new Job and add a `tSnowflakeConnection` component, a `tFixedFlowInput` component, a `tSnowflakeOutputBulk` component, a `tSnowflakeBulkExec` component, a `tSnowflakeInput` component, a `tSnowflakeClose` component, and two `tLogRow` components by typing their names in the design workspace or dropping them from the Palette.

2. Link the `tFixedFlowInput` component to the first `tLogRow` component using a Row > Main connection.

3. Do the same to link the first `tLogRow` component to the `tSnowflakeBulkExec` component and link the `tSnowflakeInput` component to the second `tLogRow` component.

4. Link the `tSnowflakeConnection` component to the `tFixedFlowInput` component using a Trigger > OnSubjobOk connection.

5. Do the same to link the `tFixedFlowInput` component to the `tSnowflakeInput` component and the `tSnowflakeInput` component to the `tSnowflakeClose` component.

6. Link the `tSnowflakeOutputBulk` component to the `tSnowflakeBulkExec` component using a Trigger > OnComponentOk connection.

Opening a connection to access a snowflake database

Configure the `tSnowflakeConnection` component to open a connection to access a Snowflake database.

Procedure

1. Double-click the `tSnowflakeConnection` component to open its Basic settings view.

2. In the Account, User Id, Password, Warehouse, Schema and Database fields, specify the authentication information required to access the Snowflake Database.

3. Select an AWS region available for the Snowflake database from the Snowflake Region drop-down list. In this example, it is AWS US West.

Loading data to the Snowflake table

Configure the `tSnowflakeOutputBulk` and `tSnowflakeBulkExec` components to load data to the Snowflake table.

Procedure

1. Double-click the `tFixedFlowInput` component to open its Basic settings view.
2. Click the button next to **Edit schema** to define the schema. In this example, the schema has only one column: Name.

3. In the **Mode** area, select **Use Inline Table**. Then add three records. In this example, they are:

   Bill
   Franklin
   Jimmy

4. Double-click the first **tLogRow** component to open its **Basic settings** view.

5. In the **Mode** area, select **Table** to display data.

6. Double-click the **tSnowflakeOutputBulk** component to open its **Basic settings** view.

7. Specify the connection details required to access Snowflake. In this example, from the **Connection Component** drop-down list displayed, select the connection component to reuse its connection details you have already defined.

8. If needed, click the **Sync columns** button to make sure the schema is properly retrieved from the preceding component.
9. Select Internal from the Storage drop-down list and enter demo within double quotes in the Stage Folder field.

10. Double-click the tSnowflakeBulkExec component to open its Basic settings view.

11. Specify the connection details required to access Snowflake. In this example, from the Connection Component drop-down list displayed, select the connection component to reuse its connection details you have already defined.

12. Click the button next to the Table field to select the table you want to load data. In this example, it is DEMO_NAMES.

13. If needed, click the Sync columns button to make sure the schema is properly retrieved from the preceding component.
14. Select INSERT from the Output Action drop-down list to insert data to the table DEMO_NAMES.
15. Select Internal from the Storage drop-down list and enter demo in the Stage Folder field.

**Using custom stage path to load data**

Configure the Advanced settings of the tSnowflakeOutputBulk and tSnowflakeBulkExec components to use the Custom Stage Path property to load data.

**Procedure**

1. Click Advanced settings of the tSnowflakeOutputBulk component to open its Advanced settings view.

2. Select the Use Custom Stage Path check box and enter @~/demo within double quotes. As a result, the Stage Folder you specified in the Basic settings is disabled.
3. Select Default from the Put Command Options drop-down list.
4. Set Put Command Error Retry to 3.
5. Clear the Stop on non-empty Storage Folder check box.
6. Click Advanced settings of the tSnowflakeBulkExec component to open its Advanced settings view.
7. Select the **Convert columns and table to uppercase** check box to convert the columns to uppercase.

8. Select **Use Custom Stage Path** and enter `@~/demo` within double quotes. As a result, the **Stage Folder** you specified in the **Basic settings** is disabled.

9. Clear the **Use Custom Storage Location** check box.

10. Select **Manual** from the **Copy Command Options** drop-down list and enter `ON_ERROR='continue' FILE_FORMAT=(type=csv field_delimiter=',' compression=gzip field_optionally_enclosed_by='"')` within double quotes.

**Retrieving data from the Snowflake table**

Configure the **tSnowflakeInput** component to retrieve data from the Snowflake table, and then configure the second **tLogRow** component to get and display data on the console.

**Procedure**

1. Double-click the **tSnowflakeInput** component to open its **Basic settings** view.

2. Specify the connection details required to access Snowflake. In this example, from the **Connection Component** drop-down list displayed, select the connection component to reuse its connection details you have already defined.

3. Click the **Table** field to select the table you want to retrieve data. In this example, it is `DEMO_NAMES`.

4. Click the **Edit schema** button to open the schema dialog box and define the schema. In this example, the schema has only one column: Name.
5. Click **Advanced settings** to open the **Advanced settings** view.

6. Select the **Convert columns and table to uppercase** check box to convert the columns to uppercase.

7. Double-click the second **tLogRow** component to open its **Basic settings** view.

8. In the **Mode** area, select **Table** to display data.

**Executing the Job**

**Procedure**

Press **Ctrl + S** to save the Job and then **F6** to execute the Job.
As shown above, the Job is executed successfully and the records are displayed on the console.

**Related scenarios**

For use cases in relation with **tSnowflakeBulkExec**, see the following scenarios:

- Inserting transformed data in MySQL database on page 2493.
- Inserting data in bulk in MySQL database on page 2500.
- Truncating and inserting file data into an Oracle database on page 2700.
tSnowflakeClose

Closes an active Snowflake connection to release the occupied resources.

**tSnowflakeClose Standard properties**

These properties are used to configure tSnowflakeClose running in the Standard Job framework.

The Standard tSnowflakeClose component belongs to the Cloud family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

</thead>
</table>

**Related scenario**

For a related scenario, see Writing data into and reading data from a Snowflake table on page 3492.
tSnowflakeConnection

Opens a connection to Snowflake that can then be reused by other Snowflake components.

**tSnowflakeConnection Standard properties**

These properties are used to configure tSnowflakeConnection running in the Standard Job framework.

The Standard tSnowflakeConnection component belongs to the Cloud family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

</tbody>
</table>
Schema
Enter, within double quotation marks, the name of the database schema to be used. This name is case-sensitive and is normally upper case in Snowflake.

Database
Enter, within double quotation marks, the name of the Snowflake database to be used. This name is case-sensitive and is normally upper case in Snowflake.

Advanced settings

Use Custom Snowflake Region
Select this check box to use the customized Snowflake region.
- **Region ID**: enter, within double quotation marks, a region ID, for example eu-west-1 or east-us-2.azure.

Login Timeout
Specify how long to wait for a response when connecting to Snowflake before returning an error.

Role
Enter, within double quotation marks, the default access control role to use to initiate the Snowflake session.
This role must already exist and has been granted to the user ID you are using to connect to Snowflake. If this field is left empty, the PUBLIC role is automatically granted. For further information about the Snowflake access control model, see Snowflake documentation at Understanding the Access Control Model.

TrStatCatcher Statistics
Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

Global variables

ERROR_MESSAGE
The error message generated by the component when an error occurs. This is an After variable and it returns a string.

Usage

Usage rule
This component is more commonly used with other Snowflake components. It creates a Snowflake connection and works with other subJobs that reuse this connection using a Trigger link.

Tracing Snowflake JDBC logs
If you wish to merge the Snowflake JDBC driver logs with the logs of the current Job, add this JVM argument, -Dnet.snowflake.jdbc.loggerImpl=net.snowflake.client.log.JDK14Logger, in the Run > Advanced settings tab of the Job you are running.

Related scenario
For a related scenario, see Writing data into and reading data from a Snowflake table on page 3492.
tSnowflakeInput

Reads data from a Snowflake table into the data flow of your Job based on an SQL query.

**tSnowflakeInput Standard properties**

These properties are used to configure tSnowflakeInput running in the Standard Job framework.

The Standard tSnowflakeInput component belongs to the Cloud family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

<tr>
<td><strong>Table</strong></td>
<td>Click the [...] button and in the displayed wizard, select the Snowflake table to be used.</td>
</tr>
</tbody>
</table>
| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.  
**Built-In**: You create and store the schema locally for this component only.  
**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.  
If the Snowflake data type to be handled is VARIANT, OBJECT or ARRAY, while defining the schema in the component, select `String` for the corresponding data in the `Type` column of the schema editor wizard.  
Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
• View schema: choose this option to view the schema only.  
• Change to built-in property: choose this option to change the schema to Built-in for local changes.  
• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.  
Note that if the input value of any non-nullable primitive field is null, the row of data including that field will be rejected. |
| **Manual query** | Select this check box and in the Full SQL query string field, enter, within double quotation marks, the query statement to be executed. For more explanations about the Snowflake SQL commands, see SQL Command Reference. |
| **Condition** | Enter, within double quotation marks, the boolean expression to be used to filter data from your Snowflake table. This expression is actually used as WHERE clause in the SELECT query run by tSnowflakeInput. |

Writing data into and reading data from a Snowflake table

Here is an example of using Talend Snowflake components to connect to Snowflake, create a Snowflake table, write data into the table, then read data from this table, finally close the connection to Snowflake.
Creating a Job for writing and reading Snowflake data

Create a Job to connect to Snowflake, create a Snowflake table, write data into the table and then read data from the table, finally close the connection to Snowflake.

Before you begin

- The Snowflake data warehouse to be used is started but not in the Suspended status.
- The Snowflake role assigned to you has read and write permissions to the database to be connected.

If you are not sure about these requirements, ask the administrator of your Snowflake system.

Procedure

1. In the Integration perspective of the Studio, create a new Job from the Job Designs node in the Repository tree view.
2. Add a tSnowflakeConnection component, a tSnowflakeRow component, a tFixedFlowInput component, a tSnowflakeOutput component, a tSnowflakeInput component, a tLogRow component, and a tSnowflakeClose component to the Job.
3. Connect the tFixedFlowInput component to the tSnowflakeOutput component using a Row > Main connection.
4. Do the same to connect the tSnowflakeInput component to the tLogRow component.
5. Connect the `tSnowflakeConnection` component to the `tSnowflakeRow` component using a Trigger > On Subjob Ok connection.

6. Do the same to connect the `tSnowflakeRow` component to the `tFixedFlowInput` component, the `tFixedFlowInput` component to the `tSnowflakeInput` component, and the `tSnowflakeInput` component to the `tSnowflakeClose` component.

**Connecting to Snowflake**

Configure the `tSnowflakeConnection` component to connect to Snowflake.

**Procedure**

1. Double-click the `tSnowflakeConnection` component to open its Basic settings view.
2. In the Account field, enter the account name assigned by Snowflake.
3. In the Snowflake Region field, select the region where the Snowflake database locates.
4. In the User Id and the Password fields, enter the authentication information accordingly.

   Note that this user ID is your user login name. If you do not know your user login name yet, ask the administrator of your Snowflake system for details.
5. In the Warehouse field, enter the name of the data warehouse to be used in Snowflake.
6. In the Schema field, enter the name of the database schema to be used.
7. In the Database field, enter the name of the database to be used.

**Creating a Snowflake table**

Configure the `tSnowflakeRow` component to create a new table.

**Procedure**

1. Double-click the `tSnowflakeRow` component to open its Basic settings view on the Component tab.
2. From the Connection Component drop-down list, select the `tSnowflakeConnection` component to reuse the connection created by it. In this example, it is `tSnowflakeConnection_1`.
3. In the Query field, enter the SQL statement used to create a new table into which the data will be written.

   In this example, the following SQL statement is used to create or replace a table `EMPLOYEE` with four columns, ID of INT type, NAME of VARCHAR type, ONBOARD of DATE type, and SALARY of VARIANT type.

   ```sql
   "CREATE OR REPLACE TABLE EMPLOYEE (" +
   "ID INT NOT NULL primary key," +
   "NAME VARCHAR (50), " +
   "ONBOARD DATE," +
   "SALARY VARIANT" +
   ") COMMENT = 'Created By Doc Team'"
   ```

**Writing data into Snowflake**

Configure the `tFixedFlowInput` component and the `tSnowflakeOutput` component to write data into Snowflake.
Procedure

1. Double-click the tFixedFlowInput component to open its Basic settings view.

   ![tFixedFlowInput component]

   - Number of rows: 5
   - Mode: Use Single Table
   - Values:
     - Column: ID, NAME, ONBOARD, SALARY
     - Value: Numeric.sequence("id", 1, 1), TalendDataGenerator.getFirstName(), TalendDate.getRandomDate("2007-09-01", "2017-09-01");
     - SALARY: "{\"Salary\": value}"

2. Click the [...] button next to Edit schema and in the pop-up schema dialog box, define the schema by adding four columns, ID of int type, NAME and SALARY of String type, and ONBOARD of Date type.

   ![Pop-up schema dialog box]

3. Click OK to validate these changes and accept the propagation prompted by the pop-up dialog box.

4. In the Number of rows field, enter the number of records to be generated, 5 in this example.

5. In the Mode area, select Use Single Table and specify the value for each column.
   - ID: the automatically incremented number generated by the routine Numeric.sequence("id", 1, 1).
   - NAME: the random first name generated by the routine TalendDataGenerator.getFirstName().
   - ONBOARD: the random date generated by the routine TalendDate.getRandomDate("2007-09-01", "2017-09-01").
   - SALARY: the semi-structured JSON data with the format {"Salary": value}, where the salary value is generated by the routine Numeric.random(100000, 200000).

6. Double-click the tSnowflakeOutput component to open its Basic settings view.
7. From the **Connection Component** drop-down list, select the **tSnowflakeConnection** component to reuse the connection created by it.

8. Click the [...] button next to the **Table** field and in the pop-up dialog box, select the **Use custom object** check box and enter the name of the table into which the data will be written in the **Object Name** field. In this example, it is **EMPLOYEE**, the table created by the **tSnowflakeRow** component. When done, click **OK** to close the dialog box.

9. From the **Output action** drop-down list, select **Insert** to write data to the table **EMPLOYEE**.

**Reading data from Snowflake**

Configure the **tSnowflakeInput** component and the **tLogRow** component to retrieve data from Snowflake and output the data on the console.

**Procedure**

1. Double-click the **tSnowflakeInput** component to open its **Basic settings** view.
2. From the **Connection Component** drop-down list, select the **tSalesforceConnection** component to reuse the connection created by it.
3. Click the [...] button next to the **Table** field and in the pop-up dialog box, select the **Use custom object** check box and enter the name of the table from which the data will be retrieved in the **Object Name** field. In this example, it is **EMPLOYEE**, the table created by the **tSnowflakeRow** component. When done, click **OK** to close the dialog box.
4. Click the [...] button next to **Edit schema** and in the pop-up schema dialog box, define the schema by adding four columns, **ID** of int type, **NAME** and **SALARY** of String type, and **ONBOARD** of Date type. This schema is the same as the schema of the **tSnowflakeOutput** component.
5. Click **OK** to validate these changes and accept the propagation prompted by the pop-up dialog box.
6. Double-click the **tLogRow** component to open its **Component** view.
7. In the **Mode** area, select **Vertical (each row is a key/value list)** for better readability of the results.

**Closing the Snowflake connection**

Configure the **tSnowflakeClose** component to close the connection to Snowflake.

**Procedure**

1. Double-click the **tSnowflakeClose** component to open the **Component** tab.
2. From the **Connection Component** drop-down list, select the component that opens the connection you need to close, **tSnowflakeConnection_1** in this example.

**Executing the Job to write and read data in Snowflake**

After setting up the Job and configuring the components used in the Job for writing and reading Snowflake data, you can then execute the Job and verify the Job execution result.

**Procedure**

1. Press **Ctrl + S** to save the Job.
2. Press **F6** to run the Job.
As shown below, the data is written into the table `EMPLOYEE` in Snowflake, then read from this table and outputted on the console in the Run view of the Studio.
tSnowflakeOutput

Uses the data incoming from its preceding component to insert, update, upsert or delete data in a Snowflake table.
tSnowflakeOutput uses the bulk loader provided by Snowflake for high performance database operations.

**tSnowflakeOutput Standard properties**

These properties are used to configure tSnowflakeOutput running in the Standard Job framework. The Standard tSnowflakeOutput component belongs to the Cloud family. The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property Type</td>
<td>Select the way the connection details will be set.</td>
</tr>
<tr>
<td>• Built-In</td>
<td>The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.</td>
</tr>
<tr>
<td>• Repository</td>
<td>The connection details stored centrally in Repository &gt; Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up Repository Content dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in.</td>
</tr>
<tr>
<td>This property is not available when other connection component is selected from the Connection Component drop-down list.</td>
<td></td>
</tr>
<tr>
<td>Connection Component</td>
<td>Select the component that opens the database connection to be reused by this component.</td>
</tr>
<tr>
<td>Account</td>
<td>In the <strong>Account</strong> field, enter, within double quotation marks, the name that has been assigned to you by Snowflake.</td>
</tr>
<tr>
<td>Snowflake Region</td>
<td>Select an AWS region or an Azure region from the Snowflake Region drop-down list.</td>
</tr>
<tr>
<td>User Id and Password</td>
<td>Enter, within double quotation marks, your authentication information to log in Snowflake.</td>
</tr>
<tr>
<td>• In the <strong>User ID</strong> field, enter, within double quotation marks, your login name that has been defined in Snowflake using the LOGIN_NAME parameter of Snowflake. For details, ask the administrator of your Snowflake system.</td>
<td></td>
</tr>
</tbody>
</table>
- To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

<table>
<thead>
<tr>
<th><strong>Warehouse</strong></th>
<th>Enter, within double quotation marks, the name of the Snowflake warehouse to be used. This name is case-sensitive and is normally upper case in Snowflake.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Schema</strong></td>
<td>Enter, within double quotation marks, the name of the database schema to be used. This name is case-sensitive and is normally upper case in Snowflake.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Enter, within double quotation marks, the name of the Snowflake database to be used. This name is case-sensitive and is normally upper case in Snowflake.</td>
</tr>
<tr>
<td><strong>Table</strong></td>
<td>Click the [...] button and in the displayed wizard, select the Snowflake table to be used.</td>
</tr>
</tbody>
</table>

**Schema and Edit Schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `LINE` when naming the fields.

**Built-In**: You create and store the schema locally for this component only.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

If the Snowflake data type to be handled is VARIANT, OBJECT or ARRAY, while defining the schema in the component, select **String** for the corresponding data in the Type column of the schema editor wizard.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

Note that if the input value of any non-nullable primitive field is null, the row of data including that field will be rejected.

**Output Action**

Select the operation to insert, delete, update or merge data in Snowflake tables.

The **Upsert** operation allows you to merge data in a Snowflake table based on the data that is incoming to **tSnowflakeOutput**. After selecting **Upsert**, select the column to be used as the join key of this operation.
### Advanced settings

<table>
<thead>
<tr>
<th>Advanced setting</th>
<th>Description</th>
</tr>
</thead>
</table>
| Use Custom Snowflake Region                           | Select this check box to use the customized Snowflake region.  
• **Region ID**: enter, within double quotation marks, a region ID, for example eu-west-1 or east-us-2.azure.                                      |
| Login Timeout                                         | Specify how long to wait for a response when connecting to Snowflake before returning an error.                                                                                                             |
| Tracing                                               | Select the log level for the Snowflake JDBC driver. If enabled, a standard Java log is generated.                                                                                                          |
| Role                                                  | Enter, within double quotation marks, the default access control role to use to initiate the Snowflake session.  
This role must already exist and has been granted to the user ID you are using to connect to Snowflake. If this field is left empty, the PUBLIC role is automatically granted. For further information about the Snowflake access control model, see Snowflake documentation at Understanding the Access Control Model. |
| Allow Snowflake to convert columns and tables to upper case | Select this check box to convert lowercase in the defined table name and schema column names to uppercase. Note that unquoted identifiers should match the Snowflake Identifier Syntax.  
If you deselect the check box, all identifiers are automatically quoted.  
This property is not available when you select the **Manual Query** check box.  
For more information on the Snowflake Identifier Syntax, refer to Identifier Syntax. |
| tStatCatcher Statistics                               | Select this check box to gather the Job processing metadata at the Job level as well as at each component level.                                                                                     |

### Global Variables

<table>
<thead>
<tr>
<th>Global Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE</strong></td>
<td>The number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_SUCCESS</strong></td>
<td>The number of rows successfully processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_REJECT</strong></td>
<td>The number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>ERROR_MESSAGE</strong></td>
<td>The error message generated by the component when an error occurs. This is an After variable and it returns a string.</td>
</tr>
</tbody>
</table>

### Usage

| Usage rule             | This component is end component of a data flow in your Job. It receives data from other components via a Row > Main link.                     |
It can also send error messages to other components via a Row > Rejects link. The provided information about an error could be:

- The name of the column in error.
- The number of the row in error.
- The category of the error, such as a parsing error or a conversion error.
- The character offset in the line in error.
- The related error message.
- The offset of the byte in error.
- The number of the line in error.
- SQLSTATE for the error.
- Snowflake error code.

### Related scenario

For a related scenario, see Writing data into and reading data from a Snowflake table on page 3492.
tSnowflakeOutputBulk

Writes a file with data to an internal Snowflake storage or other storage including S3 and Azure.

The tSnowflakeOutputBulk and tSnowflakeBulkExec components work together in a two-step process:

1. An output file is generated.
2. The generated file is used in the INSERT, UPDATE, UPSERT, and DELETE statements in the tSnowflakeBulkExec component, which feed data to the database.

These two steps are fused together in the tSnowflakeOutputBulkExec component, detailed in a separate section. With a two-step process, data can be transformed before it is loaded in the database.

tSnowflakeOutputBulk Standard properties

These properties are used to configure tSnowflakeOutputBulk running in the Standard Job framework.

The Standard tSnowflakeOutputBulk component belongs to the Cloud family.

The component in this framework is available in all subscription-based Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

This field appears when you select Azure from the Storage drop-down list.

**Container**
Specify the Azure container used for storing data.
This field appears when you select Azure from the Storage drop-down list.

**SAS Token**
Specify the SAS token to grant limited access to objects in your storage account.
To enter the SAS token, click the [...] button next to the SAS token field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.
This field appears when you select Azure from the Storage drop-down list.

### Advanced settings

**Use Custom Snowflake Region**
Select this check box to use the customized Snowflake region.
- **Region ID**: enter, within double quotation marks, a region ID, for example eu-west-1 or east-us-2.azure.

For more information on Snowflake Region ID, see https://docs.snowflake.net/manuals/user-guide/intro-regions.html#region-ids-in-account-urls.

**Login Timeout**
Specify how long to wait for a response when connecting to Snowflake before returning an error.

**Tracing**
Select the log level for the Snowflake JDBC driver. If enabled, a standard Java log is generated.

**Role**
Enter, within double quotation marks, the default access control role to use to initiate the Snowflake session.
This role must already exist and has been granted to the user ID you are using to connect to Snowflake. If this field is left empty, the PUBLIC role is automatically granted. For further information about the Snowflake access control model, see Snowflake documentation at Understanding the Access Control Model.

**Use Custom Stage Path**
Select this check box to use the specified storage to upload data.
This field is available only when Internal is selected from the Storage drop-down list in the Basic Settings. Once selected, the Stage Folder in Basic settings is disabled.

**Put Command Options**
Select a PUT command mode from the drop-down list:
- **Default**: By default, only read-only string properties with options are used.
- **Table**: A table with two columns, Option and Value, are used to configure the command options.
- **Manual**: You can set any custom options using a string property.

This field appears when you select Internal from the Storage drop-down list.
### Put Command Error Retry
Specify the retry times when there is an error during data uploading with the Put command.

### S3 Max Error Retry
Specify the maximum retry times when an error occurs during loading data to the S3 bucket.
This field is available only when S3 is selected from the Storage drop-down list in the basic settings.

### Azure Max Error Retry
Specify the maximum retry times when an error occurs during loading data to the Azure container.
This field is available only when Azure is selected from the Storage drop-down list in the basic settings.

### Stop on non-empty Storage Folder
Select this check box to stop the job when the folder used for storing data is not empty.

### Chunk Size (bytes)
Specify the size of a CSV file, which is 52428800 bytes by default.
Since records must be fully stored inside a single CSV file, the size of the CSV file can be larger than the specified value, but no more than the size of the last record stored in the file.

### Number of file requests threads
Specify the number of threads used for sending Put requests in parallel when splitting data in a file by the size specified in the Chunk Size property.

### tStatCatcher Statistics
Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NB_LINE</td>
<td>The number of rows processed. This is an After variable and it returns an integer.</td>

</tbody>
</table>
| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word **line** when naming the fields.  
**Built-In**: You create and store the schema locally for this component only.  
**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.  
If the Snowflake data type to be handled is VARIANT, OBJECT or ARRAY, while defining the schema in the component, select **String** for the corresponding data in the **Type** column of the schema editor wizard.  
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
- **View schema**: choose this option to view the schema only.  
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.  
Note that if the input value of any non-nullable primitive field is null, the row of data including that field will be rejected. |
| **Output Action** | Select the operation to insert, delete, update or merge data in the Snowflake table. By now user should already define a Snowflake table.  
- **INSERT**: insert new records in a Snowflake table.  
- **UPDATE**: update existing records in a Snowflake table.  
- **UPSERT**: create new records and update existing records. In the **Upsert Key Column** field displayed, specify the key column to be used as the join key for the upsert operation. |
• **DELETE**: remove records from a Snowflake table.

| Storage | Select the type of storage into which data will be loaded.  
|---------|---------------------------------------------------------|
| • **Internal**: Select an internal storage to load data. User needs to specify credentials in order to connect to the default Snowflake storage specified in **Stage Folder**.  
| • **S3**: Select an Amazon S3 bucket to load data.  
| • **Azure**: Select an Azure container to load data. |

| Stage Folder | Specify the path to the default Snowflake stage.  
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>This field appears when you select <strong>Internal</strong> from the <strong>Storage</strong> drop-down list.</td>
<td></td>

</tbody>
</table>

| Region | Specify the region where the S3 bucket locates.  
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>This field appears when you select <strong>S3</strong> from the <strong>Storage</strong> drop-down list.</td>
<td></td>
</tr>
</tbody>
</table>

| Access Key and Secret Key | Enter the authentication information required to connect to the Amazon S3 bucket to be used.  
|---------------------------|--------------------------------------------------|
| To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.  
| This field appears when you select **S3** from the **Storage** drop-down list. |

| Bucket | Enter the name of the bucket to be used to load data. This bucket must already exist.  
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>This field appears when you select <strong>S3</strong> from the <strong>Storage</strong> drop-down list.</td>
<td></td>
</tr>
</tbody>
</table>

| Folder | Enter the directory in which you want to store data. This directory is created if it does not exist at runtime.  
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>This property is available only when <strong>S3</strong> or <strong>Azure</strong> is selected from the <strong>Storage</strong> drop-down list.</td>
<td></td>
</tr>
</tbody>
</table>

| Server-Side Encryption | This property is checked by default. Select this check box to encrypt the files to be uploaded to the S3 bucket on the server side.  
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>This field appears when you select <strong>S3</strong> from the <strong>Storage</strong> drop-down list.</td>
<td></td>
</tr>
</tbody>
</table>

| Protocol | Select the protocol used to create Azure connection.  
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>This field appears when you select <strong>Azure</strong> from the <strong>Storage</strong> drop-down list.</td>
<td></td>
</tr>
</tbody>
</table>

| Account Name | Enter the name of the Azure storage account you need to access.  
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>This field appears when you select <strong>Azure</strong> from the <strong>Storage</strong> drop-down list.</td>
<td></td>
</tr>
</tbody>
</table>

| Container | Specify the Azure container used for storing and managing data.  
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>This field appears when you select <strong>Azure</strong> from the <strong>Storage</strong> drop-down list.</td>
<td></td>
</tr>
</tbody>
</table>
| **SAS Token** | Specify the SAS token to grant limited access to objects in your storage account.  
To enter the SAS token, click the [...] button next to the SAS token field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.  
This field appears when you select Azure from the Storage drop-down list. |
| **Advanced settings** |  |
| **Use Custom Snowflake Region** | Select this check box to use the customized Snowflake region.  
- **Region ID**: enter, within double quotation marks, a region ID, for example eu-west-1 or east-us-2.azure.  
For more information on Snowflake Region ID, see [https://docs.snowflake.net/manuals/user-guide/intro-regions.html#region-ids-in-account-urls](https://docs.snowflake.net/manuals/user-guide/intro-regions.html#region-ids-in-account-urls).  |
| **Login Timeout** | Specify how long to wait for a response when connecting to Snowflake before returning an error.  |
| **Tracing** | Select the log level for the Snowflake JDBC driver. If enabled, a standard Java log is generated.  |
| **Role** | Enter, within double quotation marks, the default access control role to use to initiate the Snowflake session.  
This role must already exist and has been granted to the user ID you are using to connect to Snowflake. If this field is left empty, the PUBLIC role is automatically granted. For further information about the Snowflake access control model, see Snowflake documentation at [Understanding the Access Control Model](https://docs.snowflake.net/manuals/user-guide/intro-regions.html#region-ids-in-account-urls).  |
| **Allow Snowflake to convert columns and tables to uppercase** | Select this check box to convert lowercase in the defined table name and schema column names to uppercase. Note that unquoted identifiers should match the Snowflake Identifier Syntax.  
If you deselect the check box, all identifiers are automatically quoted.  
This property is not available when you select the **Manual Query** check box.  
For more information on the Snowflake Identifier Syntax, refer to [Identifier Syntax](https://docs.snowflake.net/manuals/user-guide/intro-regions.html#region-ids-in-account-urls).  |
| **Custom DB Type** | Select this check box to specify the data type for each column in the schema.  
This property is available only when you select an action with Create Table from the **Table Action** drop down list in the **Basic settings**.  |
| **Delete Storage Files On Success** | Delete all files in your storage folder once the job is run successfully.  
This field is unavailable when you select **Use Custom Storage Location**.  |
| **Use Custom Stage Path** | Select this check box to use the specified stage to upload data.  
This field appears when you select **Internal** from the **Storage** drop-down list.  
Once selected, the **Stage Folder** in Basic settings is disabled. |
|--------------------------|--------------------------------------------------------------------------------------------------|
| **S3 Max Error Retry** | Specify the maximum retry times when an error occurs during loading data to the S3 bucket.  
This field appears when you select **S3** from the **Storage** drop-down list. |
| **Copy Command Options** | Select a Copy command mode from the drop-down list to copy data to one of the following Snowflake stage.  
- **Default**: By default, only read-only string properties with options are used.  
- **Table**: A table with two columns, Option and Value, are used to configure the command options.  
- **Manual**: You can set any custom options using a string property. |
| **Put Command Options** | Select a PUT command mode from the drop-down list:  
- **Default**: By default, only read-only string properties with options are used.  
- **Table**: A table with two columns, Option and Value, are used to configure the command options.  
- **Manual**: You can set any custom options using a string property. |
| **Put Command Error Retry** | Specify the retry times when there is an error during data uploading with the Put command. |
| **Azure Max Error Retry** | Specify the maximum retry times when an error occurs during loading data to the Azure container.  
This field appears when you select **Azure** from the **Storage** drop-down list. |
| **Stop on non-empty Storage Folder** | Stop the operation when the storage folder used for loading data is not empty. |
| **Chunk Size (bytes)** | Specify the size of a CSV file, which is 52428800 bytes by default.  
Since records must be fully stored inside a single CSV file, the size of the CSV file can be larger than the specified value, but no more than the size of the last record stored in the file. |
| **Number of file requests threads** | Specify the number of threads used for sending Put requests in parallel when splitting data in a file by the size specified in the **Chunk Size** property. |
| **tStatCatcher Statistics** | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |
Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NB_LINE</td>
<td>The number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>NB_SUCCESS</td>
<td>The number of rows successfully processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>NB_REJECT</td>
<td>The number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>ERROR_MESSAGE</td>
<td>The error message generated by the component when an error occurs. This is an After variable and it returns a string.</td>
</tr>
</tbody>
</table>

Usage

Usage rule

This component is an end component of a data flow in your Job. It receives data from other components through the Row > Main link. It can also send error messages to other components via a Row > Rejects link. The provided information about an error could be:

- The name of the column in error.
- The number of the row in error.
- The category of the error, such as a parsing error or a conversion error.
- The character offset in the line in error.
- The related error message.
- The offset of the byte in error.
- The number of the line in error.
- SQLSTATE for the error.
- Snowflake error code.

Loading Data Using COPY Command

This scenario describes a Job that loads data into a Snowflake table using the COPY command, where Copy Command Options is customized in ON_ERROR form in case any record is rejected.

The input data contains several records, one of which violates the length limitation.

<table>
<thead>
<tr>
<th>#Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Harry</td>
</tr>
<tr>
<td>veryveryveryLongName</td>
</tr>
<tr>
<td>Jack</td>
</tr>
</tbody>
</table>

Then, the input data is inserted into a Snowflake table and the record that violates the length limitation is rejected.

Creating a Job for loading data using the COPY command

Create a Job to open a connection to access a Snowflake database, then create a Snowflake table and several records and insert these records into the table using the COPY command, and finally get and display the records on the console.
Procedure

1. Create a new Job and add a `tSnowflakeConnection` component, a `tFixedFlowInput` component, a `tSnowflakeOutputBulkExec` component, a `tSnowflakeInput` component, a `tSnowflakeClose` component, two `tSnowflakeRow` components and two `tLogRow` components by typing their names in the design workspace or dropping them from the Palette.

2. Link the `tFixedFlowInput` component to the `tSnowflakeOutputBulkExec` component using a Row > Main connection.

3. Do the same to link the `tSnowflakeOutputBulkExec` component to the first `tLogRow` component and link the `tSnowflakeInput` component to the second `tLogRow` component.

4. Link the `tSnowflakeConnection` component to the first `tSnowflakeRow` component using a Trigger > OnSubjobOk connection.

5. Do the same to link the first `tSnowflakeRow` component to the second `tSnowflakeRow` component, the second `tSnowflakeRow` component to the `tFixedFlowInput` component, the `tFixedFlowInput` component to the `tSnowflakeInput` component, the `tSnowflakeInput` component to the `tSnowflakeClose` component.

Opening a connection to access a Snowflake database

Configure the `tSnowflakeConnection` component to open a connection to access a Snowflake database.

Procedure

1. Double-click the `tSnowflakeConnection` component to open its Basic settings view.
2. In the Account, User Id, Password, Warehouse, Schema and Database fields, specify the authentication information required to access the Snowflake database.

3. Select an AWS region available for the Snowflake database from the Snowflake Region drop-down list. In this example, it is AWS US West.

Creating a Snowflake table

Configure the tSnowflakeRow to create a table. If the table already exists, it will be dropped and then created. Next, configure the tFixedFlowInput component to generate several records, one of which violates the length limitation.

Procedure

1. Double-click the tSnowflakeRow component to open its Basic settings view.

2. Specify the connection details required to access Snowflake. In this example, from the Connection Component drop-down list displayed, select the connection component to reuse its connection details you have already defined.

3. In the Queue field, enter the query statement between double quotation marks to drop the table if it already exists. In this example, it is drop table if exists demo_names.

4. Double-click the tSnowflakeRow component to open its Basic settings view.
5. Specify the connection details required to access Snowflake. In this example, from the **Component List** drop-down list displayed, select the connection component to reuse its connection details you have already defined.

6. In the **Queue** field, enter the query statement between double quotation marks to create a table. In this example, it is `create table demo_names (name varchar(10));`.

7. Double-click the **tFixedFlowInput** component to open its **Basic settings** view.

8. Click the **Edit schema** button to define the schema. In this example, the schema has only one column: Name.

9. In the **Mode** area, select **Use Inline Content**. Then add three records. In this example, they are:

<table>
<thead>
<tr>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Harry</td>
</tr>
<tr>
<td>veryveryveryLongName</td>
</tr>
<tr>
<td>Jack</td>
</tr>
</tbody>
</table>

**Loading data to the Snowflake table**

Configure the **Basic settings** of the **tSnowflakeOutputBulkExec** component to insert data to the Snowflake table.

**Procedure**

1. Double-click the **tSnowflakeOutputBulkExec** component to open its **Basic settings** view.
2. Specify the connection details required to access Snowflake. In this example, from the **Connection Component** drop-down list displayed, select the connection component to reuse its connection details you have already defined.

3. In the **Table** field, select the table you created in the second **tSnowflakeRow** component in the previous step. In this example, it is `DEMO_NAMES`.

4. If needed, click the **Sync columns** button to make sure the schema is properly retrieved from the preceding component.

5. Select **INSERT** from the **Output Action** drop-down list.

6. Select **Internal** from the **Storage** drop-down list and enter `demo` in the **Stage Folder** field.

**Using COPY command to load data**

Configure the **Advanced settings** of the **tSnowflakeOutputBulkExec** component to use the COPY command to load data, and then configure the first **tLogRow** component to display data on the console.

**Procedure**

1. Click **Advanced settings** to open the Advanced settings view.

2. Select the **Convert columns and table to uppercase** check box and the **Delete Storage Files On Success** check box to convert the columns to uppercase and delete all files in the storage once the Job runs successfully.

3. Clear the **Use Custom Stage Path** check box. Otherwise, the **Stage Folder** you specified in the **Basic settings** makes no effect.

4. Select **Manual** from the **Copy Command Options** drop-down list and enter `ON_ERROR='continue' FILE_FORMAT=(type=csv field_delimiter=',' compression=gzip field_optionally_enclosed_by='"')` within double quotes.

5. Select **Default** from the **Put Command Options** drop-down list.

6. Set **Put Command Error Retry** to 3.

7. Clear the **Stop on non-empty Storage Folder** check box.
8. Double-click the first `tLogRow` component to open its **Basic settings** view.

9. In the **Mode** area, select **Table** to display data.

**Retrieving data from the Snowflake table**

Configure the `tSnowflakeInput` component to retrieve data from the Snowflake table, and then configure the second `tLogRow` component to display data on the console.

**Procedure**

1. Double-click the `tSnowflakeInput` component to open its **Basic settings** view.

2. Specify the connection details required to access Snowflake. In this example, from the **Connection Component** drop-down list displayed, select the connection component to reuse its connection details you have already defined.

3. In the **Table** field, select the table you created in the second `tSnowflakeRow` component in the previous step. In this example, it is `DEMO_NAMES`.

4. Click the button next to **Edit schema** to open the schema dialog box and define the schema. In this example, the schema has only one column: Name.
5. Click **Advanced settings** to open the Advanced settings view.

6. Select the check box of **Convert columns and table to uppercase** to convert the columns to uppercase.

7. Double-click the second **tLogRow** component to open its **Basic settings** view.

8. In the **Mode** area, select **Table** to display data.

### Executing the Job

**Procedure**

Press **Ctrl + S** to save the Job and then **F6** to execute the Job.

```
| statistics | connecting to socket on port 3508  
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>tLogRow_1</td>
</tr>
<tr>
<td></td>
<td>columnRow[0] [category] [character] [error][message]</td>
</tr>
<tr>
<td></td>
<td><code>&quot;DB_MMSL_20180902_287294_47D[&quot;NAME&quot;]&quot;</code></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>tLogRow_2</td>
</tr>
<tr>
<td></td>
<td>NAME</td>
</tr>
<tr>
<td></td>
<td>Party</td>
</tr>
</tbody>
</table>
```
As shown above, the Job is executed successfully and the records are displayed on the console, and the one that violates the length limitation is rejected.

**Related scenarios**

For use cases in relation with `tSnowflakeOutputBulkExec`, see the following scenario:

- Inserting data in bulk in MySQL database on page 2500.
tSnowflakeRow

Executes the SQL command stated onto a specified Snowflake database.

**tSnowflakeRow Standard properties**

These properties are used to configure tSnowflakeRow running in the Standard Job framework.

The Standard tSnowflakeRow component belongs to the Cloud family.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>

### Dynamic settings

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic settings</td>
<td>Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>
Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NB_LINE</td>
<td>The number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>ERROR_MESSAGE</td>
<td>The error message generated by the component when an error occurs. This is an After variable and it returns a string.</td>
</tr>
</tbody>
</table>

Usage

| Usage rule                                                                 | This component offers the flexibility of the database query and covers all possible SQL queries. |

Related scenario

For a related scenario, see Writing data into and reading data from a Snowflake table on page 3492.
tSOAP

Calls a method via a Web service in order to retrieve the values of the parameters defined in the component editor.

tSOAP sends the defined SOAP message with the given parameters to the invoked Web service and returns the value as defined, based on the given parameters.

**tSOAP Standard properties**

These properties are used to configure tSOAP running in the Standard Job framework.

The Standard tSOAP component belongs to the Internet family.

The component in this framework is available in all Talend products.

**Basic settings**

| Schema and Edit schema | A schema is a row description, it defines the number of fields that will be processed and passed on to the next component.  
This component always uses a built-in, read-only schema.  
By default, the schema contains three **String** type columns:  
- **Header**: stores the SOAP message header of the response from the server end.  
- **Body**: stores the SOAP message body of the response from the server end.  
- **Fault**: stores the error information when an error occurs during the SOAP message processing.  
If the **Output in Document** check box is selected, the schema then contains only one **Document** type column named **Soap**, which stores the whole response SOAP message in the XML format.  
Click **Edit schema** to view the schema structure.  

**Warning:**  
Changing the schema type may result in loss of the schema structure and therefore failure of the component. |
|---|---|
| Use NTLM | Select this check box if you want to use the NTLM authentication protocol.  
**Domain**: Name of the client domain. |
| Need authentication | Select this check box and enter a user name and a password in the corresponding fields if this is necessary to access the service.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings. |
<table>
<thead>
<tr>
<th>Use http proxy</th>
<th>Select this check box if you are using a proxy server and fill in the necessary information.</th>
</tr>
</thead>
</table>
| Trust server with SSL | Select this check box to validate the server certificate to the client via an SSL protocol and fill in the corresponding fields:  
**TrustStore file**: enter the path (including filename) to the certificate TrustStore file that contains the list of certificates that the client trusts.  
**TrustStore password**: enter the password used to check the integrity of the TrustStore data. |
| ENDPOINT | Type in the URL address of the invoked Web server. |
| SOAP Action | Type in the URL address of the SOAPAction HTTP header field to be used to identify the intent of the SOAP HTTP request. |
| SOAP version | Select the version of the SOAP system you are using.  
**Warning**:  
The required SOAP Envelope varies among versions. |
| Use a message from the input schema | Select this check box to read a SOAP message from the preceding component to send to the invoked Web service.  
When this check box is selected, the **SOAP message** field becomes a drop-down list allowing you to select a **Document** type column to read an input XML file.  
**Warning**:  
This option makes sense only when the tSOAP component is connected with an input component the schema of which contains a **Document** type column to read a valid SOAP message. |
| Output in Document | Select this check box to output the response message in XML format. |
| SOAP message | Type in the SOAP message to be sent to the invoked Web service. The global and context variables can be used when you write a SOAP message.  
**Note**:  
To use special Latin characters, use encoding CP1252 in the SOAP message instead.  
For further information about the context variables, see Talend Studio User Guide. |
| Advanced settings |  
| Use Kerberos | Select this check box to choose a tSetKerberosConfiguration component from the Kerberos configuration list. |
Note:
The OnSubjobOk trigger of tSetKerberosConfiguration should be used for connection with tSoap.

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | This component can be used as an input or as an intermediate component. |

Connections

| Outgoing links (from this component to another): | Row: Main; Iterate Trigger: Run if; On Component Ok; On Component Error. |

| Incoming links (from one component to this one): | Row: Main; Iterate Trigger: Run if; On Component Ok; On Component Error. For further information regarding connections, see Talend Studio User Guide. |

Fetching the country name information using a Web service

This scenario describes a two-component Job that uses a Web service to retrieve the country name information of a given country code.

Procedure

Procedure

1. Drop the following components from the Palette onto the design workspace: tSOAP and tLogRow.
2. Connect tSOAP to tLogRow using a Row > Main link.
3. Double-click tSOAP to open its Basic settings view and define the component properties.

   ![Basic settings view](image)

4. In ENDPOINT field, type in or copy-paste the URL address of the Web service to be used between the quotation marks: "http://www.webservicex.net/country.asmx".
5. In the SOAP Action field, type in or copy-paste the URL address of the SOAPAction HTTP header field that indicates that you want to retrieve the country name information: http://www.webserviceX.NET/GetCountryByCountryCode.

   **Note:**
   You can see this address by looking at the WSDL for the Web service you are calling. For the Web service of this example, in a web browser, append ?wsdl on the end of the URL of the Web service used in the ENDPOINT field, open the corresponding web page, and then see the SOAPAction defined under the operation node:

   ```xml
   <wsdl:operation name="GetCountryByCountryCode">
   </wsdl:operation>
   ```

6. From the SOAP Version list, select the version of the SOAP system being used. In this scenario, the version is SOAP 1.1.
7. In the **SOAP message** field, enter the XML-format message used to retrieve the country name information from the invoked Web service. In this example, **IS** is used as the country code, so the message is:

```
"<soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
xmlns:web="http://www.webserviceX.NET">
<soapenv:Header/>
<soapenv:Body>
<web:GetCountryByCountryCode>
  <!--Optional:-->
</web:GetCountryByCountryCode>
</soapenv:Body>
</soapenv:Envelope>"
```

8. Save your Job and press **F6** to execute it.

The country name information of the given country code **IS** is returned and displayed on the console of the **Run** view.

```
statistics connecting to socket on port 3879
statistics connected
  &lt;countrycode&gt;IS&lt;/countrycode&gt;
  <name>IceLand</name>
</NewDataSet&gt;</br:GetCountryByCountryCodeResponse>
statistics disconnected
```

**Using a SOAP message from an XML file to get country name information and saving the information to an XML file**

This scenario describes a three-component Job that uses a SOAP message from an input XML file to invoke a Web service for the country name information which corresponds to the country code **IR**, and writes the response to an XML file.

**Dropping and linking the components**

**Procedure**

1. Drop the following components from the **Palette** onto the design workspace: **tFileInputXML**, **tSOAP**, and **tFileOutputXML**.

2. Connect the components using **Row > Main** links.

**Configuring the input component**

**Procedure**

1. Double-click the **tFileInputXML** component to open its **Basic settings** view.
2. Click the [...] button next to Edit schema to open the Schema dialog box.

3. Click the [+] button to add a column, give it a name, getCountryName in this example, and select Document from the Type list. Then, click OK to close the dialog box.

4. In the File name/Stream field, enter the path to the input XML file that contains the SOAP message to be used, or browse to the path by clicking the [...] button.

The input file contains the following SOAP message and you can see that the given country code is IR:

```xml
<soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
 xmlns:web="http://www.webserviceX.NET">
  <soapenv:Header/>
  <soapenv:Body>
    <web:GetCountryByCountryCode>
      <web:CountryCode>IR</web:CountryCode>
    </web:GetCountryByCountryCode>
  </soapenv:Body>
</soapenv:Envelope>
```

5. In the Loop XPath query field, enter "/" to define the root as the loop node of the input file structure.

6. In the Mapping table, fill the XPath query column with "." to extract all data from context node of the source, and select the Get Nodes check box to build a Document type data flow.
Configuring the Web service via the tSOAP component

Procedure

1. Double-click the tSOAP component to open its Basic settings view.

2. In ENDPOINT field, enter or copy-paste the URL address of the Web service to be used between the quotation marks: "http://www.webservicex.net/country.asmx".

3. In the SOAP Action field, enter or copy-paste the URL address of the SOAPAction HTTP header field that indicates that you want to retrieve the country name information: http://www.webserviceX.NET/GetCountryByCountryCode.

4. Select the Use a message from the schema check box, and select a Document type column from the SOAP Message list to read the SOAP message from the input file to send to the Web service. In this example, the input schema has only one column, getCountryName.

5. Select the Output in Document check box to output the response message in XML format.

Configuring the output component

Procedure

1. Double-click the tFileOutputXML component to open its Basic settings view.

2. In the File Name field, enter the path to the output XML file.

3. Select the Incoming record is a document check box to retrieve the incoming data flow as an XML document. Note that a Column list appears allowing you choose a column to retrieve data from. In this example, the schema contains only one column.
Executing the Job

Procedure

1. Press Ctrl+S to save your Job.
2. Press F6, or click Run on the Run tab to execute the Job.

The country name information that corresponds to the country code of IR is returned and the information is saved in the defined XML file.

```xml
<?xml version="1.0" encoding="ISO-8859-15"?>
<soap:Envelope xmlns:soap="http://schemas.xmlsoap.org/soap/envelope/"
  <soap:Body>
      <GetCountryByCountryCodeResult>
        <NewDataSet>
          <Table>
            <countrycode>ir</countrycode>
            <name>Iran</name>
          </Table>
        </NewDataSet>
      </GetCountryByCountryCodeResult>
    </GetCountryByCountryCodeResponse>
  </soap:Body>
</soap:Envelope>
```
tSocketInput

Opens the socket port and listens for the incoming data. tSocketInput is a listening component, allowing to pass data via a defined port.

**tSocketInput Standard properties**

These properties are used to configure tSocketInput running in the Standard Job framework. The Standard tSocketInput component belongs to the Internet family. The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>

<td>Character used to enclose text.</td>
</tr>
</tbody>
</table>

**Schema type and Edit Schema**

A schema is a row description, that is to say, it defines the number of fields to be processed and passed on to the next component. The schema is either **Built-in** or stored remotely in the **Repository**.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.
| Encoding type | Select the encoding from the list or select Custom and define it manually. This field is compulsory for DB data handling. |

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

**Global Variables**

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  
NB_LINE: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.  
For further information about variables, see Talend Studio User Guide. |

**Usage**

| Usage rule | This component opens a point of access to a workstation or server. This component starts a Job and only stops after the time goes out. |

| Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |
Passing on data to the listening port

The following scenario describes two Jobs aiming at passing data via a listening port. The first Job (*SocketInput*) opens the listening port and waits for the data to be sent over. The second Job (*SocketOutput*) passes delimited data from a file to a defined port number corresponding to the listening port.

Another application for the Socket components would be to allow controlled communication between servers which cannot communicate directly.

Dropping and linking components

Procedure

1. For the first Job, drop a *tSocketInput* component and a *tLogRow* component from the Palette to the design workspace, and link them using a Row > Main connection.
2. For the second Job, drop a *tFileInputDelimited* component and a *tSocketOutput* component from the Palette to the design workspace, and link them using a Row > Main connection.

Configuring the Jobs

Procedure

1. On the second Job, select the *tFileInputDelimited* and on the Basic Settings tab of the Component view, set the access parameters to the input file.

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Built-In</th>
</tr>
</thead>
<tbody>
<tr>
<td>File Name/Stream</td>
<td>&quot;D://Input/us_state.txt&quot;</td>
</tr>
<tr>
<td>Row Separator</td>
<td>&quot;</td>
</tr>
<tr>
<td>Header</td>
<td>1</td>
</tr>
<tr>
<td>Scheme</td>
<td>Repository DELM:Us_States - metadata</td>
</tr>
<tr>
<td>Skip empty rows</td>
<td>checked</td>
</tr>
<tr>
<td>Uncompress as zip file</td>
<td>unchecked</td>
</tr>
<tr>
<td>File on error</td>
<td>unchecked</td>
</tr>
</tbody>
</table>
2. In **File Name**, browse to the file, and fill the **Row, Field separators**, and **Header** fields according to the input file used.

3. Describe the **Schema** of the data to be passed on to the **tSocketOutput** component.

![Schema Table](image)

The schema should be propagated automatically to the output component.

4. Select the **tSocketOutput** component and set the parameters on the **Basic Settings** tab of the **Component** view.

![Component View](image)

5. Define the **Host** IP address and the **Port** number where the data will be passed on to.

6. Set the number of retries in the **Retry** field and the amount of time (in seconds) after which the **Job** will time out.

7. Now on the other **Job** (SocketInput) design, define the parameters of the **tSocketInput** component.

![Input View](image)

8. Define the **Host** IP address and the listening **Port** number where the data are passed on to.

9. Set the amount of time (in seconds) after which the **Job** will time out.

10. Edit the schema and set it to reflect the whole or part of the other Job’s schema.

### Executing the Jobs

**Procedure**

1. Press **F6** to execute this Job (SocketInput) first, in order to open the listening port and prepare it to receive the passed data.

2. Before the time-out, launch the other Job (SocketOutput) to pass on the data.
The result displays on the **Run** view, along with the opening socket information.

Starting job SocketInput at 17:53 04/02/2008.

**Schema and Edit Schema**

A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either **Built-in** or stored remotely in the **Repository**.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.
**Built-in**: The schema will be created and stored locally for this component only. Related topic: see *Talend Studio User Guide*.

**Repository**: The schema already exists and is stored in the Repository, hence can be reused in various projects and job flowcharts. Related topic: see *Talend Studio User Guide*.

**Encoding**

Select the encoding from the list or select Custom and define it manually. This field is compulsory for DB data handling.

**Global Variables**

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the *Die on error* check box is cleared, if the component has this check box.

**NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press *Ctrl + Space* to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

**Usage**

**Usage rule**

This component opens a point of access to a workstation or server. This component starts a Job and only stops after the time goes out.

**Limitation**

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the *Install* button on the *Component* tab view. You can also find out and add all missing JARs easily on the *Modules* tab in the *Integration* perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

**Related Scenario**

For use cases in relation with *tSocketOutput*, see *Passing on data to the listening port* on page 3535.
**tSortRow**

Helps creating metrics and classification table.

**tSortRow Standard properties**

These properties are used to configure tSortRow running in the Standard Job framework.

The Standard tSortRow component belongs to the Processing family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Schema and Edit Schema</th>
<th>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. If the current schema is of the Repository type, three options are available:</th>
</tr>
</thead>
</table>
|                        | • View schema: choose this option to view the schema only.  
|                        | • Change to built-in property: choose this option to change the schema to Built-in for local changes.  
|                        | • Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |
|                        | Click Sync columns to retrieve the schema from the previous component connected in the Job. |
| Built-In: | You create and store the schema locally for this component only. |
| Repository: | You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. |

**Criteria**

<table>
<thead>
<tr>
<th>Criteria</th>
<th>Click + to add as many lines as required for the sort to be complete. By default the first column defined in your schema is selected.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Schema column:</td>
<td>Select the column label from your schema, which the sort will be based on. Note that the order is essential as it determines the sorting priority.</td>
</tr>
<tr>
<td>Sort type:</td>
<td>Numerical and Alphabetical order are proposed. More sorting types to come.</td>
</tr>
</tbody>
</table>
Advanced settings

| Sort on disk | Customize the memory used to temporarily store output data.  
| Temp data directory path: Set the location where the temporary files should be stored.  
| Create temp data directory if not exists: Select this check box to create the directory if it does not exist.  
| Buffer size of external sort: Type in the size of physical memory you want to allocate to sort processing. |

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  
| A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
| To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.  
| For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | This component handles flow of data therefore it requires input and output, hence is defined as an intermediary step. |

Sorting entries

This scenario describes a three-component Job. A tRowGenerator is used to create random entries which are directly sent to a tSortRow to be ordered following a defined value entry. In this scenario, we suppose the input flow contains names of salespersons along with their respective sales and their years of presence in the company. The result of the sorting operation is displayed on the Run console.

- Drop the three components required for this use case: tRowGenerator, tSortRow and tLogRow from the Palette to the design workspace.
• Connect them together using **Row main** links.
• On the **tRowGenerator** editor, define the values to be randomly used in the Sort component. For more information regarding the use of this particular component, see **tRowGenerator** on page 3224

<table>
<thead>
<tr>
<th>Column</th>
<th>Key</th>
<th>Type</th>
<th>N...</th>
<th>Functions</th>
<th>Environment variables</th>
<th>Preview</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td></td>
<td>int</td>
<td></td>
<td>sequence</td>
<td>sequence identifier=...</td>
<td>1</td>
</tr>
<tr>
<td>YearsInComp</td>
<td></td>
<td>int</td>
<td></td>
<td>random</td>
<td>min value=&gt;1 ; max ...</td>
<td>2</td>
</tr>
<tr>
<td>Name</td>
<td></td>
<td>String</td>
<td></td>
<td>get.Last...</td>
<td></td>
<td>Harrison</td>
</tr>
<tr>
<td>Sales</td>
<td></td>
<td>int</td>
<td></td>
<td>random</td>
<td>min value=&gt;1 ; max ...</td>
<td>33</td>
</tr>
</tbody>
</table>

• In this scenario, we want to rank each salesperson according to its **Sales** value and to its number of years in the company.
• Double-click **tSortRow** to display the **Basic settings** tab panel. Set the sort priority on the Sales value and as secondary criteria, set the number of years in the company.

![Sorting(tSortRow_1)](image)

• Use the plus button to add the number of rows required. Set the type of sorting, in this case, both criteria being integer, the sort is numerical. At last, given that the output wanted is a rank classification, set the order as descending.
• Display the **Advanced Settings** tab and select the **Sort on disk** check box to modify the temporary memory parameters. In the **Temp data directory path** field, type the path to the directory where you want to store the temporary data. In the **Buffer size of external sort** field, set the maximum buffer value you want to allocate to the processing.

**Warning:**

*The default buffer value is 1000000 but the more rows and/or columns you process, the higher the value needs to be to prevent the Job from automatically stopping. In that event, an ‘out of memory’ error message displays.*

• Make sure you connected this flow to the output component, **tLogRow**, to display the result in the Job console.
• Press **F6** to run the Job. The ranking is based first on the Sales value and then on the number of years of experience.

tSplitRow

Splits one input row into several output rows.

**tSplitRow Standard properties**

These properties are used to configure tSplitRow running in the Standard Job framework.

The Standard tSplitRow component belongs to the Processing family.

The component in this framework is available in all Talend products.

### Basic settings

| **Schema and Edit Schema** | A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either **Built-in** or stored remotely in the **Repository**. Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
- **View schema**: choose this option to view the schema only.  
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window. Click **Sync columns** to retrieve the schema from the previous component connected in the Job. |
| **Built-in**: The schema will be created and stored locally for this component only. Related topic: see [Talend Studio User Guide](#). |
| **Repository**: The schema already exists and is stored in the Repository, hence can be reused in various projects and Job flowcharts. Related topic: see [Talend Studio User Guide](#). |
| **Columns mapping** | Click the plus button to add as many lines as needed by mappings from input columns onto output columns. |

### Advanced settings

| **tStatCatcher Statistics** | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

---
Global Variables

- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

- **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

Usage

| Usage rule | This component splits one input row into multiple output rows by mapping input columns onto output columns. |

Splitting one row into two rows

This scenario describes a three-component Job. A row of data containing information of two companies will be split up into two rows.

![Diagram of the process](image)

Procedure

1. Drop the following components required for this use case: **tFixedFlowInput**, **tSplitRow** and **tLogRow** from the **Palette** to the design workspace.
2. Connect them together using **Row Main** connections.
3. Double-click **tFixedFlowInput** to open its **Basic settings** view.
4. Select **Use Inline Content (delimited file)** in the **Mode** area.

5. Fill the **Content** area with the following scripts:

   `Talend;LA;California;537;5thAvenue;IT;Lionbridge;Memphis;Tennessee;537;Lincoln Road;IT Service;`

6. Click **Edit schema** to open a dialog box to edit the schema for the input data.

7. Click the plus button to add twelve lines for the input columns: **Company**, **City**, **State**, **CountryCode**, **Street**, **Industry**, **Company2**, **City2**, **State2**, **CountryCode2**, **Street2** and **Industry2**.

8. Click **OK** to close the dialog box.

9. Double-click **tSplitRow** to open its **Basic settings** view.
10. Click **Edit schema** to set the schema for the output data.

<table>
<thead>
<tr>
<th>Column</th>
<th>Key</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Company</td>
<td></td>
<td></td>
</tr>
<tr>
<td>City</td>
<td></td>
<td></td>
</tr>
<tr>
<td>State</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CountryCode</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Street</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Industry</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Company2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>City2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>State2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CountryCode2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Street2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Industry2</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

11. Click the plus button beneath the tSplitRow_1(Output) table to add four lines for the output columns: **Company**, **CountryCode**, **Address** and **Industry**.

12. Click **OK** to close the dialog box. Then an empty table with column names defined in the preceding step will appear in the **Columns mapping** area:

<table>
<thead>
<tr>
<th>Columns mapping</th>
</tr>
</thead>
<tbody>
<tr>
<td>Company</td>
</tr>
<tr>
<td>CountryCode</td>
</tr>
<tr>
<td>Address</td>
</tr>
<tr>
<td>Industry</td>
</tr>
</tbody>
</table>

13. Click the plus button beneath the empty table in the **Columns mapping** area to add two lines for the output rows.

14. Fill the table in the **Columns mapping** area by columns with the following values:

- **Company**: row1.Company, row1.Company2;
Industry: row1.Industry, row1.Industry2;

Note:
The value in Address column, for example, row1.Street","row1.City","row1.State, will display an absolute address by combining values in Street column, City column and State column together. The "row1" used in the values of each column refers to the input row from tFixedFlowInput.

15. Double-click tLogRow to open its Basic settings view.

16. Click Sync columns to retrieve the schema defined in the preceding component.
17. Select Table in the Mode area.
18. Save the Job and press F6 to run it.

Job Split ended at 18:21 27/10/2011. [exit code=0]

The input data in one row is split into two rows of data containing the same company information.
tSplunkEventCollector

Sends the event data to Splunk through Splunk HTTP Event Collector. tSplunkEventCollector collects and sends the event data to Splunk.

tSplunkEventCollector Standard properties

These properties are used to configure tSplunkEventCollector running in the Standard Job framework. The Standard tSplunkEventCollector component belongs to the Business Intelligence family. The component in this framework is available in all Talend products.

Basic settings

<table>
<thead>
<tr>
<th>Schema and Edit schema</th>
<th>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• <strong>Built-In</strong>: You create and store the schema locally for this component only. • <strong>Repository</strong>: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
</tr>
<tr>
<td>Note that the schema of this component has been set by default with the following fields. You can click the [...] button next to <strong>Edit schema</strong> to view and change the predefined schema.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• <strong>time</strong>: the event time. Note that the input data is in Java Date format, and it will be transformed to the epoch time format required by Splunk before sending to Splunk HTTP Event Collector. • <strong>source</strong>: the source value of the event data. It is usually the file or directory path, network port, or script from which the event originated. • <strong>sourcetype</strong>: the source type of the event data. It tells what kind of data it is. • <strong>host</strong>: the host of the event data. It is usually the host name, IP address, or fully qualified domain name of the network machine from which the event originated. • <strong>index</strong>: the name of the index by which the event data is to be indexed. It must be within the list of allowed indexes if the token has the <em>indexes</em> parameter set.</td>
</tr>
<tr>
<td>For more information about the format of the event data sent to Splunk HTTP Event Collector, see About the JSON event protocol in HTTP Event Collector.</td>
<td></td>
</tr>
</tbody>
</table>

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

• **View schema**: choose this option to view the schema only.
• **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
• **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

<table>
<thead>
<tr>
<th>Splunk Server URL</th>
<th>Enter the URL used to access the Splunk Web Server.</th>

<tr>
<th><strong>Extended output</strong></th>
<th>Select this check box to send the event data to Splunk in batch mode. In the field displayed, enter the number of events to be processed in each batch. By default, this check box is selected and the number of events to be processed in each batch is <strong>100</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to gather the Job processing metadata at the Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

### Global Variables

**Global Variables**

- **NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.
- **RESPONSE_CODE**: the response code from Splunk. This is an After variable and it returns an integer.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

### Usage

**Usage rule**

This component is usually used as an end component of a Job or Subjob and it always needs an input link.

### Related scenario

No scenario is available for this component yet.
**tSPSSInput**

Addresses SPSS .sav data to write it for example in another file.
tSPSSInput reads data from an SPSS .sav file.

**tSPSSInput Standard properties**

These properties are used to configure tSPSSInput running in the Standard Job framework.
The Standard tSPSSInput component belongs to the Business Intelligence family.
The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Sync schema</th>
<th>Click this button to synchronize with the columns of the input SPSS .sav file.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Warning:</strong> The component cannot import schema from a .sav file properly in a 64-bit environment. To do so, you need to make sure all of the following are of 32 bits: • OS • JVM • Talend studio launcher • SPSS software</td>
<td></td>
</tr>
</tbody>
</table>

| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. The schema metadata in this component is retrieved directly from the input SPSS .sav file and thus is read-only. You can click Edit schema to view the retrieved metadata. |

| Filename | Name or path of the SPSS .sav file to be read. |

| Translate labels | Select this check box to translate the labels of the stored values. |
| **Note:** If you select this check box, you need to retrieve the metadata again. |

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |
**Global Variables**

**NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

**Usage**

**Usage rule**

This component is used as a start component. It requires an output flow.

**Warning:**

Before being able to benefit from all functional objectives of the SPSS components, make sure to do the following: - If you have already installed SPSS, add the path to the SPSS directory as the following: `SET PATH=%PATH%;<DR>:\program\SPSS`, or - If you have not installed SPSS, you must copy the SPSS IO `spssio32.dll` lib from the SPSS installation CD and paste it in Talend root directory.

**Limitation**

This component is for 32-bit JVMs only. To use it on a 64-bit platform, you need to set up a 32-bit JVM before executing the job, as described below.

1. Open the Job containing the component in *Talend Studio*.
2. Switch to the **Run** tab and enter the **Advanced settings** view.
3. Select the **Use specific JVM arguments** check box and click the **New...** button. The **Set the VM Argument** dialog box appears.
4. Type `–d32` in the **Argument** text box of the **Set the VM Argument** dialog box and click **OK** for validation.

**Displaying the content of an SPSS .sav file**

The following scenario creates a two-component Job, which aims at reading each row of a .sav file and displaying the output on the log console.
Setting up the Job

Procedure

1. Drop a **tSPSSInput** component and a **tLogRow** component from the Palette onto the design workspace.

![Diagram](image)

2. Right-click on **tPSSInput** and connect it to **tLogRow** using a **Main Row** link.

Configuring the input component

Procedure

1. Click **tSPSSInput** to display its **Basic settings** view and define the component properties.

![Basic settings](image)

2. Click the three-dot button next to the **Filename** field and browse to the SPSS .sav file you want to read.

3. Click the three-dot button next to **Sync schema**. A message opens up prompting you to accept retrieving the schema from the defined SPSS file.

![Sync Schema](image)

4. Click **Yes** to close the message and proceed to the next step.

5. If required, click the three-dot button next to **Edit schema** to view the pre-defined data structure of the source SPSS file.
6. Click **OK** to close the dialog box.

**Job execution**

Save the Job and press **F6** to execute it.

The SPSS file is read row by row and the extracted fields are displayed on the log console.

```
Starting job SPSS at 10:28 20/01/2010
[statistics] connecting to socket on port 3802
[statistics] connected
1.0 1.0 572997.0 198522.0

[statistics] disconnected
Job SPSS ended at 10:28 20-01-2010. [exit code=0]
```

**Translating the stored values**

**About this task**

To translate the stored values, complete the following:

**Procedure**

1. In the **Basic settings** view, select the **Translate label** check box.
2. Click **Sync Schema** a second time to retrieve the schema after translation.
   A message opens up prompting you to accept retrieving the schema from the defined SPSS file.
3. Click **Yes** to close the message and proceed to the next step.
   A second message opens up prompting you to accept propagating the changes.
4. Click **Yes** to close the message and proceed to the next step.
5. Save the Job and press **F6** to execute it.

**Results**

The SPSS file is read row by row and the extracted fields are displayed on the log console after translating the stored values.
Starting job SPSS at 10:32 20/01/2010.

</tbody>
</table>

**Schema and Edit Schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

<table>
<thead>
<tr>
<th>Built-in</th>
<th>The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Repository</td>
<td>The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>
Filename
Name or path of the SPSS .sav file to be written.

Write Type
Select an operation from the list:
- **Write**: simply writes the new data.
- **Append**: writes the new data at the end of the existing data.

Advanced settings

**tStat Catcher Statistics**
Select this check box to collect log data at the component level.

Global Variables

**Global Variables**

- **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

Usage

**Usage rule**
This component can not be used as start component. It requires an input flow.

**Warning:**
Before being able to benefit from all functional objectives of the SPSS components, make sure to do the following: -If you have already installed SPSS, add the path to the SPSS directory as the following: `SET PATH=%PATH%;<DR>:\program\SPSS`, or -If you have not installed SPSS, you must copy the SPSS IO "spssio32.dll" lib from the SPSS installation CD and paste it in Talend root directory.

**Limitation**
This component is for 32-bit JVMs only. To use it on a 64-bit platform, you need to set up a 32-bit JVM before executing the job, as described below.

1. Open the Job containing the component in Talend Studio.
2. Switch to the Run tab and enter the Advanced settings view.
### Writing data in an .sav file

This Java scenario describes a very simple Job that writes data entries in an .sav file.

#### Setting up the Job

**Procedure**

1. Drop a `tRowGenerator` component and a `tSPSSOutput` component from the Palette onto the design workspace.
2. Right-click on `tRowGenerator` and connect it to `tSPSSOutput` using a Main Row link.

![Diagram showing connection between `tRowGenerator` and `tSPSSOutput`]

#### Configuring the input component

**Procedure**

1. In the design workspace, double click `tRowGenerator` to display its Basic Settings view and open its editor. Here you can define your schema.

<table>
<thead>
<tr>
<th>Column</th>
<th>Key</th>
<th>Type</th>
<th>N..</th>
<th>Length</th>
<th>Precision</th>
<th>Default</th>
<th>Comment</th>
<th>Functions</th>
<th>Environ...</th>
<th>Preview</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td></td>
<td>String</td>
<td></td>
<td>6</td>
<td></td>
<td></td>
<td></td>
<td>getAsci...</td>
<td>length=...</td>
<td>R82xSO</td>
</tr>
<tr>
<td>country</td>
<td></td>
<td>String</td>
<td></td>
<td>50</td>
<td></td>
<td></td>
<td></td>
<td>getUs5b...</td>
<td>Burnett Road</td>
<td></td>
</tr>
</tbody>
</table>

![Schema table with column definitions]

2. Click the plus button to add the columns you want to write in the .sav file.
3. Define the schema and set the parameters to the columns.

**Warning:**

*Make sure to define the length of your columns. Otherwise, an error message will display when building your Job.*

4. Click **OK** to validate your schema and close the editor.

**Configuring the output component**

**Procedure**

1. Click **tSPSSOutput** to display its **Basic settings** view and define the component properties.

![tSPSSOutput component settings](image)

2. Click the three-dot button next to the **Filename** field and browse to the SPSS .sav file in which you want to write data.

3. Click the three-dot button next to **Sync columns** to synchronize columns with the previous component. In this example, the schema to be inserted in the .sav file consists of the two columns: *id* and *country*.

4. If required, click **Edit schema** to view/edit the defined schema.

5. From the **Write Type** list, select **Write** or **Append** to simply write the input data in the .sav file or add it to the end of the .sav file.

**Job execution**

Save the Job and press **F6** to execute it.

The data generated by the **tRowGenerator** component is written in the defined .sav file.
tSPSSProperties

Obtains information about the main properties of a defined SPSS .sav file.
tSPSSProperties describes the properties of a defined SPSS .sav file.

tSPSSProperties Standard properties

These properties are used to configure tSPSSProperties running in the Standard Job framework.
The Standard tSPSSProperties component belongs to the Business Intelligence family.
The component in this framework is available in all Talend products.

Basic settings

<table>
<thead>
<tr>
<th>Schema and Edit Schema</th>
</tr>
</thead>
<tbody>
<tr>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. The schema metadata in this component is predefined and thus read-only. You can click Edit schema to view the predefined metadata.</td>
</tr>
</tbody>
</table>

**Warning:** The component cannot import schema from a .sav file properly in a 64-bit environment. To do so, you need to make sure all of the following are of 32 bits:
• OS
• JVM
• Talend studio launcher
• SPSS software

<table>
<thead>

</tr>
</tbody>
</table>
and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>Use this component as a start component. It needs an output flow.</th>
</tr>
</thead>
</table>

**Warning:**
In order to benefit from all of the functional objectives of the SPSS components, do the following:
- If you have already installed SPSS, add the path to the SPSS directory as the following: 
  ```
  SET PATH=%PATH%;<DR>:
  \program\SPSS
  , or
  ```
- If you have not installed SPSS, you must copy the SPSS IO `spssio32.dll` lib from the SPSS installation CD and paste it in the *Talend* root directory.

### Limitation

This component is for 32-bit JVMs only. To use it on a 64-bit platform, you need to set up a 32-bit JVM before executing the job, as described below.

1. Open the Job containing the component in *Talend Studio*.
2. Switch to the **Run** tab and enter the **Advanced settings** view.
3. Select the **Use specific JVM arguments** check box and click the **New...** button. The **Set the VM Argument** dialog box appears.
4. Type `-d32` in the **Argument** text box of the **Set the VM Argument** dialog box and click **OK** for validation.

### Related scenarios

For related topics, see:

- Reading master data from an MDM hub on page 2117.
- Writing data in an `.sav` file on page 3558.
**tSPSSStructure**

Retrieves information about the variables inside .sav files.

**tSPSSStructure** addresses variables inside .sav files. You can use this component in combination with tFileList to gather information about existing *.sav files to further analyze or check the findings.

**tSPSSStructure Standard properties**

These properties are used to configure tSPSSStructure running in the Standard Job framework.

The Standard tSPSSStructure component belongs to the Business Intelligence family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Schema and Edit Schema</th>

tSQLDWHBulkExec

Loads data into an Azure SQL Data Warehouse table from either Azure Blob Storage or Azure Data Lake Storage.

For more information about loading data into Azure SQL Data Warehouse, see Designing Extract, Load, and Transform (ELT) for Azure SQL Data Warehouse.

**tSQLDWHBulkExec Standard properties**

These properties are used to configure tSQLDWHBulkExec running in the Standard Job framework. The Standard tSQLDWHBulkExec component belongs to two families: Cloud and Databases. The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property Type</td>
<td>Select the way the connection details will be set.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Built-in</strong>: The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Repository</strong>: The connection details stored centrally in Repository &gt; Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up Repository Content dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in.</td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

**JDBC Provider**

Select the provider of the JDBC driver to be used.

**Host**

Specify the IP address or hostname of the Azure SQL Data Warehouse to be used.

**Port**

Specify the listening port number of the Azure SQL Data Warehouse to be used.
<table>
<thead>
<tr>
<th><strong>Schema</strong></th>
<th>Enter the name of the Azure SQL Data Warehouse schema.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Specify the name of the Azure SQL Data Warehouse to be used.</td>
</tr>
</tbody>
</table>
| **Username and Password** | Enter the user authentication data to access the Azure SQL Data Warehouse.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| **Additional JDBC Parameters** | Specify additional connection properties for the database connection you are creating. The properties are separated by semicolon and each property is a key-value pair. For example, encrypt=true;trustServerCertificate=false;hostNameInCertificate=*.database.windows.net;loginTimeout=30; for Azure SQL database connection. |
| **Table** | Specify the name of the SQL Data Warehouse table into which data will be loaded. |
| **Action on table** | Select an operation to be performed on the table defined.  
- **None**: No operation is carried out.  
- **Drop and create table**: The table is removed and created again.  
- **Create table**: The table does not exist and gets created.  
- **Create table if not exists**: The table is created if it does not exist.  
- **Drop table if exists and create**: The table is removed if it already exists and created again.  
- **Clear table**: The table content is deleted. You have the possibility to rollback the operation.  
- **Truncate table**: The table content is deleted. You do not have the possibility to rollback the operation. |
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.  
- **Built-In**: You create and store the schema locally for this component only.  
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.  
Click **Edit schema** to make changes to the schema. Note that if you make changes, the schema automatically becomes built-in.  
- **View schema**: choose this option to view the schema only.  
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon |
### Azure Storage
Select the type of the Azure Storage from which data will be loaded, either Blob Storage or Data Lake Store.

### Account Name
Enter the account name for your Azure Blob Storage or Azure Data Lake Storage to be accessed.

### Access key
Enter the key associated with the storage account you need to access. Two keys are available for each account and by default, either of them can be used for this access.
This property is available when Blob Storage is selected from the Azure Storage drop-down list.

### Container
Enter the name of the blob container.
This property is available when Blob Storage is selected from the Azure Storage drop-down list.

### Authentication key
Enter the authentication key needed to access your Azure Data Lake Storage.
This property is available when Data Lake Storage is selected from the Azure Storage drop-down list.

### Client Id
Enter your application ID (also called client ID).
This property is available when Data Lake Storage is selected from the Azure Storage drop-down list.

### OAuth 2.0 token endpoint
In the Token endpoint field, copy-paste the OAuth 2.0 token endpoint that you can obtain from the Endpoints list accessible on the App registrations page on your Azure portal.
This property is available when Data Lake Storage is selected from the Azure Storage drop-down list.

### Azure Storage Location
Specify the location where your Azure Blob Storage or Azure Data Lake Storage account is created.

#### Advanced settings

### File format
Select the file format that defines external data stored in your Azure Blob Storage or Azure Data Lake Storage, Delimited Text, Hive RCFile, Hive ORC, or Parquet.
For more information about the file formats, see CREATE EXTERNAL FILE FORMAT.

### Field separator
Specify the character(s) that indicate the end of each field in the delimited text file.
This property is available when Delimited Text is selected from the File format drop-down list.
<table>
<thead>
<tr>
<th>Enclosed by</th>
<th>Select this check box and in the field next to it, specify the character that encloses the string in the delimited file. This property is available when Delimited Text is selected from the File format drop-down list.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Date format</td>
<td>Select this check box and in the field next to it, specify the custom format for all date and time data in the delimited file. For more information about the date format, see CREATE EXTERNAL FILE FORMAT. This property is available when Delimited Text is selected from the File format drop-down list.</td>
</tr>
<tr>
<td>Use type default</td>
<td>Select this check box to store each missing value using the default value of the data type of the corresponding column. Clear this check box to store each missing value in the delimited file as NULL. This property is available when Delimited Text is selected from the File format drop-down list.</td>
</tr>
<tr>
<td>Serde Method</td>
<td>Select a Hive serializer and deserializer method. This property is available when Hive RCFile is selected from the File format drop-down list.</td>
</tr>
<tr>
<td>Compressed by</td>
<td>Select this check box if external data is compressed, and from the drop-down list displayed next to it, select the compression method.</td>
</tr>
</tbody>
</table>
| Data import reject options | Select this check box to specify the following reject options.  
  - **Reject type**: Specify how you want to deal with reject rows.  
    - **Value**: If the number of rejected rows exceeds the value specified in the Reject value field, the load fails.  
    - **Percentage**: If the percentage of rejected rows exceeds the value specified in the Reject value field, the load fails.  
    - **Reject value**: The reject value according to the reject type. For percentage, it is the percent value without the symbol %.  
    - **Reject sample value**: The reject percentage sample value.  
  For more information about the reject options, see CREATE EXTERNAL TABLE. |
| Distribution Option | Select the sharding pattern used to distribute data in the table, Round Robin, Hash, or Replicate. For more information about the sharding pattern supported by Azure SQL Data Warehouse, see Azure SQL Data Warehouse - Massively parallel processing (MPP) architecture. This property is available when any option related to table creation is selected from the Action on table drop-down list. |
| Distribution Column Name | The name of the distribution column for a hash-distribution table. This property is available when Hash is selected from the Distribution Option drop-down list. |
### Table Option

Select the index type of the table, **Clustered Columnstore Index**, **Heap**, or **Clustered Index**. For more information, see [Indexing tables in SQL Data Warehouse](#).

This property is available when any option related to table creation is selected from the **Action on table** drop-down list.

### Index column(s)

Specify the name of one or more key columns in the index. If multiple columns are specified, separate them with comma.

This property is available when **Clustered Index** is selected from the **Table Option** drop-down list.

### Partition

Select this check box to specify the following partition options:

- **Partition column name**: Specify the name of the column used to partition the table.
- **Range**: Specify how the limit value is included in the range of the limit.
  - **Left**: The limit value is included in the left range of the limit.
  - **Right**: The limit value is included in the right range of the limit.
- **Partition For Values**: Specify the values (separated by comma) used for partition.

For more information about the table partition, see [Partitioning tables in SQL Data Warehouse](#).

This property is available when any option related to table creation is selected from the **Action on table** drop-down list.

### tStatCatcher Statistics

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERROR_MESSAGE</td>
<td>The error message generated by the component when an error occurs. This is an After variable and it returns a string.</td>
</tr>
<tr>
<td>NB_LINE_INSERTED</td>
<td>The number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
</tbody>
</table>

### Usage

| Usage rule               | This component can be used as a standalone component of a Job or Subjob. |

### Limitation

Note that some features that are supported by other databases are not supported by Azure SQL Data Warehouse. For more information, see [Unsupported table features](#).

### Related scenario

No scenario is available for this component yet.
tSQLDWHClose

Closes an active connection to an Azure SQL Data Warehouse database.

**tSQLDWHClose Standard properties**

These properties are used to configure tSQLDWHClose running in the Standard Job framework.

The Standard tSQLDWHClose component belongs to two families: Cloud and Databases.

The component in this framework is available in all Talend products.

**Basic settings**

| Component List | Select the **tSQLDWHConnection** component that opens the connection you need to close from the list. |

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global Variables**

| ERROR_MESSAGE | The error message generated by the component when an error occurs. This is an After variable and it returns a string. |

**Usage**

| Usage rule | This component is more commonly used with other Azure SQL Data Warehouse components, especially with the **tSQLDWHConnection** and **tSQLDWHCommit** components. |

**Dynamic settings**

| Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. |

Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.
| Limitation | Note that some features that are supported by other databases are not supported by Azure SQL Data Warehouse. For more information, see [Unsupported table features](#). |

**Related scenario**

No scenario is available for this component yet.
tSQLDWHCommit

Commits in one go a global transaction instead of doing that on every row or every batch and thus provides gain in performance.

If you need to commit each statement as an individual transaction, you have to use the Auto Commit function available in the connection component.

**tSQLDWHCommit Standard properties**

These properties are used to configure tSQLDWHCommit running in the Standard Job framework.

The Standard tSQLDWHCommit component belongs to two families: Cloud and Databases.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Component List</th>
<th>Select the tSQLDWHConnection component in the list if more than one connection are planned for the current Job.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task. Note that if you want to use a Row &gt; Main connection to link tSQLDWHCommit to your Job, your data will be committed row by row. In this case, do not select the Close connection check box or your connection will be closed before the end of your first row commit.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global Variables**

| ERROR_MESSAGE | The error message generated by the component when an error occurs. This is an After variable and it returns a string. |

**Usage**

| Usage rule | This component is more commonly used with other Azure SQL Data Warehouse components, especially with the tSQLDWHConnection and tSQLDWHRollback components. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for |
Related scenario

No scenario is available for this component yet.
tSQLDWHConnection

Opens a connection to an Azure SQL Data Warehouse database.

**tSQLDWHConnection Standard properties**

These properties are used to configure tSQLDWHConnection running in the Standard Job framework. The Standard tSQLDWHConnection component belongs to two families: Cloud and Databases. The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Select the way the connection details will be set.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• <strong>Built-In</strong>: The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Repository</strong>: The connection details stored centrally in Repository &gt; Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up Repository Content dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>JDBC Provider</th>
<th>Select the provider of the JDBC driver to be used.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>Specify the IP address or hostname of the Azure SQL Data Warehouse to be used.</td>
</tr>
<tr>
<td>Port</td>
<td>Specify the listening port number of the Azure SQL Data Warehouse to be used.</td>
</tr>
<tr>
<td>Schema</td>
<td>Enter the name of the Azure SQL Data Warehouse schema.</td>
</tr>
<tr>
<td>Database</td>
<td>Specify the name of the Azure SQL Data Warehouse to be used.</td>
</tr>
</tbody>
</table>

| Username and Password | Enter the user authentication data to access the Azure SQL Data Warehouse. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |

| Additional JDBC Parameters | Specify additional connection properties for the database connection you are creating. The properties are separated by semicolon and each property is a key-value pair. For example, encrypt=true;trustServerCertificate=false;hostNameInCertificate=*.database.windows.net;loginTimeout=30; for Azure SQL database connection. |

| Use or register a shared DB Connection | Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the Shared DB Connection Name field displayed, enter the name for the shared database connection. This |
allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child.

This option is incompatible with the **Use dynamic job** and **Use an independent process to run subjob** options of the **tRunJob** component. Using a shared connection together with a **tRunJob** component with either of these two options enabled will cause your Job to fail.

This check box is not available when the **Specify a data source alias** check box is selected.

<table>
<thead>
<tr>
<th>Specify a data source alias</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select this check box and in the <strong>Data source alias</strong> field displayed, specify the alias of a data source created on Talend Runtime side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in Talend Runtime. This check box is not available when the <strong>Use or register a shared DB Connection</strong> check box is selected.</td>
</tr>
</tbody>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th>Auto Commit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select this check box to commit any changes to the database automatically upon the transaction. With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component. Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Share identity insert in multi table</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select this check box to share IDENTITY_INSERT with multiple tables in one connection.</td>
</tr>
</tbody>

</tr>
</tbody>
</table>

**Global Variables**

<table>
<thead>
<tr>
<th>ERROR_MESSAGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>The error message generated by the component when an error occurs. This is an After variable and it returns a string.</td>
</tr>
</tbody>
</table>

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
</tr>
</thead>
<tbody>
<tr>
<td>This component is more commonly used with other Azure SQL Data Warehouse components and it opens a connection that can be reused by them.</td>
</tr>
</tbody>
</table>
Limitation

Note that some features that are supported by other databases are not supported by Azure SQL Data Warehouse. For more information, see Unsupported table features.

Related scenario

No scenario is available for this component yet.
tSQLDWHInput

Reads data and extracts fields based on a query from an Azure SQL Data Warehouse database.

**tSQLDWHInput Standard properties**

These properties are used to configure tSQLDWHInput running in the Standard Job framework.
The Standard tSQLDWHInput component belongs to two families: Cloud and Databases.
The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to: 1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection. 2. In the child level, use a dedicated connection component to read that registered database connection. For an example about how to share a database connection across Job levels, see Talend Studio User Guide.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property Type</td>
<td>Select the way the connection details will be set.</td>
</tr>
<tr>
<td>JDBC Provider</td>
<td>Select the provider of the JDBC driver to be used.</td>
</tr>
<tr>
<td>Host</td>
<td>Specify the IP address or hostname of the Azure SQL Data Warehouse to be used.</td>
</tr>
<tr>
<td>Port</td>
<td>Specify the listening port number of the Azure SQL Data Warehouse to be used.</td>
</tr>
<tr>
<td>Schema</td>
<td>Enter the name of the Azure SQL Data Warehouse schema.</td>
</tr>
<tr>
<td>Database</td>
<td>Specify the name of the Azure SQL Data Warehouse to be used.</td>
</tr>
</tbody>
</table>
**Username and Password**
Enter the user authentication data to access the Azure SQL Data Warehouse.
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

**Schema and Edit schema**
A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.
- **Built-In**: You create and store the schema locally for this component only.
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

Click **Edit schema** to make changes to the schema. Note that if you make changes, the schema automatically becomes built-in.
- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

**Table name**
Specify the name of the table to be used.

**Query Type**
Select the way the query will be set.
- **Built-in**: Fill in manually the query statement or build it graphically using SQLBuilder.
- **Repository**: Select the relevant query stored in the Repository. The Query field gets accordingly filled in.

**Guess Query**
Click this button to generate the query which corresponds to your table schema in the Query field.

**Guess schema**
Click this button to generate the schema columns based on the query specified in the Query field.

**Query**
Specify the query paying particularly attention to properly sequence the fields in order to match the schema definition.

**Specify a data source alias**
Select this check box and in the Data source alias field displayed, specify the alias of a data source created on Talend Runtime side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in Talend Runtime.
This check box is not available when the **Use an existing Connection** check box is selected.
Advanced settings

**Additional JDBC Parameters**
Specify additional connection properties for the database connection you are creating. The properties are separated by semicolon and each property is a key-value pair. For example,
\[
encrypt=true;trustServerCertificate=false;
hostNameInCertificate=*.database.windows.net;loginTimeout=30;
\]
for Azure SQL database connection.

**Trim all the String/Char columns**
Select this check box to remove leading and trailing whitespace from all the String/Char columns.

**Trim column**
Select the check box(es) in the Trim column to remove leading and trailing whitespace from the corresponding column(s).
This property is not available if the Trim all the String/Char columns check box is selected.

**tStatCatcher Statistics**
Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

Global Variables

**ERROR_MESSAGE**
The error message generated by the component when an error occurs. This is an After variable and it returns a string.

**NB_LINE**
The number of rows processed. This is an After variable and it returns an integer.

**QUERY**
The query statement being processed. This is a Flow variable and it returns a string.

Usage

**Usage rule**
This component is usually used as a start component of a Job or Subjob and it always needs an output link.

**Dynamic settings**
Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic...

<td>Enter the user authentication data to access the Azure SQL Data Warehouse. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td>---</td>
<td>---</td>
</tr>
<tr>
<td>Table</td>
<td>Specify the name of the table to be used.</td>
</tr>
<tr>
<td>Action on table</td>
<td>Select an operation to be performed on the table defined.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Default</strong>: No operation is carried out.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Drop and create table</strong>: The table is removed and created again.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Create table</strong>: The table does not exist and gets created.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Create table if does not exist</strong>: The table is created if it does not exist.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Drop table if exist and create</strong>: The table is removed if it already exists and created again.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Clear table</strong>: The table content is deleted. You have the possibility to rollback the operation.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Truncate</strong>: The table content is deleted.</td>
</tr>
<tr>
<td>Turn on identity insert</td>
<td>Select this check box to use your own sequence for the identity value of the inserted records (instead of having the SQL Server pick the next sequential value).</td>
</tr>
<tr>
<td>Action on data</td>
<td>Select an action to be performed on data of the table defined.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Insert</strong>: Add new entries to the table. If duplicates are found, job stops.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Single Insert Query</strong>: Add entries to the table in a batch.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Update</strong>: Make changes to existing entries.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Insert or update</strong>: Insert a new record. If the record with the given reference already exists, an update would be made.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Update or insert</strong>: Update the record with the given reference. If the record does not exist in the index pool, a new record would be inserted.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Delete</strong>: Remove entries corresponding to the input flow.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Insert if not exist</strong>: Add new entries to the table if they do not exist.</td>
</tr>
</tbody>
</table>

It is necessary to specify at least one column as a primary key on which the **Update** and **Delete** operations are based. You can do that by clicking **Edit Schema** and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the **Advanced settings** view where you can simultaneously define primary keys for the **Update** and **Delete** operations. To do that, select the **Use field options** check box and then in the **Key in update column**, select the check boxes next to the column names you want to use as a base for the **Update** operation. Do the same in the **Key in delete column** for the **Delete** operation.

The dynamic schema feature can be used in the following modes: **Insert**, **Update**, **Insert or update**, **Update or insert**, and **Delete**.
**Specify identity field**

Select this check box to specify the identity field, which is made up of an automatically incrementing identification number.

When this check box is selected, three other fields are displayed:

- **Identity field**: select the column you want to define as the identity field from the list.
- **Start value**: type in a start value, used for the very first row loaded into the table.
- **Step**: type in an incremental value, added to the value of the previous row that was loaded.

This check box is available only when you select *Drop and create table*, *Create table*, *Create table if not exists*, or *Drop table if exists* from the *Action on table* list, and will disappear if you select the *Enable parallel execution* check box in the *Advanced settings* view. If you select this check box with the *Turn on identity insert* check box cleared and the *Create table if not exists* option selected from the *Action on table* list and if the specified table does not exist, only a table will be created without inserting data into it.

Note that you can also specify the identity field from the schema of the component. To do so, set the *DB Type* of the relevant column to *INT IDENTITY*.

When the *Specify identity field* check box is selected, the *DB Type* *INT IDENTITY* in the schema is ignored.

---

**Schema and Edit schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

- **Built-In**: You create and store the schema locally for this component only.
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

Click *Edit schema* to make changes to the schema. Note that if you make changes, the schema automatically becomes built-in.

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to *Built-in* for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select *No* upon completion and choose this schema metadata again in the *Repository Content* window.

---

**Specify a data source alias**

Select this check box and in the *Data source alias* field displayed, specify the alias of a data source created on Talend Runtime side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in Talend Runtime.
### Advanced settings

<table>
<thead>
<tr>
<th><strong>Advanced settings</strong></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Additional JDBC Parameters</strong></td>
<td>Specify additional connection properties for the database connection you are creating. The properties are separated by semicolon and each property is a key-value pair. For example, <code>encrypt=true;trustServerCertificate=false;hostNameInCertificate=*.database.windows.net;loginTimeout=30;</code> for Azure SQL database connection.</td>
</tr>
<tr>
<td><strong>Commit every</strong></td>
<td>Enter the number of rows to be completed before committing batches of rows together into the database. This option ensures transaction quality (but not rollback) and above all better performance on executions.</td>
</tr>
</tbody>
</table>
| **Additional Columns** | This option is not offered if you create (with or without drop) the database table. This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing.  
  - **Name**: Type in the name of the schema column to be altered or inserted as new column.  
  - **SQL expression**: Type in the SQL statement to be executed in order to alter or insert the relevant column data.  
  - **Position**: Select **Before**, **Replace** or **After** following the action to be performed on the reference column.  
  - **Reference column**: Type in a column of reference that can be used to place or replace the new or altered column. |
| **Use field options** | Select this check box to customize a request, especially when there is double action on data. |
| **Ignore date out of range** | Select this check box to ignore the date validation and insert the data directly into the database for the data types of DATE, DATETIME, DATETIME2 and DATETIMEOFFSET. |
| **Enable debug mode** | Select this check box to display each step during processing entries in a database. |
| **Support null in "SQL WHERE" statement** | Select this check box if you want to deal with the Null values contained in a database table. Make sure that the **Nullable** check box is selected for the corresponding columns in the schema. |
| **Use Batch** | Select this check box to activate the batch mode for data processing. This check box is available only when you have selected the **Insert**, the **Update**, the **Single Insert Query** or the **Delete** option in the **Action on data** list. |
Note that if you select the **Single Insert Query** option in the **Action on data** list, be aware that the batch size must be lower than or equal to the limit of parameter markers authorized by the JDBC driver (generally 2000) divided by the number of columns. For more information, see related description in **Limitation** below.

**Batch Size**

Specify the number of records to be processed in each batch.

This field appears only when the **Use batch mode** check box is selected.

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERROR_MESSAGE</td>
<td>The error message generated by the component when an error occurs. This is an After variable and it returns a string.</td>
</tr>
<tr>
<td>NB_LINE</td>
<td>The number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>NB_LINE_UPDATED</td>
<td>The number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>NB_LINE_INSERTED</td>
<td>The number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>NB_LINE_DELETED</td>
<td>The number of rows deleted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>NB_LINE_REJECTED</td>
<td>The number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
</tbody>
</table>

### Usage

**Usage rule**

This component is usually used as an end component of a Job or Subjob and it always needs an input link.

**Dynamic settings**

Click the [*] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see **Reading data from databases through context-based dynamic connections** on page 2457 and **Reading data from different MySQL databases using dynamically loaded connection**.
tSQLDWHOutput

Limitation

When the Single Insert Query option is selected in the Action on data list, an SQL Prepared Statement is generated, for example, INSERT INTO table (col1, col2, col3) VALUES (?, ?, ?), (?, ?, ?), (?, ?, ?). Within brackets are the groups of parameters the number of which cannot exceed 2000, generally, depending on the JDBC driver. Therefore, the batch size should be set so that this limit is respected.

Note that some features that are supported by other databases are not supported by Azure SQL Data Warehouse. For more information, see Unsupported table features.

Also note that when creating or deleting a table with this component, it is recommended to use the auto commit function by reusing the database connection created by a tSQLDWHConnection component and selecting the Auto Commit check box on the Advanced settings view of the tSQLDWHConnection component, instead of using a tSWLDDWHCommit component.

Related scenario

No scenario is available for this component yet.
tSQLDWHRollback

Cancels the transaction commit in the connected Azure SQL Data Warehouse database to prevent partial transaction commit if an error occurs.

**tSQLDWHRollback Standard properties**

These properties are used to configure tSQLDWHRollback running in the Standard Job framework.
The Standard tSQLDWHRollback component belongs to two families: Cloud and Databases.
The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Component List</th>
<th>Select the tSQLDWHConnection component in the list if more than one connection are planned for the current Job.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the operation is done. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global Variables**

| ERROR_MESSAGE | The error message generated by the component when an error occurs. This is an After variable and it returns a string. |

**Usage**

| Usage rule | This component is more commonly used with other Azure SQL Data Warehouse components, especially with the tSQLDWHConnection and tSQLDWHCommit components. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different. |
MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

**Limitation**

Note that some features that are supported by other databases are not supported by Azure SQL Data Warehouse. For more information, see Unsupported table features.

**Related scenario**

No scenario is available for this component yet.
**tSQLDWHRow**

Executes an SQL query stated on an Azure SQL Data Warehouse database.

**tSQLDWHRow Standard properties**

These properties are used to configure tSQLDWHRow running in the Standard Job framework.

The Standard tSQLDWHRow component belongs to two families: Cloud and Databases.

The component in this framework is available in all Talend products.

**Basic settings**

| Use an existing connection | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.

2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide. |
| --- | --- |

| Property Type | Select the way the connection details will be set.  
• **Built-In**: The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.  
• **Repository**: The connection details stored centrally in Repository > Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up Repository Content dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in. |
| --- | --- |

<table>
<thead>
<tr>
<th>JDBC Provider</th>
<th>Select the provider of the JDBC driver to be used.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Host</th>
<th>Specify the IP address or hostname of the Azure SQL Data Warehouse to be used.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Port</th>
<th>Specify the listening port number of the Azure SQL Data Warehouse to be used.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Schema</th>
<th>Enter the name of the Azure SQL Data Warehouse schema.</th>
</tr>
</thead>
</table>

<p>| Database | Specify the name of the Azure SQL Data Warehouse to be used. |</p>
<table>
<thead>
<tr>
<th><strong>Username and Password</strong></th>
<th>Enter the user authentication data to access the Azure SQL Data Warehouse. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</th>
</tr>
</thead>
</table>
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.  
• **Built-In**: You create and store the schema locally for this component only.  
• **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.  
Click **Edit schema** to make changes to the schema. Note that if you make changes, the schema automatically becomes built-in.  
• **View schema**: choose this option to view the schema only.  
• **Change to built-in property**: choose this option to change the schema to Built-in for local changes.  
• **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the **Repository Content** window. |
| **Table name** | Specify the name of the table to be used. |
| **Turn on identity insert** | Select this check box to use your own sequence for the identity value of the inserted records (instead of having the SQL Server pick the next sequential value). |
| **Query Type** | Select the way the query will be set.  
• **Built-in**: Fill in manually the query statement or build it graphically using SQLBuilder.  
• **Repository**: Select the relevant query stored in the Repository. The **Query** field gets accordingly filled in. |
| **Guess Query** | Click the **Guess Query** button to generate the query which corresponds to your table schema in the **Query** field. |
| **Query** | Specify your database query paying particularly attention to properly sequence the fields in order to match the schema definition. |
| **Specify a data source alias** | Select this check box and in the Data source alias field displayed, specify the alias of a data source created on Talend Runtime side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in Talend Runtime.  
This check box is not available when the **Use an existing Connection** check box is selected. |
**Advanced settings**

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Die on error</strong></td>
<td>Select the check box to stop the execution of the Job when an error occurs. Clear the check box to skip any rows on error and complete the process for error-free rows. When errors are skipped, you can collect the rows on error using a Row &gt; Reject connection.</td>
</tr>
<tr>
<td><strong>Additional JDBC Parameters</strong></td>
<td>Specify additional connection properties for the database connection you are creating. The properties are separated by semicolon and each property is a key-value pair. For example, <code>encrypt=true;trustServerCertificate=false;hostNameInCertificate=*.database.windows.net;loginTimeout=30</code> for Azure SQL database connection.</td>
</tr>
<tr>
<td><strong>Propagate QUERY’s recordset</strong></td>
<td>Select this check box to insert the result of the query into a column of the current flow. Select this column from the use column list. This option allows the component to have a different schema from that of the preceding component. Moreover, the column that holds the QUERY’s recordset should be set to the type of Object and this component is usually followed by tParseRecordSet.</td>
</tr>
</tbody>
</table>
| **Use PreparedStatement**                   | Select this check box if you want to query the database using a PreparedStatement. In the Set PreparedStatement Parameters table, define the parameters represented by “?” in the SQL instruction of the Query field in the Basic Settings tab.  
  - **Parameter Index**: Enter the parameter position in the SQL instruction.  
  - **Parameter Type**: Enter the parameter type.  
  - **Parameter Value**: Enter the parameter value. This option is very useful if you need to execute the same query several times. Performance levels are increased. |
| **Commit every**                             | Enter the number of rows to be completed before committing batches of rows together into the database. This option ensures transaction quality (but not rollback) and above all better performance on executions. |
| **tStatCatcher Statistics**                  | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global Variables**

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERROR_MESSAGE</td>
<td>The error message generated by the component when an error occurs. This is an After variable and it returns a string.</td>
</tr>
<tr>
<td>QUERY</td>
<td>The query statement being processed. This is a Flow variable and it returns a string.</td>
</tr>
</tbody>
</table>
### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component offers the flexibility of the DB query and covers all possible SQL queries.</th>
</tr>
</thead>
</table>

**Dynamic settings**

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

**Limitation**

Note that some features that are supported by other databases are not supported by Azure SQL Data Warehouse. For more information, see Unsupported table features.

Also note that when creating or deleting a table with this component, it is recommended to use the auto commit function by reusing the database connection created by a tSQLDWHConnection component and selecting the Auto Commit check box on the Advanced settings view of the tSQLDWHConnection component, instead of using a tSWLDWHCommit component.

### Related scenario

No scenario is available for this component yet.
tSQLiteClose

Closes a transaction committed in the connected DB.

**tSQLiteClose Standard properties**

These properties are used to configure tSQLiteClose running in the Standard Job framework.
The Standard tSQLiteClose component belongs to the Databases family.
The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tSQLiteConnection component in the list if more than one connection are planned for the current Job.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is to be used along with SQLite components, especially with tSQLiteConnection and tSQLiteCommit. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |
Related scenarios

No scenario is available for the Standard version of this component yet.
tSQLiteCommit

Commits in one go, using a unique connection, a global transaction instead of doing that on every row or every batch and thus provides gain in performance.

tSQLiteCommit validates the data processed through the Job into the connected DB

**tSQLiteCommit Standard properties**

These properties are used to configure tSQLiteCommit running in the Standard Job framework.

The Standard tSQLiteCommit component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the <strong>tSQLiteConnection</strong> component in the list if more than one connection are planned for the current Job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Warning:**

If you want to use a Row > Main connection to link tSQLiteCommit to your Job, your data will be committed row by row. In this case, do not select the Close connection check box or your connection will be closed before the end of your first row commit.

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is more commonly used with other tSQLite* components, especially with the tSQLiteConnection and tSQLiteRollback components. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to acces |
s database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenario

For tSQLiteCommit related scenario, see Inserting data in mother/daughter tables on page 2437.
tSQLiteConnection

Opens a connection to the database for a current transaction.

**tSQLiteConnection Standard properties**

These properties are used to configure tSQLiteConnection running in the Standard Job framework.

The Standard tSQLiteConnection component belongs to the Databases and the ELT families.

The component in this framework is available in all Talend products.

*Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.*

**Basic settings**

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td><strong>Property type</strong></td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database.</td>
</tr>
<tr>
<td><strong>Use or register a shared DB Connection</strong></td>
<td>Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the <strong>Shared DB Connection Name</strong> field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child. This option is incompatible with the <strong>Use dynamic job</strong> and <strong>Use an independent process to run subjob</strong> options of the <strong>tRunJob</strong> component. Using a shared connection together with a <strong>tRunJob</strong> component with either of these two options enabled will cause your Job to fail.</td>
</tr>
</tbody>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Auto Commit</strong></td>
<td>Select this check box to commit any changes to the database automatically upon the transaction. With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes</td>
</tr>
</tbody>
</table>

must be committed explicitly using the corresponding commit component. Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component.

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
<th>Select this check box to gather the job processing metadata at a Job level as well as at each component level.</th>
</tr>
</thead>
</table>

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is more commonly used with other tSQLite components, especially with the tSQLiteCommit and tSQLiteRollback components.</th>
</tr>
</thead>
</table>

### Related scenarios

For **tSQLiteConnection** related scenario, see **tMysqlConnection** on page 2436.
tSQLiteInput

Executes a DB query with a defined command which must correspond to the schema definition. It passes on rows to the next component via a Main row link.

tSQLiteInput reads a database file and extracts fields based on an SQL query. As it embeds the SQLite engine, no need of connecting to any database server.

**tSQLiteInput Standard properties**

These properties are used to configure tSQLiteInput running in the Standard Job framework.
The Standard tSQLiteInput component belongs to the Databases family.
The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Data Source</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in</strong>: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td><strong>Repository</strong>: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
<td></td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined.

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

Click this icon to open a database connection wizard and store the database connection parameters you set in the component **Basic settings** view.
For more information about setting up and storing database connection parameters, see *Talend Studio User Guide*.

<table>

</tr>
</tbody>
</table>
| **Global Variables** | **NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.  
**QUERY**: the query statement being processed. This is a Flow variable and it returns a string. |
**tSQLiteInput**

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

| Usage rule | This component is standalone as it includes the SQLite engine. This is a startable component that can initiate a data flow processing. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |

### Filtering SQLite data

This scenario describes a rather simple job which uses a select statement based on a filter to extract rows from a source SQLite Database and feed an output SQLite table.

- Drop from the Palette, a **tSQLiteInput** and a **tSQLiteOutput** component from the Palette to the design workspace.
- Connect the input to the output using a row main link.
• On the **tSQLiteInput** Basic settings, type in or browse to the SQLite Database input file.

The file contains hundreds of lines and includes an **ip** column which the select statement will based on

• On the **tSQLite** Basic settings, edit the schema for it to match the table structure.

  Property Type  Built-In
  Use an existing connection
  Database "C:\Input/Talend_r5\SQLite/bcountry.dat"
  Schema
  Table Name
  Query Type
  Query "select * from download where ip=1195650472"

• In the **Query** field, type in your select statement based on the **ip** column.

• On the **tSQLiteOutput** component **Basic settings** panel, select the **Database** filepath.

• Type in the **Table** to be fed with the selected data.
• Select the **Action on table** and **Action on Data**. In this use case, the action on table is *Drop and create* and the action on data is *Insert*.
• The schema should be synchronized with the input schema.
• Save the job and run it.

<table>
<thead>
<tr>
<th>id</th>
<th>version</th>
<th>download_date</th>
<th>ip</th>
<th>type</th>
<th>type_os</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>20028</td>
<td>TOS-Win32-200510</td>
<td>13/11/2006</td>
<td>1195650472</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>20031</td>
<td>TOS-Win32-200610</td>
<td>13/11/2006</td>
<td>1195650472</td>
<td>1</td>
</tr>
<tr>
<td>3</td>
<td>20032</td>
<td>TOS-Win32-200610</td>
<td>13/11/2006</td>
<td>1195650472</td>
<td>1</td>
</tr>
</tbody>
</table>

The data queried is returned in the defined SQLite file.
tSQLiteOutput

Executes the action defined on the table and/or on the data contained in the table, based on the flow incoming from the preceding component in the job.

tSQLiteOutput writes, updates, makes changes or suppresses entries in an SQLite database. As it embeds the SQLite engine, no need of connecting to any database server.

**tSQLiteOutput Standard properties**

These properties are used to configure tSQLiteOutput running in the Standard Job framework.

The Standard tSQLiteOutput component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

Click this icon to open a database connection wizard and store the database connection parameters you set in the component Basic settings view.
<table>
<thead>
<tr>
<th><strong>Database</strong></th>
<th>Filepath to the Database file</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Table</strong></td>
<td>Name of the table to be written. Note that only one table can be written at a time</td>
</tr>
</tbody>
</table>
| **Action on table** | On the table defined, you can perform one of the following operations:  
| **None** | No operation is carried out.  
| **Drop and create a table** | The table is removed and created again.  
| **Create a table** | The table does not exist and gets created.  
| **Create a table if not exists** | The table is created if it does not exist.  
| **Drop a table if exists and create** | The table is removed if it already exists and created again.  
| **Clear a table** | The table content is deleted. |
| **Action on data** | On the data of the table defined, you can perform:  
| **Insert** | Add new entries to the table. If duplicates are found, job stops.  
| **Update** | Make changes to existing entries  
| **Insert or update** | Insert a new record. If the record with the given reference already exists, an update would be made.  
| **Update or insert** | Update the record with the given reference. If the record does not exist, a new record would be inserted.  
| **Delete** | Remove entries corresponding to the input flow. |

**Warning:**
It is necessary to specify at least one column as a primary key on which the Update and Delete operations are based. You can do that by clicking Edit Schema and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the Advanced settings view where you can simultaneously define primary keys for the Update and Delete operations. To do that: Select the Use field options check box and then in the Key in update column, select the check boxes next to the column names you want to use as a base for the Update operation. Do the same in the Key in delete column for the Delete operation.

**Schema and Edit Schema**
A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

**Built-In:** You create and store the schema locally for this component only.
Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Die on error**

This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a **Row > Rejects** link.

### Advanced settings

**Commit every**

Enter the number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and, above all, better performance at execution.

**Additional Columns**

This option is not offered if you create (with or without drop) the DB table. This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing.

**Name**: Type in the name of the schema column to be altered or inserted as new column

**SQL expression**: Type in the SQL statement to be executed in order to alter or insert the relevant column data.

**Position**: Select **Before**, **Replace** or **After** following the action to be performed on the reference column.

**Reference column**: Type in a column of reference that the **tDBOutput** can use to place or replace the new or altered column.
<table>
<thead>
<tr>
<th>Use field options</th>
<th>Select this check box to customize a request, especially when there is double action on data.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable debug mode</td>
<td>Select this check box to display each step during processing entries in a database.</td>
</tr>
<tr>
<td>Use Batch</td>
<td>Select this check box to activate the batch mode for data processing.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> This check box is available only when you have selected the Insert, Update, or Delete option in the Action on data option.</td>
</tr>
<tr>
<td>Batch Size</td>
<td>Specify the number of records to be processed in each batch.. This field appears only when the Use batch mode check box is selected.</td>
</tr>
<tr>

<td></td>
<td><strong>NB_LINE</strong>: the number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td><strong>NB_LINE_UPDATED</strong>: the number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td><strong>NB_LINE_INSERTED</strong>: the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td><strong>NB_LINE_DELETED</strong>: the number of rows deleted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td><strong>NB_LINE_REJECTED</strong>: the number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td><strong>QUERY</strong>: the query statement processed. This is an After variable and it returns a string.</td>
</tr>
<tr>
<td></td>
<td><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td></td>
<td>For further information about variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>
### Usage

| Usage rule | This component must be connected to an Input component. It allows you to carry out actions on a table or on the data of a table in an SQLite database. It also allows you to create reject flows using a Row > Reject link to filter erroneous data. For an example of tSQLiteOutput in use, see Retrieving data in error with a Reject link on page 2485. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.  

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.  

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |

### Related Scenario

For scenarios related to tSQLiteOutput, see Retrieving data in error with a Reject link on page 2485.
tSQLiteRollback

Cancels the transaction committed in the SQLite database.

**tSQLiteRollback Standard properties**

These properties are used to configure tSQLiteRollback running in the Standard Job framework.

The Standard tSQLiteRollback component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tSQLiteConnection component in the list if more than one connection are planned for the current Job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is more commonly used with other tSQLite* components, especially with the tSQLiteConnection and tSQLiteCommit components. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic... |
Related scenarios

For **tSQLiteRollback** related scenario, see [Rollback from inserting data in mother/daughter tables](#) on page 2440.
**tSQLiteRow**

Executes the defined query onto the specified database and uses the parameters bound with the column.

A prepared statement uses the input flow to replace the placeholders with the values for each parameters defined. This component can be very useful for updates.

**tSQLiteRow Standard properties**

These properties are used to configure tSQLiteRow running in the Standard Job framework.

The Standard tSQLiteRow component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
<tr>
<td><strong>Property type</strong></td>
<td>Either Built-in or Repository. Built-in: No property data stored centrally. Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><strong>Use an existing connection</strong></td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. <strong>Note:</strong> When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to: 1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection. 2. In the child level, use a dedicated connection component to read that registered database connection. For an example about how to share a database connection across Job levels, see Talend Studio User Guide.</td>
</tr>
<tr>
<td><strong>Schema and Edit Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next...</td>
</tr>
</tbody>
</table>
When you create a Spark Job, avoid the reserved word `line` when naming the fields.

**Built-in:** The schema is created and stored locally for this component only. Related topic: see *Talend Studio User Guide*.

**Repository:** The schema already exists and is stored in the Repository, hence can be reused. Related topic: see *Talend Studio User Guide*.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema:** choose this option to view the schema only.
- **Change to built-in property:** choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection:** choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Query type**

Either **Built-in** or **Repository**.

**Built-in:** Fill in manually the query statement or build it graphically using SQLBuilder.

**Repository:** Select the relevant query stored in the Repository. The Query field gets accordingly filled in.

**Query**

Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.

**Die on error**

Clear this check box to skip the row on error and complete the process for error-free rows.

### Advanced settings

**Propagate QUERY’s recordset**

Select this check box to insert the result of the query into a COLUMN of the current flow. Select this column from the **use column** list.

**Note:**

This option allows the component to have a different schema from that of the preceding component. Moreover, the column that holds the QUERY’s recordset should be set to the type of **Object** and this component is usually followed by **tParseRecordSet**.

**Use PreparedStatement**

Select this check box if you want to query the database using a PreparedStatement. In the **Set PreparedStatement Parameter** table, define the parameters represented by "?" in...
the SQL instruction of the Query field in the Basic Settings tab.

**Parameter Index**: Enter the parameter position in the SQL instruction.

**Parameter Type**: Enter the parameter type.

**Parameter Value**: Enter the parameter value.

**Note**: This option is very useful if you need to execute the same query several times. Performance levels are increased.

<table>
<thead>
<tr>
<th>Commit every</th>
<th>Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions.</th>
</tr>
</thead>
<tbody>
<tr>
<td>tStat Catcher Statistics</td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

**Global Variables**

| Global Variables | QUERY: the query statement being processed. This is a Flow variable and it returns a string. ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

**Usage**

| Usage rule | This component offers the flexibility of the DB query and covers all possible SQL queries. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic |
settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Updating SQLite rows

This scenario describes a job which updates an SQLite database file based on a prepared statement and using a delimited file.

- Drop a tFileInputDelimited and a tSQLiteRow component from the Palette to the design workspace.
- On the tFileInputDelimited Basic settings panel, browse to the input file that will be used to update rows in the database.

There is no Header nor Footer. The Row separator is a carriage return and the Field separator is a semi-colon.

- Click the [...] button next to Edit schema and define the schema structure in case it is not stored in the Repository.

Make sure the length and type are respectively correct and large enough to define the columns.
- Then in the tSQLiteRow Basic settings panel, set the Database filepath to the file to be updated.
• The schema is read-only as it is required to match the input schema.
• Type in the query or retrieve it from the Repository. In this use case, we updated the `type_os` for the `id` defined in the Input flow. The statement is as follows: "Update download set `type_os`=? where `id`=?".
• Then select the **Use PreparedStatement** check box to display the placeholders’ parameter table.

• In the Input parameters table, add as many lines as necessary to cover all placeholders. In this scenario, `type_os` and `id` are to be defined.
• Set the **Commit every** field.
• Save the job and press **F6** to run it.

The **download** table from the SQLite database is thus updated with new `type_os` code according to the delimited input file.
Related scenarios

For a related scenario, see:

- Combining two flows for selective output on page 2514
tSQLTemplate

Executes the common database actions or customized SQL statement templates, for example to drop/create a table.

tSQLTemplate offers a range of SQL statement templates for a number of DBMSs to facilitate some of the most common database actions. These templates are accessible via the SQL Template view. Additionally, you are allowed to customize the SQL statement templates as needed.

**tSQLTemplate Standard properties**

These properties are used to configure tSQLTemplate running in the Standard Job framework.
The Standard tSQLTemplate component belongs to the ELT family.
The component in this framework is available in all Talend products.

### Basic settings

<table>
<thead>
<tr>
<th>Database Type</th>
<th>Select the database type you want to connect to from the list.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component List</td>
<td>Select the relevant database connection component in the list if you use more than one connection in the current Job.</td>
</tr>
<tr>
<td>Database name</td>
<td>Name of the database.</td>
</tr>
<tr>
<td>Table name</td>
<td>Name of the table on which the SQL statement templates will be executed.</td>
</tr>
</tbody>
</table>

**Schema and Edit schema**

A schema is a row description, that is to say, it defines the number of fields that will be processed and passed on to the next component. The schema is either built-in or remote in the Repository.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the Repository Content window.

**Built-in**: You create and store the schema locally for this component only. Related topic: see *Talend Studio User Guide*.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job flowcharts. Related topic: see *Talend Studio User Guide*. 
Advanced settings

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

Global Variables

| Global Variables | NB_LINE: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer. |
| | QUERY: the query statement being processed. This is a Flow variable and it returns a string. |
| | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. |
| | A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. |
| | To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. |
| | For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | As a start component, this component is used with other database components, especially the database connection and commit components. |

SQL Template

| SQL Template List | SQL Template List |

Dynamic settings

| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your HDFS connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access files in different HDFS systems or different distributions, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. |
| | The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. |
| | For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |
Related scenarios

For a related scenario, see Filtering and aggregating table columns directly on the DBMS on page 3621.
tSQLTemplateAggregate

Provides a set of matrix based on values or calculations.

tSQLTemplateAggregate collects data values from one or more columns with the intent to manage the collection as a single unit. This component has real-time capabilities since it runs the data transformation on the DBMS itself.

tSQLTemplateAggregate Standard properties

These properties are used to configure tSQLTemplateAggregate running in the Standard Job framework.

The Standard tSQLTemplateAggregate component belongs to the ELT family.

The component in this framework is available in all Talend products.

Basic settings

### Advanced settings

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

### Global Variables

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE:</strong> the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.</td>
</tr>
</tbody>
</table>

| **QUERY:** the query statement being processed. This is a Flow variable and it returns a string. |

| **ERROR_MESSAGE:** the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. |

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide.*
**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is used as an intermediate component with other relevant DB components, especially the DB connection and commit components.</th>
</tr>
</thead>
<tbody>
<tr>

<td>SQL Template List</td>
</tr>
</tbody>
</table>

**Filtering and aggregating table columns directly on the DBMS**

The following scenario creates a Job that opens a connection to a Mysql database and:

- instantiates the schemas from a database table whose rows match the column names specified in the filter,
- filters a column in the same database table to have only the data that matches a WHERE clause,
- collects data grouped by specific value(s) from the filtered column and writes aggregated data in a target database table.

To filter and aggregate database table columns:

- Drop the following components from the Palette onto the design workspace: tELTMysqlconnection, tSQLTemplateFilterColumns, tSQLTemplateFilterRows, tSQLTemplateAggregate, tSQLTemplateCommit, and tSQLTemplateRollback.
- Connect the five first components using OnComponentOk links.
- Connect tSQLTemplateAggregate to tSQLTemplateRollback using an OnComponentError link.

- In the design workspace, select tMysqlConnection and click the Component tab to define the basic settings for tMysqlConnection.
- In the Basic settings view, set the database connection details manually or select Repository from the Property Type list and select your DB connection if it has already been defined and stored in the Metadata area of the Repository tree view.

For more information about Metadata, see Talend Studio User Guide.
In the design workspace, select `tSQLTemplateFilterColumns` and click the `Component` tab to define its basic settings.

- On the `Database type` list, select the relevant database.
- On the `Component list`, select the relevant database connection component if more than one connection is used.
- Enter the names for the database, source table, and target table in the corresponding fields and click the three-dot buttons next to `Edit schema` to define the data structure in the source and target tables.

**Note:**

When you define the data structure for the source table, column names automatically appear in the `Column list` in the `Column filters` panel.

In this scenario, the source table has five columns: `id`, `First_Name`, `Last_Name`, `Address`, and `id_State`.

- In the `Column filters` panel, set the column filter by selecting the check boxes of the columns you want to write in the source table.

In this scenario, the `tSQLTemplateFilterColumns` component instantiates only three columns: `id`, `First_Name`, and `id_State` from the source table.
Note:

In the **Component** view, you can click the **SQL Template** tab and add system SQL templates or create your own and use them within your Job to carry out the coded operation. For more information, see tSQLTemplateFilterColumns Standard properties on page 3627.

- In the design workspace, select **tSQLTemplateFilterRows** and click the **Component** tab to define its basic settings.
  - On the **Database type** list, select the relevant database.
  - On the **Component list**, select the relevant database connection component if more than one connection is used.
  - Enter the names for the database, source table, and target table in the corresponding fields and click the three-dot buttons next to **Edit schema** to define the data structure in the source and target tables.

In this scenario, the source table has the three initially instantiated columns: **id**, **First_Name**, and **id_State** and the source table has the same three-column schema.

- In the **Where condition** field, enter a WHERE clause to extract only those records that fulfill the specified criterion.

In this scenario, the **tSQLTemplateFilterRows** component filters the **First_Name** column in the source table to extract only the first names that contain the “a” letter.

- In the design workspace, select **tSQLTemplateAggregate** and click the **Component** tab to define its basic settings.
  - On the **Database type** list, select the relevant database.
  - On the **Component list**, select the relevant database connection component if more than one connection is used.
  - Enter the names for the database, source table, and target table in the corresponding fields and click the three-dot buttons next to **Edit schema** to define the data structure in the source and target tables.

The schema for the source table consists of the three columns: **id**, **First_Name**, and **id_State**. The schema for the target table consists of two columns: **customers_status** and **customers_number**. In this scenario, we want to group customers by their marital status and count customer number in each marital group. To do that, we define the **Operations** and **Group by** panels accordingly.
In the Operations panel, click the plus button to add one or more lines and then click in the Output column line to select the output column that will hold the counted data.

Click in the Function line and select the operation to be carried on.

In the Group by panel, click the plus button to add one or more lines and then click in the Output column line to select the output column that will hold the aggregated data.

In the design workspace, select tSQLTemplateCommit and click the Component tab to define its basic settings.

On the Database type list, select the relevant database.

On the Component list, select the relevant database connection component if more than one connection is used.

Do the same for tSQLTemplateRollback.

Save your Job and press F6 to execute it.

A two-column table aggregate_customers is created in the database. It groups customers according to their marital status and count customer number in each marital group.
tSQLTemplateCommit

Commits a global action in one go using a single connection, instead of doing so for every row or every batch of rows separately. This provides a gain in performance.

tSQLTemplateCommit validates the data processed in a Job in a specified database.

**tSQLTemplateCommit Standard properties**

These properties are used to configure tSQLTemplateCommit running in the Standard Job framework.
The Standard tSQLTemplateCommit component belongs to the ELT family.
The component in this framework is available in all Talend products.

**Basic settings**

<table>

</table>
| Schema and Edit schema | A schema is a row description, it defines the number of fields that will be processed and passed on to the next component. The schema is either built-in or remote in the Repository. Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
  - **View schema**: choose this option to view the schema only.  
  - **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
  - **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.  
| Built-in               | You create and store the schema locally for this component only. Related topic: see *Talend Studio User Guide*. |
| Repository             | You have already created the schema and stored it in the Repository. You can reuse it in various |
projects and Job flowcharts. Related topic: see *Talend Studio User Guide*.

### Column Filters

In the table, click the **Filter** check box to filter all of the columns. To select specific columns for filtering, select the check box(es) which correspond(s) to the column name(s).

### Advanced settings

#### tStatCatcher Statistics

Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

### Global Variables

**Global Variables**

- **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.
- **QUERY**: the query statement being processed. This is a Flow variable and it returns a string.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

**Usage rule**

This component is used as an intermediary component with other relevant DB components, especially DB connection components.

**SQL Template**

**SQL Template List**

### Related Scenario

For a related scenario, see *Filtering and aggregating table columns directly on the DBMS* on page 3621.
tSQLTemplateFilterRows

Sets row filters for any given data source, based on a WHERE clause.

tSQLTemplateFilterRows allows you to define a row filter on one table. This component has real-time capabilities since it runs the data filtering on the DBMS itself.

**tSQLTemplateFilterRows Standard properties**

These properties are used to configure tSQLTemplateFilterRows running in the Standard Job framework.

The Standard tSQLTemplateFilterRows component belongs to the ELT family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database Type</td>
<td>Select the type of database you want to work on from the drop down list.</td>
</tr>

</tr>
</tbody>
</table>

**Schema and Edit schema**

A schema is a row description, it defines the number of fields that will be processed and passed on to the next component. The schema is either built-in or remote in the Repository.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Built-in**: You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various
Where condition | Use a WHERE clause to set the criteria that you want the rows to meet. You can use the WHERE clause to select specific rows from the table that match specified criteria or conditions.

Advanced settings

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

Global Variables

| Global Variables | NB_LINE: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer. QUERY: the query statement being processed. This is a Flow variable and it returns a string. ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide.

Usage

| Usage rule | This component is used as an intermediary component with other DB components, particularly DB connection components.

| SQL Template | SQL Template List

Related Scenario

For a related scenario, see Filtering and aggregating table columns directly on the DBMS on page 3621.
tSQLTemplateMerge

Merges data into a database table directly on the DBMS by creating and executing a MERGE statement.

tSQLTemplateMerge creates an SQL MERGE statement to merge data into a database table.

**tSQLTemplateMerge Standard properties**

These properties are used to configure tSQLTemplateMerge running in the Standard Job framework. The Standard tSQLTemplateMerge component belongs to the ELT family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Database Type</th>
<th>Select the type of database you want to work on from the drop-down list.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the relevant DB connection component from the list if you use more than one connection in the current Job.</td>
</tr>
<tr>
<td>Source table name</td>
<td>Name of the database table holding the data you want to merge into the target table.</td>
</tr>
<tr>
<td>Target table name</td>
<td>Name of the table you want to merge data into.</td>
</tr>
</tbody>
</table>

**Schema and Edit schema**

This component involves two schemas: source schema and target schema.

A schema is a row description, that is to say, it defines the number of fields to be processed and passed on to the next component. The schema is either built-in or remotely stored in the Repository.

Click **Edit schema** to make changes to the schema. If the current schema is of the *Repository* type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to *Built-in* for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select *No* upon completion and choose this schema metadata again in the **Repository Content** window.

**Built-in**: The schema is created and stored locally for this component only. Related topic: see *Talend Studio User Guide*.

**Repository**: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see *Talend Studio User Guide*.
### Merge ON
Specify the target and source columns you want to use as the primary keys.

### Use UPDATE (WHEN MATCHED)
Select this check box to update existing records. With the check box selected, the UPDATE Columns table appears, allowing you to define the columns in which records are to be updated.

### Specify additional output columns
Select this check box to update records in additional columns other than those listed in the UPDATE Columns table. With this check box selected, the Additional UPDATE Columns table appears, allowing you to specify additional columns.

### Specify UPDATE WHERE clause
Select this check box and type in a WHERE clause in the WHERE clause field to filter data during the update operation.

**Note:**
This option may not work with certain database versions, including Oracle 9i.

### Use INSERT (WHEN MATCHED)
Select this check box to insert new records. With the check box selected, the INSERT Columns table appears, allowing you to specify the columns to be involved in the insert operation.

### Specify additional output columns
Select this check box to insert records to additional columns other than those listed in the INSERT Columns table. With this check box selected, the Additional INSERT Columns table appears, allowing you to specify additional columns.

### Specify INSERT WHERE clause
Select this check box and type in a WHERE clause in the WHERE clause field to filter data during the insert operation.

**Note:**
This option may not work with certain database versions, including Oracle 9i.

### Advanced settings

#### tStatCatcher Statistics
Select this check box to gather the Job processing metadata at a Job level as well as at component level.

### Global Variables

#### Global Variables
- **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.
- **NB_LINE_MERGED**: the number of rows merged. This is an After variable and it returns an integer.
- **QUERY**: the query statement being processed. This is a Flow variable and it returns a string.
**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is used as an intermediate component with other relevant DB components, especially the DB connection and commit components.</th>

</tbody>
</table>

**Merging data directly on the DBMS**

This scenario describes a simple Job that opens a connection to a MySQL database, merges data from a source table into a target table according to customer IDs, and displays the contents of the target table before and after the merge action. A WHERE clause is used to filter data during the merge operation.
- Drop a `tMysqlConnection` component, a `tSQLTemplateMerge` component, two `tMysqlInput` components and two `tLogRow` components from the Palette onto the design workspace.
- Connect the `tMysqlConnection` component to the first `tMysqlInput` component using a Trigger > OnSubjobOK connection.
- Connect the first `tMysqlInput` component to the first `tLogRow` component using a Row > Main connection. This row will display the initial contents of the target table on the console.
- Connect the first `tMysqlInput` component to the `tSQLTemplateMerge` component, and the `tSQLTemplateMerge` component to the second `tMysqlInput` component using Trigger > OnSubjobOK connections.
- Connect the second `tMysqlInput` component to the second `tLogRow` component using a Row > Main connection. This row will display the merge result on the console.
- Double-click the `tMysqlConnection` component to display its Basic settings view.

### tMysqlConnection_1

<table>
<thead>
<tr>
<th>Basic settings</th>
<th>Property Type</th>
<th>DB Version</th>
<th>Host</th>
<th>Port</th>
</tr>
</thead>
<tbody>
<tr>
<td>Advanced settings</td>
<td>Mysql 5</td>
<td></td>
<td>&quot;localhost&quot;</td>
<td>&quot;3306&quot;</td>
</tr>
<tr>
<td>Dynamic settings</td>
<td>Database</td>
<td>&quot;talend&quot;</td>
<td></td>
<td>Additional JDBC Parameters</td>
</tr>
<tr>
<td>View</td>
<td>Username</td>
<td>&quot;root&quot;</td>
<td></td>
<td>Password</td>
</tr>
<tr>
<td>Documentation</td>
<td>Use or register a shared DB Connection</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- Set the database connection details manually or select Repository from the Property Type list and select your DB connection if it has already been defined and stored in the Metadata area of the Repository tree view.
- For more information about Metadata, see Talend Studio User Guide.
- Double-click the first `tMysqlInput` component to display its Basic settings view.

### tMysqlInput_1

<table>
<thead>
<tr>
<th>Basic settings</th>
<th>Use an existing connection</th>
<th>Component List</th>
<th>Schema</th>
<th>Table Name</th>
<th>Query Type</th>
<th>Query</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic settings</td>
<td>Edit schema</td>
<td></td>
<td></td>

<td></td>
<td></td>
</tr>
<tr>
<td>View</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Documentation</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Validation Rules</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- Select the Use an existing connection check box. If you are using more than one DB connection component in your Job, select the component you want to use from the Component List.
- Click the three-dot button next to Edit schema and define the data structure of the target table, or select Repository from the Schema list and select the target table if the schema has already been defined and stored in the Metadata area of the Repository tree view.
In this scenario, we use built-in schemas.

- Define the columns as shown above, and then click **OK** to propagate the schema structure to the output component and close the schema dialog box.
- Fill the **Table Name** field with the name of the target table, `customer_info_merge` in this scenario.
- Click the **Guess Query** button, or type in "SELECT * FROM customer_info_merge" in the **Query** area, to retrieve all the table columns.
- Define the properties of the second `tMysqlInput` component, using exactly the same settings as for the first `tMysqlInput` component.
- In the **Basic settings** view of each `tLogRow` component, select the **Table** option in the **Mode** area so that the contents will be displayed in table cells on the console.

- Double-click the `tSQLTemplateMerge` component to display its **Basic settings** view.
Type in the names of the source table and the target table in the relevant fields.

In this scenario, the source table is `new_customer_info`, which contains eight records; the target table is `customer_info_merge`, which contains five records, and both tables have the same data structure.

**Note:**
The source table and the target table may have different schema structures. In this case, however, make sure that the source column and target column specified in each line of the Merge ON table, the UPDATE Columns table, and the INSERT Columns table are identical in data type and the target column length allows the insertion of the data from the corresponding source column.

Define the source schema manually, or select Repository from the Schema list and select the relevant table if the schema has already been defined and stored in the Metadata area of the Repository tree view.

In this scenario, we use built-in schemas.

Define the columns as shown above and click OK to close the schema dialog box, and do the same for the target schema.

Click the green plus button beneath the Merge ON table to add a line, and select the ID column as the primary key.
Select the **Use UPDATE** check box to update existing data during the merge operation, and define the columns to be updated by clicking the green plus button and selecting the desired columns. In this scenario, we want to update all the columns according to the customer IDs. Therefore, we select all the columns except the `ID` column.

**Warning:**
The columns defined as the primary key **CANNOT** and **MUST NOT** be made subject to updates.

Select the **Specify UPDATE WHERE clause** check box and type `customer_info_merge.ID >= 4` within double quotation marks in the **WHERE clause** field so that only those existing records with an ID equal to or greater than 4 will be updated.

Select the **Use INSERT** check box and define the columns to take data from and insert data to in the **INSERT Columns** table.

In this example, we want to insert all the records that do not exist in the target table.
Select the SQL Template view to display and add the SQL templates to be used.
By default, the SQLTemplateMerge component uses two system SQL templates: MergeUpdate and MergeInsert.

Note:
In the SQL Template tab, you can add system SQL templates or create your own and use them within your Job to carry out the coded operation. For more information, see tSQLTemplateFilterColumns Standard properties on page 3627.

- Click the Add button to add a line and select Commit from the template list to commit the merge result to your database.

Alternatively, you can connect the tSQLTemplateMerge component to a tSQLTemplateCommit or tMysqlCommit component using a Trigger > OnSubjobOK connection to commit the merge result to your database.
- Save your Job and press F6 to run it.

Both the original contents of the target table and the merge result are displayed on the console. In the target table, records No. 4 and No. 5 contain the updated information, and records No. 6 through No. 8 contain the inserted information.
Starting job MergeData at 10:55 01/04/2011.

Related scenarios

For a tSQLTemplateRollback related scenario, see Filtering and aggregating table columns directly on the DBMS on page 3621.
**tSqoopExport**

Defines the arguments required by Sqoop for transferring data to a RDBMS.

tSqoopExport calls sqoop to transfer data from the Hadoop Distributed File System (HDFS) to a relational database management system (RDBMS).

Please be aware that some features provided by this component are only supported by the latest Sqoop version. For further information about the availability of each feature, see Apache's documentation about Sqoop.

**Note:**
Sqoop is typically installed in every Hadoop distribution. But if the Hadoop distribution you need to use have no Sqoop installed, you have to install one on your own and ensure to add the Sqoop command line to the PATH variable of that distribution. For further information about how to install Sqoop, see the documentation of Sqoop.

Commandline mode | Java API mode
---|---
--hive-import | hive.import
--hive-overwrite | hive.overwrite.table
--hive-table | hive.table.name
--class-name | codegen.java.classname
--jar-file | codegen.jar.file
--outdir | codegen.output.dir
--package-name | codegen.java.packagename

For further information about the arguments available in the Sqoop commandline mode, see the documentation of Sqoop.

The arguments listed earlier for the Java API mode are subject to updates and changes by Java. For further information about these arguments, see http://svn.apache.org/repos/asf/sqoop/trunk/src/java/org/apache/sqoop/SqoopOptions.java

**tSqoopExport Standard properties**

These properties are used to configure tSqoopExport running in the Standard Job framework.

The Standard tSqoopExport component belongs to the Big Data and the File families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

**Mode**

Select the mode in which Sqoop is called in a Job execution.

**Use Commandline:** the Sqoop shell is used to call Sqoop. You can read data from either HDFS or HCatalog. In this mode, you have to deploy and run the Job in the host where Sqoop is installed. Therefore, if you are a subscription-based user, we recommend installing and using a Jobserver provided by Talend in that host to run the Job; if you are using one of the Talend solutions with Big Data, you have to ensure that the Studio and the Sqoop to be used are in the same machine.

**Use Java API:** the Java API is used to call Sqoop. In this mode, the Job can be run locally in the Studio but you need to configure the connection to the Hadoop distribution to be used. Note that JDK is required to execute the Job in the Java API mode and the versions of the JDK kits installed in both machines must be compatible with each other; for example, the versions are the same or the JDK version of the Hadoop machine is more recent.

**Hadoop properties**

Either **Built-in** or **Repository**:
**Built-in:** you enter the configuration information of the Hadoop distribution to be used locally for this component only.

**Repository:** you have already created the Hadoop connection and stored it in the Repository; therefore, you reuse it directly for the component configuration and the Job design. For further information about how to create a centralized Hadoop connection, see *Talend Open Studio for Big Data Getting Started Guide*.

Distribution

Select the cluster you are using from the drop-down list. The options in the list vary depending on the component you are using. Among these options, the following ones requires specific configuration:

- If available in this Distribution drop-down list, the **Microsoft HD Insight** option allows you to use a Microsoft HD Insight cluster. For this purpose, you need to configure the connections to the HD Insight cluster and the Windows Azure Storage service of that cluster in the areas that are displayed. For detailed explanation about these parameters, search for configuring the connection manually on Talend Help Center (https://help.talend.com).

- If you select **Amazon EMR**, you can find more details about how to configure an Amazon EMR cluster in Talend Help Center (https://help.talend.com).

- The **Custom** option allows you to connect to a cluster different from any of the distributions given in this list, that is to say, to connect to a cluster not officially supported by Talend.

1. Select **Import from existing version** to import an officially supported distribution as base and then add other required jar files which the base distribution does not provide.

2. Select **Import from zip** to import the configuration zip for the custom distribution to be used. This zip file should contain the libraries of the different Hadoop elements and the index file of these libraries.

In **Talend Exchange**, members of **Talend** community have shared some ready-for-use configuration zip files which you can download from this Hadoop configuration list and directly use them in your connection accordingly. However, because of the ongoing evolution of the different Hadoop-related projects, you might not be able to find the configuration zip corresponding to your distribution from this list; then it is recommended to use the **Import from existing version** option to take an existing distribution as base to add the jars required by your distribution.

Note that custom versions are not officially supported by Talend. Talend and its community provide you with the opportunity to connect to custom versions from the Studio but cannot guarantee that the configuration of whichever version you choose will be easy, due to the wide range of different Hadoop distributions and versions that are available. As such, you should only attempt to set up such a connection if you have sufficient Hadoop experience to handle any issues on your own.
### Hadoop Version
Select the version of the Hadoop distribution you are using. The available options vary depending on the component you are using.

### NameNode URI
Type in the URI of the Hadoop NameNode, the master node of a Hadoop system. For example, we assume that you have chosen a machine called `masternode` as the NameNode, then the location is `hdfs://masternode:portnumber`. If you are using WebHDFS, the location should be `webhdfs://masternode:portnumber`. WebHDFS with SSL is not supported yet.

### JobTracker Host
Select this check box and in the displayed field, enter the location of the ResourceManager of your distribution. For example, `tal-qall14.talend.lan:8050`.

This property is required when the query you want to use is executed in Windows and it is a Select query. For example, `SELECT your_column_name FROM your_table_name`

Then you can continue to set the following parameters depending on the configuration of the Hadoop cluster to be used (if you leave the check box of a parameter clear, then at runtime, the configuration about this parameter in the Hadoop cluster to be used will be ignored):

1. Select the **Set resourcemanager scheduler address** check box and enter the Scheduler address in the field that appears.
2. Select the **Set jobhistory address** check box and enter the location of the JobHistory server of the Hadoop cluster to be used. This allows the metrics information of the current Job to be stored in that JobHistory server.
3. Select the **Set staging directory** check box and enter this directory defined in your Hadoop cluster for temporary files created by running programs. Typically, this directory can be found under the `yarn.app.mapreduce.am.staging-dir` property in the configuration files such as `yarn-site.xml` or `mapred-site.xml` of your distribution.
4. Allocate proper memory volumes to the **Map** and the **Reduce** computations and the ApplicationMaster of YARN by selecting the **Set memory** check box in the **Advanced settings** view.
5. Select the **Set Hadoop user** check box and enter the user name under which you want to execute the Job. Since a file or a directory in Hadoop has its specific owner with appropriate read or write rights, this field allows you to execute the Job directly under the user.

---

**Note:**
In this dialog box, the active check box must be kept selected so as to import the jar files pertinent to the connection to be created between the custom distribution and this component.

For a step-by-step example about how to connect to a custom distribution and share this connection, see [Connecting to a custom Hadoop distribution](#) on page 1569.
name that has the appropriate rights to access the file or directory to be processed.

6. Select the **Use datanode hostname** check box to allow the Job to access datanodes via their hostnames. This actually sets the `dfs.client.use.datanode.hostname` property to `true`. When connecting to a S3N filesystem, you must select this check box.

For further information about these parameters, see the documentation or contact the administrator of the Hadoop cluster to be used.

### Use kerberos authentication

If you are accessing the Hadoop cluster running with Kerberos security, select this check box, then, enter the Kerberos principal name for the NameNode in the field displayed. This enables you to use your user name to authenticate against the credentials stored in Kerberos.

- If this cluster is a MapR cluster of the version 5.0.0 or later, you can set the MapR ticket authentication configuration in addition or as an alternative by following the explanation in Connecting to a security-enabled MapR on page 1629.

Keep in mind that this configuration generates a new MapR security ticket for the username defined in the Job in each execution. If you need to reuse an existing ticket issued for the same username, leave both the **Force MapR ticket authentication** check box and the **Use Kerberos authentication** check box clear, and then MapR should be able to automatically find that ticket on the fly.

In addition, since this component performs Map/Reduce computations, you also need to authenticate the related services such as the Job history server and the Resource manager or Jobtracker depending on your distribution in the corresponding field. These principals can be found in the configuration files of your distribution. For example, in a CDH4 distribution, the Resource manager principal is set in the `yarn-site.xml` file and the Job history principal in the `mapred-site.xml` file.

This check box is available depending on the Hadoop distribution you are connecting to.

### Use a keytab to authenticate

Select the **Use a keytab to authenticate** check box to log into a Kerberos-enabled system using a given keytab file. A keytab file contains pairs of Kerberos principals and encrypted keys. You need to enter the principal to be used in the **Principal** field and the access path to the keytab file itself in the **Keytab** field. This keytab file must be stored in the machine in which your Job actually runs, for example, on a Talend Jobserver.

Note that the user that executes a keytab-enabled Job is not necessarily the one a principal designates but must have the right to read the keytab file being used. For example, the user name you are using to execute a Job is `user1` and the principal to be used is `guest`; in this situation, ensure that `user1` has the right to read the keytab file to be used.
**Hadoop user name**

Enter the user name under which you want to execute the Job. Since a file or a directory in Hadoop has its specific owner with appropriate read or write rights, this field allows you to execute the Job directly under the user name that has the appropriate rights to access the file or directory to be processed. Note that this field is available depending on the distribution you are using.

**JDBC property**

Either **Built-in** or **Repository**:
- **Built-in**: you enter the connection information of the database to be used locally for this component only.
- **Repository**: you have already created the database connection and stored it in the Repository; therefore, you reuse it directly for the component configuration and the Job design. For further information about how to create a centralized database connection, see *Talend Studio User Guide*.

Note that only the **General JDBC** connection stored in the Repository is supported.

**Connection Type in the JDBC URL used to connect to the target database.**

**User name and Password**

Type in the authentication information to the target database.

To enter the password, click the `[...]` button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

If your password is stored in a file, select the **The password is stored in a file** check box and enter the path to that file in the **File path** field that is displayed.

- This file can be stored either in the machine where the Job is to be executed or in the HDFS system of the Hadoop cluster to be used.
- The password stored in this file must not contain `\n` (the newline escape) at the end, that is to say, you must not insert a new line at the end of the password even though this line is empty.

Note that this feature is available depending on the Sqoop version you are using.

**Driver JAR**

In either the **Use Commandline** mode or the **Java API** mode, you must add the driver file of the database to be used to the *lib* folder of the Hadoop distribution you are using. For that purpose, use this **Driver JAR** table to add that driver file for the current Job you are designing.

**Driver class name**

Enter the class name for the specified driver between double quotation marks. For example, for the `RedshiftJDBC41-1.1.13.1013.jar` driver, the name to be entered is `com.amazon.redshift.jdbc41.Driver`.

**Table Name**

Type in the name of the target table to which data is transferred from HDFS or HCatalog. This table must already exist in the target database. The input files are read and
parsed into a set of records according to the user-specified delimiters.

<table>
<thead>
<tr>
<th><strong>Input source</strong></th>
<th>Select the type of the source system from which data is read. This system could be:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• <strong>HDFS</strong>: the source system is HDFS. In the Export dir field that is displayed, enter the path to the source data to be transferred in HDFS.</td>
</tr>
<tr>
<td></td>
<td>• <strong>HCatalog</strong>: the source system is HCatalog. In the HCatalog database and the HCatalog table fields that are displayed, enter the database name and the table name to be used, respectively.</td>
</tr>
</tbody>
</table>

| **Direct** | Select this check box to use the export fast path. |

| **Specify Number of Mappers** | Select this check box to indicate the number of map tasks (parallel processes) used to perform the data transfer.  
If you do not want Sqoop to work in parallel, enter 1 in the displayed field. |

| **Call a stored procedure** | Select this check box to enable the component to call a specific store procedure to write data into the target database.  
You need to enter the name of the stored procedure to be used in the field that is displayed.  
Syntax and capabilities of stored procedures vary among different databases; for this reason, you are recommended to consult the documentation of the database you want to use for details about how a given stored procedure could be called. |

| **Use batch mode** | Select this check box to execute the statements in batch mode instead of running a multi-row INSERT statement to write multiple records in the target database. |

| **Clear staging table** | If you are using a specific staging table for the desired data transfer, select this check box to ensure that the staging table is empty when the data transfer runs. |

| **Define a staging table** | Select this check box to create a staging table for the data to be transferred. The transferred data is staged within this table before being written into the target table so as to avoid only a part of the data being committed to the target table when the transfer fails.  
For further information about whether a staging table is supported for a given data transfer, see Apache’s documentation for Sqoop. |

| **Specify how updates are performed when new rows are found with non-match keys in database** | Select this check box to determine the action to be taken when a given update key does not have any matching records in the target table. You can then select either of the following options:  
• **Update only**: this updates only the records that already exist in the target table.  
• **Allow insert**: this works like the SQL UPSERT statement. It writes new records in the table if they do not exist there. |
<table>
<thead>
<tr>
<th>Use column for update</th>
<th>Select this check box and in the table that is displayed, add the columns to be used as the update key.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Print Log</td>
<td>Select this check box to activate the Verbouse check box.</td>
</tr>
<tr>
<td>Verbose</td>
<td>Select this check box to print more information while working, for example, the debugging information.</td>
</tr>
</tbody>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th>Use MySQL default delimiters</th>
<th>Select this check box to use MySQL’s default delimiter set. This check box is available only to the Commandline mode.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Define Java mapping</td>
<td>Sqoop provides default configuration that maps most SQL types to appropriate Java types. If you need to use your custom map to overwrite the default ones at runtime, select this check box and define the map(s) you want to use in the table that appears.</td>
</tr>
</tbody>
</table>

**Additional arguments**

Table to use additional arguments if needed be. By adding additional arguments, you are able to perform multiple operations in one single transaction. For example, you can use `--hive-import` and `--hive-table` in the Commandline mode or `hive.import` and `hive.table.name` in the Java API mode to create Hive table and write data in at the runtime of the transaction writing data in HDFS. For further information about the available Sqoop arguments in the Commandline mode and the Java API mode, respectively, see Additional arguments on page 3642.

**Use speed parallel data transfers**

Select this check box to enable quick parallel data transfers between the Teradata database and the Hortonworks Hadoop distribution. Then the **Specific params** table and the Use additional params check box appear to allow you to specify the Teradata parameters required by parallel transfers.

- In the **Specific params** table, two columns are available:
  - **Argument**: select the parameters as needed from the drop-down list. They are the most common parameters for the parallel transfer.
  - **Value**: type in the value of the parameters.
- By selecting the **Additional params** check box, you make the **Specific additional params** field displayed. In this field, you can enter the Teradata parameters that you need to use but are not provided in the **Specific params** table. The syntax for a parameter is `--parameter=value` and when you put more than one parameter in this field, separate them using whitespace.

You must ensure that the Hortonworks Connector for Teradata has been installed in your Hortonworks cluster. The latest connector can be downloaded from the website of Hortonworks and installed by following the explanations from [http://hortonworks.com/wp-content/uploads/2014/02/bk_HortonworksConnectorForTeradata.pdf](http://hortonworks.com/wp-content/uploads/2014/02/bk_HortonworksConnectorForTeradata.pdf). In the same document, you can as well find the detailed explanations.
about each parameter that is available for the parallel transfer purpose.
Available in the **Use Commandline** mode only.

| Hadoop properties | Talend Studio uses a default configuration for its engine to perform operations in a Hadoop distribution. If you need to use a custom configuration in a specific situation, complete this table with the property or properties to be customized. Then at runtime, the customized property or properties will override those default ones.  
• Note that if you are using the centrally stored metadata from the Repository, this table automatically inherits the properties defined in that metadata and becomes uneditable unless you change the Property type from Repository to Built-in.  
For further information about the properties required by Hadoop and its related systems such as HDFS and Hive, see the documentation of the Hadoop distribution you are using or see Apache’s Hadoop documentation on [http://hadoop.apache.org/docs](http://hadoop.apache.org/docs) and then select the version of the documentation you want. For demonstration purposes, the links to some properties are listed below:  
• Typically, the HDFS-related properties can be found in the `hdfs-default.xml` file of your distribution, such as [http://hadoop.apache.org/docs/r2.6.0/hadoop-project-dist/hadoop-hdfs/hdfs-default.xml](http://hadoop.apache.org/docs/r2.6.0/hadoop-project-dist/hadoop-hdfs/hdfs-default.xml).  
• Apache also provides a page to list the Hive-related properties: [https://cwiki.apache.org/confluence/display/Hive/Configuration+Properties](https://cwiki.apache.org/confluence/display/Hive/Configuration+Properties). |
|-------------------|---|
| **Mapred job map memory mb** and **Mapred job reduce memory mb** | You can tune the map and reduce computations by selecting the Set memory check box to set proper memory allocations for the computations to be performed by the Hadoop system.  
In that situation, you need to enter the values you need in the **Mapred job map memory mb** and the **Mapred job reduce memory mb** fields, respectively. By default, the values are both 1000 which are normally appropriate for running the computations.  
The memory parameters to be set are **Map (in Mb)**, **Reduce (in Mb)** and **ApplicationMaster (in Mb)**. These fields allow you to dynamically allocate memory to the map and the reduce computations and the ApplicationMaster of YARN. |
| **Path separator in server** | Leave the default value of the **Path separator in server** as it is, unless you have changed the separator used by your Hadoop distribution’s host machine for its PATH variable or in other words, that separator is not a colon (:). In that situation, you must change this value to the one you are using in that host. |
| **tStatCatcher Statistics** | Select this check box to collect log data at the component level. |

### Global Variables

| **Global Variables** | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable |
and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

EXIT_CODE: the exit code of the remote command. This is an After variable and it returns an integer.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule

This component is used standalone. It respects the Sqoop prerequisites. You need necessary knowledge about Sqoop to use it.

We recommend using the Sqoop of version 1.4+ in order to benefit the full functions of these components.

For further information about Sqoop, see the Sqoop manual on: http://sqoop.apache.org/docs/

Prerequisites

The Hadoop distribution must be properly installed, so as to guarantee the interaction with Talend Studio. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native. For example, the library for Windows is \lib\native\MapRClient.dll in the MapR client jar file. For further information, see the following link from MapR: http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr.

Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path.

- Set the -Djava.library.path argument, for example, in the Job Run VM arguments area of the Run/Debug view in the Preferences dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

Limitation

If you have selected the Use Commandline mode, you need to use the host where Sqoop is installed to run the Job using this component.
Connections

Outgoing links (from this component to another):

**Trigger**: Run if; On Subjob Ok; On Subjob Error.

Incoming links (from one component to this one):

**Row**: Iterate;

**Trigger**: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error

For further information regarding connections, see *Talend Studio User Guide*.

## Related scenarios

No scenario is available for the Standard version of this component yet.
tSqoopImport

Defines the arguments required by Sqoop for writing the data of your interest into HDFS.

tSqoopImport calls Sqoop to transfer data from a relational database management system (RDBMS) such as MySQL or Oracle into the Hadoop Distributed File System (HDFS).

**Note:**
Sqoop is typically installed in every Hadoop distribution. But if the Hadoop distribution you need to use have no Sqoop installed, you have to install one on your own and ensure to add the Sqoop command line to the PATH variable of that distribution. For further information about how to install Sqoop, see the documentation of Sqoop.

**tSqoopImport Standard properties**

These properties are used to configure tSqoopImport running in the Standard Job framework.

The Standard tSqoopImport component belongs to the Big Data and the File families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Mode</th>
<th>Select the mode in which Sqoop is called in a Job execution.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use Commandline</td>
<td>the Sqoop shell is used to call Sqoop. You can read data from either HDFS or HCatalog. In this mode, you have to deploy and run the Job in the host where Sqoop is installed. Therefore, if you are a subscription-based user, we recommend installing and using a Jobserver provided by Talend in that host to run the Job; if you are using one of the Talend solutions with Big Data, you have to ensure that the Studio and the Sqoop to be used are in the same machine.</td>
</tr>
<tr>

</tbody>
</table>
Select the cluster you are using from the drop-down list. The options in the list vary depending on the component you are using. Among these options, the following ones require specific configuration:

- If available in this **Distribution** drop-down list, the **Microsoft HD Insight** option allows you to use a Microsoft HD Insight cluster. For this purpose, you need to configure the connections to the HD Insight cluster and the Windows Azure Storage service of that cluster in the areas that are displayed. For detailed explanation about these parameters, search for configuring the connection manually on Talend Help Center ([https://help.talend.com](https://help.talend.com)).

- If you select **Amazon EMR**, you can find more details about how to configure an Amazon EMR cluster in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

- The **Custom** option allows you to connect to a cluster different from any of the distributions given in this list, that is to say, to connect to a cluster not officially supported by Talend.

1. **Select Import from existing version** to import an officially supported distribution as base and then add other required jar files which the base distribution does not provide.

2. **Select Import from zip** to import the configuration zip for the custom distribution to be used. This zip file should contain the libraries of the different Hadoop elements and the index file of these libraries.

   In **Talend Exchange**, members of **Talend** community have shared some ready-for-use configuration zip files which you can download from this **Hadoop configuration** list and directly use them in your connection accordingly. However, because of the ongoing evolution of the different Hadoop-related projects, you might not be able to find the configuration zip corresponding to your distribution from this list; then it is recommended to use the **Import from existing version** option to take an existing distribution as base to add the jars required by your distribution.

   Note that custom versions are not officially supported by Talend. Talend and its community provide you with the opportunity to connect to custom versions from the Studio but cannot guarantee that the configuration of whichever version you choose will be easy, due to the wide range of different Hadoop distributions and versions that are available. As such, you should only attempt to set up such a connection if you have sufficient Hadoop experience to handle any issues on your own.

   **Note:**

   In this dialog box, the active check box must be kept selected so as to import the jar files pertinent to the connection to be created between the custom distribution and this component.

   For a step-by-step example about how to connect to a custom distribution and share this connection, see...
<table>
<thead>
<tr>

Select the Set jobhistory address check box and enter the location of the JobHistory server of the Hadoop cluster to be used. This allows the metrics information of the current Job to be stored in that JobHistory server. 3. Select the Set staging directory check box and enter this directory defined in your Hadoop cluster for temporary files created by running programs. Typically, this directory can be found under the yarn.app.mapreduce.am.staging-dir property in the configuration files such as yarn-site.xml or mapred-site.xml of your distribution. 4. Allocate proper memory volumes to the Map and the Reduce computations and the ApplicationMaster of YARN by selecting the Set memory check box in the Advanced settings view. 5. Select the Set Hadoop user check box and enter the user name under which you want to execute the Job. Since a file or a directory in Hadoop has its specific owner with appropriate read or write rights, this field allows you to execute the Job directly under the user name that has the appropriate rights to access the file or directory to be processed. 6. Select the Use datanode hostname check box to allow the Job to access datanodes via their hostnames. This actually sets the dfs.client.use.datanode.hostname property to true. When connecting to a S3N filesystem, you must select this check box. For further information about these parameters, see the documentation or contact the administrator of the Hadoop cluster to be used.</td>
</tr>
</tbody>
</table>

### Use kerberos authentication

If you are accessing the Hadoop cluster running with Kerberos security, select this check box, then, enter the Kerberos principal name for the NameNode in the field displayed. This enables you to use your user name to authenticate against the credentials stored in Kerberos.

- If this cluster is a MapR cluster of the version 5.0.0 or later, you can set the MapR ticket authentication configuration in addition or as an alternative by following the explanation in [Connecting to a security-enabled MapR](page 1629).

Keep in mind that this configuration generates a new MapR security ticket for the username defined in the Job in each execution. If you need to reuse an existing ticket issued for the same username, leave both the **Force MapR ticket authentication** check box and the **Use Kerberos authentication** check box clear, and then MapR should be able to automatically find that ticket on the fly.

In addition, since this component performs Map/Reduce computations, you also need to authenticate the related services such as the Job history server and the Resource manager or Jobtracker depending on your distribution in the corresponding field. These principals can be found in the configuration files of your distribution. For example, in a CDH4 distribution, the Resource manager principal is set in the `yarn-site.xml` file and the Job history principal in the `mapred-site.xml` file.

This check box is available depending on the Hadoop distribution you are connecting to.

### Use a keytab to authenticate

Select the **Use a keytab to authenticate** check box to log into a Kerberos-enabled system using a given keytab file. A keytab file contains pairs of Kerberos principals and encrypted keys. You need to enter the principal to be used in the **Principal** field and the access path to the keytab file itself in the **Keytab** field. This keytab file must be stored in the machine in which your Job actually runs, for example, on a Talend Jobserver.

Note that the user that executes a keytab-enabled Job is not necessarily the one a principal designates but must have the right to read the keytab file being used. For example, the user name you are using to execute a Job is *user1* and the principal to be used is *guest*; in this situation, ensure that *user1* has the right to read the keytab file to be used.

### Hadoop user name

Enter the user name under which you want to execute the Job. Since a file or a directory in Hadoop has its specific owner with appropriate read or write rights, this field allows you to execute the Job directly under the user name that has the appropriate rights to access the file or directory to be processed. Note that this field is available depending on the distribution you are using.

### JDBC property

Either **Built-in** or **Repository**:

- **Built-in**: you enter the connection information of the database to be used locally for this component only.
- **Repository**: you have already created the database connection and stored it in the **Repository**; therefore, you reuse it directly for the component configuration and the Job design. For further information about how to create a centralized database connection, see *Talend Studio User Guide*.

Note that only the **General JDBC** connection stored in the **Repository** is supported.

<table>
<thead>
<tr>
<th>Connection</th>
<th>Enter the JDBC URL used to connect to the database where the source data is stored.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>User name and Password</strong></td>
<td>Enter the authentication information used to connect to the source database. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings. If your password is stored in a file, select the <strong>The password is stored in a file</strong> check box and enter the path to that file in the <strong>File path</strong> field that is displayed. • This file can be stored either in the machine where the Job is to be executed or in the HDFS system of the Hadoop cluster to be used. • The password stored in this file must not contain \n (the newline escape) at the end, that is to say, you must not insert a new line at the end of the password even though this line is empty. Note that this feature is available depending on the Sqoop version you are using.</td>
</tr>
<tr>
<td><strong>Driver JAR</strong></td>
<td>In either the <strong>Use Commandline</strong> mode or the <strong>Java API</strong> mode, you must add the driver file of the database to be used to the <strong>lib</strong> folder of the Hadoop distribution you are using. For that purpose, use this <strong>Driver JAR</strong> table to add that driver file for the current Job you are designing.</td>
</tr>
</tbody>
</table>
| **Class name** | Enter the class name for the specified driver between double quotation marks. For example, for the RedshiftJDBC41-1.1.13.1013.jar driver, the name to be entered is **com.amazon.redshift.jdbc41.Driver**. When executing a query to import data from an Oracle database, if you encounter the error similar to the following one: 

```
ORA-00933: SQL command not properly ended
```

change the driver class name in **Class name** field in your Job from **oracle.jdbc.driver.OracleDriver** to an empty string, that is to say, "". |
| **Table Name** | Type in the name of the table to be transferred into HDFS. This field is not available when you are using the free-form query mode by selecting the **Use query** check box. |
| **File format** | Select a file format for the data to be transferred: • **textfile** |
- sequencefile
- Avro file
- Parquet file: the version of Sqoop must be 1.4.6.

<table>
<thead>
<tr>
<th>Delete target directory</th>
<th>Select this check box to remove the target directory of the transfer.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Append</td>
<td>Select this check box to append transferred data to an existing dataset in HDFS.</td>
</tr>
<tr>
<td>Compress</td>
<td>Select this check box to enable compression.</td>
</tr>
<tr>
<td>Direct</td>
<td>Select this check box to use the import fast path.</td>
</tr>
<tr>
<td>Specify columns</td>
<td>Select this check box to display the column table where you can specify the columns you want to transfer into HDFS.</td>
</tr>
<tr>
<td>Use WHERE clause</td>
<td>Select this check box to use a WHERE clause that controls the rows to be transferred. In the field displayed, you can type in the condition used to select the rows you want. For example, type in <code>id &gt;400</code> to import only the rows where the <code>id</code> column has a value greater than 400.</td>
</tr>
<tr>
<td>Use query</td>
<td>Select this check box to use the free-form query mode provided by Sqoop. Once selecting it, you are able to enter the free-form query you need to use. Then, you must specify the target directory and if the Sqoop imports data in parallel, specify as well the <code>Split by</code> argument.</td>
</tr>
</tbody>
</table>

**Warning:**
Once queries are entered here, the value of the argument `--fields-terminated-by` can only be set to `"\t"` in the Additional arguments table in the Advanced settings tab.

<table>
<thead>
<tr>
<th>Specify Target Dir</th>
<th>Select this check box to enter the path to the target location, in HDFS, where you want to transfer the source data to. This location should be a new directory; otherwise, you must select the Append check box.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specify Split by</td>
<td>Select this check box, then, enter the table column you need and are able to use as the splitting column to split the workload. For example, for a table where the <code>id</code> column is the key column, enter <code>tablename.id</code>. Then Sqoop will split the data to be transferred according to their ID values and imports them in parallel.</td>
</tr>
<tr>
<td>Specify Number of Mappers</td>
<td>Select this check box to indicate the number of map tasks (parallel processes) used to perform the data transfer. If you do not want Sqoop to work in parallel, enter 1 in the displayed field.</td>
</tr>
<tr>
<td>Print Log</td>
<td>Select this check box to activate the Verbose check box.</td>
</tr>
<tr>
<td><strong>Verbose</strong></td>
<td>Select this check box to print more information while working, for example, the debugging information.</td>
</tr>
<tr>
<td>-------------</td>
<td>--------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th><strong>Use MySQL default delimiters</strong></th>
<th>Select this check box to use MySQL’s default delimiter set. This check box is available only to the Commandline mode.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th><strong>Define Java mapping</strong></th>
<th>Sqoop provides default configuration that maps most SQL types to appropriate Java types. If you need to use your custom map to overwrite the default ones at runtime, select this check box and define the map(s) you want to use in the table that appears.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th><strong>Define Hive mapping</strong></th>
<th>Sqoop provides default configuration that maps most SQL types to appropriate Hive types. If you need to use your custom map to overwrite the default ones at runtime, select this check box and define the map(s) you want to use in the table that appears.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th><strong>Additional arguments</strong></th>
<th>Complete this table to use additional arguments if needs be. By adding additional arguments, you are able to perform multiple operations in one single transaction. For example, you can use <code>--hive-import</code> and <code>--hive-table</code> in the Commandline mode or <code>hive.import</code> and <code>hive.table.name</code> in the Java API mode to create Hive table and write data in at the runtime of the transaction writing data in HDFS. For further information about the available Sqoop arguments in the Commandline mode and the Java API mode, respectively, see Additional arguments on page 3642.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th><strong>Use speed parallel data transfers</strong></th>
<th>Select this check box to enable quick parallel data transfers between the Teradata database and the Hortonworks Hadoop distribution. Then the Specific params table and the Use additional params check box appear to allow you to specify the Teradata parameters required by parallel transfers.</th>
</tr>
</thead>
</table>

- In the Specific params table, two columns are available:
  - **Argument**: select the parameters as needed from the drop-down list. They are the most common parameters for the parallel transfer.
  - **Value**: type in the value of the parameters.
- By selecting the Additional params check box, you make the Specific additional params field displayed. In this field, you can enter the Teradata parameters that you need to use but are not provided in the Specific params table. The syntax for a parameter is `-Dparameter=value` and when you put more than one parameter in this field, separate them using whitespace.

You must ensure that the Hortonworks Connector for Teradata has been installed in your Hortonworks cluster. The latest connector can be downloaded from the website of Hortonworks and installed by following the explanations from [http://hortonworks.com/wp-content/uploads/2014/02/bk_HortonworksConnectorForTeradata.pdf](http://hortonworks.com/wp-content/uploads/2014/02/bk_HortonworksConnectorForTeradata.pdf). In the same document, you can as well find the detailed explanations.
about each parameter that is available for the parallel transfer purpose. Available in the Use Commandline mode only.

### Hadoop properties

Talend Studio uses a default configuration for its engine to perform operations in a Hadoop distribution. If you need to use a custom configuration in a specific situation, complete this table with the property or properties to be customized. Then at runtime, the customized property or properties will override those default ones.

- Note that if you are using the centrally stored metadata from the Repository, this table automatically inherits the properties defined in that metadata and becomes uneditable unless you change the Property type from Repository to Built-in.

For further information about the properties required by Hadoop and its related systems such as HDFS and Hive, see the documentation of the Hadoop distribution you are using or see Apache’s Hadoop documentation on http://hadoop.apache.org/docs and then select the version of the documentation you want. For demonstration purposes, the links to some properties are listed below:

- Typically, the HDFS-related properties can be found in the `hdfs-default.xml` file of your distribution, such as [http://hadoop.apache.org/docs/r2.6.0/hadoop-project-dist/hadoop-hdfs/hdfs-default.xml](http://hadoop.apache.org/docs/r2.6.0/hadoop-project-dist/hadoop-hdfs/hdfs-default.xml).
- Apache also provides a page to list the Hive-related properties: [https://cwiki.apache.org/confluence/display/Hive/Configuration+Properties](https://cwiki.apache.org/confluence/display/Hive/Configuration+Properties).

### Mapred job map memory mb and Mapred job reduce memory mb

You can tune the map and reduce computations by selecting the Set memory check box to set proper memory allocations for the computations to be performed by the Hadoop system.

In that situation, you need to enter the values you need in the Mapred job map memory mb and the Mapred job reduce memory mb fields, respectively. By default, the values are both 1000 which are normally appropriate for running the computations.

The memory parameters to be set are Map (in Mb), Reduce (in Mb) and ApplicationMaster (in Mb). These fields allow you to dynamically allocate memory to the map and the reduce computations and the ApplicationMaster of YARN.

### Path separator in server

Leave the default value of the Path separator in server as it is, unless you have changed the separator used by your Hadoop distribution’s host machine for its PATH variable or in other words, that separator is not a colon (:). In that situation, you must change this value to the one you are using in that host.

### tStatCatcher Statistics

Select this check box to collect log data at the component level.

---

## Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable</th>
</tr>
</thead>
</table>
and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

**EXIT_CODE**: the exit code of the remote command. This is an After variable and it returns an integer.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

---

### Usage

#### Usage rule

This component is used standalone. It respects the Sqoop prerequisites. You need necessary knowledge about Sqoop to use it.

We recommend using the Sqoop of version 1.4+ in order to benefit the full functions of these components.

For further information about Sqoop, see the Sqoop manual on: [http://sqoop.apache.org/docs/](http://sqoop.apache.org/docs/)

#### Prerequisites

The Hadoop distribution must be properly installed, so as to guarantee the interaction with *Talend Studio*. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under `MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native`. For example, the library for Windows is `\lib\native\MapRClient.dll` in the MapR client jar file. For further information, see the following link from MapR: [http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr/](http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr/).

Without adding the specified library or libraries, you may encounter the following error: `no MapRClient in java.library.path`.

- Set the `-Djava.library.path` argument, for example, in the **Job Run VM arguments** area of the **Run/Debug** view in the **Preferences** dialog box in the **Window** menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the **Data viewer** to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

#### Limitation

If you have selected the **Use Commandline** mode, you need to use the host where Sqoop is installed to run the Job using this component.
Importing a MySQL table to HDFS

This scenario applies only to Talend products with Big Data.

This scenario illustrates how to use tSqoopImport to import a MySQL table to a given HDFS system.

The sample data to be used in this scenario reads as follows:

<table>
<thead>
<tr>
<th>id, wage, mod_date</th>
</tr>
</thead>
<tbody>
<tr>
<td>0, 2000, 2008-06-26 04:25:59</td>
</tr>
<tr>
<td>1, 2300, 2011-06-12 05:29:45</td>
</tr>
<tr>
<td>3, 3000, 2010-05-02 15:34:05</td>
</tr>
</tbody>
</table>

The data is stored in a MySQL table called sqoopmerge.

Before starting to replicate this scenario, ensure that you have appropriate rights and permissions to access the Hadoop distribution to be used. Then proceed as follows:

Dropping the component

Procedure

1. In the Integration perspective of the Studio, create an empty Job from the Job Designs node in the Repository tree view.
   
   For further information about how to create a Job, see the Talend Studio User Guide.

2. Drop tSqoopImport onto the workspace.

Importing the MySQL table

About this task
Configuring tSqoopImport
Procedure

1. Double-click **tSqoopImport** to open its **Component** view.

   ![tSqoopImport component view](image)

   - **Mode area**: Select Use Java API.
   - **Version area**: Select the Hadoop distribution to be used and its version. If you cannot find from the list the distribution corresponding to yours, select **Custom** so as to connect to a Hadoop distribution not officially supported in the Studio.
   - **For a step-by-step example about how to use this Custom option, see Connecting to a custom Hadoop distribution on page 1569.**

2. In the **Mode** area, select **Use Java API**.

3. In the **Version** area, select the Hadoop distribution to be used and its version. If you cannot find from the list the distribution corresponding to yours, select **Custom** so as to connect to a Hadoop distribution not officially supported in the Studio.

   - For a step-by-step example about how to use this **Custom** option, see Connecting to a custom Hadoop distribution on page 1569.
In the **NameNode URI** field, enter the location of the master node, the NameNode, of the distribution to be used. If you are using WebHDFS, the location should be webhdfs://masternode:portnumber; WebHDFS with SSL is not supported yet.

In the **Resource Manager** field, enter the location of the ResourceManager of your distribution. Note that the notion Job in this term JobTracker designates the MR or the MapReduce jobs described in Apache’s documentation on [http://hadoop.apache.org/](http://hadoop.apache.org/).

If the distribution to be used requires Kerberos authentication, select the **Use Kerberos authentication** check box and complete the authentication details. Otherwise, leave this check box clear.

If you need to use a Kerberos keytab file to log in, select **Use a keytab to authenticate**. A keytab file contains pairs of Kerberos principals and encrypted keys. You need to enter the principal to be used in the **Principal** field and the access path to the keytab file itself in the **Keytab** field. This keytab file must be stored in the machine in which your Job actually runs, for example, on a Talend Jobserver.

Note that the user that executes a keytab-enabled Job is not necessarily the one a principal designates but must have the right to read the keytab file being used. For example, the user name you are using to execute a Job is *user1* and the principal to be used is *guest*; in this situation, ensure that *user1* has the right to read the keytab file to be used.

In the **Connection** field, enter the URI of the MySQL database where the source table is stored. For example, `jdbc:mysql://10.42.10.13/mysql`.

**Username** and **Password**, enter the authentication information.

Under the **Driver JAR** table, click the **[+]** button to add one row, then in this row, click the **[...]** button to display the drop-down list and select the jar file to be used from that list. In this scenario, it is `mysql-connector-java-5.1.30-bin.jar`.

If the **[...]** button does not appear, click anywhere in this row to make it displayed.

In the **Table Name** field, enter the name of the source table. In this scenario, it is `sqoopmerge`.

From the **File format** list, select the format that corresponds to the data to be used, `textfile` in this scenario.

Select the **Specify target dir** check box and enter the directory where you need to import the data to. For example, `/user/ychen/target_old`.

### Configuring tSqoopImport

**Procedure**

1. Double-click **tSqoopImport** to open its **Component** view.
2. In the **Mode** area, select **Use Java API**.

3. In the **Version** area, select the Hadoop distribution to be used and its version. If you cannot find from the list the distribution corresponding to yours, select **Custom** so as to connect to a Hadoop distribution not officially supported in the Studio.

   For a step-by-step example about how to use this **Custom** option, see **Connecting to a custom Hadoop distribution** on page 1569.

4. In the **NameNode URI** field, enter the location of the master node, the NameNode, of the distribution to be used. For example, `hdfs://talend-cdh4-namenode:8020`. If you are using WebHDFS, the location should be `webhdfs://masternode:portnumber`; WebHDFS with SSL is not supported yet.
5. In the **JobTracker Host** field, enter the location of the JobTracker of your distribution. For example, `talend-cdh4-namenode:8021`.

   Note that the notion Job in this term JobTracker designates the MR or the MapReduce jobs described in Apache's documentation on [http://hadoop.apache.org/](http://hadoop.apache.org/).

6. If the distribution to be used requires Kerberos authentication, select the **Use Kerberos authentication** check box and complete the authentication details. Otherwise, leave this check box clear.

   If you need to use a Kerberos keytab file to log in, select **Use a keytab to authenticate**. A keytab file contains pairs of Kerberos principals and encrypted keys. You need to enter the principal to be used in the **Principal** field and the access path to the keytab file itself in the **Keytab** field. This keytab file must be stored in the machine in which your Job actually runs, for example, on a Talend Jobserver.

   Note that the user that executes a keytab-enabled Job is not necessarily the one a principal designates but must have the right to read the keytab file being used. For example, the user name you are using to execute a Job is `user1` and the principal to be used is `guest`; in this situation, ensure that `user1` has the right to read the keytab file to be used.

7. In the **Connection** field, enter the URI of the MySQL database where the source table is stored. For example, `jdbc:mysql://10.42.10.13/mysql`.

8. In **Username** and **Password**, enter the authentication information.

9. Under the **Driver JAR** table, click the `[+]` button to add one row, then in this row, click the `[…]'` button to display the drop-down list and select the jar file to be used from that list. In this scenario, it is `mysql-connector-java-5.1.30-bin.jar`.

   If the `[…]'` button does not appear, click anywhere in this row to make it displayed.

10. In the **Table Name** field, enter the name of the source table. In this scenario, it is `sqoopmerge`.

11. From the **File format** list, select the format that corresponds to the data to be used, **textfile** in this scenario.

12. Select the **Specify target dir** check box and enter the directory where you need to import the data to. For example, `/user/ychen/target_old`.

**Executing the Job**

Then you can press **F6** to run this Job.

Once done, you can verify the results in the target directory you have specified, in the web console of the Hadoop distribution used.
If you need to obtain more details about the Job, it is recommended to use the web console of the Jobtracker provided by the Hadoop distribution you are using.

### Contents of directory `/user/ychen/target_old`

</table>
tSqoopImportAllTables

Defines the arguments required by Sqoop for writing all of the tables of a database into HDFS.

tSqoopImportAllTables calls Sqoop to transfer all of the tables of a relational database management system (RDBMS) such as MySQL or Oracle into the Hadoop Distributed File System (HDFS).

Note:
Sqoop is typically installed in every Hadoop distribution. But if the Hadoop distribution you need to use have no Sqoop installed, you have to install one on your own and ensure to add the Sqoop command line to the PATH variable of that distribution. For further information about how to install Sqoop, see the documentation of Sqoop.

tSqoopImportAllTables Standard properties

These properties are used to configure tSqoopImportAllTables running in the Standard Job framework.
The Standard tSqoopImportAllTables component belongs to the Big Data and the File families.
The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

Basic settings

<table>
<thead>
<tr>
<th>Mode</th>
<th>Select the mode in which Sqoop is called in a Job execution. Use Commandline: the Sqoop shell is used to call Sqoop. You can read data from either HDFS or HCatalog. In this mode, you have to deploy and run the Job in the host where Sqoop is installed. Therefore, if you are a subscription-based user, we recommend installing and using a Jobserver provided by Talend in that host to run the Job; if you are using one of the Talend solutions with Big Data, you have to ensure that the Studio and the Sqoop to be used are in the same machine. Use Java API: the Java API is used to call Sqoop. In this mode, the Job can be run locally in the Studio but you need to configure the connection to the Hadoop distribution to be used. Note that JDK is required to execute the Job in the Java API mode and the versions of the JDK kits installed in both machines must be compatible with each other; for example, the versions are the same or the JDK version of the Hadoop machine is more recent.</th>
</tr>
</thead>
</table>

Hadoop properties

Either Built-in or Repository:
- Built-in: you enter the configuration information of the Hadoop distribution to be used locally for this component only.
- Repository: you have already created the Hadoop connection and stored it in the Repository; therefore, you reuse it directly for the component configuration and the Job design. For further information about how to create a centralized Hadoop connection, see Talend Open Studio for Big Data Getting Started Guide.
Select the cluster you are using from the drop-down list. The options in the list vary depending on the component you are using. Among these options, the following ones require specific configuration:

- If available in this Distribution drop-down list, the Microsoft HD Insight option allows you to use a Microsoft HD Insight cluster. For this purpose, you need to configure the connections to the HD Insight cluster and the Windows Azure Storage service of that cluster in the areas that are displayed. For detailed explanation about these parameters, search for configuring the connection manually on Talend Help Center (https://help.talend.com).
- If you select Amazon EMR, you can find more details about how to configure an Amazon EMR cluster in Talend Help Center (https://help.talend.com).
- The Custom option allows you to connect to a cluster different from any of the distributions given in this list, that is to say, to connect to a cluster not officially supported by Talend.

1. Select Import from existing version to import an officially supported distribution as base and then add other required jar files which the base distribution does not provide.
2. Select Import from zip to import the configuration zip for the custom distribution to be used. This zip file should contain the libraries of the different Hadoop elements and the index file of these libraries.

In Talend Exchange, members of Talend community have shared some ready-for-use configuration zip files which you can download from this Hadoop configuration list and directly use them in your connection accordingly. However, because of the ongoing evolution of the different Hadoop-related projects, you might not be able to find the configuration zip corresponding to your distribution from this list; then it is recommended to use the Import from existing version option to take an existing distribution as base to add the jars required by your distribution.

Note that custom versions are not officially supported by Talend. Talend and its community provide you with the opportunity to connect to custom versions from the Studio but cannot guarantee that the configuration of whichever version you choose will be easy, due to the wide range of different Hadoop distributions and versions that are available. As such, you should only attempt to set up such a connection if you have sufficient Hadoop experience to handle any issues on your own.

**Note:**

In this dialog box, the active check box must be kept selected so as to import the jar files pertinent to the connection to be created between the custom distribution and this component.

For a step-by-step example about how to connect to a custom distribution and share this connection, see
### Hadoop Version
Select the version of the Hadoop distribution you are using. The available options vary depending on the component you are using.

### NameNode URI
Type in the URI of the Hadoop NameNode, the master node of a Hadoop system. For example, we assume that you have chosen a machine called masternode as the NameNode, then the location is hdfs://masternode:portnumber. If you are using WebHDFS, the location should be webhdfs://masternode:portnumber; WebHDFS with SSL is not supported yet.

### JobTracker Host
Select this check box and in the displayed field, enter the location of the ResourceManager of your distribution. For example, tal-qa114.talend.lan:8050.

This property is required when the query you want to use is executed in Windows and it is a Select query. For example, `SELECT your_column_name FROM your_table_name`

Then you can continue to set the following parameters depending on the configuration of the Hadoop cluster to be used (if you leave the check box of a parameter clear, then at runtime, the configuration about this parameter in the Hadoop cluster to be used will be ignored):

1. Select the Set resourcemanager scheduler address check box and enter the Scheduler address in the field that appears.
2. Select the Set jobhistory address check box and enter the location of the JobHistory server of the Hadoop cluster to be used. This allows the metrics information of the current Job to be stored in that JobHistory server.
3. Select the Set staging directory check box and enter this directory defined in your Hadoop cluster for temporary files created by running programs. Typically, this directory can be found under the `yarn.app.mapreduce.am.staging-dir` property in the configuration files such as `yarn-site.xml` or `mapred-site.xml` of your distribution.
4. Allocate proper memory volumes to the Map and the Reduce computations and the ApplicationMaster of YARN by selecting the Set memory check box in the Advanced settings view.
5. Select the Set Hadoop user check box and enter the user name under which you want to execute the Job. Since a file or a directory in Hadoop has its specific owner with appropriate read or write rights, this field allows you to execute the Job directly under the user name that has the appropriate rights to access the file or directory to be processed.
6. Select the Use datanode hostname check box to allow the Job to access datanodes via their hostnames. This actually sets the `dfs.client.use.datanode.hostname` property to true. When connecting to a S3N filesystem, you must select this check box.

For further information about these parameters, see the documentation or contact the administrator of the Hadoop cluster to be used.
For further information about the Hadoop Map/Reduce framework, see the Map/Reduce tutorial in Apache’s Hadoop documentation on http://hadoop.apache.org.

Use kerberos authentication

If you are accessing the Hadoop cluster running with Kerberos security, select this check box, then, enter the Kerberos principal name for the NameNode in the field displayed. This enables you to use your user name to authenticate against the credentials stored in Kerberos.

- If this cluster is a MapR cluster of the version 5.0.0 or later, you can set the MapR ticket authentication configuration in addition or as an alternative by following the explanation in Connecting to a security-enabled MapR on page 1629.

Keep in mind that this configuration generates a new MapR security ticket for the username defined in the Job in each execution. If you need to reuse an existing ticket issued for the same username, leave both the Force MapR ticket authentication check box and the Use Kerberos authentication check box clear, and then MapR should be able to automatically find that ticket on the fly.

In addition, since this component performs Map/Reduce computations, you also need to authenticate the related services such as the Job history server and the Resource manager or Jobtracker depending on your distribution in the corresponding field. These principals can be found in the configuration files of your distribution. For example, in a CDH4 distribution, the Resource manager principal is set in the yarn-site.xml file and the Job history principal in the mapred-site.xml file.

This check box is available depending on the Hadoop distribution you are connecting to.

Use a keytab to authenticate

Select the Use a keytab to authenticate check box to log into a Kerberos-enabled system using a given keytab file. A keytab file contains pairs of Kerberos principals and encrypted keys. You need to enter the principal to be used in the Principal field and the access path to the keytab file itself in the Keytab field. This keytab file must be stored in the machine in which your Job actually runs, for example, on a Talend Jobserver.

Note that the user that executes a keytab-enabled Job is not necessarily the one a principal designates but must have the right to read the keytab file being used. For example, the user name you are using to execute a Job is user1 and the principal to be used is guest; in this situation, ensure that user1 has the right to read the keytab file to be used.

Hadoop user name

Enter the user name under which you want to execute the Job. Since a file or a directory in Hadoop has its specific owner with appropriate read or write rights, this field allows you to execute the Job directly under the user name that has the appropriate rights to access the file or directory to be processed. Note that this field is available depending on the distribution you are using.

JDBC property

Either Built-in or Repository:
- **Built-in**: you enter the connection information of the database to be used locally for this component only.
• **Repository**: you have already created the database connection and stored it in the **Repository**; therefore, you reuse it directly for the component configuration and the Job design. For further information about how to create a centralized database connection, see *Talend Studio User Guide*.

Note that only the **General JDBC** connection stored in the **Repository** is supported.

<table>
<thead>
<tr>
<th><strong>Connection</strong></th>
<th>Enter the JDBC URL used to connect to the database where the source data is stored.</th>
</tr>
</thead>
</table>
| **User name and Password** | Enter the authentication information used to connect to the source database.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.  
If your password is stored in a file, select the **The password is stored in a file** check box and enter the path to that file in the **File path** field that is displayed.  
• This file can be stored either in the machine where the Job is to be executed or in the HDFS system of the Hadoop cluster to be used.  
• The password stored in this file must not contain \n (the newline escape) at the end, that is to say, you must not insert a new line at the end of the password even though this line is empty.  
Note that this feature is available depending on the Sqoop version you are using. |
| **Driver JAR** | In either the **Use Commandline** mode or the **Java API** mode, you must add the driver file of the database to be used to the **lib** folder of the Hadoop distribution you are using. For that purpose, use this **Driver JAR** table to add that driver file for the current Job you are designing. |
| **Driver class name** | Enter the class name for the specified driver between double quotation marks. For example, for the RedshiftJDBC41-1.1.13.1013.jar driver, the name to be entered is com.amazon.redshift.jdbc41.Driver. |
| **File format** | Select a file format for the data to be transferred:  
• **textfile**  
• **sequencefile**  
• **Avro file**  
• **Parquet file**: the version of Sqoop must be 1.4.6. |
| **Specify Number of Mappers** | Select this check box to indicate the number of map tasks (parallel processes) used to perform the data transfer.  
If you do not want Sqoop to work in parallel, enter 1 in the displayed field. |
| **Compress** | Select this check box to enable compression. |
| **Direct** | Select this check box to use the import fast path. |
### Exclude table
Select this check box and enter the name of the table(s) to be excluded from the import process.

### Print Log
Select this check box to activate the **Verbose** check box.

### Verbose
Select this check box to print more information while working, for example, the debugging information.

### Advanced settings

#### Define Hive mapping
Sqoop provides default configuration that maps most SQL types to appropriate Hive types. If you need to use your custom map to overwrite the default ones at runtime, select this check box and define the map(s) you want to use in the table that appears.

#### Use MySQL default delimiters
Select this check box to use MySQL’s default delimiter set. This check box is available only to the Commandline mode.

#### Additional arguments
Complete this table to use additional arguments if needs be.

By adding additional arguments, you are able to perform multiple operations in one single transaction. For example, you can use `--hive-import` and `--hive-table` in the Commandline mode or `hive.import` and `hive.table.name` in the Java API mode to create Hive table and write data in at the runtime of the transaction writing data in HDFS. For further information about the available Sqoop arguments in the Commandline mode and the Java API mode, respectively, see Additional arguments on page 3642.

#### Hadoop properties
*Talend Studio* uses a default configuration for its engine to perform operations in a Hadoop distribution. If you need to use a custom configuration in a specific situation, complete this table with the property or properties to be customized. Then at runtime, the customized property or properties will override those default ones.

- Note that if you are using the centrally stored metadata from the **Repository**, this table automatically inherits the properties defined in that metadata and becomes uneditable unless you change the **Property type** from **Repository** to **Built-in**.

For further information about the properties required by Hadoop and its related systems such as HDFS and Hive, see the documentation of the Hadoop distribution you are using or see Apache’s Hadoop documentation on [http://hadoop.apache.org/docs][1] and then select the version of the documentation you want. For demonstration purposes, the links to some properties are listed below:

- Typically, the HDFS-related properties can be found in the `hdfs-default.xml` file of your distribution, such as [http://hadoop.apache.org/docs/r2.6.0/hadoop-project-dist/hadoop-hdfs/hdfs-default.xml][2].
- Apache also provides a page to list the Hive-related properties: [https://cwiki.apache.org/confluence/display/Hive/Configuration+Properties][3].
### Mapred job map memory mb and Mapred job reduce memory mb

You can tune the map and reduce computations by selecting the **Set memory** check box to set proper memory allocations for the computations to be performed by the Hadoop system.

In that situation, you need to enter the values you need in the `Mapred job map memory mb` and the `Mapred job reduce memory mb` fields, respectively. By default, the values are both **1000** which are normally appropriate for running the computations.

The memory parameters to be set are **Map (in Mb)**, **Reduce (in Mb)** and **ApplicationMaster (in Mb)**. These fields allow you to dynamically allocate memory to the map and the reduce computations and the ApplicationMaster of YARN.

#### Path separator in server

Leave the default value of the **Path separator in server** as it is, unless you have changed the separator used by your Hadoop distribution's host machine for its PATH variable or in other words, that separator is not a colon (:). In that situation, you must change this value to the one you are using in that host.

#### tStatCatcher Statistics

Select this check box to collect log data at the component level.

### Global Variables

**Global Variables**

- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.
- **EXIT_CODE**: the exit code of the remote command. This is an After variable and it returns an integer.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see the [*Talend Studio User Guide*](http://sqoop.apache.org/docs/).

### Usage

**Usage rule**

This component is used standalone. It respects the Sqoop prerequisites. You need necessary knowledge about Sqoop to use it.

We recommend using the Sqoop of version 1.4+ in order to benefit the full functions of these components.

For further information about Sqoop, see the Sqoop manual on: [http://sqoop.apache.org/docs/](http://sqoop.apache.org/docs/)

**Prerequisites**

The Hadoop distribution must be properly installed, so as to guarantee the interaction with [*Talend Studio*](http://sqoop.apache.org/docs/). The following list presents MapR related information for example.
• Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under `MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native`. For example, the library for Windows is `\lib\native\MapRClient.dll` in the MapR client jar file. For further information, see the following link from MapR: [http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr](http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr).

Without adding the specified library or libraries, you may encounter the following error: `no MapRClient in java.library.path`.

• Set the `-Djava.library.path` argument, for example, in the Job Run VM arguments area of the Run/Debug view in the Preferences dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

---

**Limitation**

If you have selected the Use Commandline mode, you need to use the host where Sqoop is installed to run the Job using this component.

The preconditions required by Sqoop for using its `import-all-tables` tool must be satisfied. For further information, please see the manual of Sqoop.

**Connections**

Outgoing links (from this component to another):

**Trigger**: Run if; On Subjob Ok; On Subjob Error.

Incoming links (from one component to this one):

**Row**: Iterate;

**Trigger**: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error

For further information regarding connections, see [Talend Studio User Guide](#).

---

**Related scenarios**

No scenario is available for the Standard version of this component yet.
tSqoopMerge

Performs an incremental import that updates an older dataset with newer records. The file types of the newer and the older datasets must be the same.

tSqoopMerge reads two datasets in HDFS and combines them both using a merge class that is able to parse the datasets, with the newer records overwriting the older records.

Note:
Sqoop is typically installed in every Hadoop distribution. But if the Hadoop distribution you need to use have no Sqoop installed, you have to install one on your own and ensure to add the Sqoop command line to the PATH variable of that distribution. For further information about how to install Sqoop, see the documentation of Sqoop.

tSqoopMerge Standard properties

These properties are used to configure tSqoopMerge running in the Standard Job framework.
The Standard tSqoopMerge component belongs to the Big Data and the File families.
The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

Basic settings

<table>
<thead>
<tr>
<th>Mode</th>
<th>Select the mode in which Sqoop is called in a Job execution.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use Commandline</td>
<td>the Sqoop shell is used to call Sqoop. You can read data from either HDFS or HCatalog. In this mode, you have to deploy and run the Job in the host where Sqoop is installed. Therefore, if you are a subscription-based user, we recommend installing and using a Jobserver provided by Talend in that host to run the Job; if you are using one of the Talend solutions with Big Data, you have to ensure that the Studio and the Sqoop to be used are in the same machine.</td>
</tr>
<tr>
<td>Use Java API</td>
<td>the Java API is used to call Sqoop. In this mode, the Job can be run locally in the Studio but you need to configure the connection to the Hadoop distribution to be used. Note that JDK is required to execute the Job in the Java API mode and the versions of the JDK kits installed in both machines must be compatible with each other; for example, the versions are the same or the JDK version of the Hadoop machine is more recent.</td>
</tr>
</tbody>
</table>

Hadoop properties

Either Built-in or Repository:
- Built-in: you enter the configuration information of the Hadoop distribution to be used locally for this component only.
- Repository: you have already created the Hadoop connection and stored it in the Repository; therefore, you reuse it directly for the component configuration and the Job design. For further information about how
to create a centralized Hadoop connection, see *Talend Open Studio for Big Data Getting Started Guide*.

**Distribution**

Select the cluster you are using from the drop-down list. The options in the list vary depending on the component you are using. Among these options, the following ones requires specific configuration:

- If available in this Distribution drop-down list, the **Microsoft HD Insight** option allows you to use a Microsoft HD Insight cluster. For this purpose, you need to configure the connections to the HD Insight cluster and the Windows Azure Storage service of that cluster in the areas that are displayed. For detailed explanation about these parameters, search for configuring the connection manually on Talend Help Center (https://help.talend.com).

- If you select **Amazon EMR**, you can find more details about how to configure an Amazon EMR cluster in Talend Help Center (https://help.talend.com).

- The **Custom** option allows you to connect to a cluster different from any of the distributions given in this list, that is to say, to connect to a cluster not officially supported by *Talend*.

1. Select **Import from existing version** to import an officially supported distribution as base and then add other required jar files which the base distribution does not provide.

2. Select **Import from zip** to import the configuration zip for the custom distribution to be used. This zip file should contain the libraries of the different Hadoop elements and the index file of these libraries.

In *Talend Exchange*, members of *Talend* community have shared some ready-for-use configuration zip files which you can download from this Hadoop configuration list and directly use them in your connection accordingly. However, because of the ongoing evolution of the different Hadoop-related projects, you might not be able to find the configuration zip corresponding to your distribution from this list; then it is recommended to use the **Import from existing version** option to take an existing distribution as base to add the jars required by your distribution.

Note that custom versions are not officially supported by *Talend*. *Talend* and its community provide you with the opportunity to connect to custom versions from the Studio but cannot guarantee that the configuration of whichever version you choose will be easy, due to the wide range of different Hadoop distributions and versions that are available. As such, you should only attempt to set up such a connection if you have sufficient Hadoop experience to handle any issues on your own.

**Note:**

In this dialog box, the active check box must be kept selected so as to import the jar files pertinent to the connection to be created between the custom distribution and this component.
For a step-by-step example about how to connect to a custom distribution and share this connection, see [Connecting to a custom Hadoop distribution](#) on page 1569.

<table>
<thead>
<tr>
<th><strong>Hadoop Version</strong></th>
<th>Select the version of the Hadoop distribution you are using. The available options vary depending on the component you are using.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NameNode URI</strong></td>
<td>Type in the URI of the Hadoop NameNode, the master node of a Hadoop system. For example, we assume that you have chosen a machine called <em>masternode</em> as the NameNode, then the location is <code>hdfs://masternode:portnumber</code>. If you are using WebHDFS, the location should be <code>webhdfs://masternode:portnumber</code>; WebHDFS with SSL is not supported yet.</td>
</tr>
</tbody>
</table>
| **JobTracker Host**        | Select this check box and in the displayed field, enter the location of the ResourceManager of your distribution. For example, `tal-qall14.talend.lan:8050`. This property is required when the query you want to use is executed in Windows and it is a Select query. For example, `SELECT your_column_name FROM your_table_name` Then you can continue to set the following parameters depending on the configuration of the Hadoop cluster to be used (if you leave the check box of a parameter clear, then at runtime, the configuration about this parameter in the Hadoop cluster to be used will be ignored):

1. Select the **Set resourcemanager scheduler address** check box and enter the Scheduler address in the field that appears.
2. Select the **Set jobhistory address** check box and enter the location of the JobHistory server of the Hadoop cluster to be used. This allows the metrics information of the current Job to be stored in that JobHistory server.
3. Select the **Set staging directory** check box and enter this directory defined in your Hadoop cluster for temporary files created by running programs. Typically, this directory can be found under the `yarn.app.mapreduce.am.staging-dir` property in the configuration files such as `yarn-site.xml` or `mapred-site.xml` of your distribution.
4. Allocate proper memory volumes to the **Map** and the **Reduce** computations and the **ApplicationMaster** of YARN by selecting the **Set memory** check box in the **Advanced settings** view.
5. Select the **Set Hadoop user** check box and enter the user name under which you want to execute the Job. Since a file or a directory in Hadoop has its specific owner with appropriate read or write rights, this field allows you to execute the Job directly under the user name that has the appropriate rights to access the file or directory to be processed.
6. Select the **Use datanode hostname** check box to allow the Job to access datanodes via their hostnames. This actually sets the `dfs.client.use.datanode.hostname` property to `true`. When connecting to a S3N filesystem, you must select this check box.
For further information about these parameters, see the documentation or contact the administrator of the Hadoop cluster to be used.

For further information about the Hadoop Map/Reduce framework, see the Map/Reduce tutorial in Apache’s Hadoop documentation on http://hadoop.apache.org.

| Use kerberos authentication | If you are accessing the Hadoop cluster running with Kerberos security, select this check box, then, enter the Kerberos principal name for the NameNode in the field displayed. This enables you to use your user name to authenticate against the credentials stored in Kerberos.  

- If this cluster is a MapR cluster of the version 5.0.0 or later, you can set the MapR ticket authentication configuration in addition or as an alternative by following the explanation in Connecting to a security-enabled MapR on page 1629.  

  Keep in mind that this configuration generates a new MapR security ticket for the username defined in the Job in each execution. If you need to reuse an existing ticket issued for the same username, leave both the Force MapR ticket authentication check box and the Use Kerberos authentication check box clear, and then MapR should be able to automatically find that ticket on the fly.  

  In addition, since this component performs Map/Reduce computations, you also need to authenticate the related services such as the Job history server and the Resource manager or Jobtracker depending on your distribution in the corresponding field. These principals can be found in the configuration files of your distribution. For example, in a CDH4 distribution, the Resource manager principal is set in the yarn-site.xml file and the Job history principal in the mapred-site.xml file.  

  This check box is available depending on the Hadoop distribution you are connecting to. |
| Use a keytab to authenticate | Select the Use a keytab to authenticate check box to log into a Kerberos-enabled system using a given keytab file.  

  A keytab file contains pairs of Kerberos principals and encrypted keys. You need to enter the principal to be used in the Principal field and the access path to the keytab file itself in the Keytab field. This keytab file must be stored in the machine in which your Job actually runs, for example, on a Talend Jobserver.  

  Note that the user that executes a keytab-enabled Job is not necessarily the one a principal designates but must have the right to read the keytab file being used. For example, the user name you are using to execute a Job is user1 and the principal to be used is guest; in this situation, ensure that user1 has the right to read the keytab file to be used. |
<p>| Hadoop user name | Enter the user name under which you want to execute the Job. Since a file or a directory in Hadoop has its specific owner with appropriate read or write rights, this field allows you to execute the Job directly under the user name that has the appropriate rights to access the file or directory to be processed. Note that this field is available depending on the distribution you are using. |</p>
<table>
<thead>
<tr>
<th><strong>Old data directory</strong></th>
<th>Enter the path to the older dataset to be merged.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>New data directory</strong></td>
<td>Enter the path to the newer dataset to be merged.</td>
</tr>
<tr>
<td><strong>Target directory</strong></td>
<td>Enter the directory where you need to put the output of the merging.</td>
</tr>
<tr>
<td><strong>Merge key</strong></td>
<td>Enter the name of the column used as the key of each record for the merging. This primary key must be unique.</td>
</tr>
<tr>
<td><strong>Need to generate the JAR file</strong></td>
<td>Select this check box to generate the merge jar file and the merge class required to parse the datasets to be merged. The default name of the jar file and the class is <code>SqoopMerge_component_ID</code>. This <code>component_ID</code> is the ID of the <code>tSqoopMerge</code> component that generates the jar file and the class, such as <code>tSqoopMerge_1</code>, or <code>tSqoopMerge_2</code>. As this jar file is generated from the source table of the imported data, selecting this check box displays the corresponding parameters to be set for connecting to that table.</td>
</tr>
</tbody>
</table>
| **JDBC property**      | Either Built-in or Repository:  
  - **Built-in**: You enter the connection information of the database to be used locally for this component only.  
  - **Repository**: You have already created the database connection and stored it in the Repository; therefore, you reuse it directly for the component configuration and the Job design. For further information about how to create a centralized database connection, see [Talend Studio User Guide](#). Note that only the General JDBC connection stored in the Repository is supported. |
| **Connection**         | Enter the JDBC URL used to connect to the database where the source data is stored. |
| **User name and Password** | Enter the authentication information used to connect to the source database. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| **Table Name**         | Type in the name of the source table. This name is used to name the generated jar file. |
| **Driver JAR**         | In either the Use Commandline mode or the Java API mode, you must add the driver file of the database to be used to the lib folder of the Hadoop distribution you are using. For that purpose, use this Driver JAR table to add that driver file for the current Job you are designing. This driver jar is required only when you need to connect to the database to be used to generate the merge jar file; therefore this Driver JAR table is available only when you have selected the Need to generate the JAR file check box. |
| **JAR file** | If a required merge class already exists and is available, specify the access path to the jar file that contains that class for reusing the class.

In this situation, you need to enter the name of the class in the **Class name** field in the **Advanced settings** tab. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Print Log</strong></td>
<td>Select this check box to activate the <strong>Verbose</strong> check box.</td>
</tr>
<tr>
<td><strong>Verbose</strong></td>
<td>Select this check box to print more information while working, for example, the debugging information.</td>
</tr>
</tbody>
</table>

### Advanced settings

| **Custom class name** | Select this check box to display the **Class name** field and enter the name of the merge class you need to use.

This check box must be clear if you use **Generate the JAR file** in the **Basic settings** tab. |
| **Additional arguments** | Complete this table to use additional arguments if needs be.

By adding additional arguments, you are able to perform multiple operations in one single transaction. For example, you can use `--hive-import` and `--hive-table` in the Commandline mode or `hive.import` and `hive.table.name` in the Java API mode to create Hive table and write data in at the runtime of the transaction writing data in HDFS. For further information about the available Sqoop arguments in the Commandline mode and the Java API mode, respectively, see **Additional arguments** on page 3642. |
| **Hadoop properties** | **Talend Studio** uses a default configuration for its engine to perform operations in a Hadoop distribution. If you need to use a custom configuration in a specific situation, complete this table with the property or properties to be customized. Then at runtime, the customized property or properties will override those default ones.

- Note that if you are using the centrally stored metadata from the **Repository**, this table automatically inherits the properties defined in that metadata and becomes uneditable unless you change the **Property type** from **Repository** to **Built-in**.

For further information about the properties required by Hadoop and its related systems such as HDFS and Hive, see the documentation of the Hadoop distribution you are using or see Apache’s Hadoop documentation on [http://hadoop.apache.org/docs](http://hadoop.apache.org/docs) and then select the version of the documentation you want. For demonstration purposes, the links to some properties are listed below:

- Typically, the HDFS-related properties can be found in the `hdfs-default.xml` file of your distribution, such as [http://hadoop.apache.org/docs/r2.6.0/hadoop-project-dist/hadoop-hdfs/hdfs-default.xml](http://hadoop.apache.org/docs/r2.6.0/hadoop-project-dist/hadoop-hdfs/hdfs-default.xml).
- Apache also provides a page to list the Hive-related properties: [https://cwiki.apache.org/confluence/display/Hive/Configuration+Properties](https://cwiki.apache.org/confluence/display/Hive/Configuration+Properties). |
You can tune the map and reduce computations by selecting the Set memory check box to set proper memory allocations for the computations to be performed by the Hadoop system.

In that situation, you need to enter the values you need in the Mapred job map memory mb and the Mapred job reduce memory mb fields, respectively. By default, the values are both 1000 which are normally appropriate for running the computations.

The memory parameters to be set are Map (in Mb), Reduce (in Mb) and ApplicationMaster (in Mb). These fields allow you to dynamically allocate memory to the map and the reduce computations and the ApplicationMaster of YARN.

Path separator in server

Leave the default value of the Path separator in server as it is, unless you have changed the separator used by your Hadoop distribution’s host machine for its PATH variable or in other words, that separator is not a colon (:). In that situation, you must change this value to the one you are using in that host.

tStatCatcher Statistics

Select this check box to collect log data at the component level.

Global Variables

Global Variables

ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

EXIT_CODE: the exit code of the remote command. This is an After variable and it returns an integer.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule

This component is used standalone. It respects the Sqoop prerequisites. You need necessary knowledge about Sqoop to use it.

We recommend using the Sqoop of version 1.4+ in order to benefit the full functions of these components.

For further information about Sqoop, see the Sqoop manual on: http://sqoop.apache.org/docs/

Prerequisites

The Hadoop distribution must be properly installed, so as to guarantee the interaction with Talend Studio. The following list presents MapR related information for example.
- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under \MAPR\INSTALL\hadoop\hadoop-VERSION\lib\native. For example, the library for Windows is \lib\native\MapRClient.dll in the MapR client jar file. For further information, see the following link from MapR: [http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr](http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr).

Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path.

- Set the -Djava.library.path argument, for example, in the Job Run VM arguments area of the Run/Debug view in the Preferences dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

---

### Limitation

If you have selected the Use Commandline mode, you need to use the host where Sqoop is installed to run the Job using this component.

### Connections

Outgoing links (from this component to another):

**Trigger**: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error.

Incoming links (from one component to this one):

**Row**: Iterate;

**Trigger**: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error

For further information regarding connections, see [Talend Studio User Guide](#).

---

### Merging two datasets in HDFS

This scenario applies only to [Talend products with Big Data](#).

This scenario illustrates how to use **tSqoopMerge** to merge two datasets that are sequentially imported to HDFS from the same MySQL table, with modifications of a record in between.
The first dataset (the old one before the modifications) to be used in this scenario reads as follows:

<table>
<thead>
<tr>
<th>id, wage, mod_date</th>
</tr>
</thead>
<tbody>
<tr>
<td>0, 2000, 2008-06-26 04:25:59</td>
</tr>
<tr>
<td>1, 2300, 2011-06-12 05:29:45</td>
</tr>
<tr>
<td>3, 3000, 2010-05-02 15:34:05</td>
</tr>
</tbody>
</table>

The path to it in HDFS is /user/ychen/target_old.

The second dataset (the new one after the modifications) to be used reads as follows:

<table>
<thead>
<tr>
<th>id, wage, mod_date</th>
</tr>
</thead>
<tbody>
<tr>
<td>0, 2000, 2008-06-26 04:25:59</td>
</tr>
<tr>
<td>1, 2300, 2011-06-12 05:29:45</td>
</tr>
<tr>
<td>3, 4000, 2013-10-14 18:00:00</td>
</tr>
</tbody>
</table>

The path to it in HDFS is /user/ychen/target_new.

These datasets were both imported by tSqoopImport. For a scenario about how to use tSqoopImport, see Importing a MySQL table to HDFS on page 3662.

The Job in this scenario merges these two datasets with the newer record overwriting the older one.

Before starting to replicate this scenario, ensure that you have appropriate rights and permissions to access the Hadoop distribution to be used. Then proceed as follows:

**Dropping the component**

**Procedure**

1. In the Integration perspective of the Studio, create an empty Job from the Job Designs node in the Repository tree view.
   
   For further information about how to create a Job, see Talend Studio User Guide.

2. Drop tSqoopMerge onto the workspace.
   
   In this scenario, the required jar file for the merge is not available, you then need to use tSqoopMerge to generate it at runtime from the source MySQL table.

**Configuring tSqoopMerge**

**Procedure**

1. Double-click tSqoopMerge to open its Component view.
2. In the **Mode** area, select **Use Java API**.

3. In the **Version** area, select the Hadoop distribution to be used and its version. If you cannot find from the list the distribution corresponding to yours, select **Custom** so as to connect to a Hadoop distribution not officially supported in the Studio.

For a step-by-step example about how to use this **Custom** option, see Connecting to a custom Hadoop distribution on page 1569.

4. In the **NameNode URI** field, enter the location of the master node, the NameNode, of the distribution to be used. For example, `hdfs://talend-cdh4-namenode:8020`. If you are using WebHDFS, the location should be `webhdfs://masternode:portnumber`; WebHDFS with SSL is not supported yet.

5. In the **Resource Manager** field, enter the location of the ResourceManager of your distribution.
6. If the distribution to be used requires Kerberos authentication, select the **Use Kerberos authentication** check box and complete the authentication details. Otherwise, leave this check box clear.

If you need to use a Kerberos keytab file to log in, select **Use a keytab to authenticate**. A keytab file contains pairs of Kerberos principals and encrypted keys. You need to enter the principal to be used in the **Principal** field and the access path to the keytab file itself in the **Keytab** field. This keytab file must be stored in the machine in which your Job actually runs, for example, on a Talend Jobserver.

Note that the user that executes a keytab-enabled Job is not necessarily the one a principal designates but must have the right to read the keytab file being used. For example, the user name you are using to execute a Job is *user1* and the principal to be used is *guest*; in this situation, ensure that *user1* has the right to read the keytab file to be used.

7. In the **Old data directory** and the **New data directory** fields, enter the path, or browse to the directory in HDFS where the older and the newer datasets are stored, respectively.

8. In the **Target directory** field, enter the path, or browse to the folder you need to store the merge result in.

9. In the **Merge key** field, enter the column to be used as the key for the merge. In this scenario, the column is *id*.

10. Select **Need to generate the JAR file** to display the connection parameters to the source database table.

11. In the **Connection** field, enter the URI of the MySQL database where the source table is stored. For example, *jdbc:mysql://10.42.10.13/mysql*.

12. In the **Table Name** field, enter the name of the source table. In this scenario, it is *sqoopmerge*.

13. In **Username** and **Password**, enter the authentication information.

14. Under the **Driver JAR** table, click the [+ ] button to add one row, then in this row, click the [...] button to display the drop-down list and select the jar file to be used from that list. In this scenario, it is *mysql-connector-java-5.1.30-bin.jar*.

   If the [...] button does not appear, click anywhere in this row to make it displayed.

15. If the field delimiter of the source table is not comma (, ), you still need to specify the delimiter in the **Additional Arguments** table in the **Advanced settings** tab. The argument to be used is *codegen.output.delimiters.field* for the **Use Java API** mode or *--fields-terminated-by* for the **Use CommandLine** mode.

**Executing the Job**

Then you can press **F6** to run this Job.

During the execution, the jar file and the class for the merge are generated in the local machine.
Once done, you can verify the results in the target directory you have specified, in the web console of the Hadoop distribution used.

File: /user/ychen/merged/part-r-00000

Go back to dir listing
Advanced view/download options

If you need to obtain more details about the Job, it is recommended to use the web console of the Jobtracker provided by the Hadoop distribution you are using.

If you continue to import updated datasets to HDFS from the same source table, you can reuse the generated merge class to merge the datasets.
tSQSConnection

Opens a connection to Amazon Simple Queue Service that can then be reused by other SQS components.

**tSQSConnection Standard properties**

These properties are used to configure tSQSConnection running in the Standard Job framework.

The Standard tSQSConnection component belongs to the Cloud family.

The component in this framework is available in all Talend products.

**Basic settings**

| **Access Key** and **Secret Key** | Specify the access keys (the access key ID in the **Access Key** field and the secret access key in the **Secret Key** field) required to access the Amazon Web Services. For more information on AWS access keys, see Access keys (access key ID and secret access key).

To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings. |
| Inherit credentials from AWS role | Select this check box to leverage the instance profile credentials. These credentials can be used on Amazon EC2 instances, and are delivered through the Amazon EC2 metadata service. To use this option, your Job must be running within Amazon EC2 or other services that can leverage IAM Roles for access to resources. For more information, see Using an IAM Role to Grant Permissions to Applications Running on Amazon EC2 Instances. |
| **Assume Role** | If you temporarily need some access permissions associated to an AWS IAM role that is not granted to your user account, select this check box to assume that role. Then specify the values for the following parameters to create a new assumed role session.

Ensure that access to this role has been granted to your user account by the trust policy associated to this role. If you are not certain about this, ask the owner of this role or your AWS administrator.

- **Role ARN**: the Amazon Resource Name (ARN) of the role to assume. You can find this ARN name on the Summary page of the role to be used on your AWS portal, for example, this role ARN could read like `am:aws:iam::[aws_account_number]:role/[role_name]`.
- **Role session name**: enter the name you want to use to uniquely identify your assumed role session. This name can contain upper- and lower-case alphanumeric characters with no spaces. You can also include underscores or any of the following characters: =,@,-.
- **Session duration (minutes)**: the duration (in minutes) for which you want the assumed role session to be |
tSQSConnection active. This duration cannot exceed the maximum duration which your AWS administrator has set. For an example about an IAM role and its related policy types, see Create and Manage AWS IAM Roles from the AWS documentation.

**Region**

Specify the AWS region by selecting a region name from the list or entering a region between double quotation marks (for example "us-east-1") in the list. For more information on AWS Regions, see AWS Regions and Endpoints.

---

## Advanced settings

**Config client**

Select this check box and in the table displayed specify the client configuration parameters. Click the [+button below the table to add as many rows as needed, each row for a client configuration parameter, and set the value of the following attributes for each parameter:

- **Client Parameter**: click the cell and select a parameter from the drop-down list.
- **Value**: enter the value for the corresponding parameter.

**STS Endpoint**

Select this check box and in the field displayed, specify the AWS Security Token Service endpoint, for example, st.s.amazonaws.com, where session credentials are retrieved from.

This service allows you to request temporary, limited-privilege credentials for the AWS user you authenticate; therefore, you still need to provide the access key and secret key to authenticate the AWS account to be used.

For a list of the STS endpoints you can use, see AWS Security Token Service. For further information about the STS temporary credentials, see Temporary Security Credentials. Both articles are from the AWS documentation.

This check box is available only when the Assume role check box is selected.

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

---

## Global variables

**ERROR_MESSAGE**

The error message generated by the component when an error occurs. This is an After variable and it returns a string.

---

## Usage

**Usage rule**

This component can be used as a standalone component of a Job or Subjob.

---

## Related scenarios

- Delivering messages to an Amazon SQS queue on page 3708
• Listing Amazon SQS queues in an AWS region on page 3725
• Retrieving messages from an Amazon SQS queue on page 3694
tSQSInput

Retrieves one or more messages, with a maximum limit of ten messages, from an Amazon SQS (Simple Queue Service) queue.

**tSQSInput Standard properties**

These properties are used to configure tSQSInput running in the Standard Job framework.

The Standard tSQSInput component belongs to the Cloud family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>

</tr>
</thead>
<tbody>
<tr>
<td>Queue (Name or URL)</td>
<td>Specify the name or the URL of the queue from which messages will be retrieved.</td>
</tr>
</tbody>
</table>
| Schema and Edit schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word **line** when naming the fields. The schema of this component is predefined with the following four String type message attributes:  
  - **MessageId**: the ID of the message.  
  - **ReceiptHandle**: the receipt handle of the message.  
  - **MD5OfBody**: the MD5 digest of the message body.  
  - **Body**: the message body.  

You can click the button next to **Edit schema** to view its schema and edit the schema by removing existing attributes or adding standard SQS attributes and customized user attributes. |
| Read standard attributes | Select this check box to retrieve standard Amazon SQS attributes along with each message. For more information on the Amazon SQS attributes, see ReceiveMessage > Request Parameters. |
| Read custom user attributes | Select this check box to retrieve customized user attributes along with each message. |
| Custom visibility timeout | Select this check box and in the field displayed specify the visibility timeout (in seconds) for the received messages. If not specified, the overall visibility timeout for the queue will be used for the received messages. For more information, see Visibility Timeout. |
| Custom wait time | Select this check box and in the field displayed specify the duration (in seconds) for which the call will wait for the message to arrive in the queue before returning. |
| Delete the messages while streaming | Select this check box to delete the message while retrieving it from the queue. |
| Read all messages from the queue | Select this check box to retrieve all messages from the queue.  

This check box is not available when the **Delete the messages while streaming** check box is cleared. |
### Max number of message to return per request
Specify the maximum number of messages to return per each request. Valid values are 1 to 10.

### Die on error
Select the check box to stop the execution of the Job when an error occurs. Clear the check box to skip any error and continue the Job execution process.

### Advanced settings

#### Config client
Select this check box and in the table displayed specify the client configuration parameters. Click the [+] button below the table to add as many rows as needed, each row for a client configuration parameter, and set the value of the following attributes for each parameter:
- **Client Parameter**: click the cell and select a parameter from the drop-down list.
- **Value**: enter the value for the corresponding parameter.

#### STS Endpoint
Select this check box and in the field displayed, specify the AWS Security Token Service endpoint, for example, sts.amazonaws.com, where session credentials are retrieved from.

This service allows you to request temporary, limited-privilege credentials for the AWS user you authenticate; therefore, you still need to provide the access key and secret key to authenticate the AWS account to be used.

For a list of the STS endpoints you can use, see [AWS Security Token Service](https://docs.aws.amazon.com/STS/latest/APIReference/) For further information about the STS temporary credentials, see [Temporary Security Credentials](https://docs.aws.amazon.com/STS/latest/APIReference/). Both articles are from the AWS documentation.

This check box is available only when the **Assume role** check box is selected.

#### tStatCatcher Statistics
Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

Retrieving messages from an Amazon SQS queue

Here's an example of using Talend components to retrieve all messages from an existing Amazon SQS (Simple Queue Service) queue and then delete the empty queue.

Creating a Job for retrieving Amazon SQS messages

Create a Job to open a connection to access Amazon SQS, then retrieve all messages from an existing Amazon SQS queue, finally delete the queue.

Prerequisites: You must deliver the following message creator attribute and message body data to the Amazon SQS queue named `talend` in order to replicate this scenario.

```plaintext
#Creator;Body
Talend DOC Team;the 1st message from Talend DOC team
Talend DEV Team;the 2nd message from Talend DEV team
Talend QA Team;the 3rd message from Talend QA team
```

Procedure

1. Create a new Job and add a `tSQSConnection` component, a `tSQSInput` component, a `tLogRow` component, and a `tSQSQueueDelete` component by typing their names in the design workspace or dropping them from the Palette.

2. Link the `tSQSInput` component to the `tLogRow` component using a Row > Main connection.

3. Link the `tSQSConnection` component to the `tSQSInput` component using a Trigger > OnSubjobOk connection.

4. Link the `tSQSInput` component to the `tSQSQueueDelete` component using a Trigger > OnSubjobOk connection.

Opening a connection to access Amazon SQS

Configure the `tSQSConnection` component to open a connection to access Amazon SQS.

Procedure

1. Double-click the `tSQSConnection` component to open its Basic settings view.
2. In the **Access Key** and **Secret Key** fields, specify the authentication information required to access Amazon SQS.

3. Select an AWS region available for Amazon SQS from the **Region** drop-down list. In this example, it is Asia Pacific (Tokyo).

### Retrieving messages from an Amazon SQS queue

Configure the **tSQSInput** component and the **tLogRow** component to retrieve all messages from an existing Amazon SQS queue and display the retrieved messages on the console of Talend Studio.

#### Procedure

1. Double-click the **tSQSInput** component to open its **Basic settings** view.

2. Specify the connection details required to access Amazon SQS. In this example, select the **Use an existing connection** check box and from the **Component List** drop-down list displayed, select the connection component to reuse its connection details you have already defined.

3. In the **Queue (Name or URL)** field, enter the name for the queue from which the messages will be retrieved. In this example, it is talend.

4. Click the **button next to Edit schema** to open the schema dialog box.
You can see the schema of the `tSQSInput` component is predefined with four columns of String type: `MessageId`, `ReceiptHandle`, `MD5OfBody` and `Body`.

5. Click the button to add five columns of String type, including four Amazon SQS attributes `ApproximateFirstReceiveTimestamp`, `ApproximateReceiveCount`, `SenderId` and `SentTimestamp` and one customized attribute `Creator`.

6. Click OK to save the changes and close the schema dialog box.

7. Select the Read standard attributes and Read custom user attributes check boxes to retrieve the value of four Amazon SQS attributes and one customized user attribute along with each message.

8. Double-click the `tLogRow` component to open its Basic settings view, and then select Table (print values in cells of a table) in the Mode area for better readability of the result.

Deleting an Amazon SQS queue

Configure the `tSQSQueueDelete` component to create an Amazon SQS queue.

Procedure

1. Double-click the `tSQSQueueDelete` component to open its Basic settings view.
2. Specify the connection details required to access Amazon SQS. In this example, select the **Use an existing connection** check box and from the **Component List** drop-down list displayed, select the connection component to reuse its connection details you have already defined.

3. In the **Queue (Name or URL)** field, enter the name for the queue to be deleted. In this example, it is `talend`.

### Executing the Job to retrieve Amazon SQS messages

After setting up the Job and configuring the components used in the Job for retrieving Amazon SQS messages, you can then execute the Job and verify the Job execution result.

**Procedure**

1. Press **Ctrl + S** to save the Job and then **F6** to execute the Job.

As shown above, all three messages and their attributes are retrieved and displayed on the console.

2. View the queue details on the AWS console to validate the Job execution result.
You can see the queue `talend` has already been deleted and is not on the AWS console any more.
**tSQSMessageChangeVisibility**

Changes the visibility timeout of a specified message in an Amazon SQS (Simple Queue Service) queue.

**tSQSMessageChangeVisibility Standard properties**

These properties are used to configure `tSQSMessageChangeVisibility` running in the Standard Job framework.

The Standard tSQSMessageChangeVisibility component belongs to the Cloud family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
</table>
| **Access Key** and **Secret Key** | Specify the access keys (the access key ID in the Access Key field and the secret access key in the Secret Key field) required to access the Amazon Web Services. For more information on AWS access keys, see Access keys (access key ID and secret access key).

To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| **Inherit credentials from AWS role** | Select this check box to leverage the instance profile credentials. These credentials can be used on Amazon EC2 instances, and are delivered through the Amazon EC2 metadata service. To use this option, your Job must be running within Amazon EC2 or other services that can leverage IAM Roles for access to resources. For more information, see Using an IAM Role to Grant Permissions to Applications Running on Amazon EC2 Instances. |
| **Assume Role** | If you temporarily need some access permissions associated to an AWS IAM role that is not granted to your user account, select this check box to assume that role. Then specify the values for the following parameters to create a new assumed role session.

Ensure that access to this role has been granted to your user account by the trust policy associated to this role. If you are not certain about this, ask the owner of this role or your AWS administrator.

- **Role ARN**: the Amazon Resource Name (ARN) of the role to assume. You can find this ARN name on the Summary page of the role to be used on your AWS portal, for example, this role ARN could read like `am:aws:iam::[aws_account_number]:role/[role_name]`.
- **Role session name**: enter the name you want to use to uniquely identify your assumed role session. This |
name can contain upper- and lower-case alphanumeric characters with no spaces. You can also include underscores or any of the following characters: =,.@-.

- **Session duration (minutes):** the duration (in minutes) for which you want the assumed role session to be active. This duration cannot exceed the maximum duration which your AWS administrator has set.

For an example about an IAM role and its related policy types, see *Create and Manage AWS IAM Roles* from the AWS documentation.

<table>
<thead>
<tr>
<th>Region</th>

Then specify the values for the following parameters to create a new assumed role session. Ensure that access to this role has been granted to your user account by the trust policy associated to this role. If you are not certain about this, ask the owner of this role or your AWS administrator. • Role ARN: the Amazon Resource Name (ARN) of the role to assume. You can find this ARN name on the Summary page of the role to be used on your AWS portal, for example, this role ARN could read like am:aws:iam::[aws_account_number]:role/[role_name]. • Role session name: enter the name you want to use to uniquely identify your assumed role session. This name can contain upper- and lower-case alphanumeric characters with no spaces. You can also include underscores or any of the following characters: _@-.
• **Session duration (minutes):** the duration (in minutes) for which you want the assumed role session to be active. This duration cannot exceed the maximum duration which your AWS administrator has set.

For an example about an IAM role and its related policy types, see [Create and Manage AWS IAM Roles](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_roles_what-is.html) from the AWS documentation.

**Region**

Specify the AWS region by selecting a region name from the list or entering a region between double quotation marks (for example "us-east-1") in the list. For more information on AWS Regions, see [AWS Regions and Endpoints](https://docs.aws.amazon.com/AmazonS3/latest/userguide/using-regions.html).

**Queue (Name or URL)**

Specify the name or the URL of the queue from which a message will be deleted.

**Receipt Handle**

Specify the receipt handle associated with the message to be deleted.

**Die on error**

Select the check box to stop the execution of the Job when an error occurs.

Clear the check box to skip any error and continue the Job execution process.

**Advanced settings**

**Config client**

Select this check box and in the table displayed specify the client configuration parameters. Click the [+] button below the table to add as many rows as needed, each row for a client configuration parameter, and set the value of the following attributes for each parameter:

- **Client Parameter:** click the cell and select a parameter from the drop-down list.
- **Value:** enter the value for the corresponding parameter.

**STS Endpoint**

Select this check box and in the field displayed, specify the AWS Security Token Service endpoint, for example, `sts.amazonaws.com`, where session credentials are retrieved from.

This service allows you to request temporary, limited-privilege credentials for the AWS user you authenticate; therefore, you still need to provide the access key and secret key to authenticate the AWS account to be used.

For a list of the STS endpoints you can use, see [AWS Security Token Service](https://docs.aws.amazon.com/AmazonS3/latest/userguide/using-regions.html). For further information about the STS temporary credentials, see [Temporary Security Credentials](https://docs.aws.amazon.com/AmazonS3/latest/userguide/using-regions.html). Both articles are from the AWS documentation.

This check box is available only when the **Assume role** check box is selected.

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

**Global variables**

**ERROR_MESSAGE**

The error message generated by the component when an error occurs. This is an After variable and it returns a string.
<table>
<thead>
<tr>
<th></th>
<th>This variable functions only if the <strong>Die on error</strong> check box is selected.</th>
</tr>
</thead>
</table>

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component can be used as a standalone component of a Job or Subjob.</th>
</tr>
</thead>
</table>

### Related scenario

No scenario is available for this component yet.
tSQSOutput

Delivers one or more messages to an Amazon SQS (Simple Queue Service) queue.

**tSQSOutput Standard properties**

These properties are used to configure tSQSOutput running in the Standard Job framework.

The Standard tSQSOutput component belongs to the Cloud family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Access Key</strong> and <strong>Secret Key</strong></td>
<td>Specify the access keys (the access key ID in the <strong>Access Key</strong> field and the secret access key in the <strong>Secret Key</strong> field) required to access the Amazon Web Services. For more information on AWS access keys, see Access keys (access key ID and secret access key). To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Inherit credentials from AWS role</strong></td>
<td>Select this check box to leverage the instance profile credentials. These credentials can be used on Amazon EC2 instances, and are delivered through the Amazon EC2 metadata service. To use this option, your Job must be running within Amazon EC2 or other services that can leverage IAM Roles for access to resources. For more information, see Using an IAM Role to Grant Permissions to Applications Running on Amazon EC2 Instances.</td>
</tr>
</tbody>
</table>
| **Assume Role** | If you temporarily need some access permissions associated to an AWS IAM role that is not granted to your user account, select this check box to assume that role. Then specify the values for the following parameters to create a new assumed role session. Ensure that access to this role has been granted to your user account by the trust policy associated to this role. If you are not certain about this, ask the owner of this role or your AWS administrator.  
  - **Role ARN**: the Amazon Resource Name (ARN) of the role to assume. You can find this ARN name on the Summary page of the role to be used on your AWS portal, for example, this role ARN could read like am:aws:iam::[aws_account_number]:role/[role_name].  
  - **Role session name**: enter the name you want to use to uniquely identify your assumed role session. This name can contain upper- and lower-case alphanumeric characters with no spaces. You can also include underscores or any of the following characters:._@-.
**Session duration (minutes)**: the duration (in minutes) for which you want the assumed role session to be active. This duration cannot exceed the maximum duration which your AWS administrator has set.

For an example about an IAM role and its related policy types, see Create and Manage AWS IAM Roles from the AWS documentation.

<table>
<thead>
<tr>
<th>Region</th>
<th>Specify the AWS region by selecting a region name from the list or entering a region between double quotation marks (for example &quot;us-east-1&quot;) in the list. For more information on AWS Regions, see AWS Regions and Endpoints.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Queue (Name or URL)</td>
<td>Specify the name or the URL of the queue to which messages will be delivered. The name of a FIFO queue must end with the .fifo suffix.</td>
</tr>
</tbody>
</table>
| Schema and **Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. The schema of this component is predefined with the following columns. You can click the [...] button next to **Edit schema** to view its schema and edit the schema by adding some customized attributes for the messages to be delivered.  
  - **Body**: the body of the message to be delivered.  
  - **MessageGroupId**: the specific message group that the message belongs to. Available only when the **Use FIFO queues (first-in-first-out)** check box is selected.  
  - **MessageDeduplicationId**: the token used for deduplication of the message. Available only when the **Use FIFO queues (first-in-first-out)** check box is selected and the **Use Content Based Deduplication** check box is cleared.  
  For more information on each predefined column, see SendMessage. |
| Use batch mode | Select this check box to deliver messages to the queue using batch request. In the **Batch size** field displayed, enter the number of messages to be delivered in each batch. Note that the maximum number of messages delivered in each batch is 10. |
| Use FIFO (first-in-first-out) queues | Select this check box to deliver messages to a FIFO queue. For more information on the FIFO queue, see FIFO (First-In-First-Out) Queues. |
| Use Content Based Deduplication | Select this check box to enable content-based deduplication. With this check box selected, Amazon SQS will use a SHA-256 hash to generate the message deduplication ID using the body of the message. This property is available only when the **Use FIFO (first-in-first-out) queues** check box is selected. |
| Die on error | Select the check box to stop the execution of the Job when an error occurs. |
Clear the check box to skip any error and continue the Job execution process.

**Advanced settings**

**Config client**
Select this check box and in the table displayed specify the client configuration parameters. Click the [+] button below the table to add as many rows as needed, each row for a client configuration parameter, and set the value of the following attributes for each parameter:
- **Client Parameter**: click the cell and select a parameter from the drop-down list.
- **Value**: enter the value for the corresponding parameter.

**STS Endpoint**
Select this check box and in the field displayed, specify the AWS Security Token Service endpoint, for example, sts.amazonaws.com, where session credentials are retrieved from.

This service allows you to request temporary, limited-privilege credentials for the AWS user you authenticate; therefore, you still need to provide the access key and secret key to authenticate the AWS account to be used.

For a list of the STS endpoints you can use, see AWS Security Token Service. For further information about the STS temporary credentials, see Temporary Security Credentials. Both articles are from the AWS documentation.

This check box is available only when the Assume role check box is selected.

**tStatCatcher Statistics**
Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

**Global variables**

| **NB_LINE** | The number of rows processed. This is an After variable and it returns an integer. |
| **NB_LINE_SUCCESS** | The number of rows successfully processed. This is an After variable and it returns an integer. |
| **NB_LINE_REJECTED** | The number of rows rejected. This is an After variable and it returns an integer. |
| **ERROR_MESSAGE** | The error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is selected. |

**Usage**

**Usage rule**
This component is usually used as an end component of a Job or Subjob and it always needs an input link.
Delivering messages to an Amazon SQS queue

Here's an example of using Talend components to create an Amazon SQS (Simple Queue Service) queue, then deliver a couple of messages to the queue, finally get and display the attributes of the queue on the console.

The input messages in this example are as follows, and each message contains the message creator attribute and the message body information.

#Creator;Body
Talend DOC Team;the 1st message from Talend DOC team
Talend DEV Team;the 2nd message from Talend DEV team
Talend QA Team;the 3rd message from Talend QA team

Creating a Job for delivering Amazon SQS messages

Create a Job to open a connection to access Amazon SQS, then create an Amazon SQS queue and deliver a couple of messages to the queue, finally get and display the attributes of the queue on the console.

Procedure

1. Create a new Job and add a `tSQSConnection` component, a `tSQSQueueCreate` component, a `tFixedFlowInput` component, a `tSQSOutput` component, a `tSQSQueueAttributes` component, and a `tLogRow` component by typing their names in the design workspace or dropping them from the Palette.
2. Link the `tFixedFlowInput` component to the `tSQSOutput` component using a Row > Main connection.
3. Do the same to link the `tSQSQueueAttributes` component to the `tLogRow` component.
4. Link the `tSQSConnection` component to the `tSQSQueueCreate` component using a `Trigger > OnSubjobOk` connection.

5. Do the same to link the `tSQSQueueCreate` component to the `tFixedFlowInput` component and the `tFixedFlowInput` component to the `tSQSQueueAttributes` component.

**Opening a connection to access Amazon SQS**

Configure the `tSQSConnection` component to open a connection to access Amazon SQS.

**Procedure**

1. Double-click the `tSQSConnection` component to open its `Basic settings` view.

   ![tSQSConnection component](image)

   2. In the **Access Key** and **Secret Key** fields, specify the authentication information required to access Amazon SQS.

   3. Select an AWS region available for Amazon SQS from the **Region** drop-down list. In this example, it is **Asia Pacific (Tokyo)**.

**Creating an Amazon SQS queue**

Configure the `tSQSQueueCreate` component to create an Amazon SQS queue.

**Procedure**

1. Double-click the `tSQSQueueCreate` component to open its `Basic settings` view.

   ![tSQSQueueCreate component](image)

   2. Specify the connection details required to access Amazon SQS. In this example, select the **Use an existing connection** check box and from the **Component List** drop-down list displayed, select the connection component to reuse its connection details you have already defined.
3. In the **Queue (Name or URL)** field, specify the name for the queue to be created. In this example, it is *talend*.

4. If needed, specify the attributes for the queue to be created in the **Queue Attributes** table. In this example, the **MessageRetentionPeriod** attribute is added and its value is set to 86400, which means Amazon SQS will retain the messages delivered to the queue for 86400 seconds (1 day) instead of the default 345600 seconds (4 day).

**Delivering messages to the Amazon SQS queue**

Configure the **tFixedFlowInput** component and the **tSQSOutput** component to deliver messages to the new empty Amazon SQS queue.

**Procedure**

1. Double-click the **tSQSOutput** component to open its **Basic settings** view.

   ![tSQSOutput Component Settings](image)

   2. Specify the connection details required to access Amazon SQS. In this example, select the **Use an existing connection** check box and from the **Component List** drop-down list displayed, select the connection component to reuse its connection details you have already defined.

   3. In the **Queue (Name or URL)** field, enter the name for the queue to which the messages will be delivered. In this example, it is *talend*.

   4. Click the button next to **Edit schema** to open the schema dialog box.

   ![Schema Dialog Box](image)

   You can see the schema of the **tSQSOutput** component is predefined with a single String column **Body** that stores the body of each message to be delivered.

   5. Click the button in the right panel to add one column **Creator** of String type, which will hold the customized creator attribute value of each message.

   6. Click the button to copy all columns from the output schema to the input schema. In the pop-up dialog box, click **OK** to accept the changes.
7. Click **OK** to close the schema dialog box.

8. Double-click the **tFixedFlowInput** component to open its **Basic settings** view.

9. In the **Mode** area, select **Use Inline Content(delimited file)**. Then in the **Content** field displayed, enter the creator attribute and body data of the messages to be delivered to Amazon SQS. In this example, it is:

   - Talend DOC Team; the 1st message from Talend DOC team
   - Talend DEV Team; the 2nd message from Talend DEV team
   - Talend QA Team; the 3rd message from Talend QA team

Getting attributes of the Amazon SQS queue

Configure the **tSQSQueueAttributes** component and the **tLogRow** component to get and display the attributes of the Amazon SQS queue on the console.

**Procedure**

1. Double-click the **tSQSQueueAttributes** component to open its **Basic settings** view.

2. Specify the connection details required to access Amazon SQS. In this example, select the **Use an existing connection** check box and from the **Component List** drop-down list displayed, select the connection component to reuse its connection details you have already defined.

3. In the **Queue (Name or URL)** field, enter the name for the queue whose attributes will be retrieved. In this example, it is **talend**.

4. Double-click the **tLogRow** component to open its **Basic settings** view.

5. In the **Mode** area, select **Vertical** to display each attribute and its value in a row.

Executing the Job to deliver Amazon SQS messages

After setting up the Job and configuring the components used in the Job for delivering Amazon SQS messages, you can then execute the Job and verify the Job execution result.

**Procedure**

1. Press **Ctrl + S** to save the Job and then **F6** to execute the Job.
As shown above, the Job is executed successfully and the attributes of the queue is displayed on the console.

2. View the queue details on the AWS console to validate the Job execution result.

You can see the queue talend is created successfully with the retention period for one day, and three messages are now available in the queue.

3. Select the queue talend on the AWS console and then click **Queue Actions > View/Delete Messages** to view messages in the queue.
You can see the three messages are now available in the queue.

4. Click **More Details** for one of the messages to view the detailed information of the message.

You can see the customized **Creator** attribute value for the message is listed on the **Message Attributes** tab.
tSQSQueueAttributes

Gets attributes for a specified Amazon SQS (Simple Queue Service) queue.

**tSQSQueueAttributes Standard properties**

These properties are used to configure tSQSQueueAttributes running in the Standard Job framework. The Standard tSQSQueueAttributes component belongs to the Cloud family. The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access Key and Secret Key</td>
<td>Specify the access keys (the access key ID in the Access Key field and the secret access key in the Secret Key field) required to access the Amazon Web Services. For more information on AWS access keys, see Access keys (access key ID and secret access key). To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Inherit credentials from AWS role</td>
<td>Select this check box to leverage the instance profile credentials. These credentials can be used on Amazon EC2 instances, and are delivered through the Amazon EC2 metadata service. Select the check box to stop the execution of the Job when an error occurs.
Clear the check box to skip any error and continue the Job execution process.

**Advanced settings**

**Config client**
Select this check box and in the table displayed specify the client configuration parameters. Click the [+ ] button below the table to add as many rows as needed, each row for a client configuration parameter, and set the value of the following attributes for each parameter:

- **Client Parameter:** click the cell and select a parameter from the drop-down list.
- **Value:** enter the value for the corresponding parameter.

**STS Endpoint**
Select this check box and in the field displayed, specify the AWS Security Token Service endpoint, for example, sts.amazonaws.com, where session credentials are retrieved from.

This service allows you to request temporary, limited-privilege credentials for the AWS user you authenticate; therefore, you still need to provide the access key and secret key to authenticate the AWS account to be used.

For a list of the STS endpoints you can use, see AWS Security Token Service. For further information about the STS temporary credentials, see Temporary Security Credentials. Both articles are from the AWS documentation.

This check box is available only when the Assume role check box is selected.

**tStatCatcher Statistics**
Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

**Global variables**

**ERROR_MESSAGE**
The error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is selected.
Usage

| Usage rule | This component can be used as a standalone component of a Job or Subjob. |

Related scenario

Retrieving messages from an Amazon SQS queue on page 3694
tSQSQueueList

Iterates and lists the URL of Amazon SQS (Simple Queue Service) queues in a specified region.

**tSQSQueueList Standard properties**

These properties are used to configure tSQSQueueList running in the Standard Job framework.

The Standard tSQSQueueList component belongs to the Cloud family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access Key and Secret Key</td>
<td>Specify the access keys (the access key ID in the Access Key field and the secret access key in the Secret Key field) required to access the Amazon Web Services. For more information on AWS access keys, see Access keys (access key ID and secret access key). To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Inherit credentials from AWS role</td>
<td>Select this check box to leverage the instance profile credentials. These credentials can be used on Amazon EC2 instances, and are delivered through the Amazon EC2 metadata service. To use this option, your Job must be running within Amazon EC2 or other services that can leverage IAM Roles for access to resources. For more information, see Using an IAM Role to Grant Permissions to Applications Running on Amazon EC2 Instances.</td>
</tr>
</tbody>
</table>
| Assume Role                 | If you temporarily need some access permissions associated to an AWS IAM role that is not granted to your user account, select this check box to assume that role. Then specify the values for the following parameters to create a new assumed role session. Ensure that access to this role has been granted to your user account by the trust policy associated to this role. If you are not certain about this, ask the owner of this role or your AWS administrator.  
  - **Role ARN**: the Amazon Resource Name (ARN) of the role to assume. You can find this ARN name on the Summary page of the role to be used on your AWS portal, for example, this role ARN could read like am:aws:iam::[aws_account_number]:role/[role_name].  
  - **Role session name**: enter the name you want to use to uniquely identify your assumed role session. This name can contain upper- and lower-case alphanumeric characters with no spaces. You can also include underscores or any of the following characters: _, @-, .- |
- **Session duration (minutes)**: the duration (in minutes) for which you want the assumed role session to be active. This duration cannot exceed the maximum duration which your AWS administrator has set.

For an example about an IAM role and its related policy types, see [Create and Manage AWS IAM Roles](https://docs.aws.amazon.com/IAM/latest/userguide/IAM_Which_IAM_Is.html) from the AWS documentation.

**Region**

Specify the AWS region by selecting a region name from the list or entering a region between double quotation marks (for example "us-east-1") in the list. For more information on AWS Regions, see [AWS Regions and Endpoints](https://aws.amazon.com/about-aws/global-infrastructure/)

### Advanced settings

**Config client**

Select this check box and in the table displayed specify the client configuration parameters. Click the [+] button below the table to add as many rows as needed, each row for a client configuration parameter, and set the value of the following attributes for each parameter:

- **Client Parameter**: click the cell and select a parameter from the drop-down list.
- **Value**: enter the value for the corresponding parameter.

**STS Endpoint**

Select this check box and in the field displayed, specify the AWS Security Token Service endpoint, for example, `sts.amazonaws.com`, where session credentials are retrieved from.

This service allows you to request temporary, limited-privilege credentials for the AWS user you authenticate; therefore, you still need to provide the access key and secret key to authenticate the AWS account to be used.

For a list of the STS endpoints you can use, see [AWS Security Token Service](https://docs.aws.amazon.com/IAM/latest/userguide/sigv4-signed-requests.html). For further information about the STS temporary credentials, see [Temporary Security Credentials](https://docs.aws.amazon.com/IAM/latest/userguide/sigv4-signed-requests.html). Both articles are from the AWS documentation.

This check box is available only when the **Assume role** check box is selected.

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>CURRENT_QUEUE_NAME</code></td>
<td>The URL of the queue being processed. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td><code>NB_QUEUE</code></td>
<td>The number of queues processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><code>ERROR_MESSAGE</code></td>
<td>The error message generated by the component when an error occurs. This is an After variable and it returns a string.</td>
</tr>
</tbody>
</table>
Usage

| Usage rule | This component is usually used as a start component of a Job or Subjob and it always needs an output link. |

### Listing Amazon SQS queues in an AWS region

Here's an example of using Talend components to iterate and list the URLs of all Amazon SQS (Simple Queue Service) queues in an AWS region.

### Creating a Job for listing Amazon SQS queues

Create a Job to open a connection to access Amazon SQS, then iterate and list the URLs of all Amazon SQS queues in a specified region, finally display the total number of the queues in the region.

**Prerequisites**: You must create several Amazon SQS queues in an AWS region in order to replicate this scenario. In this example, four queues `talend`, `talend-dev`, `talend-doc` and `talend-qa` have been created in the region `Asia Pacific (Tokyo)` as shown in below figure.
Procedure

1. Create a new Job and add a tSQSConnection component, a tSQSQueueList component, a tIterateToFlow component, a tLogRow component, and a tJava component by typing their names in the design workspace or dropping them from the Palette.

2. Link the tSQSQueueList component to the tIterateToFlow component using a Row > Iterate connection.

3. Link the tIterateToFlow component to the tLogRow component using a Row > Main connection.

4. Link the tSQSConnection component to the tSQSQueueList component using a Trigger > OnSubjobOk connection.

5. Link the tSQSQueueList component to the tJava component using a Trigger > OnSubjobOk connection.

Opening a connection to access Amazon SQS

Configure the tSQSConnection component to open a connection to access Amazon SQS.

Procedure

1. Double-click the tSQSConnection component to open its Basic settings view.

2. In the Access Key and Secret Key fields, specify the authentication information required to access Amazon SQS.

3. Select an AWS region available for Amazon SQS from the Region drop-down list. In this example, it is Asia Pacific (Tokyo).

Listing all Amazon SQS queues in an AWS region

Configure the tSQSQueueList component, the tIterateToFlow component, the tLogRow component, and the tJava component to list the URLs of all Amazon SQS queues in an AWS region and display the total number of the queues in the region on the console of Talend Studio.

Procedure

1. Double-click the tSQSQueueList component to open its Basic settings view.
2. Specify the connection details required to access Amazon SQS. In this example, select the **Use an existing connection** check box and from the **Component List** drop-down list displayed, select the connection component to reuse its connection details you have already defined.

3. Double-click the **tIterateToFlow** component to open its **Basic settings** view.

4. Click the \(\text{button next to Edit schema}\) to open the schema dialog box.

5. Click the \(\text{button to add one String type column CurrentQueueURL that will hold the URLs of the queues to be listed. When done, click \text{OK} to close the dialog box.}\)

6. In the **Mapping** table, set the value for the **CurrentQueueURL** column. In this example, the value is set to \((\text{String})\text{globalMap.get("tSQSQueueList\_1\_CURRENT\_QUEUE\_NAME")})\), which is the value of the global variable \text{CURRENT\_QUEUE\_NAME} for the **tSQSQueueList** component.

   Note that you can fill the value by pressing \text{Ctrl + Space} to access the global variables list and then selecting **tSQSQueueList\_1\_CURRENT\_QUEUE\_NAME** from the list.

7. Double-click the **tLogRow** component to open its **Basic settings** view, and then select **Table (print values in cells of a table)** in the **Mode** area for better readability of the result.
8. Double-click the **tJava** component to open its **Basic settings** view.

9. In the **Code** field, enter the following code to display the total number of the queues in the region.

   ```java
   System.out.println("The number of queues: " + ((Integer)globalMap.get("tSQSQueueList_1_NB_QUEUE"));
   ```

**Executing the Job to list Amazon SQS queues**

After setting up the Job and configuring the components used in the Job for listing Amazon SQS queues, you can then execute the Job and verify the Job execution result.

**Procedure**

1. Press **Ctrl + S** to save the Job.
2. Press **F6** to execute the Job.

   ```
   [statistics] connecting to socket on port 3889
   [statistics] connected
   ----------------------------------------
   |CurrentQueueURL
   |https://sqs.ap-northeast-1.amazonaws.com/855211627039/talend
   |https://sqs.ap-northeast-1.amazonaws.com/855211627039/talend-dev
   |https://sqs.ap-northeast-1.amazonaws.com/855211627039/talend-doc
   |https://sqs.ap-northeast-1.amazonaws.com/855211627039/talend-sa
   |The number of queues: 4
   [statistics] disconnected
   ```

As shown above, the URLs of all queues in the **Asia Pacific (Tokyo)** region and the total number of the queues are displayed on the console.
**tSQSQueuePurge**

Purges messages in an Amazon SQS (Simple Queue Service) queue.

### tSQSQueuePurge Standard properties

These properties are used to configure tSQSQueuePurge running in the Standard Job framework. The Standard tSQSQueuePurge component belongs to the Cloud family. The component in this framework is available in all Talend products.

#### Basic settings

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Access Key</strong> and <strong>Secret Key</strong></td>
<td>Specify the access keys (the access key ID in the <strong>Access Key</strong> field and the secret access key in the <strong>Secret Key</strong> field) required to access the Amazon Web Services. For more information on AWS access keys, see Access keys (access key ID and secret access key). To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td><strong>Inherit credentials from AWS role</strong></td>
<td>Select this check box to leverage the instance profile credentials. These credentials can be used on Amazon EC2 instances, and are delivered through the Amazon EC2 metadata service. To use this option, your Job must be running within Amazon EC2 or other services that can leverage IAM Roles for access to resources. For more information, see Using an IAM Role to Grant Permissions to Applications Running on Amazon EC2 Instances.</td>
</tr>
<tr>
<td><strong>Assume Role</strong></td>
<td>If you temporarily need some access permissions associated to an AWS IAM role that is not granted to your user account, select this check box to assume that role. Then specify the values for the following parameters to create a new assumed role session. Ensure that access to this role has been granted to your user account by the trust policy associated to this role. If you are not certain about this, ask the owner of this role or your AWS administrator.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Role ARN</strong>: the Amazon Resource Name (ARN) of the role to assume. You can find this ARN name on the Summary page of the role to be used on your AWS portal, for example, this role ARN could read like am:aws:iam::[aws_account_number]:role/[role_name].</td>
</tr>
</tbody>
</table>
| | • **Role session name**: enter the name you want to use to uniquely identify your assumed role session. This name can contain upper- and lower-case alphanumeric characters with no spaces. You can also include underscores or any of the following characters: _.,@-.
**Session duration (minutes):** The duration (in minutes) for which you want the assumed role session to be active. This duration cannot exceed the maximum duration which your AWS administrator has set.

For an example about an IAM role and its related policy types, see [Create and Manage AWS IAM Roles](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_roles_manage.html) from the AWS documentation.

**Region**
Specify the AWS region by selecting a region name from the list or entering a region between double quotation marks (for example "us-east-1") in the list. For more information on AWS Regions, see [AWS Regions and Endpoints](https://docs.aws.amazon.com/general/latest/gr/about-aws-regions.html).

**Queue (Name or URL)**
Specify the name or the URL of the queue in which messages will be purged.

**Die on error**
Select the check box to stop the execution of the Job when an error occurs.
Clear the check box to skip any error and continue the Job execution process.

### Advanced settings

**Config client**
Select this check box and in the table displayed specify the client configuration parameters. Click the [+ ] button below the table to add as many rows as needed, each row for a client configuration parameter, and set the value of the following attributes for each parameter:

- **Client Parameter**: click the cell and select a parameter from the drop-down list.
- **Value**: enter the value for the corresponding parameter.

**STS Endpoint**
Select this check box and in the field displayed, specify the AWS Security Token Service endpoint, for example, `sts.amazonaws.com`, where session credentials are retrieved from.

This service allows you to request temporary, limited-privilege credentials for the AWS user you authenticate; therefore, you still need to provide the access key and secret key to authenticate the AWS account to be used.

This check box is available only when the **Assume role** check box is selected.

**tStatCatcher Statistics**
Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global variables

**ERROR_MESSAGE**
The error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is selected.
## Usage

| Usage rule | This component can be used as a standalone component of a Job or Subjob. |

## Related scenario

No scenario is available for this component yet.
tSSH

Establishes a communication with distant server and returns securely sensible information.
Returns data from a remote computer, based on the secure shell command defined.

**tSSH Standard properties**

These properties are used to configure tSSH running in the Standard Job framework.
The Standard tSSH component belongs to the System family.
The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Schema and Edit Schema</th>
<th>A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either Built-in or stored remotely in the Repository. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:</th>
</tr>
</thead>
<tbody>
<tr>
<td>• View schema: choose this option to view the schema only.</td>
<td></td>
</tr>
<tr>
<td>• Change to built-in property: choose this option to change the schema to Built-in for local changes.</td>
<td></td>
</tr>
<tr>
<td>• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. Click Sync columns to retrieve the schema from the preceding component in the Job.</td>
<td></td>
</tr>
<tr>
<td>Built-in: You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.</td>
<td></td>
</tr>
<tr>
<td>Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and job flowcharts. Related topic: see Talend Studio User Guide</td>
<td></td>
</tr>
<tr>
<td>Host</td>
<td>IP address</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number</td>
</tr>
<tr>
<td>User</td>
<td>User authentication information</td>
</tr>
<tr>
<td>Public Key/Key Passphrase/Private Key</td>
<td>Select the relevant option. In case of Public Key, type in the passphrase, if required, in the Key Passphrase field and then in the Private key field, type in the private key or click the three dot button next to the Private key field to browse to it.</td>
</tr>
</tbody>
</table>
To enter the passphrase, click the [...] button next to the passphrase field, and then in the pop-up dialog box enter the passphrase between double quotes and click **OK** to save the settings.

**Password/Password**  
Select the relevant option.  
In case of **Password**, type in the required password in the **Password** field.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

**Keyboard Interactive/Password**  
Select the relevant option.  
In case of **Keyboard Interactive**, type in the required password in the **Password** field.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

**Pseudo terminal**  
Select this check box to call the interactive shell that performs the terminal operations.

**Command separator**  
Type in the command separator required. Once the **Pseudo terminal** check box is selected, this field becomes unavailable.

**Commands**  
Type in the command for the relevant information to be returned from the remote computer. When you select the **Pseudo terminal** check box, this table becomes a terminal emulator and each row in this table is a single command.

**Use timeout**  
Define the timeout time period. A timeout message will be generated if the actual response time exceeds this expected processing time.

**Standard Output**  
Select the destination to which the standard output is returned. The output may be returned to:  
- **to console**: the output is displayed in the console of the **Run** view.  
- **to global variable**: the output is indicated by the corresponding global variable.  
- **both to console and global variable**: the output is indicated both of the two means.  
- **normal**: the output is a standard ssh output.

**Error Output**  
Select the destination to which the error output is returned. The output may be returned to:  
- **to console**: the output is displayed in the console of the **Run** view.  
- **to global variable**: the output is indicated by the corresponding global variable.  
- **both to console and global variable**: the output is indicated both of the two means.  
- **normal**: the output is a standard ssh output.

</tr>
</thead>
</table>
Displaying remote system information via SSH

The following use case describes a basic Job that uses SSH command to display the hostname of the distant server being connected to, and the current date on this remote system.

The tSSH component is sufficient for this Job. Drop it from the Palette to the design workspace. Double-click on the tSSH component and select the Basic settings view tab.

Procedure

1. Type in the name of the Host to be accessed through SSH as well as the Port number.
2. Fill in the User identification name on the remote machine.
3. Select the Authentication method on the list. For this use case, the authentication method used is the public key.
4. Thus fill in the corresponding Private key.
5. On the Command field, type in the following command. For this use case, type in hostname; date between double quotes.
6. Select the Use timeout check box and set the time before falling in error to 5 seconds.

picasso
Wed Sep 26 14:24:15 CEST 2007
Job uniteElisa ended at 16:26 26/09/2007. [exit code=0]
Results

The remote machine returns the host name and the current date and time as defined on its system.
tStatCatcher

Gathers the Job processing metadata at the Job level and at the component level and transfers the log data to the subsequent component for display or storage.

Based on the pre-defined schema, tStatCatcher gathers the Job processing metadata at the Job level and at the component level when the tStatCatcher Statistics check box is selected.

**tStatCatcher Standard properties**

These properties are used to configure tStatCatcher running in the Standard Job framework.

The Standard tStatCatcher component belongs to the Logs & Errors family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Schema</th>
<th>A schema is a row description, it defines the fields to be processed and passed on to the next component. In this particular case, the schema is read-only, as this component gathers standard log information including:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Moment</strong>: Processing time and date</td>
</tr>
<tr>

</tr>
<tr>
<td></td>
<td><strong>Job_repository_id</strong>: ID of the Job’s .item file stored in the repository.</td>
</tr>
<tr>
<td></td>
<td><strong>Job_version</strong>: Version of the current Job.</td>
</tr>
<tr>
<td></td>
<td><strong>Context</strong>: Name of the current context</td>
</tr>
<tr>
<td></td>
<td><strong>Origin</strong>: Name of the component if any</td>
</tr>
<tr>
<td></td>
<td><strong>Message_type</strong>: Begin or End.</td>
</tr>
<tr>
<td></td>
<td><strong>Message</strong>: Success or Failure.</td>
</tr>
<tr>
<td></td>
<td><strong>Duration</strong>: Time for the execution of a Job or a component with the tStatCatcher Statistics check box selected.</td>
</tr>
</tbody>
</table>
Global Variables

| Global Variables | ERROR MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | This component is the start component of a secondary Job which triggers automatically at the end of the main Job. The processing time is also displayed at the end of the log. |

Displaying the statistics log of Job execution

This scenario collects the statistics log for the Job execution and displays it on the Run console. Note that, since the tStatCatcher Statistics check box is not selected for the components, the statistics log applies solely to this specific Job.

Linking the components

Procedure

1. Drop tFixedFlowInput, tFileOutputDelimited, tStatCatcher and tLogRow onto the workspace.
2. Link tFixedFlowInput to tFileOutputDelimited using a Row > Main connection.
3. Link tStatCatcher to tLogRow using a Row > Main connection.
Configuring the components

Procedure

1. Double-click **tFixedFlowInput** to open its **Basic settings** view.

   ![tFixedFlowInput Basic settings](image)

   - **Number of rows**: 1
   - **Mode**: Use Inline Table
   - **Row Separator**: 
   - **Field Separator**: 
   - **Content**: 1; Andrew; 888

2. Click the **Edit schema** button to open the schema editor.

   ![tFixedFlowInput Schema](image)

3. Click the **[+]** button to add three columns, namely **ID_Owners**, **Name_Customer** and **ID_Insurance**, of the Integer and String types respectively.

4. Click **Ok** to validate the setup and close the editor.

5. In the dialog box that appears, click **Yes** to propagate the changes to the subsequent component.

   ![Propagate](image)

6. Select the **Use Inline Content (delimited file)** option.

7. In the **Content** box, enter 1; Andrew; 888.

8. Double-click **tFileOutputDelimited** to open its **Basic settings** view.
9. In the **File Name** field, enter the full name of the file to save the statistics data.

10. Double-click **tLogRow** to open its **Basic settings** view.

11. Select **Vertical (each row is a key/value list)** for a better display of the results.

**Executing the Job**

**Procedure**

1. Press **Ctrl + S** to save the Job.

2. Press **F6** to run the Job.
As shown above, the statistics log of the Job execution is correctly generated.

tSugarCRMInput

Extracts data from a SugarCRM database based on a query.
tSugarCRMInput connects to a Sugar CRM database module via the relevant webservice.

tSugarCRMInput Standard properties

These properties are used to configure tSugarCRMInput running in the Standard Job framework.
The Standard tSugarCRMInput component belongs to the Business and the Cloud families.
The component in this framework is available in all Talend products.

Basic settings

<table>
<thead>
<tr>
<th>Basic settings</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SugarCRM Webservice URL</td>
<td>Type in the webservice URL to connect to the SugarCRM DB.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>Type in the Webservice user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Module</td>
<td>Select the relevant module from the list</td>
</tr>
</tbody>
</table>

**Note:**
To use customized tables, select Use custom module from the list. The Custom module package name and Custom module name fields which appear are automatically filled in with the relevant names.

<table>
<thead>

</tr>
</thead>
<tbody>
<tr>
<td>Usually used as a Start component. An output component is required.</td>
</tr>
</tbody>
</table>

Extracting account data from SugarCRM

This scenario describes a two-component Job which extracts account information from a SugarCRM database and writes it to an Excel output file.

Setting up the Job

Procedure

1. Drop a tSugarCRMInput and a tFileOutputExcel component from the Palette onto the workspace.
2. Connect the input component to the output component using a Row > Main connection.
Configuring the input component

Procedure

1. Double-click **tSugarCRMInput** to define the component properties in its **Basic settings** view.

   2. Fill the **SugarCRM WebService URL** field with the connection information, and the **Username** and **Password** fields with the authentication you have.

   3. Select the **Module** from the list of modules offered. In this example, **Accounts** is selected.

   4. In the **Query Condition** field, type in the query you want to extract from the CRM. In this example: "billing_address_city='Sunnyvale'".

Job execution

Procedure

1. Double-click **tFileOutputExcel** to define the component properties in its **Basic settings** view.

   2. Set the destination file name as well as the **Sheet** name and select the **Include header** check box.

   3. Press **CTRL+S** to save your Job and press **F6** to execute it.
The filtered data is output in the defined spreadsheet of the specified Excel file.
tSugarCRMOutput

Writes data into a SugarCRM database.
tSugarCRMOutput writes in a Sugar CRM database module via the relevant webservice.

**tSugarCRMOutput Standard properties**

These properties are used to configure tSugarCRMOutput running in the Standard Job framework. The Standard tSugarCRMOutput component belongs to the Business and the Cloud families. The component in this framework is available in all Talend products.

**Basic settings**

<table>

</tr>
</tbody>
</table>

Usage

| Usage rule | Used as an output component. An Input component is required. |

Related scenarios

No scenario is available for the Standard version of this component yet.
tSVNLogInput

Retrieves the information of a specified revision or range of revisions from an SVN repository.

**tSVNLogInput Standard properties**

These properties are used to configure tSVNLogInput running in the Standard Job framework.

The Standard tSVNLogInput component belongs to the Internet family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>URL</th>
<th>Type in the URL to the SVN repository to be accessed.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Need authentication?</td>
<td>Select this check box if authentication is needed to access the SVN repository.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>Enter the username and password to access the SVN repository if authentication is needed. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. These two fields appear only when the Need authentication? check box is selected.</td>
</tr>
<tr>
<td>From revision</td>
<td>Specify a start revision number of the revision range.</td>
</tr>
<tr>
<td>Only this revision</td>
<td>Select this check box if you need to retrieve the information of only the revision specified in the From revision field.</td>
</tr>
<tr>
<td>To revision</td>
<td>Specify an end revision number of the revision range. Enter 'HEAD' for the latest revision. This field disappears when the Only this revision check box is selected.</td>
</tr>
<tr>
<td>Schema and Edit schema</td>
<td>A schema is a row description, it defines the fields to be processed and passed on to the next component. The schema of this component is read-only. It describes the properties of the revision information. You can click the [...] button next to Edit schema to view the predefined schema which contains the following fields: • revision: the revision number of the log message. • author: the author who commits the log message. • date: the date when the log message was committed. • message: the content of the log message. • nb_file_added: the number of added files. • nb_file_modified: the number of modified files. • nb_file_deleted: the number of deleted files.</td>
</tr>
</tbody>
</table>
Advanced settings

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

Global Variables

| Global Variables | NB_LINE: the number of rows processed. This is an After variable and it returns an integer. |
|                 | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. |
|                 | A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. |
|                 | To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. |
|                 | For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | This component is usually used as a start component in a Job and it needs an output link. |
| Connections | Outgoing links (from this component to another): |
|             | Row: Main, Iterate |
|             | Trigger: On Subjob Ok, On Subjob Error, Run if, On Component Ok, On Component Error |
|             | Incoming links (from one component to this one): |
|             | Row: Main, Iterate |
|             | Trigger: On Subjob Ok, On Subjob Error, Run if, On Component Ok, On Component Error |
|             | For further information about connections, see Talend Studio User Guide. |

Retrieving a log message from an SVN repository

This scenario describes a two-component Job that retrieves the information of a specified revision from an SVN repository, and displays the information on the console.
Procedure

1. Create a new Job and add the following two components by typing their names in the design workspace or dropping them from the Palette: a tSVNLogInput component and a tLogRow component.
2. Connect tSVNLogInput to tLogRow using a Row > Main link.
3. Double-click tSVNLogInput to open its Basic settings view.

![tSVNLogInput_1](image)

4. In the URL field, enter the URL to the SVN repository to be accessed. In this example, it is `https://talend.com/svndoc/`. Note that the login credentials provided here is for demonstration only.
5. Select the Need authentication? check box and fill in the Username and Password fields with your authentication information.
6. Specify a revision or revision range. In this example, we want to retrieve the information of revision 17090 only, so enter `17090` in the From revision field and select the Only this revision check box.
7. Double-click tLogRow to open its Basic settings view.

![tLogRow_1](image)

8. Define the way you want the output data to be displayed on the console. In this example, enter `\r
` in the Field Separator field to display each field of the revision information in a separate line.
9. Select the Print schema column name in front of each value check box to show the name of each field of the revision information at the beginning of each line.
10. Press Ctrl + S to save the Job and then F6 to run the Job.
As shown above, the information of the specified revision is displayed on the console.
**tSybaseBulkExec**

Gains in performance during Insert operations to a Sybase database.

The tSybaseOutputBulk and tSybaseBulkExec components are generally used together as parts of a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tSybaseOutputBulkExec component, detailed in a separate section. The advantage of using two separate components is that the data can be transformed before it is loaded in the database.

**tSybaseBulkExec Standard properties**

These properties are used to configure tSybaseBulkExec running in the Standard Job framework.

The Standard tSybaseBulkExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

---

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

---

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td>Built-in: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
<td></td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined.

---

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see [Talend Studio User Guide](#).
<table>
<thead>
<tr>
<th><strong>DB Version</strong></th>

<td>Database server IP address</td>
</tr>
<tr>
<td></td>
<td>Available when you select <strong>Bulk Update</strong> from the <strong>Action on data</strong> list in the <strong>Advanced settings</strong> view of <strong>tSybaseBulkExec</strong>.</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td></td>
<td>Available when you select <strong>Bulk Update</strong> from the <strong>Action on data</strong> list in the <strong>Advanced settings</strong> view of <strong>tSybaseBulkExec</strong>.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Database name</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Sybase Schema</strong></td>
<td>Name of the database schema you want to use.</td>
</tr>
<tr>
<td><strong>Bcp Utility</strong></td>
<td>Name of the utility to be used to copy data over to the Sybase server.</td>
</tr>
<tr>
<td><strong>Server</strong></td>
<td>IP address of the database server for the Bcp utility connection.</td>
</tr>
<tr>
<td><strong>Batch size</strong></td>
<td>Number of lines in each processed batch.</td>
</tr>
<tr>
<td><strong>Table</strong></td>
<td>Name of the table to be written. Note that only one table can be written at a time and that the table must exist for the insert operation to succeed.</td>
</tr>
<tr>
<td><strong>Action on table</strong></td>
<td>On the table defined, you can perform one of the following operations:</td>
</tr>
<tr>
<td></td>
<td><strong>None</strong>: No operation is carried out.</td>
</tr>
<tr>
<td></td>
<td><strong>Drop and create table</strong>: The table is removed and created again.</td>
</tr>
<tr>
<td></td>
<td><strong>Create table</strong>: The table does not exist and gets created.</td>
</tr>
<tr>
<td></td>
<td><strong>Create table if not exists</strong>: The table is created if it does not exist.</td>
</tr>
<tr>
<td></td>
<td><strong>Drop table if exists and create</strong>: The table is removed if it already exists and created again.</td>
</tr>
<tr>
<td></td>
<td><strong>Clear table</strong>: The table content is deleted.</td>
</tr>
<tr>
<td></td>
<td><strong>Truncate table</strong>: The table content is deleted. You do not have the possibility to rollback the operation.</td>
</tr>
<tr>
<td><strong>File Name</strong></td>
<td>Name of the file to be loaded.</td>
</tr>
<tr>
<td><strong>Warning:</strong></td>
<td>This file should be located on the same machine as the database server.</td>
</tr>
<tr>
<td><strong>Schema and Edit Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next</td>
</tr>
</tbody>
</table>
When you create a Spark Job, avoid the reserved word `line` when naming the fields.

| **Built-In** | You create and store the schema locally for this component only. |
| **Repository** | You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually. You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com). |

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No upon completion** and choose this schema metadata again in the **Repository Content** window.

**Advanced settings**

<p>| Use an interface file | Select this check box to specify an interface file in the field <strong>Interface file</strong>. |
| Additional JDBC parameters | Specify additional connection properties in the existing DB connection, to allow specific character set support. E.G.: CHARSET=KANJISJIS_OS to get support of Japanese characters. |
| Action on data | On the data of the table defined, you can perform: <strong>Bulk Insert</strong>: Add multiple entries to the table. If duplicates are found, Job stops. <strong>Bulk Update</strong>: Make simultaneous changes to multiple entries. |
| Field Terminator | Character, string or regular expression to separate fields. <strong>Warning</strong>: With the row/field separators compliant with the Sybase syntax, this component allows for the use of Sybase-oriented characters, such as <code>\x09</code>. |
| Row Terminator | String (ex: &quot;\n&quot; in Unix) to separate lines. |</p>
<table>

<tr>
<td>As opposed to the Oracle dedicated bulk component, no action on data is possible using this Sybase dedicated component.</td>
</tr>
<tr>
<td>This component requires installation of its related jar files.</td>
</tr>
</tbody>
</table>

**Related scenarios**

For **tSybaseBulkExec** related topics, see:

- Inserting transformed data in MySQL database on page 2493.
- Truncating and inserting file data into an Oracle database on page 2700.
**tSybaseClose**

Closes a transaction committed in the connected database.

**tSybaseClose Standard properties**

These properties are used to configure tSybaseClose running in the Standard Job framework.

The Standard tSybaseClose component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the <strong>tSybaseConnection</strong> component in the list if more than one connection are planned for the current Job.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is to be used along with Sybase components, especially with **tSybaseConnection** and **tSybaseCommit**. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |
Related scenario

This component is to be used with `tSybaseConnection` and `tSybaseRollback` components. It is generally used with a `tSybaseConnection` to close a connection for the ongoing transaction.

For a related scenario `tSybaseClose`, see `tMysqlConnection` on page 2436.
**tSybaseCommit**

Commits in one go, using a unique connection, a global transaction instead of doing that on every row or every batch and thus provides gain in performance.

tSybaseCommit validates the data processed through the Job into the connected DB.

**tSybaseCommit Standard properties**

These properties are used to configure tSybaseCommit running in the Standard Job framework.

The Standard tSybaseCommit component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the <strong>tSybaseConnection</strong> component in the list if more than one connection are planned for the current Job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Warning:**

If you want to use a Row > Main connection to link tSybaseCommit to your Job, your data will be committed row by row. In this case, do not select the Close connection check box or your connection will be closed before the end of your first row commit.

### Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

### Usage

| Usage rule | This component is more commonly used with other tSybase* components, especially with the **tSybaseConnection** and **tSybaseRollback** components. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to acces |
s database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

## Related scenario

For tSybaseCommit related scenario, see Inserting data in mother/daughter tables on page 2437.
tSybaseConnection

Opens a connection to the database for a current transaction.

**tSybaseConnection Standard properties**

These properties are used to configure tSybaseConnection running in the Standard Job framework.

The Standard tSybaseConnection component belongs to the Databases and the ELT families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

<tr>
<td>Database</td>
<td>The name of the database.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>The database user authentication data.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td>Schema</td>
<td>The schema of the database.</td>
</tr>
<tr>
<td>Additional JDBC Parameters</td>
<td>Specify additional JDBC parameters for the database connection being created.</td>
</tr>
<tr>
<td>Use or register a shared DB Connection</td>
<td>Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the Shared DB Connection Name field displayed, enter the name for the shared database connection. This</td>
</tr>
</tbody>
</table>
allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child.

This option is incompatible with the Use dynamic job and Use an independent process to run subjob options of the tRunJob component. Using a shared connection together with a tRunJob component with either of these two options enabled will cause your Job to fail.

**Advanced settings**

| **Auto Commit** | Select this check box to commit any changes to the database automatically upon the transaction. With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component. Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component. |
| **tStatCatcher Statistics** | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Usage**

| **Usage rule** | This component is more commonly used with other tSybase* components, especially with the tSybaseCommit and tSybaseRollback components. |

**Related scenarios**

For a tSybaseConnection related scenario, see Inserting data in mother/daughter tables on page 2437.
tSybaseInput

Executes a DB query with a strictly defined order which must correspond to the schema definition. tSybaseInput reads a database and extracts fields based on a query. It passes on the field list to the next component via a Main row link.

**tSybaseInput Standard properties**

These properties are used to configure tSybaseInput running in the Standard Job framework. The Standard tSybaseInput component belongs to the Databases family. The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>

<td>details you already defined.</td>
</tr>
</tbody>
</table>
**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th>DB Version</th>
<th>Select the version of the Sybase database to be used from the drop-down list.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server</td>
<td>Database server IP address</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database</td>
</tr>
<tr>
<td>Sybase Schema</td>
<td>Exact name of the Sybase schema.</td>
</tr>
</tbody>
</table>

**Username and Password**

- DB user authentication data.
- To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

**Schema and Edit Schema**

- A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

- **Built-In:** You create and store the schema locally for this component only.

- **Repository:** You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

- Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:
  - **View schema:** choose this option to view the schema only.
  - **Change to built-in property:** choose this option to change the schema to **Built-in** for local changes.
  - **Update repository connection:** choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No upon**
Table Name
Name of the table to read.

Query type and Query
Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.

Advanced settings

Trim all the String/Char columns
Select this check box to remove leading and trailing whitespace from all the String/Char columns.

Trim column
Remove leading and trailing whitespace from defined columns.

tStat Catcher Statistics
Select this check box to collect log data at the component level.

Global Variables

Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NB_LINE</td>
<td>the number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>QUERY</td>
<td>the query statement being processed. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td>ERROR_MESSAGE</td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule
This component covers all possible SQL queries for Sybase databases.

Dynamic settings
Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.
The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

### Limitation

This component requires installation of its related jar files.

## Related scenarios

For related topics, see:

- Reading data from different MySQL databases using dynamically loaded connection parameters on page 491.
**tSybaseIQBulkExec**

Loads data into a Sybase database table from a flat file or other database table.

**tSybaseIQBulkExec Standard properties**

These properties are used to configure tSybaseIQBulkExec running in the Standard Job framework.

The Standard tSybaseIQBulkExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
</table>

**Property Type**

Select the way the connection details will be set.

- **Built-In**: The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.
- **Repository**: The connection details stored centrally in Repository > Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up Repository Content dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in.

**Use an existing connection**

Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined.

When reusing an existing Sybase 16 (SQL Anywhere) connection created by a tSybaseConnection component and loading data from a file located on the client side, you need to select Sybase 16 (SQL Anywhere) from the **DB Version** drop-down list to display the Is client file check box before selecting this check box.
Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

This property is not available when **Sybase IQ 15** is selected from the **DB Version** drop-down list.

<table>
<thead>

<tbody>
<tr>
<td>Lines terminated by</td>
<td>The character or sequence of characters used to separate lines. This property is not available when the Use Insert-Location check box is selected.</td>
</tr>
<tr>
<td>Fields terminated by</td>
<td>The character, string or regular expression used to separate fields.</td>
</tr>
</tbody>
</table>
With the row/field separators compliant with the Sybase syntax, this component allows the use of Sybase-oriented separators, such as `\x09`.

This property is not available when the **Use Insert-Location** or **Use fixed length** check box is selected.

**Use enclosed quotes**

Select this check box to use data enclosure characters.

This property is not available when the **Use Insert-Location** or **Use fixed length** check box is selected.

**Use fixed length**

Select this check box to set a fixed width for data lines.

This property is not available when the **Use Insert-Location** check box is selected.

**Include Header**

Select this check box if the file that will be loaded includes header.

This property is not available when the **Use Insert-Location** check box is selected.

**Blank as null**

Select this check box to store the input zero-length varchars as NULLs instead of blanks in the database during the load operation.

This property is not available when the **Use Insert-Location** or **Use fixed length** check box is selected.

**On file error**

Select the action Sybase performs when an error occurs:

- **Rollback (default)**: rolls back the entire transaction.
- **Finish**: finishes the insertions already completed and ends the load operation.
- **Continue**: skips the error and continues the load operation.

This property is available when **Sybase 16 (SQL Anywhere)** is selected from the **DB Version** drop-down list.

**Message log file**

The path to the MESSAGE LOG file that saves the log information about integrity constraint violations, the types of violations, etc. It must be specified together with the **Row log file** property.

This property is available when **Sybase 16 (SQL Anywhere)** is selected from the **DB Version** drop-down list.

**Row log file**

The path to the ROW LOG file that saves the log information about reject data, the timestamps of the start and completion of the load, etc. It must be specified together with the **Message log file** property.

This property is available when **Sybase 16 (SQL Anywhere)** is selected from the **DB Version** drop-down list.

**Location Options**

<td></td>
</tr>
<tr>
<td><strong>Word Skip Number</strong></td>
<td>Enter the number of times the error <em>Words exceeding the maximum permitted word length not supported</em> is ignored when loading data into the Sybase IQ table. This property is available only when the <strong>Insert Select Load Options</strong> check box is selected.</td>
<td></td>
</tr>
</tbody>
</table>
| **Ignore Constraint**      | Select this check box and in the table displayed you can specify the integrity constraint violation to ignore when loading data into the Sybase IQ table by clicking the [+] button to add as many rows as needed, each row for a constraint violation, and setting the value of the following columns for each constraint violation:  

  - **Constraint Type**: Click the cell and from the drop-down list displayed select the type of the constraint violation to ignore.  
  - **Number**: Enter the maximum number of the constraint violation to ignore before initiating a rollback during a load.  

  This property is available only when the **Insert Select Load Options** check box is selected. |
| **Log In File**            | Select this check box if you want to log the constraint violation information in files. This property is available only when the **Insert Select Load Options** check box is selected. |
| **Message Log**            | Specify the path to the MESSAGE LOG file. This property is available only when the **Log In File** check box is selected. |
| **Row Log**                | Specify the path to the ROW LOG file. This property is available only when the **Log In File** check box is selected. |
| **Log Delimited By**       | Specify the separator between data values in the ROW LOG file. This property is available only when the **Log In File** check box is selected. |
| **Log Filter**             | Select this check box and from the **Only Log** drop-down list displayed select the type of the constraint violation information to be logged. This property is available only when the **Log In File** check box is selected. |
| **tStatCatcher Statistics**| Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |
Usage

| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |

Related scenarios

For tSybaseIQBulkExec related topics, see:

- Bulk-loading data to a Sybase IQ 12 database on page 3779.
- Inserting transformed data in MySQL database on page 2493.
- Truncating and inserting file data into an Oracle database on page 2700.
tSybaseIQOutputBulkExec

Gains in performance during Insert operations to a Sybase IQ database.
tSybaseIQOutputBulkExec executes the Insert action on the data provided.

**tSybaseIQOutputBulkExec Standard properties**

These properties are used to configure tSybaseIQOutputBulkExec running in the Standard Job framework.

The Standard tSybaseIQOutputBulkExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>

</tbody>
</table>

This property is not available when Sybase IQ 15 is selected from the DB Version drop-down list.
| **DB Version** | Select the version of the Sybase database to be used from the drop-down list.  
  • For Sybase IQ 12 and Sybase IQ 16, the file to be bulk-loaded must be located on the same machine as the Sybase IQ server.  
  • For Sybase IQ 15, the file to be bulk-loaded can be located on the client side, however, this means certain setup on the Sybase IQ server. For more information, see Sybase IQ client-side load support enhancements.  
  • For Sybase 16 (SQL Anywhere), the file to be bulk-loaded can be located on both the server side and the client side.  
  Before loading data into Sybase 16 (SQL Anywhere), SQL Anywhere 17 must be installed. You can download it here. Once the installation is done, you need to check the system variable `Path` to make sure the installation path of SQL Anywhere 17 has been added to it, and then restart the Studio (in certain case restart the computer) to have the new `Path` variable take effect. |
| **Host** | The IP address or hostname of the database.  
  This property is not available when **Sybase IQ 15** is selected from the **DB Version** drop-down list. |
| **Port** | The listening port number of the database.  
  This property is not available when **Sybase IQ 15** is selected from the **DB Version** drop-down list. |
| **Data Source** | Select the type of the data source to be used and complete the corresponding DSN information in the field alongside.  
  The available types are DSN and FILEDSN.  
  When FILEDSN is selected, a [...] button is available next to the **Data Source** field to allow you to browse to the data source file of interest.  
  This property is available when **Sybase IQ 15** is selected from the **DB Version** drop-down list. |
| **Database** | The name of the database. |
| **Sybase Schema** | The schema of the database. |
| **Username and Password** | The database user authentication data.  
  To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings. |
| **Table** | The name of the table to be written. |
| **Action on table** | On the table defined, you can perform one of the following operations:  
  • **Default**: No operation is carried out.  
  • **Drop and create table**: The table is removed and created again.  
  • **Create table**: The table does not exist and gets created. |
<table>
<thead>
<tr>
<th><strong>tSybaseIQOutputBulkExec</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Create table if does not exist</strong>: The table is created if it does not exist.</td>
</tr>
<tr>
<td><strong>Drop table if exists and create</strong>: The table is removed if it already exists and created again.</td>
</tr>
<tr>
<td><strong>Clear table</strong>: The table content is deleted.</td>
</tr>
</tbody>
</table>

### Filename
Enter the name of the file to be generated and loaded.

### Is client file
Select this check box if you need to load data from the client side.
This property is available when Sybase 16 (SQL Anywhere) is selected from the DB Version drop-down list.

### Append the file
Select this check box to add the new rows at the end of the records.

### Schema and Edit schema
A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

- **Built-in**: You create and store the schema locally for this component only.
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Click **Edit schema** to make changes to the schema. Note that if you make changes, the schema automatically becomes built-in.

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

### Advanced settings

| **Additional JDBC Parameters** | Specify additional connection properties in the existing DB connection, to allow specific character set support. |
| **Fields terminated by** | Enter the character, string or regular expression used to separate fields. |
Warning:
As a combination of `tSybaseOutputBulk` and `tSybaseIQBulkExec`, this component does not allow the use of Sybase-oriented row/field separators, such as `\x09`. To achieve the desired effect (for example, displaying fields in the tabular form), you need to use `tSybaseOutputBulk` and `tSybaseIQBulkExec` together to replace `tSybaseIQOutputBulkExec`, with `\t` used in the former component and `\x09` used in the latter.

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lines terminated by</td>
<td>Enter the character or sequence of characters used to separate lines.</td>
</tr>
<tr>
<td>Use enclosed quotes</td>
<td>Select this check box to use data enclosure characters.</td>
</tr>
<tr>
<td>Include Head</td>
<td>Select this check box to include the column header.</td>
</tr>
<tr>
<td>Blank as null</td>
<td>Select this check box to store the input zero-length vchars as NULLs instead of blanks in the database during the load operation.</td>
</tr>
<tr>
<td>On file error</td>
<td>Select the action Sybase performs when an error occurs:</td>
</tr>
<tr>
<td></td>
<td>• Rollback (default): rolls back the entire transaction.</td>
</tr>
<tr>
<td></td>
<td>• Finish: finishes the insertions already completed and ends the load operation.</td>
</tr>
<tr>
<td></td>
<td>• Continue: skips the error and continues the load operation.</td>
</tr>
<tr>
<td>Message log file</td>
<td>The path to the MESSAGE LOG file that saves the log information about integrity constraint violations, the types of violations, etc. It must be specified together with the Row log file property.</td>
</tr>

<tr>
<td></td>
<td>This property is available when Sybase 16 (SQL Anywhere) is selected from the DB Version drop-down list.</td>
</tr>
<tr>
<td>Encoding</td>
<td>Select the encoding type from the list or select Custom and define it manually. This field is compulsory for DB data handling.</td>
</tr>
<tr>
<td>tStatCatcher Statistics</td>
<td>Select this check box to gather the Job processing metadata at the Job level as well as at each component level.</td>
</tr>
</tbody>
</table>
**Usage**

| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see **Reading data from databases through context-based dynamic connections** on page 2457 and **Reading data from different MySQL databases using dynamically loaded connection parameters** on page 491. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide. |
| Usage rule | This component is mainly used when no particular transformation is required on the data to be loaded onto the database. |

---

**Bulk-loading data to a Sybase IQ 12 database**

This scenario describes a Job that writes data generated by a **tRowGenerator** component into a file and then bulk-loads the data from the file to a Sybase IQ 12 database.

![Diagram](image)

**Adding and linking the components**

**Procedure**

1. Create a new Job and add a **tRowGenerator** component and a **tSybaseIQOutputBulkExec** component by typing their names in the design workspace or dropping them from the **Palette**.
2. Link the **tRowGenerator** component to the **tSybaseIQOutputBulkExec** component using a **Row > Main** connection.

**Configuring the components**

**Procedure**

1. Double-click the **tRowGenerator** component to open its **RowGenerator Editor**.
2. Click the [+] button to add two columns and set their properties:
   - `id`, Integer type, using `Numeric.sequence(String,int,int)` from the Functions list to generate sequence numbers.
   - `name`, String type, using `TalendDataGenerator.getFirstName()` from the Functions list to generate random first names.
3. In the Number of Rows for RowGenerator field, enter the number of rows to be generated. In this example, keep the default value 100.
4. Click OK to close the editor and in the pop-up dialog box click Yes to propagate the schema to the next component.
5. Double-click the tSybaseIQOutputBulkExec component to open its Basic settings view.
6. In the **Host**, **Port**, **Database**, **Username** and **Password** fields, enter the information required to access the Sybase IQ 12 database.

7. In the **Table** field, enter the name of the table into which the data will be written. In this example, it is **staff**.

8. In the **Action on table** list, select **Create table if not exists**.

9. In the **Filename** field, enter the full path of the file to hold the data.

### Saving and executing the Job

**Procedure**

1. Press **Ctrl+S** to save the Job.

2. Press **F6** to run the Job.

   ```
   Starting job usecase_sybase at 14:50 14/11/2012
   [statistics] connecting to socket on port 3643
   [statistics] connected
   [statistics] disconnected
   Job usecase_sybase ended at 14:50 14/11/2012. [exit code=0]
   ```

3. In the Sybase Central console, open the table **staff** to check the data:
As shown above, the table is created with data inserted.

**Related scenarios**

For use cases in relation with `tSybaseIQOutputBulkExec`, see the following scenarios:

- Inserting transformed data in MySQL database on page 2493.
- Inserting data in bulk in MySQL database on page 2500.
- Truncating and inserting file data into an Oracle database on page 2700.
tSybaseOutput

Executes the action defined on the table and/or on the data contained in the table, based on the flow incoming from the preceding component in the job.

tSybaseOutput writes, updates, makes changes or suppresses entries in a database.

**tSybaseOutput Standard properties**

These properties are used to configure tSybaseOutput running in the Standard Job framework.

The Standard tSybaseOutput component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in:</strong> No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td><strong>Repository:</strong> Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
<td></td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined.

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

Click this icon to open a database connection wizard and store the database connection parameters you set in the component **Basic settings** view.
<table>
<thead>
<tr>
<th><strong>DB Version</strong></th>
<th>Select the version of the Sybase database to be used from the drop-down list.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Server</strong></td>
<td>Database server IP address</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database</td>
</tr>
<tr>
<td><strong>Sybase Schema</strong></td>
<td>Exact name of the Sybase schema.</td>
</tr>
</tbody>
</table>
| **Username and Password** | DB user authentication data.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| **Table**      | Name of the table to be written. Note that only one table can be written at a time |
| **Action on table** | On the table defined, you can perform one of the following operations:  
  **Default:** No operation is carried out.  
  **Drop and create table:** The table is removed and created again.  
  **Create table:** The table does not exist and gets created.  
  **Create table if not exists:** The table is created if it does not exist.  
  **Drop table if exists and create:** The table is removed if it already exists and created again.  
  **Clear table:** The table content is deleted.  
  **Truncate table:** The table content is deleted. You do not have the possibility to rollback the operation. |
| **Turn on identity insert** | Select this check box to use your own sequence for the identity value of the inserted records (instead of having the SQL Server pick the next sequential value). |
| **Action on data** | On the data of the table defined, you can perform:  
  **Insert:** Add new entries to the table. If duplicates are found, job stops.  
  **Update:** Make changes to existing entries  
  **Insert or update:** Insert a new record. If the record with the given reference already exists, an update would be made.  
  **Update or insert:** Update the record with the given reference. If the record does not exist, a new record would be inserted.  
  **Delete:** Remove entries corresponding to the input flow. |
Warning:

It is necessary to specify at least one column as a primary key on which the Update and Delete operations are based. You can do that by clicking Edit Schema and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the Advanced settings view where you can simultaneously define primary keys for the Update and Delete operations. To do that:

Select the Use field options check box and then in the Key in update column, select the check boxes next to the column names you want to use as a base for the Update operation. Do the same in the Key in delete column for the Delete operation.

<table>
<thead>
<tr>
<th>Schema and Edit schema</th>
<th>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Built-In: You create and store the schema locally for this component only.</td>
<td>Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually. You can find more details about how to verify default values in retrieved schema in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
</tbody>
</table>
| Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available: • **View schema:** choose this option to view the schema only. • **Change to built-in property:** choose this option to change the schema to Built-in for local changes. • **Update repository connection:** choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. | Die on error
This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a Row > Rejects link. |

Advanced settings

| Commit every | Enter the number of rows to be completed before committing batches of rows together into the DB. This |
option ensures transaction quality (but not rollback) and, above all, better performance at execution.

### Additional Columns
This option is not offered if you create (with or without drop) the DB table. This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing.

- **Name:** Type in the name of the schema column to be altered or inserted as new column
- **SQL expression:** Type in the SQL statement to be executed in order to alter or insert the relevant column data.
- **Position:** Select Before, Replace or After following the action to be performed on the reference column.
- **Reference column:** Type in a column of reference that the tDBOutput can use to place or replace the new or altered column.

### Use field options
Select this check box to customize a request, especially when there is double action on data.

### Enable debug mode
Select this check box to display each step during processing entries in a database.

### Use Batch
Select this check box to activate the batch mode for data processing.

**Note:**
This check box is available only when you have selected the Insert, the Update or the Delete option in the Action on data field.

### Batch Size
Specify the number of records to be processed in each batch.
This field appears only when the Use batch mode check box is selected.

### tStatCatcher Statistics
Select this check box to collect log data at the component level.

### Global Variables
- **NB_LINE:** the number of rows processed. This is an After variable and it returns an integer.
- **NB_LINE_UPDATED:** the number of rows updated. This is an After variable and it returns an integer.
- **NB_LINE_INSERTED:** the number of rows inserted. This is an After variable and it returns an integer.
- **NB_LINE_DELETED:** the number of rows deleted. This is an After variable and it returns an integer.
- **NB_LINE_REJECTED:** the number of rows rejected. This is an After variable and it returns an integer.
### Usage

**Usage rule**

This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible.

This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in a Sybase database. It also allows you to create a reject flow using a Row > Rejects link to filter data in error.

For an example of tMySqlOutput in use, see Retrieving data in error with a Reject link on page 2485.

**Dynamic settings**

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

**Limitation**

This component requires installation of its related jar files.

### Related scenarios

For use cases in relation with tSybaseOutput, see:

- Inserting a column and altering data using tMysqlOutput on page 2477.
tSybaseOutputBulk

Prepares the file to be used as parameter in the INSERT query to feed the Sybase database.

The tSybaseOutputBulk and tSybaseBulkExec components are generally used together as parts of a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tSybaseOutputBulkExec component, detailed in a separate section. The advantage of using two separate components is that the data can be transformed before it is loaded in the database.

Writes a file with columns based on the defined delimiter and the Sybase standards.

**tSybaseOutputBulk Standard properties**

These properties are used to configure tSybaseOutputBulk running in the Standard Job framework. The Standard tSybaseOutputBulk component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>

</tr>
</tbody>
</table>
**Repository:** You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema:** choose this option to view the schema only.
- **Change to built-in property:** choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection:** choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

### Advanced settings

<table>
<thead>
<tr>
<th><strong>Row separator</strong></th>
<th>String (ex: &quot;\n&quot;on Unix) to distinguish rows.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Field separator</strong></td>
<td>Character, string or regular expression to separate fields.</td>
</tr>
</tbody>
</table>

**Warning:** 
*Fully in line with the Java syntax, this component does not allow the use of Sybase-orientated row/field separators, such as \x09.*

<table>
<thead>
<tr>
<th><strong>Include header</strong></th>
<th>Select this check box to include the column header in the file.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Encoding</strong></td>
<td>Select the encoding from the list or select Custom and define it manually. This field is compulsory for DB data handling.</td>
</tr>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to collect log data at the component level</td>
</tr>
</tbody>
</table>

### Global Variables

- **NB_LINE:** the number of rows processed. This is an After variable and it returns an integer.
- **ERROR_MESSAGE:** the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component requires installation of its related jar files. This component is to be used along with <em>tSybaseBulkExec</em> component. Used together they offer gains in performance while feeding a Sybase database.</th>
</tr>
</thead>
</table>

| Component family | Databases/Sybase |

**Related scenarios**

For use cases in relation with *tSybaseOutputBulk*, see the following scenarios:

- Inserting transformed data in MySQL database on page 2493.
- Inserting data in bulk in MySQL database on page 2500.
- Truncating and inserting file data into an Oracle database on page 2700.
tSybaseOutputBulkExec

Gains in performance during Insert operations to a Sybase database.

The tSybaseOutputBulk and tSybaseBulkExec components are generally used together as parts of a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tSybaseOutputBulkExec component.

tSybaseOutputBulkExec Standard properties

These properties are used to configure tSybaseOutputBulkExec running in the Standard Job framework.

The Standard tSybaseOutputBulkExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>

</tr>
</tbody>
</table>

Use an existing connection

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
<table>
<thead>
<tr>
<th><strong>DB Version</strong></th>
<th>Select the version of the Sybase database to be used from the drop-down list.</th>
</tr>
</thead>
</table>
| **Server**     | Database server IP address  
Currently, only `localhost`, `127.0.0.1` or the exact IP address of the local machine is allowed for proper functioning. In other words, the database server must be installed on the same machine where the Studio is installed or where the Job using `tSybaseOutputBulkExec` is deployed. |
| **Port**       | Listening port number of DB server. |
| **Database**   | Name of the database |
| **Username and Password** | DB user authentication data.  
To enter the password, click the `[...]` button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| **Bcp utility** | Name of the utility to be used to copy data over to the Sybase server. |
| **Batch row number** | Number of lines in each processed batch. |
| **Table**      | Name of the table to be written. Note that only one table can be written at a time and that the table must exist for the insert operation to succeed. |
| **Action on table** | On the table defined, you can perform one of the following operations:  
- **None**: No operation is carried out.  
- **Drop and create a table**: The table is removed and created again.  
- **Create a table**: The table does not exist and gets created.  
- **Create a table if not exists**: The table is created if it does not exist.  
- **Clear a table**: The table content is deleted. |
| **File Name**   | Name of the file to be generated and loaded.  
**Warning:**  
This file is generated on the machine specified by the URI in the **Server** field so it should be on the same machine as the database server. |
| **Append**     | Select this check box to add the new rows at the end of the records. |
| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `LINE` when naming the fields.  
**Built-In**: You create and store the schema locally for this component only. |
**Repository:** You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema:** choose this option to view the schema only.
- **Change to built-in property:** choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection:** choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No upon completion** and choose this schema metadata again in the **Repository Content** window.

### Advanced settings

<table>
<thead>
<tr>
<th>Use an interface file</th>
<th>Select this check box to specify an interface file in the field <a href="#">Interface file</a>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Additional JDBC parameters</td>
<td>Specify additional connection properties in the existing DB connection, to allow specific character set support. E.G.: CHARSET=KANJISJIS_OS to get support of Japanese characters.</td>
</tr>
<tr>
<td>Action on data</td>
<td>On the data of the table defined, you can perform: <strong>Bulk Insert</strong>: Add multiple entries to the table. If duplicates are found, job stops. <strong>Bulk Update</strong>: Make simultaneous changes to multiple entries.</td>
</tr>
<tr>
<td>Field terminator</td>
<td>Character, string or regular expression to separate fields. <strong>Warning:</strong> As a combination of tSybaseOutputBulk and tSybaseBulkExec, this component does not allow the use of Sybase-oriented row/field separators, such as \x09. To achieve the desired effect (for example, displaying fields in the tabular form), you need to use tSybaseOutputBulk and tSybaseBulkExec together to replace tSybaseOutputBulk, with \t used in the former component and \x09 used in the latter.</td>
</tr>
<tr>
<td>DB Row terminator</td>
<td>String (ex: &quot;\n&quot; on Unix) to distinguish rows in the DB.</td>
</tr>
<tr>
<td><strong>First row NO. of file</strong></td>
<td>Type in the number of the file row where the action should start at.</td>
</tr>
<tr>
<td>--------------------------</td>
<td>---------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>FILE Row terminator</strong></td>
<td>Character, string or regular expression to separate fields in a file.</td>
</tr>
<tr>
<td><strong>Include Head</strong></td>
<td>Select this check box to include the column header.</td>
</tr>
<tr>
<td><strong>Encoding</strong></td>
<td>Regarding the source data, select the appropriate encoding from the list or select Custom and define it manually. This field is compulsory for DB data handling.</td>
</tr>
<tr>
<td><strong>Sybase encoding type</strong></td>
<td>Select the Sybase-specific encoding type for the data to be processed. This encoding type allows tSybaseOutputBulkExec to properly generate the Sybase Bulk command.</td>
</tr>
<tr>
<td><strong>Output</strong></td>
<td>Select the type of output for the standard output of the Sybase database: to console, to global variable.</td>
</tr>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

**Usage**

<table>
<thead>
<tr>
<th><strong>Usage rule</strong></th>
<th>This component is mainly used when no particular transformation is required on the data to be loaded onto the database.</th>
</tr>
</thead>
</table>
| **Dynamic settings** | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |

**Limitation**

| **Limitation** | This component requires installation of its related jar files. The database server/client must be installed on the same machine where the Studio is installed or where the Job using tSybaseOutputBulkExec is deployed, so that the component functions properly. |
Related scenarios

For use cases in relation with tSybaseOutputBulkExec, see the following scenarios:

• Inserting transformed data in MySQL database on page 2493.
• Inserting data in bulk in MySQL database on page 2500.
• Truncating and inserting file data into an Oracle database on page 2700.
**tSybaseRollback**

Cancels the transaction committed in the Sybase database.

**tSybaseRollback Standard properties**

These properties are used to configure tSybaseRollback running in the Standard Job framework.

The Standard tSybaseRollback component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tSybaseConnection component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is more commonly used with other tSybase* components, especially with the tSybaseConnection and tSybaseCommit components. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic |
Related scenarios

For **tSybaseRollback** related scenario, see *Rollback from inserting data in mother/daughter tables* on page 2440.
**tSybaseRow**

Acts on the actual DB structure or on the data (although without handling data).

tSybaseRow is the specific component for this database query. It executes the SQL query stated onto the specified database. The row suffix means the component implements a flow in the job design although it doesn’t provide output.

The SQLBuilder tool helps you write easily your SQL statements.

**tSybaseRow Standard properties**

These properties are used to configure tSybaseRow running in the Standard Job framework.

The Standard tSybaseRow component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>

<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><strong>Use an existing connection</strong></td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see **Talend Studio User Guide**.
<table>
<thead>
<tr>
<th>DB Version</th>

</tr>
<tr>
<td>Sybase Schema</td>
<td>Exact name of the sybase schema.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data. To enter the password, click the […] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Table Name</td>
<td>Name of the table to be processed.</td>
</tr>
<tr>
<td>Turn on identity insert</td>
<td>Select this check box to use your own sequence for the identity value of the inserted records (instead of having the SQL Server pick the next sequential value).</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-In</strong>: You create and store the schema locally for this component only.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
</tr>
<tr>
<td></td>
<td>Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:</td>
</tr>
<tr>
<td></td>
<td>• View schema: choose this option to view the schema only.</td>
</tr>
<tr>
<td></td>
<td>• Change to built-in property: choose this option to change the schema to Built-in for local changes.</td>
</tr>
<tr>
<td></td>
<td>• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.</td>
</tr>
<tr>
<td>Query type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-in</strong>: Fill in manually the query statement or build it graphically using SQLBuilder</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: Select the relevant query stored in the Repository. The Query field gets accordingly filled in.</td>
</tr>
</tbody>
</table>
### Query
Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.

### Die on error
This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a Row > Rejects link.

#### Advanced settings

**Propagate QUERY’s recordset**
Select this check box to insert the result of the query into a COLUMN of the current flow. Select this column from the use column list.

**Note:**
This option allows the component to have a different schema from that of the preceding component. Moreover, the column that holds the QUERY’s recordset should be set to the type of Object and this component is usually followed by tParseRecordSet.

**Use PreparedStatement**
Select this check box if you want to query the database using a PreparedStatement. In the Set PreparedStatement Parameter table, define the parameters represented by “?” in the SQL instruction of the Query field in the Basic Settings tab.

- **Parameter Index**: Enter the parameter position in the SQL instruction.
- **Parameter Type**: Enter the parameter type.
- **Parameter Value**: Enter the parameter value.

**Note:**
This option is very useful if you need to execute the same query several times. Performance levels are increased.

**Commit every**
Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions.

**tStat Catcher Statistics**
Select this check box to collect log data at the component level.

#### Global Variables

**Global Variables**

- **QUERY**: the query statement being processed. This is a Flow variable and it returns a string.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>This component offers the flexibility of the DB query and covers all possible SQL queries.</td>
<td></td>
</tr>
</tbody>
</table>

Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Limitation

This component requires installation of its related jar files.

Related scenarios

For tSybaseRow related topics, see:

- Combining two flows for selective output on page 2514.
- Procedure on page 625.
- Removing and regenerating a MySQL table index on page 2508.
tSybaseSCD

Addresses Slowly Changing Dimension needs, reading regularly a source of data and logging the changes into a dedicated SCD table.

`tSybaseSCD` reflects and tracks changes in a dedicated Sybase SCD table.

**tSybaseSCD Standard properties**

These properties are used to configure `tSybaseSCD` running in the Standard Job framework.

The Standard `tSybaseSCD` component belongs to the Business Intelligence and the Databases families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th><strong>Database</strong></th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Property type</strong></td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in:</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository:</strong></td>
<td>Select the Repository file where Properties are stored. The following fields are pre-filled in using fetched data.</td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined.

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

| **DB Version** | Select the version of the Sybase database to be used from the drop-down list. |
### Host
Database server IP address.

### Port
Listening port number of DB server.

### Database
Name of the database.

### Username and Password
DB user authentication data.
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

### Table
Name of the table to be written. Note that only one table can be written at a time.

### Schema and Edit schema
A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word **line** when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Built-in**: The schema is created and stored locally for this component only. Related topic: see *Talend Studio User Guide*.

**Repository**: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see *Talend Studio User Guide*.

### SCD Editor
The SCD editor helps to build and configure the data flow for slowly changing dimension outputs.

For more information, see *SCD management methodology* on page 2522.

### Use memory saving Mode
Select this check box to maximize system performance.

### Die on error
This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

## Advanced settings

### Additional JDBC parameters
Specify additional connection properties for the DB connection you are creating. This option is not available if
you have selected the **Use an existing connection** check box in the **Basic settings**.

**End date time details**
Specify the time value of the SCD end date time setting in the format of `HH:mm:ss`. The default value for this field is `12:00:00`.
This field appears only when SCD **Type 2** is used and **Fixed year value** is selected for creating the SCD end date.

**tStatCatcher Statistics**
Select this check box to collect log data at the component level.

**Debug mode**
Select this check box to display each step during processing entries in a database.

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th><strong>NB_LINE_UPDATED</strong>: the number of rows updated. This is an After variable and it returns an integer. <strong>NB_LINE_INSERTED</strong>: the number of rows inserted. This is an After variable and it returns an integer. <strong>NB_LINE_REJECTED</strong>: the number of rows rejected. This is an After variable and it returns an integer. <strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press <strong>Ctrl + Space</strong> to access the variable list and choose the variable to use from it. For further information about variables, see <em>Talend Studio User Guide</em>.</th>
</tr>
</thead>
</table>

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is used as Output component. It requires an Input component and Row main link as input.</th>
</tr>
</thead>
</table>

**Dynamic settings**
Click the `[+]` button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.
For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

| Limitation | This component does not support using SCD type 0 together with other SCD types. |

**Related scenarios**

For related topics, see tMysqlSCD on page 2519.
tSybaseSCDELT

Addresses Slowly Changing Dimension needs through SQL queries (server-side processing mode), and logs the changes into a dedicated Sybase SCD table.

tSybaseSCDELT reflects and tracks changes in a dedicated Sybase SCD table.

**tSybaseSCDELT Standard properties**

These properties are used to configure tSybaseSCDELT running in the Standard Job framework.

The Standard tSybaseSCDELT component belongs to the Business Intelligence and the Databases families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

<td><strong>Dynamic settings</strong></td>
<td>Click the [+] button to add a row in the table and fill the <strong>Code</strong> field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. The <strong>Dynamic settings</strong> table is available only when the <strong>Use an existing connection</strong> check box is selected in the <strong>Basic settings</strong> view. Once a dynamic parameter is defined, the <strong>Component List</strong> box in the <strong>Basic settings</strong> view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on <strong>Dynamic settings</strong> and context variables, see Talend Studio User Guide.</td>
</tr>
<tr>
<td><strong>Limitation</strong></td>
<td>The Stored Procedures syntax should match the Database syntax. This component requires installation of its related jar files.</td>
</tr>
</tbody>
</table>

Related scenarios

For related scenarios, see:
• Retrieving personal information using a stored procedure on page 2415.
• Using tMysqlSP to find a State Label using a stored procedure on page 2539.
• Checking number format using a stored procedure on page 2754.
• Executing a stored procedure using tMDMSP on page 2159.

Check tMysqlConnection on page 2436 as well if you want to analyze a set of records from a database table or DB query and return single records.
**tSystem**

Calls other system processing commands, already up and running in a larger Job.

**tSystem Standard properties**

These properties are used to configure tSystem running in the Standard Job framework. The Standard tSystem component belongs to the System family. The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Use home directory</th>
<th>Select this check box to change the name and path of a dedicated directory.</th>
</tr>
</thead>
</table>

**Use Single Command**

When the required command is very simple, to the degree that, for example, only one parameter is used and without space, select this option to activate its Command field. In this field, enter the simple system command. Note that the syntax is not checked.

**Warning:**

*In Windows, the MS-DOS commands do not allow you to pass directly from the current folder to the folder containing the file to be launched. To launch a file, you must therefore use an initial command to change the current folder, then a second one to launch the file.*

**Use Array Command**

Select this option to activate its Command field. In this field, enter the system command in array, one parameter per line.

For example, enter the following command with consecutive spaces in array for Linux:

```plaintext
"cp" "/temp/source.txt" "/temp/copy to/
```

**Standard Output and Error Output**

Select the type of output for the processed data to be transferred to.

- **to console**: data is passed on to be viewed in the Run view.
- **to global variable**: data is passed on to an output variable linked to the tSystem component.

**to console and to global variable**: data is passed on to the Run view and to an output variable linked to the tSystem component.
**normal**: data is passed on to the component that comes next.

**Schema and Edit Schema**

A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either **Built-in** or stored remotely in the **Repository**.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No upon completion** and choose this schema metadata again in the **Repository Content** window.

Click **Sync columns** to retrieve the schema from the preceding component in the Job.

**Built-in**: You create and store the schema locally for this component only. Related topic: see **Talend Studio User Guide**.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and job flowcharts. Related topic: see **Talend Studio User Guide**.

**Environment variables**

Click the [+] button to add as many global variables as needed.

- **name**: Enter the syntax of the new variable.
- **value**: Enter a value for this variable according to the context.

**Advanced settings**

**tStatCatcher Statistics**

Select this check box to collect log data at the component level.

**Global Variables**

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

**OUTPUT**: the standard output from a process. This is an After variable and it returns a string.

**ERROROUTPUT**: the erroneous output from a process. This is an After variable and it returns a string.
**EXIT_VALUE**: the exit code from a process. This is an After variable and it returns an integer.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

---

**Usage**

**Usage rule**

This component can typically used for companies which already implemented other applications that they want to integrate into their processing flow through Talend.

**Connections**

Outgoing links (from this component to another):
- **Row**: Main.
- **Trigger**: On Subjob Ok; On Subjob Error; Run if.

Incoming links (from one component to this one):
- **Row**: Main; Reject; Iterate.
- **Trigger**: On Subjob Ok; On Subjob Error; Run if; On Component Ok; On Component Error; Synchronize; Parallelize.

For further information regarding connections, see *Talend Studio User Guide*.

---

**Echoing 'Hello World!'**

This scenario is one single component *tSystem* to execute a system command and shows the results in the **Run view** "console".

To replicate this scenario, proceed as follows:

**Procedure**

1. Drop a *tSystem* component from the **Palette** to the design workspace.
2. Double-click *tSystem* to open its **Component** view.
3. Select the **Use Single Command** option to activate its **Command** field and type in "cmd /c echo Hello World!".

4. In the **Standard Output** drop-down list, select **to both console and global variable**.

5. Press **F6** to run this Job.

**Results**

Starting job tSystem_scenario at 17:26 08/10/2009.

[statistics] connecting to socket on port 3951
[statistics] connected
Hello World!
[statistics] disconnected
Job tSystem_scenario ended at 17:26 08/10/2009. [exit code=0]

The Job executes an echo command and shows the output in the Console of the **Run** view.
tTeradataClose

Closes the transaction committed in the connected DB.

**tTeradataClose Standard properties**

These properties are used to configure tTeradataClose running in the Standard Job framework.

The Standard tTeradataClose component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>

</tr>
</tbody>
</table>
Related scenarios

No scenario is available for the Standard version of this component yet.
**tTeradataCommit**

Commits in one go, using a unique connection, a global transaction instead of doing that on every row or every batch and thus provides gain in performance.

tTeradataCommit validates the data processed through the Job into the connected DB.

**tTeradataCommit Standard properties**

These properties are used to configure tTeradataCommit running in the Standard Job framework.

The Standard tTeradataCommit component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>

<td>Select the tTeradataConnection component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Close connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is more commonly used with other tTeradata* components, especially with the tTeradataConnection and tTeradataRollback components. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to acces |
s database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenario

For tTeradataCommit related scenario, see Inserting data in mother/daughter tables on page 2437
**tTeradataConnection**

Opens a connection to the specified database that can then be reused in the subsequent subjob or subjobs.

tTeradataConnection opens a connection to the database for a current transaction.

**tTeradataConnection Standard properties**

These properties are used to configure tTeradataConnection running in the Standard Job framework. The Standard tTeradataConnection component belongs to the Databases and the ELT families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Host</td>
<td>Database server IP address.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Additional JDBC parameters</td>
<td>Specify additional connection properties in the existing DB connection, to allow specific character set support. E.G.: CHARSET=KANJISJIS_OS to get support of Japanese characters.</td>
</tr>
<tr>
<td>Note: You can set the encoding parameters through this field.</td>
<td></td>
</tr>
<tr>
<td>Use or register a shared DB Connection</td>
<td>Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the Shared DB Connection Name field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except...</td>
</tr>
</tbody>
</table>
the database schema setting) among several database connection components from different Job levels that can be either parent or child.

This option is incompatible with the Use dynamic job and Use an independent process to run subjob options of the tRunJob component. Using a shared connection together with a tRunJob component with either of these two options enabled will cause your Job to fail.

<table>
<thead>
<tr>
<th>Advanced settings</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Query band</strong></td>
<td>Select this check box to use the Teradata Query Banding feature to add metadata to the query to be processed, such as the user running the query. This can help you, for example, identify the origin of this query. Once selecting the check box, the Query Band parameters table is displayed, in which you need to enter the metadata information to be added. This information takes the form of key/value pairs, for example, DpiID in the Key column and Finance in the Value column. This check box actually generates the SET QUERY_BAND FOR SESSION statement with the key/value pairs declared in the Query Band parameters table. For further information about this statement, see <a href="https://docs.teradata.com/search/all?query=End+logging+syntax">https://docs.teradata.com/search/all?query=End+logging+syntax</a>.</td>
</tr>
<tr>
<td><strong>Auto Commit</strong></td>
<td>Select this check box to commit any changes to the database automatically upon the transaction. With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component. Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component.</td>
</tr>

</tbody>
</table>

### Global Variables

**Global Variables**

- **NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.
- **NB_LINE_INSERTED**: the number of rows inserted. This is an After variable and it returns an integer.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

### Usage

**Usage rule**

This component offers the flexibility benefit of the DB query and covers all possible SQL queries.

**Limitation**

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can
find more details about how to install external modules in Talend Help Center (https://help.talend.com).

Related scenarios

No scenario is available for the Standard version of this component yet.
tTeradataFastLoadUtility

Executes a database query according to a strict order which must be the same as the one in the schema.

tTeradataFastLoadUtility reads a database and extracts fields using queries. The retrieve list of fields is then transferred to the next component, using a connection flow (Main row).

**tTeradataFastLoadUtility Standard properties**

These properties are used to configure tTeradataFastLoadUtility running in the Standard Job framework.

The Standard tTeradataFastLoadUtility component belongs to the Databases family.

The component in this framework is available in all Talend products.

<tr>
<th><strong>Define character set</strong></th>
<th>Specify the character encoding you need use for your system.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Check point</strong></td>
<td>Enter the check point value.</td>
</tr>
<tr>
<td><strong>Error files</strong></td>
<td>Enter the file name where the error messages are stored. By default, the code <code>ERRORFILES table_ERR1, table_ERR2</code> is entered, meaning that the two tables <code>table_ERR1</code> and <code>table_ERR2</code> are used to record the error messages.</td>
</tr>
<tr>
<td><strong>Return fastload error</strong></td>
<td>Select this check box to specify the exit code number to indicate the point at which an error message should display in the console.</td>
</tr>
<tr>
<td><strong>ERRLIMIT</strong></td>
<td>Enter the limit number of errors detected during the loading phase. Processing stops when the limit is reached. The default error limit value is 1000000. For more information, see <em>Teradata FastLoad Reference</em> documentation.</td>
</tr>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

### Usage

| **Usage rule** | This component offers the flexibility of the DB query and covers all possible SQL queries. |
Related scenario

For related topic, see Inserting data into a Teradata database table on page 3882.
**tTeradataInput**

Executes a DB query with a strictly defined order which must correspond to the schema definition. tTeradataInput reads a database and extracts fields based on a query. It passes on the field list to the next component via a Main row link.

**tTeradataInput Standard properties**

These properties are used to configure tTeradataInput running in the Standard Job framework. The Standard tTeradataInput component belongs to the Databases family. The component in this framework is available in all Talend products.

*Note:* This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td><strong>Property type</strong></td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><strong>Use an existing connection</strong></td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

*Note:* When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

Click this icon to open a database connection wizard and store the database connection parameters you set in the component **Basic settings** view.
For more information about setting up and storing database connection parameters, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th><strong>Host</strong></th>
<th>Database server IP address</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td><strong>Schema and Edit Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-In</strong>: You create and store the schema locally for this component only.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
</tr>
<tr>
<td><strong>Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:</strong></td>
<td><img src="image1.png" alt="Image" /></td>
</tr>
<tr>
<td></td>
<td><strong>View schema</strong>: choose this option to view the schema only.</td>
</tr>
<tr>
<td></td>
<td><strong>Change to built-in property</strong>: choose this option to change the schema to <strong>Built-in</strong> for local changes.</td>
</tr>
<tr>
<td></td>
<td><strong>Update repository connection</strong>: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select <strong>No</strong> upon completion and choose this schema metadata again in the <strong>Repository Content</strong> window.</td>
</tr>
<tr>
<td><strong>Table name</strong></td>
<td>Browse to, or enter the name of the table to be used.</td>
</tr>
<tr>
<td><strong>Query type and Query</strong></td>
<td>Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.</td>
</tr>
</tbody>
</table>

### Advanced settings

| **Additional JDBC parameters** | Specify additional connection properties in the existing DB connection, to allow specific character set support. E.G.: CHARSET=KANJISJIS_OS to get support of Japanese characters. |
| **Trim all the String/Char columns** | Select this check box to remove leading and trailing whitespace from all the String/Char columns. |
| **Trim column** | Remove leading and trailing whitespace from defined columns. |
### Query band

Select this check box to use the Teradata Query Banding feature to add metadata to the query to be processed, such as the user running the query. This can help you, for example, identify the origin of this query.

Once selecting the check box, the **Query Band parameters** table is displayed, in which you need to enter the metadata information to be added. This information takes the form of key/value pairs, for example, `DpiD` in the **Key** column and `Finance` in the **Value** column.

This check box actually generates the SET QUERY_BAND FOR SESSION statement with the key/value pairs declared in the **Query Band parameters** table. For further information about this statement, see [https://docs.teradata.com/search/all?query=End+logging+syntax](https://docs.teradata.com/search/all?query=End+logging+syntax).

This check box is not available when you have selected the **Using an existing connection** check box. In this situation, if you need to use the Query Band feature, set it in the **Advanced settings** tab of the Teradata connection component to be used.

### tStatCatcher Statistics

Select this check box to collect log data at the component level.

---

### Global Variables

**NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.

**QUERY**: the query statement being processed. This is a Flow variable and it returns a string.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press `Ctrl + Space` to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](https://docs.teradata.com/search/all?query=End+logging+syntax).

### Usage

**Usage rule**

This component covers all possible SQL queries for Teradata databases.

**Dynamic settings**

Click the `[+]` button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for
example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

| Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |

### Related scenarios

For related scenarios, see:

- Loading data into a Teradata database on page 3868.
- Reading data from different MySQL databases using dynamically loaded connection parameters on page 491.
tTeradataMultiLoad

Executes a database query according to a strict order which must be the same as the one in the schema.

tTeradataMultiLoad reads a database and extracts fields using queries. The retrieved list of fields is then transferred to the next component, using a connection flow (Main row).

tTeradataMultiLoad Standard properties

These properties are used to configure tTeradataMultiLoad running in the Standard Job framework. The Standard tTeradataMultiLoad component belongs to the Databases family. The component in this framework is available in all Talend products.

Basic settings

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-in or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Execution platform</td>
<td>Select the Operating System type you use.</td>
</tr>
<tr>
<td>Host</td>
<td>Host name or IP address of the database server.</td>
</tr>
<tr>
<td>Database name</td>
<td>Database name.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Table</td>
<td>Name of the table to be written. Note that only one table can be written at a time.</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
</tbody>
</table>

- **Built-In**: You create and store the schema locally for this component only.
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:
- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

**Script generated folder**
Browse your directory and select the destination of the file which will be created.

**Action to data**
On the data of the table defined, you can perform:
- **Insert**: Add new entries to the table. If duplicates are found, job stops.
- **Update**: Make changes to existing entries
- **Insert or update**: Insert a new record. If the record with the given reference already exists, an update would be made.
- **Delete**: Remove entries corresponding to the input flow.

**Warning:**
*It is necessary to specify at least one column as a primary key on which the Update and Delete operations are based. You can do that by clicking Edit Schema and selecting the check box(es) next to the column(s) you want to set as primary key(s).*

**Where condition in case Delete**
Type in a condition, which, once verified, will delete the row. This field appears only when Delete is selected from the Action to data drop-down list.

**Load file**
Browse your directory and select the file from which you want to load data.

**Field separator**
Character, string or regular expression to separate fields.

**Error file**
Browse your directory and select the destination of the file where the error messages will be recorded.

**Advanced settings**

**Define Log table**
This check box is selected to define a log table you want to use in place of the default one that is the database table you defined in Basic settings. The syntax required to define the log table is $databasename.logtablename$.

**BEGIN LOAD**
This field allows you to define your BEGIN LOAD command to initiate or restart a load task. You can specify the number of sessions to use, the error limit, any other parameters needed to execute the task.

For more information, see Teradata MultiLoad Reference documentation.
**Return mload error**
Select this check box to specify the exit code number to indicate the point at which an error message should display in the console.

**Define character set**
Specify the character encoding you need use for your system

**tStat Catcher Statistics**
Select this check box to collect log data at the component level.

### Global Variables

**EXIT_VALUE**: the process exit code. This is an After variable and it returns an integer.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

**Usage rule**
This component offers the flexibility of the DB query and covers all possible SQL queries.

### Related scenario

For related topic, see *Inserting data into a Teradata database table* on page 3882.
tTeradataOutput

Executes the action defined on the table and/or on the data contained in the table, based on the flow incoming from the preceding component in the job.
tTeradataOutput writes, updates, makes changes or suppresses entries in a database.

**tTeradataOutput Standard properties**

These properties are used to configure tTeradataOutput running in the Standard Job framework.
The Standard tTeradataOutput component belongs to the Databases family.
The component in this framework is available in all Talend products.

---

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

---

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
<tr>
<td><strong>Property type</strong></td>
<td>Either Built-In or Repository.</td>
</tr>
<tr>
<td><strong>Built-In</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the repository file where the properties are stored.</td>
</tr>
<tr>
<td><strong>Use an existing connection</strong></td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

---

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
For more information about setting up and storing database connection parameters, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th><strong>Host</strong></th>
<th>Database server IP address</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Table</strong></td>
<td>Name of the table to be written. Note that only one table can be written at a time.</td>
</tr>
</tbody>
</table>

**Action on table**

Note:
The Action on table list will not be available if you select the Enable parallel execution check box in the Advanced settings view.

On the table defined, you can perform one of the following operations:

**None:** No operation is carried out.

**Drop and create a table:** The table is removed and created again.

**Create a table:** The table does not exist and gets created.

**Create a table if not exists:** The table is created if it does not exist.

**Drop a table if exists and create:** The table is removed if it already exists and created again.

**Clear a table:** The table content is deleted.

**Create**

This is not visible by default, until you choose to create a table from the Action on table drop-down list. The table to be created may be:

- SET TABLE: tables which do not allow to duplicate
- MULTI SET TABLE: tables allowing duplicate rows.

**Action on data**

On the data of the table defined, you can perform:

**Insert:** Add new entries to the table. If duplicates are found, job stops.

**Update:** Make changes to existing entries.

**Insert or update:** Insert a new record. If the record with the given reference already exists, an update would be made.

**Update or insert:** Update the record with the given reference. If the record does not exist, a new record would be inserted.

**Delete:** Remove entries corresponding to the input flow.
### Warning:

It is necessary to specify at least one column as a primary key on which the **Update** and **Delete** operations are based. You can do this by clicking **Edit Schema** and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the **Advanced settings** view where you can simultaneously define primary keys for the **Update** and **Delete** operations. To do that:

- Select the **Use field options** check box and then in the **Key in update column**, select the check boxes next to the column names you want to use as a base for the **Update** operation. Do the same in the **Key in delete column** for the **Delete** operation.

---

<table>
<thead>
<tr>
<th><strong>Schema and Edit schema</strong></th>
<th>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <code>line</code> when naming the fields.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-In</strong></td>
<td>You create and store the schema locally for this component only.</td>
</tr>
</tbody>
</table>
| **Repository** | You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.  
When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.  
You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com). |
| **Click Edit schema to make changes to the schema. If the current schema is of the **Repository** type, three options are available:** |  
- **View schema**: choose this option to view the schema only.  
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window. |
| **Die on error** | This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a **Row > Rejects** link. |

---

### Advanced settings

<table>
<thead>
<tr>
<th><strong>Advanced settings</strong></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Additional JDBC parameters</strong></td>
<td>Specify additional connection properties for the DB connection you are creating. This option is not available if</td>
</tr>
</tbody>
</table>
| **Commit every** | Enter the number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and, above all, better performance at execution.

This option is not available if you have selected the **Use an existing connection** check box in the **Basic settings** view.

**Note:**
If you have selected **Drop and create table**, **Create table**, **Create table if does not exist** or **Drop table if exists and create** from the **Action on table** list in the **Basic settings** view, you need to enter **0** in this field to ensure the validity of the SQL statements. For more information about the validity of the SQL statements in Teradata Database, see teradata. |

| **Additional Columns** | This option is not offered if you create (with or without drop) the DB table. This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing. |

| **Name:** Type in the name of the schema column to be altered or inserted as new column |
| **SQL expression:** Type in the SQL statement to be executed in order to alter or insert the relevant column data. |
| **Position:** Select **Before**, **Replace** or **After** following the action to be performed on the reference column. |
| **Reference column:** Type in a column of reference that the **tDBOutput** can use to place or replace the new or altered column. |

| **Query band** | Select this check box to use the Teradata Query Banding feature to add metadata to the query to be processed, such as the user running the query. This can help you, for example, identify the origin of this query. Once selecting the check box, the **Query Band parameters** table is displayed, in which you need to enter the metadata information to be added. This information takes the form of key/value pairs, for example, **DpID** in the **Key** column and **Finance** in the **Value** column. This check box actually generates the SET QUERY_BAND FOR SESSION statement with the key/value pairs declared in the **Query Band parameters** table. For further information |
This check box is not available when you have selected the Using an existing connection check box. In this situation, if you need to use the Query Band feature, set it in the Advanced settings tab of the Teradata connection component to be used.

Use field options
Select this check box to customize a request, especially when there is double action on data.

Enable debug mode
Select this check box to display each step during processing entries in a database.

tStatCatcher Statistics
Select this check box to collect log data at the component level.

Use Batch
Select this check box to activate the batch mode for data processing.

Batch Size
Specify the number of records to be processed in each batch.
This field appears only when the Use batch mode check box is selected.

Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE</strong></td>
<td>the number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_UPDATED</strong></td>
<td>the number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_INSERTED</strong></td>
<td>the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_DELETED</strong></td>
<td>the number of rows deleted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_REJECTED</strong></td>
<td>the number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>ERROR_MESSAGE</strong></td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

| Usage rule | This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible. |
This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in a Teradata database. It also allows you to create a reject flow using a Row > Rejects link to filter data in error.

| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |

| Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |

### Related scenarios

For related topics, see:

- Inserting a column and altering data using tMysqlOutput on page 2477.
tTeradataRollback

Cancels the transaction commit in the Teradata database.

**tTeradataRollback Standard properties**

These properties are used to configure tTeradataRollback running in the Standard Job framework.

The Standard tTeradataRollback component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the <strong>TeradataConnection</strong> component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is more commonly used with other tTeradata* components, especially with the **tTeradataConnection** and **tTeradataCommit** components. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on **Dynamic** |
settings and context variables, see Talend Studio User Guide.

Related scenario

For tTeradataRollback related scenario, see Rollback from inserting data in mother/daughter tables on page 2440.
tTeradataRow

Acts on the actual DB structure or on the data (although without handling data).

tTeradataRow is the specific component for this database query. It executes the SQL query stated onto the specified database. The row suffix means the component implements a flow in the job design although it doesn’t provide output.

The SQLBuilder tool helps you write easily your SQL statements.

**tTeradataRow Standard properties**

These properties are used to configure tTeradataRow running in the Standard Job framework.

The Standard tTeradataRow component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>Built-in:</strong> No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>Repository:</strong> Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<p>| Host | Database server IP address |</p>

<tr>
<td><strong>Die on error</strong></td>
<td>This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a Row &gt; Rejects link.</td>
</tr>
</tbody>
</table>
**Advanced settings**

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
</table>
| **Additional JDBC parameters** | Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the *Use an existing connection* check box in the *Basic settings*.  
This is intended to allow specific character set support.  
E.G.: CHARSET=KANJISJIS_OS to get support of Japanese characters. |
| **Propagate QUERY’s recordset** | Select this check box to insert the result of the query into a COLUMN of the current flow. Select this column from the *use column* list.  

**Note:**  
This option allows the component to have a different schema from that of the preceding component.  
Moreover, the column that holds the QUERY’s recordset should be set to the type of *Object* and this component is usually followed by tParseRecordSet. |
| **Use PreparedStatement**     | Select this check box if you want to query the database using a PreparedStatement. In the *Set PreparedStatement Parameter* table, define the parameters represented by "?" in the SQL instruction of the *Query* field in the *Basic Settings* tab.  

- **Parameter Index:** Enter the parameter position in the SQL instruction.  
- **Parameter Type:** Enter the parameter type.  
- **Parameter Value:** Enter the parameter value.  

**Note:**  
This option is very useful if you need to execute the same query several times. Performance levels are increased |
| **Commit every**               | Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions. |
| **Query band**                 | Select this check box to use the Teradata Query Banding feature to add metadata to the query to be processed, such as the user running the query. This can help you, for example, identify the origin of this query.  

Once selecting the check box, the *Query Band parameters* table is displayed, in which you need to enter the metadata information to be added. This information takes the form of key/value pairs, for example, *DpiD* in the *Key* column and *Finance* in the *Value* column.  

This check box actually generates the SET QUERY_BAND FOR SESSION statement with the key/value pairs declared in the *Query Band parameters* table. For further information about this statement, see https://docs.teradata.com/search/all?query=End+logging+syntax. |
### Global Variables

| Global Variables | QUERY: the query statement being processed. This is a Flow variable and it returns a string.  
ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.  
For further information about variables, see *Talend Studio User Guide*. |

### Usage

| Usage rule | This component offers the flexibility of the DB query and covers all possible SQL queries. |

### Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.  
The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.  
For examples on using dynamic parameters, see *Reading data from databases through context-based dynamic connections* on page 2457 and *Reading data from different MySQL databases using dynamically loaded connection parameters* on page 491. For more information on Dynamic settings and context variables, see *Talend Studio User Guide*.|

### Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the
Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

**Related scenarios**

For related scenarios, see:

- Loading data into a Teradata database on page 3868.
- Combining two flows for selective output on page 2514.
- Procedure on page 625.
- Removing and regenerating a MySQL table index on page 2508.
tTeradataSCD

Addresses Slowly Changing Dimension needs, reading regularly a source of data and logging the changes into a dedicated SCD table.

TTeradataSCD reflects and tracks changes in a dedicated Teradata SCD table.

tTeradataSCD Standard properties

These properties are used to configure tTeradataSCD running in the Standard Job framework.

The Standard tTeradataSCD component belongs to the Business Intelligence and the Databases families.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property Type</td>
<td>Either Built-In or Repository.</td>
</tr>
<tr>
<td></td>
<td>Built-In: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The database connection related fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

Use an existing connection

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

| Host            | Type in the IP address or hostname of the database. |
| **Database** | Type in the name of the database you want to use. |
| **Username and Password** | Type in the database user authentication data.<br>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings. |
| **Table** | Type in the name of the table to be written. Note that only one table can be written at a time. |
| **Action on table** | On the table defined, you can perform one of the following operations:<br>• **None**: No operation is carried out.<br>• **Create table**: The table does not exist and gets created.<br>• **Create table if not exists**: The table is created if it does not exist. |
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word **line** when naming the fields. |
|  | **Built-In**: You create and store the schema locally for this component only. |
|  | **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. |
|  | Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:<br>• **View schema**: choose this option to view the schema only.<br>• **Change to built-in property**: choose this option to change the schema to **Built-In** for local changes.<br>• **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window. |
| **SCD Editor** | The SCD editor helps to build and configure the data flow for slowly changing dimension outputs.<br>For more information, see SCD management methodology on page 2522. |
| **Use memory saving mode** | Select this check box to maximize system performance. |
| **Source keys include Null** | Select this check box to allow the source key columns to have Null values. |
Warning:
Special attention should be paid to the uniqueness of the source key(s) values when this option is selected.

| Die on error | Select the check box to stop the execution of the Job when an error occurs. Clear the check box to skip any rows on error and complete the process for error-free rows. When errors are skipped, you can collect the rows on error using a Row > Reject link. |

Advanced settings

| Additional JDBC Parameters | Specify additional connection properties for the database connection you are creating. This field is not visible when the Use an existing connection check box is selected. |
| Debug mode | Select this check box to display each step during processing entries in a database. |
| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

Global Variables

| Global Variables | NB_LINE_UPDATED: the number of rows updated. This is an After variable and it returns an integer. NB_LINE_INSERTED: the number of rows inserted. This is an After variable and it returns an integer. ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | This component is used as an Output component. It requires an Input component and a Row > Main link as input. |
| Limitation | This component does not support using SCD type 0 together with other SCD types. |
Related scenario

For a similar scenario using MySQL database, see *Tracking data changes using Slowly Changing Dimensions (type 0 through type 3)* on page 2524.
tTeradataSCDELT

Addresses Slowly Changing Dimension needs through SQL queries (server-side processing mode), and logs the changes into a dedicated Teradata SCD table.

tTeradataSCDELT reflects and tracks changes in a dedicated Teradata SCD table.

**tTeradataSCDELT Standard properties**

These properties are used to configure tTeradataSCDELT running in the Standard Job framework.

The Standard tTeradataSCDELT component belongs to the Business Intelligence and the Databases families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
</table>
| Property Type | Either **Built-In** or **Repository**.  
- **Built-In:** No property data stored centrally.  
- **Repository:** Select the repository file in which the properties are stored. The database connection fields that follow are completed automatically using the data retrieved. |
| Use an existing connection | Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined. |
| Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:  
1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.  
2. In the child level, use a dedicated connection component to read that registered database connection.  
For an example about how to share a database connection across Job levels, see **Talend Studio User Guide**. |
| Host | Enter the IP address or hostname of the database server. |
| Database | Enter the name of the database you want to use. |
**Username and Password**

Enter the user authentication data to access the database. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

**Source table**

Enter the name of the input Teradata SCD table.

**Table**

Enter the name of the table to be written. Note that only one table can be written at a time.

**Action on table**

Select one of the following operations to be performed on the table defined:

- **None**: No action carried out on the table.
- **Create table**: A new table gets created.
- **Drop and create table**: The table is removed and created again.
- **Create table if not exists**: A table gets created if it does not exist.
- **Drop table if exists and create**: The table is removed if it already exists and created again.
- **Clear table**: The table content is deleted. You have the possibility to rollback the operation.
- **Truncate table**: The table content is deleted. You do not have the possibility to rollback the operation.

**Create**

Select the type of the table to be created:

- **SET TABLE**: creates a SET table that does not allow duplicate rows to be inserted.
- **MULTISET TABLE**: creates a MULTISET table that allows duplicate rows to be inserted.

This list is available only when **Create table, Drop and create table, Create table if not exists**, or **Drop table if exists and create** is selected from the **Action on table** drop-down list.

**Schema and Edit schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

- **Built-In**: The schema is created and stored locally for this component only. Related topic: see *Talend Studio User Guide*.
- **Repository**: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see *Talend Studio User Guide*.

Click **Edit schema** to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate...
Upon completion and choose this schema metadata again in the Repository Content window.

<table>
<thead>
<tr>
<th>Surrogate key</th>
<th>Select the surrogate key column from the list.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Creation</td>
<td>Select the method to be used for the surrogate key generation. For more information about the creation methods, see SCD management methodology on page 2522.</td>
</tr>
<tr>
<td>Source Keys</td>
<td>Select one or more columns to be used as keys, to ensure the unicity of the incoming data.</td>
</tr>
<tr>
<td>Use SCD type 1 fields</td>
<td>Select this check box to use SCD Type 1 if tracking changes is not necessary. SCD Type 1 should be used for typos corrections for example.</td>
</tr>
<tr>
<td>SCD type 1 fields</td>
<td>Click the [+] button to add as many rows as needed, and in each row select an input schema column that will be checked for Type 1 changes. This table is available only when the Use SCD type 1 fields check box is selected.</td>
</tr>
<tr>
<td>Use SCD type 2 fields</td>
<td>Select this check box to use SCD Type 2 if changes need to be tracked down. SCD Type 2 should be used to trace updates for example.</td>

MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

| Limitation | This component requires installation of its related jar files. |

**Related scenario**

For related scenarios, see:

- Tracking data changes in a Snowflake table using the tJDBCSCDELT component on page 1859.
- Tracking data changes in a PostgreSQL table using the tPostgreSQLSCDELT component on page 3039.
tTeradataTPTExec

Offers high performance in inserting data from an existing file to a table in a Teradata database.

As the combination of tTeradataFastLoad, tTeradataMultiLoad, tTeradataTPump, and tTeradataFastExport, tTeradataTPTExec loads the data from an existing file to a Teradata database.

**tTeradataTPTExec Standard properties**

These properties are used to configure tTeradataTPTExec running in the Standard Job framework.

The Standard tTeradataTPTExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Either Built-In or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Built-In</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The database connection related fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

**Execution platform**

Select the Operating System that will be used to run the Job, either Windows or Unix.

**TDPID**

Specify the Teradata director program identifier. It can be either the name or the IP address of the Teradata database system being accessed.

**Database name**

Specify the name of the Teradata database.

**Username and Password**

Specify the username and the password for the Teradata database authentication.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

**Schema and Edit Schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

**Note:**

Avoid using a Teradata database keyword as a Db Column name in the schema. If you have to, be sure to enclose the column name in a pair of ". For example, when the keyword id is used as a database column name, the Db Column should be filled with \"id\".

**Built-In**

You create and store the schema locally for this component only.
### Repository
You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

### Consumer Operator
Select a consumer operator from the drop-down list.

- **Load**: writes data into an empty Teradata table using the Teradata FastLoad utility protocol.
- **Inserter**: inserts data into Teradata tables with SQL sessions.
- **Update**: performs Insert, Update, or Delete operations using the Teradata MultiLoad utility protocol.
- **Stream**: loads data continuously into Teradata tables using the Teradata TPump utility.

For more information about Teradata consumer operators, see [Teradata consumer operators](#).

### Action On Data
Select an action to be performed on the data from the drop-down list.

- **Insert**: inserts new records to the table. If duplicates are found, the Job stops.
- **Update**: updates existing records in the table.
- **InsertOrUpdate**: inserts new records or updates existing records based on the given reference key.
- **Delete**: removes records corresponding to the input flow.

**Note:**
You must specify at least one column as the primary key on which the **Update** or **Delete** operation is based. You can do that by clicking the [...] button next to **Edit schema** and selecting the check box(es) next to the column(s) you want to set as primary key(s).

This list field appears only when the **Update** or **Stream** operator is selected from the **Consumer Operator** drop-down list.

### Producer Operator
Select a producer operator from the drop-down list. Currently, only the **DataConnector** operator is supported.

**DataConnector**: accesses files either directly or through an access module, and then writes it to the data stream.
For more information about Teradata producer operators, see Teradata producer operators.

<table>
<thead>
<tr>

This field appears only when the Set Script Parameters check box is selected.</td>
</tr>
<tr>
<td>Layout Name (schema)</td>
<td>Specify a schema for the data to be loaded.</td>
</tr>
</tbody>
</table>
This field appears only when the **Set Script Parameters** check box is selected.

### Return mload error
Select this check box to specify the exit code number to indicate the point at which an error message should display in the console.

### Character set encoding of the script
This check box is selected by default, allowing you to specify the encoding to be used in the Teradata TPT script.

### Character set encoding of the data
Select this check box to specify the encoding to be used for the Teradata TPT data.
This field is not available when **Custom script** is selected.

### Apply TPT consumer operator optional attributes
Select this check box to define optional attribute(s) for the consumer operator that you have selected.

#### Optional attributes
Click the [+] button below the table to add as many rows as needed, each row for an optional attribute, and set the following two parameters for each attribute:

- **Name**: click the cell and select an optional attribute from the drop-down list. The list of optional attributes may vary depending on the consumer operator you have selected. For details about supported optional attributes for each consumer operator, see [Supported optional attributes for each consumer operator](#) on page 3867.

- **Value**: enter the value for the corresponding optional attribute.

For more information about the attribute value definition, see [Teradata Parallel Transporter Reference guide](http://developer.teradata.com/sites/all/files/documentation/linked_docs/2436020A_TPT-Reference-13.10.pdf).

This table appears only when the **Apply TPT consumer operator optional attributes** check box is selected.

### tStatCatcher Statistics
Select this check box to collect the log data at the component level.

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>EXIT_VALUE: the process exit code. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
</tbody>
</table>
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

**Usage**

**Usage rule**

Used as a single-component Job or sublob, this component offers high performance in inserting data from an existing file to a table in the Teradata database. For further information about the usage of this component, see http://developer.teradata.com/sites/all/files/documentation/linked_docs/html/online/8035-2436-088A/wwhelp/wwhimpl/js/html/wwhelp.htm.

**Limitation**

The Teradata client tool with the Teradata Parallel Transporter Base and Teradata Parallel Transporter Stream features needs to be installed on the machine where Jobs using this component are executed.

**Supported optional attributes for each consumer operator**

This section lists all supported optional attributes for each consumer operator.

**The Load operator**

BufferSize, ErrorLimit, MaxSessions, MinSessions, TenacityHours, TenacitySleep, AccountId, DataEncryption, DateForm, ErrorTable1, ErrorTable2, LogonMech, LogonMechData, NotifyExit, NotifyExitIsDLL, NotifyLevel, NotifyMethod, LogSQL, NotifyString, PauseAcq, PrivateLogName, QueryBandSessInfo, WildcardInsert, WorkingDatabase, TraceLevel.

**The Inserter operator**

AccountId, DataEncryption, DateForm, LogonMech, LogonMechData, LogSQL, PrivateLogName, QueryBandSessInfo, ReplicationOverride, TraceLevel, WorkingDatabase.

**The Update operator**

PrivateLogName, BufferSize, ErrorLimit, MaxSessions, MinSessions, TenacityHours, TenacitySleep, AccountId, AmpCheck, DataEncryption, DateForm, DeleteTask, DropErrorTable, DropLogTable, DropWorkTable, ErrorTable1, ErrorTable2, LogonMech, LogonMechData, LogSQL, NotifyExit, NotifyExitIsDLL, NotifyLevel, NotifyMethod, NotifyString, PauseAcq, QueryBandSessInfo, QueueErrorTable, WorkingDatabase, WorkTable, TraceLevel.

**The Stream operator**

Buffers, ErrorLimit, MaxSessions, MinSessions, Pack, Rate, Periodicity, TenacityHours, TenacitySleep, AccountId, AppendErrorTable, ArraySupport, DataEncryption, DateForm, DropErrorTable, DropMacro, ErrorTable, LogonMech, LogonMechData, MacroDatabase, OperatorCommandID, NotifyExit, NotifyExitIsDLL, NotifyLevel, NotifyMethod, LogSQL, NotifyString, PackMaximum, PrivateLogName, QueryBandSessInfo, QueueErrorTable, ReplicationOverride, Robust, WorkingDatabase, TraceLevel.
Loading data into a Teradata database

This scenario describes a Job that creates a new Teradata database table, writes data into a delimited file, then loads the data from the file into this table, and finally retrieves the data from the table and displays it on the console.

Dropping and linking the components

Procedure

1. Create a new Job and add the following components by typing their names in the design workspace or dropping them from the Palette: a tTeradataRow component, a tFixedFlowInput component, a tFileOutputDelimited component, a tTeradataTPTExec component, a tTeradataInput component, and a tLogRow component.
2. Connect tFixedFlowInput to tFileOutputDelimited using a Row > Main connection.
3. Do the same to connect tTeradataInput to tLogRow.
4. Connect tTeradataRow to tFixedFlowInput using a Trigger > On Subjob Ok connection.
5. Do the same to connect tFixedFlowInput to tTeradataTPTExec and tTeradataTPTExec to tTeradataInput.
Configuring the components

Creating a new Teradata database table

Procedure

1. Double-click tTeradataRow to open its Basic settings view.

   ![tTeradataRow](image)

   - Property Type: Built-In
   - Use an existing connection
   - Host: "192.168.30.67"
   - Database: "samples"
   - Username: "tduser"
   - Password: "**********"
   - Schema: Built-In
   - Query Type: Built-In
   - Query:
     ```sql
     CREATE SET TABLE samples.person, FALLBACK, NO BEFORE JOURNAL, NO AFTER JOURNAL
     ( id INTEGER NOT NULL, name VARCHAR(50), sex VARCHAR(20) )
     UNIQUE PRIMARY INDEX (id)
     ```

2. Fill in the Host, Database, Username, and Password fields with your Teradata database connection details.

3. In the Query field, enter the following SQL statement to create a new table named `person` with three columns `id`, `name`, `sex`.

   ```sql
   CREATE SET TABLE samples.person, FALLBACK, NO BEFORE JOURNAL, NO AFTER JOURNAL
   ( id INTEGER NOT NULL, name VARCHAR(50), sex VARCHAR(20) )
   UNIQUE PRIMARY INDEX (id)
   ```

Preparing the source data

Procedure

1. Double-click tFixedFlowInput to open its Basic settings view.

   ![tFixedFlowInput](image)
2. Click the [...] button next to **Edit schema** to open the schema editor.

3. Click the [+ ] button to add three columns: *id* of the integer type, *name* and *sex* of the string type.

4. Click **OK** to close the schema editor and accept the propagation prompted by the pop-up dialog box.

5. In the **Mode** area, select **Use Inline Content (delimited file)** and enter the input data in the **Content** field.

```
1;Ford;Male
2;Rose;Female
3;Sabrina;Female
4;Teddy;Male
5;Kate;Male
```

6. Double-click **tFileOutputDelimited** to open its **Basic settings** view.
In the **File Name** field, specify the file into which the input data will be written. In this example, it is `E:/person.csv`.

### Loading the source data into an empty table

#### Procedure

1. Double-click **tTeradataTPTExec** to open its **Basic settings** view.

   ![Basic settings](image)

2. Fill in the **TDPID**, **Database name**, **Username**, and **Password** fields with your Teradata database connection details.

3. In the **Table** field, enter the name of the table into which the source data will be loaded. In this example, it is `person`.

4. In the **Script generated folder** field, browse to the directory under which the Teradata Parallel Transporter script file will be created during the Job execution. In this example, it is `E:/`.

5. In the **Load file** field, browse to the file that contains the source data. In this example, it is `E:/person.csv`.

6. In the **Error file** field, specify the file in which log messages will be recorded. In this example, it is `E:/error.log`.
7. Click the [...] button next to Edit schema to open the schema editor.

Click the [+] button to add three columns: id of the integer type, name and sex of the string type. Note that id and name in Db Column are enclosed in a pair of " since they are Teradata database keywords.

Click OK to validate these changes and close the schema editor.

8. Click Advanced settings to open its view, and then select the Apply TPT consumer operator optional attributes check box and click the [+] button below the Optional attributes table to add the following attributes needed: ErrorLimit, ErrorTable1, QueryBandSessInfo, and TraceLevel.

Note:
For VARCHAR attributes, enter their values between double quotation marks.
Retrieving data from the Teradata database table

Procedure

1. Double-click tTeradataInput to open its Basic settings view.

2. In the Table Name field, enter the name of the table to read data from. In this example, it is person.

3. In the Query field, enter the following SQL statement to retrieve data from the table person.

   ```sql
   SELECT * FROM samples.person ORDER BY id
   ```

4. Click the [...] button next to Edit schema to open the schema editor.

5. Click the [+] button to add three columns: id of the integer type, name and sex of the string type. Note that id and name in Db Column are enclosed in a pair of \" since they are Teradata database keywords.

6. Click OK to close the schema editor and accept the propagation prompted by the pop-up dialog box.

7. Double-click tLogRow to open its Basic settings view.
8. In the Mode area, select the **Table (print values in cells of a table)** option for a better display of the result.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl + S** to save the Job.
2. Press **F6** to execute the Job.

```
Starting job tTeradataTPTExec_Demo at 10:35 28/09/2014.

Job tTeradataTPTExec_Demo ended at 10:35 28/09/2014. [exit code=0]
```

The data written into the specified Teradata database table is displayed on the console.
tTeradataTPTUtility

Writes the incoming data to a file and then loads the data from the file to a Teradata database.

As the combination of tTeradataFastLoad, tTeradataMultiLoad, tTeradataTPump, and tTeradataFastExport, tTeradataTPTUtility writes the incoming data to a file and then loads the data from the file to a Teradata database.

**tTeradataTPTUtility Standard properties**

These properties are used to configure tTeradataTPTUtility running in the Standard Job framework.

The Standard tTeradataTPTUtility component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Basic settings Data file**

<table>

</tr>
</tbody>
</table>
### Schema and Edit Schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

**Note:**
Avoid using a Teradata database keyword as a `Db Column` name in the schema. If you have to, be sure to enclose the column name in a pair of ". For example, when the keyword `id` is used as a database column name, the `Db Column` should be filled with `"id"`.

### Built-In

You create and store the schema locally for this component only.

### Repository

You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

### Consumer Operator

Select a consumer operator from the drop-down list.

- **Load**: writes data into an empty Teradata table using the Teradata FastLoad utility protocol.
- **Inserter**: inserts data into Teradata tables with SQL sessions.
- **Update**: performs Insert, Update, or Delete operations using the Teradata MultiLoad utility protocol.
- **Stream**: loads data continuously into Teradata tables using the Teradata TPump utility.

For more information about Teradata consumer operators, see [Teradata consumer operators](#).

### Action On Data

Select an action to be performed on the data from the drop-down list.

- **Insert**: inserts new records to the table. If duplicates are found, the Job stops.
- **Update**: updates existing records in the table.
- **InsertOrUpdate**: inserts new records or updates existing records based on the given reference key.
- **Delete**: removes records corresponding to the input flow.
**Note:**
You must specify at least one column as the primary key on which the Update or Delete operation is based. You can do that by clicking the [...] button next to Edit schema and selecting the check box(es) next to the column(s) you want to set as primary key(s).

This list field appears only when the Update or Stream operator is selected from the Consumer Operator drop-down list.

<table>
<thead>
<tr>
<th><strong>Producer Operator</strong></th>
<th>Select a producer operator from the drop-down list. Currently, only the DataConnector operator is supported. <strong>DataConnector</strong>: accesses files either directly or through an access module, and then writes it to the data stream. For more information about Teradata producer operators, see Teradata producer operators.</th>
</tr>

<tr>
<td>Define character set</td>
<td>Select this check box to specify the character encoding to be used in your system.</td>
</tr>
<tr>
<td>Apply TPT consumer operator optional attributes</td>
<td>Select this check box to define optional attribute(s) for the consumer operator that you have selected. For more information about optional attributes of each consumer operator, see Teradata Parallel Transporter Reference guide at <a href="http://developer.teradata.com/sites/all/files/documentation/linked_docs/2436020A_TPT-Reference-13.10.pdf">http://developer.teradata.com/sites/all/files/documentation/linked_docs/2436020A_TPT-Reference-13.10.pdf</a>.</td>
</tr>
</tbody>
</table>
| Optional attributes  | Click the ![+] button below the table to add as many rows as needed, each row for an optional attribute, and set the following two parameters for each attribute:  
  - **Name**: click the cell and select an optional attribute from the drop-down list. The list of optional attributes may vary depending on the consumer operator you have selected. For details about supported optional attributes for each consumer operator, see Supported optional attributes for each consumer operator on page 3867.  
  - **Value**: enter the value for the corresponding optional attribute. For more information about the attribute value definition, see Teradata Parallel Transporter Reference guide at http://developer.teradata.com/sites/all/files/documentation/linked_docs/2436020A_TPT-Reference-13.10.pdf. This table appears only when the Apply TPT consumer operator optional attributes check box is selected. |
| tStatCatcher Statistics | Select this check box to collect the log data at the component level. |

**Global Variables**

| Global Variables | EXIT_VALUE: the process exit code. This is an After variable and it returns an integer. |
ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule

Preceded by an input component, tTeradataTPTUtility writes the incoming data to a file and then loads the data from the file to the Teradata Database. High performance is provided during this process. For further information about the usage of this component, see http://developer.teradata.com/sites/all/files/documentation/linked_docs/html/online/B035-2436-088A/wwhelp/wwhimpl/js/html/wwhelp.htm.

Limitation

The Teradata client tool with the Teradata Parallel Transporter Base and Teradata Parallel Transporter Stream features needs to be installed on the machine where Jobs using this component are executed.

Related scenario

For a related scenario, see Loading data into a Teradata database on page 3868.
tTeradataTPump

Inserts, updates, or deletes data in the Teradata database with the TPump loading utility which allows near-real-time data to be achieved in the data warehouse.

Use this component particularly for environments where batch windows are shrinking and warehouse maintenance overlaps normal working hours.

**tTeradataTPump Standard properties**

These properties are used to configure tTeradataTPump running in the Standard Job framework.

The Standard tTeradataTPump component belongs to the Databases family.

The component in this framework is available in all Talend products.

</tr>
</tbody>
</table>
Return tpump error

Select this check box to specify the exit code number to indicate the point at which an error message should display in the console.

Define character set

Specify the character encoding you need use for your system.

tStat Catcher Statistics

Select this check box to collect log data at the component level.

Global Variables

| Global Variables | EXIT_VALUE: the process exit code. This is an After variable and it returns an integer. ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | This component offers the flexibility of the DB query and covers all possible SQL queries. |

Inserting data into a Teradata database table

In this scenario, you create a Job using tTeradataTPump to insert customer data into a Teradata database table and specify the exit code to be displayed in the event of an exception error.

Three components are used in this Job:

- **tRowGenerator**: generates rows as required using random customer data taken from a list.
- **tFileOutputDelimited**: outputs the customer data into a delimited file.
- **tTeradataTPump**: inserts the customer data into the Teradata database table in the Tpump mode.

Dropping components

Procedure

1. Drop the required components: tRowGenerator, tFileOutputDelimited and tTeradataTPump from the Palette onto the design workspace.
2. Link `tRowGenerator` to `tFileOutputDelimited` using a Row > Main connection.

3. Link `tRowGenerator` to `tTeradataTPump` using a Trigger > On SubjobOk connection.

![Diagram showing connections between components]

**Configuring the components**

**Procedure**

1. Double click `tRowGenerator` to open the `tRowGenerator Editor` window.
   
   In the `tRowGenerator Editor` window, define the data to be generated. For this Job, the schema is composed of two columns: ID and Name.

<table>
<thead>
<tr>
<th>Schema</th>
<th>Functions</th>
<th>Preview</th>
</tr>
</thead>
<tbody>
<tr>
<td>Column</td>
<td>Key</td>
<td>Type</td>
</tr>
<tr>
<td>id</td>
<td>✓</td>
<td>int</td>
</tr>
<tr>
<td>name</td>
<td></td>
<td>String</td>
</tr>
</tbody>
</table>

   Enter the **Number of Rows for RowGenerator** to generate.

2. Double click `tFileOutputDelimited` to define its properties in the **Component** view.

3. Next to **File Name**, browse to the output file or enter a name for the output file to be created.

4. Between double quotation marks, enter the delimiters to be used next to **Row Separator** and **Field Separator**.
5. Double click tTeradataTPump to open its Component view. 
In the Basic settings tab of the Component view, define the tTeradataTPump parameters. 

6. Enter the Database name, User name and Password in accordance with your database authentication information. 

7. Specify the Table into which you want to insert the customer data. In this scenario, it is called mytable. 

8. In the Script generated folder field, browse to the folder in which you want to store the script files generated. 

9. In the Load file field, browse to the file which contains the customer data. 

10. In the Error file field, browse to the file in which you want to log the error information. 

11. In the Action on data field, select Insert.
Executing the Job

Procedure

1. Press F6 to execute the Job.
2. The Run view console reads as follows:

```
Running job 'tpump'...
Starting job tpump at 17:01 19/07/2010.
[statistics] connecting to socket on port 3740
[statistics] connected
[statistics] disconnected
Job tpump ended at 17:02 19/07/2010. [exit code=0]
```

3. Double-click the tTeradataTPump component to go back to its Component view.
4. On the Advanced settings tab, select the Return tpump error check box and type in the exit code number to indicate the point at which an error message should be displayed in the console. In this example, enter the number 4 and use the default values for the other parameters.

```
Job( | Cont | Com | Run | Prob | Mod | Table | Sch | Job

```

5. Press F6 to run the Job.
6. The Run view console reads as follows:

```
Running job 'tpump'...
Starting job tpump at 17:56 19/07/2010.
[statistics] connecting to socket on port 3549
[statistics] connected
[statistics] disconnected
Exception in component tTeradataTPump_1
java.lang.RuntimeException: TPump returned exit code 12
 at bug,tpump_0_1, tTeradataTPump_1Process(tpump.java:307)
 at bug,tpump_0_1, tTeradataTPump_1Process.runJobInTOS(tpump.java:504)
 at bug,tpump_0_1, tTeradataTPump_1Process.main(tpump.java:378)
Job tpump ended at 17:56 19/07/2010. [exit code=0]
```

An exception error occurs and TPump returned exit code 12 is displayed. If you need to view detailed information about the exception error, you can open the log file stored in the directory you specified in the Error file field in the Basic settings tab of the Component view.
tUniqRow

Ensures data quality of input or output flow in a Job.
tUniqRow compares entries and sorts out duplicate entries from the input flow.

tUniqRow Standard properties

These properties are used to configure tUniqRow running in the Standard Job framework.
The Standard tUniqRow component belongs to the Data Quality family.
The component in this framework is available in all Talend products.

Basic settings

Schema and Edit schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- View schema: choose this option to view the schema only.
- Change to built-in property: choose this option to change the schema to Built-in for local changes.
- Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

Built-In: You create and store the schema locally for this component only.

Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

Unique key

In this area, select one or more columns to carry out de duplication on the particular column(s)
- Select the Key attribute check box to carry out deduplication on all the columns
- Select the Case sensitive check box to differentiate upper case and lower case

Advanced settings

Only once each duplicated key

Select this check box if you want to have only the first duplicated entry in the column(s) defined as key(s) sent to the output flow for duplicates.
| Use of disk (suitable for processing large row set) | Select this check box to enable generating temporary files on the hard disk when processing a large amount of data. This helps to prevent Job execution failure caused by memory overflow. With this check box selected, you need also to define:  
- **Buffer size in memory**: Select the number of rows that can be buffered in the memory before a temporary file is to be generated on the hard disk.  
- **Directory for temp files**: Set the location where the temporary files should be stored.  

**Warning:** Make sure that you specify an existing directory for temporary files; otherwise your Job execution will fail. |
<table>

### Global Variables

| Global Variables | **NB_UNIQUES**: the number of unique rows. This is an After variable and it returns an integer.  
**NB_DUPLICATES**: the number of duplicate rows. This is an After variable and it returns an integer.  
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
For further information about variables, see *Talend Studio User Guide*. |

### Usage

| Usage rule | This component handles flow of data therefore it requires input and output, hence is defined as an intermediary step. |

### Deduplicating entries

In this five-component Job, we will sort entries on an input name list, find out duplicated names, and display the unique names and the duplicated names on the **Run** console.
Setting up the Job

Procedure

1. Drop a **tFileInputDelimited**, a **tSortRow**, a **tUniqRow**, and two **tLogRow** components from the **Palette** to the design workspace, and name the components as shown above.

2. Connect the **tFileInputDelimited** component, the **tSortRow** component, and the **tUniqRow** component using **Row > Main** connections.

3. Connect the **tUniqRow** component and the first **tLogRow** component using a **Main > Uniques** connection.

4. Connect the **tUniqRow** component and the second **tLogRow** component using a **Main > Duplicates** connection.

Configuring the components

Procedure

1. Double-click the **tFileInputDelimited** component to display its **Basic settings** view.

   ![tFileInputDelimited Component](image)

   **Basic settings**

   - **Property Type**: Built-In
   - **File name/Stream**: `D:\Input\NameList.csv`
   - **Row Separator**: `;`
   - **Field Separator**: `;`
   - **Header**: 1
   - **Footer**: 0
   - **Schema**: Built-In
   - **Uncompress as zip file**: False
   - **Die on error**: False

   2. Click the [...] button next to the **File Name** field to browse to your input file.

   3. Define the header and footer rows. In this use case, the first row of the input file is the header row.

   4. Click **Edit schema** to define the schema for this component. In this use case, the input file has five columns: *Id*, *FirstName*, *LastName*, *Age*, and *City*. Then click **OK** to propagate the schema and close the schema editor.

   5. Double-click the **tSortRow** component to display its **Basic settings** view.
6. To rearrange the entries in the alphabetic order of the names, add two rows in the Criteria table by clicking the plus button, select the FirstName and LastName columns under Schema column, select alpha as the sorting type, and select the sorting order.

7. Double-click the tUniqRow component to display its Basic settings view.

8. In the Unique key area, select the columns on which you want deduplication to be carried out. In this use case, you will sort out duplicated names.

9. In the Basic settings view of each of the tLogRow components, select the Table option to view the Job execution result in table mode.

**Saving and executing the Job**

**Procedure**

1. Press Ctrl+S to save your Job.
2. Run the Job by pressing F6 or clicking the Run button on the Run tab.

   The unique names and duplicated names are displayed in different tables on the Run console.
<table>
<thead>
<tr>

</table>
tUnite

Centralizes data from various and heterogeneous sources.
tUnite merges data from various sources, based on a common schema.
Note that tUnite cannot exist in a data flow loop. For instance, if a data flow goes through several tMap components to generate two flows, they cannot be fed to tUnite.

tUnite Standard properties

These properties are used to configure tUnite running in the Standard Job framework.
The Standard tUnite component belongs to the Orchestration family.
The component in this framework is available in all Talend products.

Basic settings

| Schema and Edit Schema | A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either Built-in or stored remotely in the Repository. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
• View schema: choose this option to view the schema only.  
• Change to built-in property: choose this option to change the schema to Built-in for local changes.  
• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. Click Sync columns to retrieve the schema from the previous component in the Job. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-in</strong>: The schema will be created and stored locally for this component only. Related topic: see Talend Studio User Guide.</td>
<td></td>
</tr>
<tr>
<td><strong>Repository</strong>: The schema already exists and is stored in the Repository, hence can be reused in various projects and Job designs. Related topic: see Talend Studio User Guide.</td>
<td></td>
</tr>
</tbody>
</table>

Advanced settings

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |
Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.
|                  | NB_LINE: the number of rows processed. This is an After variable and it returns an integer.
|                  | A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.
|                  | To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.
|                  | For further information about variables, see Talend Studio User Guide.

Usage

| Usage rule | This component is not startable and requires one or several input components and an output component.

Connections

| Outgoing links (from this component to another): |
| Row: Main. |
| Trigger: Run if; On Component Ok; On Component Error |
| Incoming links (from one component to this one): |
| Row: Main; Reject. |
| For further information regarding connections, see Talend Studio User Guide. |

Iterating on files and merge the content

The following Job iterates on a list of files then merges their content and displays the final 2-column content on the console.

Dropping and linking the components

Procedure

1. Drop the following components onto the design workspace: tFileList, tFileInputDelimited, tUnite and tLogRow.
2. Connect the tFileList to the tFileInputDelimited using an Iterate connection and connect the other component using a row main link.
Configuring the components

Procedure

1. In the tFileList Basic settings view, browse to the directory, where the files to merge are stored.

   ![Image of tFileList_1 component]

   **Basic settings**
   - Directory: "D:/Input/Countries"
   - FileList Type: Files
   - Includes subdirectories: No
   - Case Sensitive: Yes
   - Generate Error if no file found: No
   - Use Glob Expressions as Filemask (Unchecked means Perl5 Regex Expressions)

   The files are pretty basic and contain a list of countries and their respective score.

   ![Image of in-01.txt, in-02.txt, in-03.txt files]

   1. france;12
   2. usa;10
   3. france;14

   ![Image of in-01.txt, in-02.txt, in-03.txt files]

   1. uk;13
   2. usa;9
   3. france;5

   ![Image of in-01.txt, in-02.txt, in-03.txt files]

   1. france;16
   2. uk;13
   3

2. In the Case Sensitive field, select Yes to consider the letter case.

3. Select the tFileInputDelimited component, and display this component’s Basic settings view.

   ![Image of tFileInputDelimited_1 component]

   **Basic settings**
   - Property Type: Built-In
   - File name/Stream: ((String)globalMap.gsh("FileList_1_Current_FILEPATH"))
   - Row Separator: "\n"
   - Field Separator: ";"
   - CSV options: No
   - Header: Yes
   - Footer: No
   - Limit: 0
   - Schema: Built-In
   - Skip empty rows: Yes
   - Uncompress as zip file: No
   - Die on error: No

4. Fill in the File Name/Stream field by using the Ctrl+Space bar combination to access the variable completion list, and selecting tFileList.CURRENT_FILEPATH from the global variable list to process all files from the directory defined in the tFileList.
5. Click the Edit Schema button and set manually the 2-column schema to reflect the input files’ content.

<table>
<thead>
<tr>
<th>Column</th>
<th>Key</th>
<th>Type</th>
<th>Nullable</th>
<th>Date...</th>
<th>Len...</th>
<th>Pre...</th>
<th>De...</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>Country</td>
<td></td>
<td>String</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Points</td>
<td></td>
<td>Integer</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

For this example, the 2 columns are Country and Points. They are both nullable. The Country column is of String type and the Points column is of Integer type.

6. Click OK to validate the setting and accept to propagate the schema throughout the Job.

7. Then select the tUnite component and display the Component view. Notice that the output schema strictly reflects the input schema and is read-only.

8. In the Basic settings view of tLogRow, select the Table option to display properly the output values.

**Saving and executing the Job**

**Procedure**

1. Press Ctrl+S to save your Job.
2. Press F6, or click Run on the Run console to execute the Job.

The console shows the data from the various files, merged into one single table.
tVectorWiseCommit

Commits a global transaction in one go using a single connection instead of doing so on every row or every batch. This provides a gain in performance.

tVectorWiseCommit validates the data processed in a Job into the connected DB.

**tVectorWiseCommit Standard properties**

These properties are used to configure tVectorWiseCommit running in the Standard Job framework.

The Standard tVectorWiseCommit component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tVectorWiseConnection component from the list if more than one connection is planned for the current job.</td>
</tr>
<tr>
<td>Close connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is more commonly used with other tVectorWise* components, especially with the tVectorWiseConnection and tVectorWiseRollback components. |

| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database |
connection dynamically from multiple connections planned in your Job.

Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

---

**Related scenario**

For a **tVectorWiseCommit** related scenario, see Inserting data in mother/daughter tables on page 2437.
**tVectorWiseConnection**

Opens a connection to the specified database that can then be reused in the subsequent subjob or subjobs.

**tVectorWiseConnection Standard properties**

These properties are used to configure `tVectorWiseConnection` running in the Standard Job framework.

The Standard `tVectorWiseConnection` component belongs to the Databases and the ELT families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file where the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Server</td>
<td>Database server IP address.</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database.</td>

<tr>
<td>Username and Password</td>
<td>Authentication information of the database user. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Use or register a shared DB Connection</td>
<td>Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the Shared DB Connection Name field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child. This option is incompatible with the Use dynamic job and Use an independent process to run subjob options of the tRunJob component. Using a shared connection together...</td>
</tr>
</tbody>
</table>
with a **tRunJob** component with either of these two options enabled will cause your Job to fail.

### Advanced settings

| Auto Commit | Select this check box to commit any changes to the database automatically upon the transaction.  
With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component.  
Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component. |
| --- | --- |

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is more commonly used with other tVectorWise* components, especially with the <strong>tVectorWiseCommit</strong> and <strong>tVectorWiseRollback</strong> components.</th>
</tr>
</thead>
</table>

| Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center ([https://help.talend.com](https://help.talend.com)). |

### Related scenario

For a **tVectorWiseConnection** related scenario, see **tMysqlConnection** on page 2436.
tVectorWiseInput

Executes a DB query with a strictly defined order which must correspond to the schema definition.
tVectorWiseInput reads a database and extracts fields based on a query. It passes on the field list to the next component via a Main row link.

**tVectorWiseInput Standard properties**

These properties are used to configure tVectorWiseInput running in the Standard Job framework.
The Standard tVectorWiseInput component belongs to the Databases family.
The component in this framework is available in all Talend products.

[Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.]

**Basic settings**

<tr>
<td>Action on data</td>
<td>On the data of the table defined, you can perform: Insert: Add new entries to the table. If duplicates are found, job stops. Update: Make changes to existing entries Insert or update: Insert a new record. If the record with the given reference already exists, an update would be made. Update or insert: Update the record with the given reference. If the record does not exist, a new record would be inserted. Delete: Remove entries corresponding to the input flow.</td>
</tr>
</tbody>
</table>
**Warning:**

It is necessary to specify at least one column as a primary key on which the Update and Delete operations are based. You can do this by clicking Edit Schema and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the Advanced settings view where you can simultaneously define primary keys for the Update and Delete operations. To do that: Select the Use field options check box and then in the Key in update column, select the check boxes next to the column names you want to use as a base for the Update operation. Do the same in the Key in delete column for the Delete operation.

<table>
<thead>
<tr>
<th>Schema and Edit Schema</th>
</tr>
</thead>
<tbody>
<tr>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
</tbody>
</table>

| Built-In: You create and store the schema locally for this component only. |

| Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. |
| When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually. You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com). |

| Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available: |
| • View schema: choose this option to view the schema only. |
| • Change to built-in property: choose this option to change the schema to Built-in for local changes. |
| • Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |

| Die on error |
| This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a Row > Rejects link. |

| Advanced settings |
| Commit every |
| Number of rows to be completed before committing batches of rows together into the DB. This option ensures |
transaction quality (but not rollback) and, above all, better performance at executions.

## Additional Columns

This option is not offered if you create (with or without drop) the DB table. This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing.

### Name

Type in the name of the schema column to be altered or inserted as new column.

### SQL expression

Type in the SQL statement to be executed in order to alter or insert the relevant column data.

### Position

Select Before, Replace or After following the action to be performed on the reference column.

### Reference column

Type in a column of reference that the **tDBOutput** can use to place or replace the new or altered column.

## Use field options

Select this check box to customize a request, especially when there is double action on data.

## Enable debug mode

Select this check box to display each step during processing entries in a database.

## Support null in "SQL WHERE" statement

Select this check box if you want to deal with the Null values contained in a DB table.

### Note

Ensure that the Nullable check box is selected for the corresponding columns in the schema.

## Use Batch

Select this check box to activate the batch mode for data processing. This option is only supported with Vectorwise version 2.5 and later, and is only available when you select Insert from the Action on data drop-down list in the Basic settings tab.

### Batch Size

Specify the number of records to be processed in each batch. This field appears only when the Use batch mode check box is selected.

## Global Variables

### NB_LINE

The number of rows processed. This is an After variable and it returns an integer.

### NB_LINE_UPDATED

The number of rows updated. This is an After variable and it returns an integer.

### NB_LINE_INSERTED

The number of rows inserted. This is an After variable and it returns an integer.
**tVectorWiseOutput**

**NB_LINE_DELETED**: the number of rows deleted. This is an After variable and it returns an integer.

**NB_LINE_REJECTED**: the number of rows rejected. This is an After variable and it returns an integer.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

### Usage

| Usage rule | This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible.
|           | This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in a Vertica database. It also allows you to create a reject flow using a **Row > Rejects** link to filter data in error. For an example of **tMysqlOutput** in use, see [Retrieving data in error with a Reject link](#) on page 2485. |

### Limitation

| Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in [Talend Help Center](https://help.talend.com). |

### Related scenario

For **tVectorWiseOutput** related topics, see:

- Inserting a column and altering data using **tMysqlOutput** on page 2477.
tVectorWiseRollback

Cancels transactions committed to the VectorWise database.

**tVectorWiseRollback Standard properties**

These properties are used to configure tVectorWiseRollback running in the Standard Job framework.

The Standard tVectorWiseRollback component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the <strong>tVectorWiseConnection</strong> component from the list if more than one connection is planned for the current job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is more commonly used with other tVectorWise* components, especially with the <strong>tVectorWiseConnection</strong> and <strong>tVectorWiseCommit</strong> components.</th>
</tr>
</thead>
</table>
| Dynamic settings | Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job.  
Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.  
For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |
Related scenario

For a \texttt{tVectorWiseRollback} related scenario, see \textit{Rollback from inserting data in mother/daughter tables} on page 2440.
tVectorWiseRow

Acts on the actual DB structure or on the data (although without handling data).

tVectorWiseRow is the specific component for this database query. It executes the SQL query stated in the specified database. The row suffix means the component implements a flow in the job design although it doesn’t provide output.

The SQLBuilder tool helps you write your SQL statements easily.

**tVectorWiseRow Standard properties**

These properties are used to configure tVectorWiseRow running in the Standard Job framework.

The Standard tVectorWiseRow component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td><strong>Property type</strong></td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in</strong>:</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong>:</td>
<td>Select the repository file where the properties are stored. The fields that follow after are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><strong>Use an existing connection</strong></td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td><strong>Host</strong></td>
<td>Database server IP address.</td>
</tr>
</tbody>
</table>

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
<table>
<thead>
<tr>
<th>Port</th>
<th>Listening port number of the DB server.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Name of the database.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>

</thead>
</table>
| QUERY                        | the query statement being processed. This is a Flow variable and it returns a string.  
**ERROR_MESSAGE:** the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.  
For further information about variables, see Talend Studio User Guide. |
### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component offers the flexibility of the DB query and covers all possible SQL queries.</th>
</tr>
</thead>
</table>

| Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center ([https://help.talend.com](https://help.talend.com)). |

### Related scenario

For related topics, see:

- [Combining two flows for selective output](#) on page 2514
- [Procedure](#) on page 625.
- [Removing and regenerating a MySQL table index](#) on page 2508.
tVerticaBulkExec

Loads data into a Vertica database table from a local file using the Vertica COPY SQL statement.

For more information about the Vertica COPY SQL statement, see COPY.

The tVerticaOutputBulk component and the tVerticaBulkExec component are generally used together as parts of a two step process. In the first step, an output file is generated. In the second step, the file is used in a bulk load operation to feed a database. These two steps are fused together in the tVerticaOutputBulkExec component. The advantage of using two separate components is that the data can be transformed before it is loaded into the database.

tVerticaBulkExec Standard properties

These properties are used to configure tVerticaBulkExec running in the Standard Job framework.

The Standard tVerticaBulkExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

</thead>
<tbody>
<tr>
<td><strong>Use schema columns for Copy</strong></td>
<td>Select this check box to use the column option in the COPY statement so that you can restrict the load to one or more specified columns in the table. For more information, see the Vertica COPY SQL Statement.</td>
</tr>
<tr>
<td><strong>File Name</strong></td>
<td>The path to the file from which data will be loaded. The file should be located on the same machine where the Studio is installed or where the Job using this component is deployed. This property is available only when there is no input flow.</td>
</tr>
<tr>
<td><strong>Compression mode</strong></td>
<td>Select the compression mode for the file from which data will be loaded. This property is available only when you are using Vertica 6.0 and later.</td>
</tr>
</tbody>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Additional JDBC Parameters</strong></td>
<td>Specify additional JDBC parameters for the database connection being created. This property is not available when the <strong>Use an existing connection</strong> check box is selected.</td>
</tr>
</tbody>
</table>
| **Action on data**                   | Select an action that will be performed on the data of the table defined.  
  - **Bulk insert**: Insert multiple rows into the table at once instead of doing single row inserts. If duplicates are found, the Job stops.  
  - **Bulk update**: Make simultaneous updates to multiple rows. |
| **Stream name**                      | The stream name of a load, which helps identify a particular load. This property is available only when you are using Vertica 6.0 and later. |
| **Write to ROS (Read Optimized Store)** | Select this check box to store data in a physical storage area, in order to optimize the reading, as the data is compressed and pre-sorted. |
| **Exit Job on no rows loaded**       | The Job automatically stops if no row has been loaded. |
| **Missing columns as null**          | Select this check box to insert NULL values for the missing columns when there is insufficient data to match the columns specified in the schema. This property is available only when you are using Vertica 6.0 and later. |
| **Skip Header** | Select this check box and in the field displayed next to it, specify the number of records to skip in the file. This property is available only when you are using Vertica 6.0 and later. |
| **Record terminator** | Select this check box and in the field displayed next to it, specify the literal character string used to indicate the end of each record in the file. This property is available only when you are using Vertica 6.0 and later. |
| **Enclosed by character** | Select this check box to set the character within which data is enclosed. This property is available only when you are using Vertica 6.0 and later. |
| **Escape char** | Select this check box and in the field displayed specify the character to be escaped when loading data into Vertica. By default, the check box is selected and the default escape character is \. |
| **Fields terminated by** | The character, string or regular expression to separate fields. |
| **Null String** | The string displayed to indicate that the value is null. |
| **Reject not fitted values** | Select this check box to reject data rows of type char, varchar, binary, and varbinary if they do not fit the target table. This property is available only when you are using Vertica 6.0 and later. |
| **Maximum number of rejected records** | Select this check box and in the field displayed next to it, specify the maximum number of records that can be rejected before a load fails. This property is available only when you are using Vertica 6.0 and later. |
| **Stop and rollback if any row is rejected** | Select this check box to stop and roll back a load without loading any data if any row is rejected. This property is available only when you are using Vertica 6.0 and later. |
| **Don't commit** | Select this check box to perform a bulk load transaction without committing the results automatically. This is useful if you want to execute multiple bulk loads in a single transaction. This property is available only when you are using Vertica 6.0 and later. |
| **Rejected data file** | Specify the file into which rejected rows will be written. This property is available only when **Bulk insert** is selected from the **Action on data** drop-down list. |
| **Exception log file** | Specify the file into which the exception log will be written. This log explains why each rejected row was rejected. |
This property is available only when Bulk insert is selected from the Action on data drop-down list.

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
<th>Select this check box to gather the Job processing metadata at the Job level as well as at each component level.</th>
</tr>
</thead>
</table>

### Global Variables

<table>
<thead>
<tr>
<th>ACCEPTED_ROW_NUMBER</th>
<th>The number of rows loaded into the database. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td>REJECTED_ROW_NUMBER</td>
<td>The number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>ERROR_MESSAGE</td>
<td>The error message generated by the component when an error occurs. This is an After variable and it returns a string.</td>
</tr>
</tbody>
</table>

### Usage

#### Usage rule

Talend Studio and the Vertica database create very fast and affordable data warehouse and data mart applications. For more information about how to configure Talend Studio to connect to Vertica, see Talend and HP Vertica Tips and Techniques.

You can use this component in either of the following two ways to write data into Vertica.

- It can be used as a Standalone component of a subJob to write data into Vertica from a file generated by a tVerticaOutputBulk component.
- You can link a tFileInputRaw component to it via a Row > Main connection to feed data into Vertica. In this way, the tFileInputRaw component should be in the Stream the file mode and there should be only one column of Object type defined in its schema.

#### Dynamic settings

Click the [+ ] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.
Related scenarios

For related topics, see:

- Inserting transformed data in MySQL database on page 2493.
- Inserting data in bulk in MySQL database on page 2500.
- Truncating and inserting file data into an Oracle database on page 2700.
tVerticaClose

Closes an active connection to a Vertica database.

**tVerticaClose Standard properties**

These properties are used to configure tVerticaClose running in the Standard Job framework.

The Standard tVerticaClose component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component List</td>
<td>Select the component in which the relevant reused connection is configured.</td>
</tr>
</tbody>
</table>

### Advanced settings

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

### Usage

**Usage rule**

This component is more commonly used with other tVertica* components, especially with the **tVerticaConnection** and **tVerticaCommit** components.

Talend Studio and the Vertica database create very fast and affordable data warehouse and data mart applications. For more information about how to configure Talend Studio to connect to Vertica, see *Talend and HP Vertica Tips and Techniques*.

**Dynamic settings**

Click the **[+]** button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see *Reading data from databases through context-based dynamic connections* on page 2457 and *Reading data from different*...
MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenarios

No scenario is available for the Standard version of this component yet.
**tVerticaCommit**

Commits in one go a global transaction using a unique connection instead of doing that on every row or every batch and thus provides gain in performance.

### tVerticaCommit Standard properties

These properties are used to configure tVerticaCommit running in the Standard Job framework. The Standard tVerticaCommit component belongs to the Databases family. The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

#### Basic settings

<table>
<thead>
<tr>

<tr>
<td>Close Connection</td>
<td>Select this check box to close the database connection once the component has performed its task. Clear this check box to continue to use the selected connection once the component has performed its task. If this component is linked to your Job via a <strong>Row &gt; Main</strong> connection, your data will be committed row by row. In this case, do not select the <strong>Close connection</strong> check box or your connection will be closed before the end of the first row commit.</td>
</tr>
</tbody>
</table>

#### Advanced settings

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

#### Usage

**Usage rule**

This component is more commonly used with other tVertica* components, especially with the `tVerticaConnection` and `tVerticaRollback` components.

Talend Studio and the Vertica database create very fast and affordable data warehouse and data mart applications. For more information about how to configure Talend Studio to connect to Vertica, see Talend and HP Vertica Tips and Techniques.

**Dynamic settings**

Click the `[+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned.
in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenario

For tVerticaCommit related scenario, see Inserting data in mother/daughter tables on page 2437
tVerticaConnection

Opens a connection to the specified database that can then be reused in the subsequent subjob or subjobs.

tVerticaConnection Standard properties

These properties are used to configure tVerticaConnection running in the Standard Job framework. The Standard tVerticaConnection component belongs to the Databases family.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Note: Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select the way the connection details will be set.</td>
</tr>
<tr>
<td>Property Type</td>
<td>• Built-In: The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.</td>
</tr>
<tr>
<td></td>
<td>• Repository: The connection details stored centrally in Repository &gt; Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up Repository Content dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in.</td>
</tr>
<tr>
<td>DB Version</td>
<td>Select the version of the database.</td>
</tr>
<tr>
<td>Host</td>
<td>The IP address or hostname of the database.</td>
</tr>
<tr>
<td>Port</td>
<td>The listening port number of the database.</td>
</tr>
<tr>
<td>Database</td>
<td>The name of the database.</td>
</tr>
<tr>
<td>Schema</td>
<td>The schema of the database.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>The database user authentication data.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Additional JDBC Parameters</td>
<td>Specify additional JDBC parameters for the database connection being created.</td>
</tr>
<tr>
<td>Use or register a shared DB Connection</td>
<td>Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the Shared DB Connection Name field displayed,</td>
</tr>
</tbody>
</table>
**tVerticaConnection**

Enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child.

This option is incompatible with the **Use dynamic job** and **Use an independent process to run subjob** options of the **tRunJob** component. Using a shared connection together with a **tRunJob** component with either of these two options enabled will cause your Job to fail.

### Advanced settings

| **Auto Commit** | Select this check box to commit any changes to the database automatically upon the transaction.
With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component.
Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component. |
| **tStatCatcher Statistics** | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

### Usage

| **Usage rule** | This component is more commonly used with other tVertica* components, especially with the **tVerticaCommit** and **tVerticaRollback** components.
Talend Studio and the Vertica database create very fast and affordable data warehouse and data mart applications. For more information about how to configure **Talend Studio** to connect to Vertica, see **Talend and HP Vertica Tips and Techniques**. |

### Related scenario

For **tVerticaConnection** related scenario, see **tMysqlConnection** on page 2436.
## tVerticaInput

Retrieves data from a Vertica database table based on a SQL query.

## tVerticaInput Standard properties

These properties are used to configure tVerticaInput running in the Standard Job framework.

The Standard tVerticaInput component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property Type</td>
<td>Select the way the connection details will be set.</td>
</tr>
<tr>
<td>Built-In</td>
<td>The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.</td>
</tr>
<tr>
<td>Repository</td>
<td>The connection details stored centrally in Repository &gt; Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up Repository Content dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in.</td>
</tr>
</tbody>
</table>

Click the icon to open a database connection wizard and store the database connection parameters you set in the component.

For more information about setting up and storing database connection parameters, see Talend Studio User Guide.

| DB Version | Select the version of the database. |
| Use an existing connection | Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined. |

When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.
For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

| **Host** | The IP address or hostname of the database. |
| **Port** | The listening port number of the database. |
| **Database** | The name of the database. |
| **Schema** | The schema of the database. |
| **Username and Password** | The database user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |

**Schema and Edit schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

- **Built-In**: You create and store the schema locally for this component only.
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

Click **Edit schema** to make changes to the schema. Note that if you make changes, the schema automatically becomes built-in.

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

| **Table Name** | The name of the table from which data will be retrieved. |

**Query Type and Query**

Specify the database query statement paying particularly attention to the properly sequence of the fields which must correspond to the schema definition.

- **Built-In**: Fill in the query statement in the **Query** field manually or click the [...] button next to the **Query** field to build the statement graphically using the SQLBuilder.
- **Repository**: Select the relevant query stored in the Repository by clicking the [...] button next to it and in the pop-up **Repository Content** dialog box, select the query to be used, and the **Query** field will be automatically filled in.
Advanced settings

**Additional JDBC Parameters**
Specify additional JDBC parameters for the database connection being created.
This property is not available when the **Use an existing connection** check box is selected.

**Trim all the String/Char columns**
Select this check box to remove leading whitespace and trailing whitespace from all String/Char columns.

**Trim column**
Select the check box for corresponding column to remove leading whitespace and trailing whitespace from it.
This property is not available when the **Trim all the String/Char columns** check box is selected.

**tStatCatcher Statistics**
Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NB_LINE</td>
<td>The number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>QUERY</td>
<td>The query statement being processed. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td>ERROR_MESSAGE</td>
<td>The error message generated by the component when an error occurs. This is an After variable and it returns a string.</td>
</tr>
</tbody>
</table>

Usage

**Usage rule**
This component covers all possible SQL queries for the Vertica database.
Talend Studio and the Vertica database create very fast and affordable data warehouse and data mart applications. For more information about how to configure Talend Studio to connect to Vertica, see Talend and HP Vertica Tips and Techniques.

**Dynamic settings**
Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the **Use an existing connection** check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection.
Related scenarios

For related scenarios, see:

- Reading data from different MySQL databases using dynamically loaded connection parameters on page 491.
tVerticaOutput

Inserts, updates, deletes, or copies data from an incoming flow into a Vertica database table.

**tVerticaOutput Standard properties**

These properties are used to configure tVerticaOutput running in the Standard Job framework.

The Standard tVerticaOutput component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

<table>
<thead>
<tr>
<th><strong>Basic settings</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
</tr>
<tr>
<td><strong>Property Type</strong></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td><strong>DB Version</strong></td>
</tr>
<tr>
<td><strong>Use an existing connection</strong></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>
For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th><strong>Host</strong></th>
<th>The IP address or hostname of the database.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Port</strong></td>
<td>The listening port number of the database.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>The name of the database.</td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>The schema of the database.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>The database user authentication data.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td><strong>Table</strong></td>
<td>The name of the table into which data will be written.</td>
</tr>
<tr>
<td><strong>Action on table</strong></td>
<td>Select an operation to be performed on the table defined.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Default</strong>: No operation is carried out.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Drop and create table</strong>: The table is removed and created again.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Create table</strong>: The table does not exist and gets created.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Create table if does not exist</strong>: The table is created if it does not exist.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Drop table if exist and create</strong>: The table is removed if it already exists and created again.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Clear table</strong>: The table content is deleted. You have the possibility to rollback the operation.</td>
</tr>
<tr>
<td><strong>Use &quot;drop cascade&quot;</strong></td>
<td>Select this check box to remove all objects related to the table which will be dropped.</td>
</tr>
<tr>
<td></td>
<td>This property is available only when a table drop related option is selected from the <strong>Action on table</strong> list.</td>
</tr>
<tr>
<td><strong>Action on data</strong></td>
<td>Select an action to be performed on data of the table defined.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Insert</strong>: Add new entries to the table. If duplicates are found, job stops.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Update</strong>: Make changes to existing entries.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Insert or update</strong>: Insert a new record. If the record with the given reference already exists, an update would be made.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Update or insert</strong>: Update the record with the given reference. If the record does not exist, a new record would be inserted.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Delete</strong>: Remove entries corresponding to the input flow.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Copy</strong>: Read data from a text file and insert tuples of entries into the WOS (Write Optimized Store) or directly into the ROS (Read Optimized Store). This option is ideal for bulk loading. For further information, see Vertica SQL Reference Manual.</td>
</tr>
</tbody>
</table>

It is necessary to specify at least one column as a primary key on which the **Update** and **Delete** operations are based. You can do that by clicking **Edit Schema** and selecting the check box(es) next to the column(s) you want to set as
primary key(s). For an advanced use, click the **Advanced settings** view where you can simultaneously define primary keys for the **Update** and **Delete** operations. To do that, select the **Use field options** check box and then in the **Update Key** column, select the check boxes next to the column names you want to use as a base for the **Update** operation. Do the same in the **Deletion key** column for the **Delete** operation.

**Schema and Edit schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

- **Built-In**: You create and store the schema locally for this component only.
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

Click **Edit schema** to make changes to the schema. Note that if you make changes, the schema automatically becomes built-in.

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No upon completion** and choose this schema metadata again in the **Repository Content** window.

**Die on error**

Select the check box to stop the execution of the Job when an error occurs.

Clear the check box to skip any rows on error and complete the process for error-free rows.

When errors are skipped, you can collect the rows on error using a **Row > Reject** connection.

**Advanced settings**

**Additional JDBC Parameters**

Specify additional JDBC parameters for the database connection being created.

This property is not available when the **Use an existing connection** check box is selected.

**Abort on error**

Select this check box to stop the **Copy** operation if any row is rejected and roll back the operation. Thus no data is loaded.
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Maximum rejects</strong></td>
<td>Type in a number to set the REJECTMAX command used by Vertica, which indicates the upper limit on the number of logical records to be rejected before a load fails. If not specified or if value is 0, an unlimited number of rejections are allowed. This property is available only when COPY is selected from the Action on data drop-down list.</td>
</tr>
<tr>
<td><strong>No commit</strong></td>
<td>Select this check box to prevent the current transaction from committing automatically. This property is available only when COPY is selected from the Action on data drop-down list.</td>
</tr>
<tr>
<td><strong>Exception file</strong></td>
<td>Type in the path to, or browse to the file in which messages are written indicating the input line number and the reason for each rejected data record. This property is available only when COPY is selected from the Action on data drop-down list.</td>
</tr>
<tr>
<td><strong>Exception file node</strong></td>
<td>Type in the node of the exception file. If not specified, operations default to the query’s initiator node. This property is available only when COPY is selected from the Action on data drop-down list.</td>
</tr>
<tr>
<td><strong>Rejected data file</strong></td>
<td>Type in the path to, or browse to the file in which to write rejected rows. This file can then be edited to resolve problems and reloaded. This property is available only when COPY is selected from the Action on data drop-down list.</td>
</tr>
<tr>
<td><strong>Rejected data file node</strong></td>
<td>Type in the node of the rejected data file. If not specified, operations default to the query’s initiator node. This property is available only when COPY is selected from the Action on data drop-down list.</td>
</tr>
<tr>
<td><strong>Commit every</strong></td>
<td>Specify the number of rows to be processed before committing batches of rows together into the database. This option ensures transaction quality (but not rollback) and, above all, better performance at executions.</td>
</tr>
<tr>
<td><strong>Use batch mode</strong></td>
<td>Select this check box to activate the batch mode for data processing, and in the Batch size field displayed, specify the number of records to be processed in each batch. This property is available only when Insert, Update, Delete or Copy is selected from the Action on data drop-down list.</td>
</tr>
</tbody>
</table>
| **Additional Columns** | This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing. It is not offered if you create (with or without drop) a database table.  
- **Name**: Type in the name of the schema column to be altered or inserted as new column. |
- **DataType**: Type in the data type for the new column.
- **SQL expression**: Type in the SQL statement to be executed in order to alter or insert the relevant column data.
- **Position**: Select Before, Replace or After following the action to be performed on the reference column.
- **Reference column**: Select a column of reference that the component can use to place or replace the new or altered column.

### Use field options

Select the check box for the corresponding column to customize a request, particularly if multiple actions are being carried out on the data.

- **Update Key**: Select the check box for the corresponding column based on which the data is updated.
- **Deletion Key**: Select the check box for the corresponding column based on which the data is deleted.
- **Updatable**: Select the check box if the data in the corresponding column can be updated.
- **Insertable**: Select the check box if the data in the corresponding column can be inserted.

### Enable debug mode

Select this check box to display each step during processing entries in a database.

### Support null in "SQL WHERE" statement

Select this check box to validate the Null value in the "SQL WHERE" statement.

### Create projection when create table

Select this check box to create a projection for a table to be created.

This check box is available only when the table creation related option is selected from the **Action on table** drop-down list.

### tStatCatcher Statistics

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE</strong></td>
<td>The number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_COPIED</strong></td>
<td>The number of rows copied. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_DELETED</strong></td>
<td>The number of rows deleted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_INSERTED</strong></td>
<td>The number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_REJECTED</strong></td>
<td>The number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_UPDATED</strong></td>
<td>The number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>ERROR MESSAGE</strong></td>
<td>The error message generated by the component when an error occurs. This is an After variable and it returns a string.</td>
</tr>
</tbody>
</table>

**Usage**

| **Usage rule** | This component is usually used as an output component. It allows you to carry out actions on a table or on data of a table in a Vertica database. It also allows you to create a reject flow using a Row > Rejects link to filter data in error. For an example of tMysqlOutput in use, see Retrieving data in error with a Reject link on page 2485.

Talend Studio and the Vertica database create very fast and affordable data warehouse and data mart applications. For more information about how to configure Talend Studio to connect to Vertica, see Talend and HP Vertica Tips and Techniques. |

| **Dynamic settings** | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |

**Related scenarios**

For **tVerticaOutput** related topics, see:

- Inserting a column and altering data using **tMysqlOutput** on page 2477.
tVerticaOutputBulk

Prepares a file to be used by the tVerticaBulkExec component to feed a Vertica database.

The tVerticaOutputBulk component and the tVerticaBulkExec component are generally used together as parts of a two step process. In the first step, an output file is generated. In the second step, the file is used in a bulk operation to feed a database. These two steps are fused together in the tVerticaOutputBulkExec component. The advantage of using two separate components is that the data can be transformed before it is loaded into the database.

tVerticaOutputBulk Standard properties

These properties are used to configure tVerticaOutputBulk running in the Standard Job framework.

The Standard tVerticaOutputBulk component belongs to the Databases family.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

Usage

| **Usage rule** | This component is more commonly used with the tVerticaBulkExec component. Used together, they offer gains in performance while feeding a Vertica database. Talend Studio and the Vertica database create very fast and affordable data warehouse and data mart applications. For more information about how to configure Talend Studio to connect to Vertica, see Talend and HP Vertica Tips and Techniques. |

not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Click **Edit schema** to make changes to the schema. Note that if you make changes, the schema automatically becomes built-in.

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.
Related scenarios

For use cases in relation with tVerticaOutputBulk, see the following scenarios:

- Inserting transformed data in MySQL database on page 2493.
- Inserting data in bulk in MySQL database on page 2500.
tVerticaOutputBulkExec

Receives data from a preceding component, writes data into a local file, and loads data into a Vertica database from the file using the Vertica COPY SQL statement.

For more information about the Vertica COPY SQL statement, see COPY.

The tVerticaOutputBulk component and the tVerticaBulkExec component are generally used together as parts of a two step process. In the first step, an output file is generated. In the second step, the file is used in a bulk load operation to feed a database. These two steps are fused together in the tVerticaOutputBulkExec component. The advantage of using two separate components is that the data can be transformed before it is loaded into the database.

tVerticaOutputBulkExec Standard properties

These properties are used to configure tVerticaOutputBulkExec running in the Standard Job framework.

The Standard tVerticaOutputBulkExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

<tr>
<td>• <strong>Repository</strong>: The connection details stored centrally in Repository &gt; Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up Repository Content dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in.</td>
<td></td>
</tr>
<tr>
<td><strong>DB Version</strong></td>
<td>Select the version of the database.</td>
</tr>
<tr>
<td><strong>Use an existing connection</strong></td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td>When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:</td>
<td></td>
</tr>
<tr>
<td>1. In the parent level, register the database connection to be shared in the Basic settings view of the connection</td>
<td></td>
</tr>
</tbody>
</table>
2. In the child level, use a dedicated connection component to read that registered database connection. For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th>Host</th>
<th>The IP address or hostname of the database.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>The listening port number of the database.</td>
</tr>
<tr>
<td>DB Name</td>
<td>The name of the database.</td>
</tr>
<tr>
<td>Schema</td>
<td>The schema of the database.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>The database user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Action on data</td>
<td>Select an action that will be performed on the data of the table defined. • <strong>Bulk insert</strong>: Insert multiple rows into the table at once instead of doing single row inserts. If duplicates are found, the Job stops. • <strong>Bulk update</strong>: Make simultaneous updates to multiple rows.</td>
</tr>
<tr>
<td>Table</td>
<td>The name of the table into which data will be written.</td>
</tr>
<tr>
<td>Action on table</td>
<td>Select an operation to be performed on the table defined. • <strong>Default</strong>: No operation is carried out. • <strong>Drop and create table</strong>: The table is removed and created again. • <strong>Create table</strong>: The table does not exist and gets created. • <strong>Create table if does not exist</strong>: The table is created if it does not exist. • <strong>Drop table if exist and create</strong>: The table is removed if it already exists and created again. • <strong>Clear table</strong>: The table content is deleted. You have the possibility to rollback the operation.</td>
</tr>
<tr>
<td>Schema and Edit schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <code>LINE</code> when naming the fields. • <strong>Built-In</strong>: You create and store the schema locally for this component only. • <strong>Repository</strong>: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.</td>
</tr>
</tbody>
</table>
You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Click Edit schema to make changes to the schema. Note that if you make changes, the schema automatically becomes built-in.

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

**File Name**
The path to the file to be generated. This file is generated on the same machine where your Studio is installed or where your Job using this component is deployed.

**Append**
Select this check box to add new rows at the end of the file.

**Use schema columns for Copy**
Select this check box to use the column option in the COPY statement so that you can restrict the load to one or more specified columns in the table. For more information, see the Vertica COPY SQL Statement.

### Advanced settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Additional JDBC Parameters</strong></td>
<td>Specify additional JDBC parameters for the database connection being created. This property is not available when the Use an existing connection check box is selected.</td>
</tr>
<tr>
<td><strong>Stream name</strong></td>
<td>The stream name of a load, which helps identify a particular load. This property is available only when you are using Vertica 6.0 and later.</td>
</tr>
<tr>
<td><strong>Write to ROS (Read Optimized Store)</strong></td>
<td>Select this check box to store data in a physical storage area, in order to optimize the reading, as the data is compressed and pre-sorted.</td>
</tr>
<tr>
<td><strong>Exit Job if no row was loaded</strong></td>
<td>The Job automatically stops if no row has been loaded.</td>
</tr>
<tr>
<td><strong>Missing columns as null</strong></td>
<td>Select this check box to insert NULL values for the missing columns when there is insufficient data to match the columns specified in the schema. This property is available only when you are using Vertica 6.0 and later.</td>
</tr>
<tr>
<td><strong>Skip Header</strong></td>
<td>Select this check box and in the field displayed next to it, specify the number of records to skip in the file.</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Record terminator</td>
<td>Select this check box and in the field displayed next to it, specify the literal character string used to indicate the end of each record in the file. This property is available only when you are using Vertica 6.0 and later.</td>
</tr>
<tr>
<td>Enclosed by character</td>
<td>Select this check box to set the character within which data is enclosed. This property is available only when you are using Vertica 6.0 and later.</td>
</tr>
<tr>
<td>Field Separator</td>
<td>The character, string or regular expression to separate fields.</td>
</tr>
<tr>
<td>Null String</td>
<td>The string displayed to indicate that the value is null.</td>
</tr>
<tr>
<td>Include Header</td>
<td>Select the check box to include the column header to the file.</td>
</tr>
<tr>
<td>Encoding</td>
<td>Select an encoding method from the list, or select <strong>CUSTOM</strong> and define it manually. This field is compulsory for database data handling.</td>
</tr>
<tr>
<td>Reject not fitted values</td>
<td>Select this check box to reject data rows of type char, varchar, binary, and varbinary if they do not fit the target table. This property is available only when you are using Vertica 6.0 and later.</td>
</tr>
<tr>
<td>Maximum number of rejected records</td>
<td>Select this check box and in the field displayed next to it, specify the maximum number of records that can be rejected before a load fails. This property is available only when you are using Vertica 6.0 and later.</td>
</tr>
<tr>
<td>Stop and rollback if any row is rejected</td>
<td>Select this check box to stop and roll back a load without loading any data if any row is rejected. This property is available only when you are using Vertica 6.0 and later.</td>
</tr>
<tr>
<td>Don’t commit</td>
<td>Select this check box to perform a bulk load transaction without committing the results automatically. This is useful if you want to execute multiple bulk loads in a single transaction. This property is available only when you are using Vertica 6.0 and later.</td>
</tr>
<tr>
<td>Rejected data file</td>
<td>Specify the file into which rejected rows will be written. This property is available only when Bulk insert is selected from the Action on data drop-down list.</td>
</tr>
<tr>
<td>Exception log file</td>
<td>Specify the file into which the exception log will be written. This log explains why each rejected row was rejected.</td>
</tr>
</tbody>
</table>
This property is available only when Bulk insert is selected from the Action on data drop-down list.

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

### Global Variables

| ACCEPTED_ROW_NUMBER | The number of rows loaded into the database. This is an After variable and it returns an integer. |
| REJECTED_ROW_NUMBER | The number of rows rejected. This is an After variable and it returns an integer. |
| ERROR_MESSAGE | The error message generated by the component when an error occurs. This is an After variable and it returns a string. |

### Usage

**Usage rule**

This component is mainly used when no particular transformation is required on the data to be loaded into the database.

Talend Studio and the Vertica database create very fast and affordable data warehouse and data mart applications. For more information about how to configure Talend Studio to connect to Vertica, see Talend and HP Vertica Tips and Techniques.

### Related scenarios

For use cases in relation with tVerticaOutputBulkExec, see the following scenarios:

- Inserting transformed data in MySQL database on page 2493.
- Inserting data in bulk in MySQL database on page 2500.
tVerticaRollback

Cancels the transaction commit in the Vertica database.

**tVerticaRollback Standard properties**

These properties are used to configure tVerticaRollback running in the Standard Job framework.

The Standard tVerticaRollback component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td>Component List</td>
<td>Select the component in which the relevant reused connection is configured.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Select this check box to close the database connection once the component has performed its task. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

### Advanced settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tStatCatcher Statistics</td>
<td>Select this check box to gather the Job processing metadata at the Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

### Usage

**Usage rule**

This component is more commonly used with other tVertica components, especially with the **tVerticaConnection** and **tVerticaCommit** components.

Talend Studio and the Vertica database create very fast and affordable data warehouse and data mart applications. For more information about how to configure Talend Studio to connect to Vertica, see Talend and HP Vertica Tips and Techniques.

**Dynamic settings**

Click the ![+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.
Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenario

For tVerticaRollback related scenario, see Rollback from inserting data in mother/daughter tables on page 2440.
tVerticaRow

Executes a Vertica SQL statement against a database table.

**tVerticaRow Standard properties**

These properties are used to configure tVerticaRow running in the Standard Job framework.

The Standard tVerticaRow component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
</table>
| Property Type | Select the way the connection details will be set.  
• **Built-In**: The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.  
• **Repository**: The connection details stored centrally in **Repository > Metadata** will be reused by this component. You need to click the [...] button next to it and in the pop-up **Repository Content** dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in. |
| DB Version | Select the version of the database. |
| Use an existing connection | Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined.  
When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:  
1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.  
2. In the child level, use a dedicated connection component to read that registered database connection.  
For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*. |
| Host | The IP address or hostname of the database. |
| Port | The listening port number of the database. |
| **Database** | The name of the database. |
| **Schema** | The schema of the database. |
| **Username and Password** | The database user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings. |
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word **line** when naming the fields. |
| | • **Built-In:** You create and store the schema locally for this component only. |
| | • **Repository:** You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. |
| | Click **Edit schema** to make changes to the schema. Note that if you make changes, the schema automatically becomes built-in. |
| | • **View schema:** choose this option to view the schema only. |
| | • **Change to built-in property:** choose this option to change the schema to **Built-in** for local changes. |
| | • **Update repository connection:** choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window. |
| **Table Name** | The name of the table to be processed. |
| **Query Type and Query** | Specify the database query statement paying particularly attention to the properly sequence of the fields which must correspond to the schema definition. |
| | • **Built-In:** Fill in the query statement in the **Query** field manually or click the [...] button next to the **Query** field to build the statement graphically using the SQLBuilder. |
| | • **Repository:** Select the relevant query stored in the Repository by clicking the [...] button next to it and in the pop-up **Repository Content** dialog box, select the query to be used, and the **Query** field will be automatically filled in. |
| **Die on error** | Select the check box to stop the execution of the Job when an error occurs. Clear the check box to skip any rows on error and complete the process for error-free rows. When errors are skipped, you can collect the rows on error using a **Row > Reject** connection. |
### Advanced settings

| **Additional JDBC Parameters** | Specify additional JDBC parameters for the database connection being created.  
This property is not available when the **Use an existing connection** check box is selected. |
|-------------------------------|------------------------------------------------------------------------------------------------------------------|
| **Propagate QUERY’s recordset** | Select this check box to propagate the result of the query to the output flow. From the **use column** list displayed, you need to select a column into which the query result will be inserted.  
This option allows the component to have a different schema from that of the preceding component. Moreover, the column that holds the query’s recordset should be set to the **Object** type and this component is usually followed by a **tParseRecordSet** component. |
| **Use PreparedStatement** | Select this check box if you want to query the database using a prepared statement. In the **Set PreparedStatement Parameters** table displayed, specify the value for each parameter represented by a question mark (?) in the SQL statement defined in the **Query** field.  
- **Parameter Index**: the position of the parameter in the SQL statement.  
- **Parameter Type**: the data type of the parameter.  
- **Parameter Value**: the value of the parameter.  
For a related use case of this property, see Using PreparedStatement objects to query data on page 2509. |
| **Commit every** | Specify the number of rows to be processed before committing batches of rows together into the database.  
This option ensures transaction quality (but not rollback) and, above all, better performance at executions. |
| **tStatCatcher Statistics** | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

### Global Variables

| **NB_LINE_DELETED** | The number of rows deleted. This is an After variable and it returns an integer. |
| **NB_LINE_INSERTED** | The number of rows inserted. This is an After variable and it returns an integer. |
| **NB_LINE_UPDATED** | The number of rows updated. This is an After variable and it returns an integer. |
| **QUERY** | The query statement being processed. This is a Flow variable and it returns a string. |
| **ERROR_MESSAGE** | The error message generated by the component when an error occurs. This is an After variable and it returns a string. |
Usage

| Usage rule | This component offers the flexibility of the DB query and covers all possible SQL queries. Talend Studio and the Vertica database create very fast and affordable data warehouse and data mart applications. For more information about how to configure Talend Studio to connect to Vertica, see Talend and HP Vertica Tips and Techniques. |

Dynamic settings

| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |

Related scenario

For related topics, see:

- Combining two flows for selective output on page 2514
- Procedure on page 625.
- Removing and regenerating a MySQL table index on page 2508.
**tVerticaSCD**

Tracks and reflects data changes in a dedicated Vertica SCD table.

**tVerticaSCD Standard properties**

These properties are used to configure tVerticaSCD running in the Standard Job framework.

The Standard tVerticaSCD component belongs to the Business Intelligence and the Databases families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

</tbody>
</table>

**Usage**

| Usage rule | Usually used as a Start component. An output component is required. |

**Related scenarios**

No scenario is available for the Standard version of this component yet.
tVtigerCRMOutput

Wrote data into a module of a VtigerCRM database.

**tVtigerCRMOutput Standard properties**

These properties are used to configure tVtigerCRMOutput running in the Standard Job framework. The Standard tVtigerCRMOutput component belongs to the Business family. The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Vtiger Version</th>
<th>Select the version of the Vtiger Web Services you want to use (either Vtiger 5.0 or Vtiger 5.1)</th>
</tr>
</thead>
</table>

When the version to be used is Vtiger 5.0:

<table>
<thead>
<tr>
<th>Server Address</th>
<th>Type in the IP address of the VtigerCRM server.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>Type in the Port number to access the server.</td>
</tr>
<tr>
<td>Vtiger Path</td>
<td>Type in the path to access the server.</td>
</tr>
</tbody>
</table>

**Username and Password**

Type in the user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

<table>
<thead>
<tr>
<th>Version</th>
<th>Type in the version of VtigerCRM you are using.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Module</th>
<th>Select the relevant module in the list</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Method</th>
<th>Select the relevant method in the list. The method specifies the action you can carry out on the VtigerCRM module selected.</th>
</tr>
</thead>
</table>

| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
- **View schema**: choose this option to view the schema only.  
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon |
|----------------------|--------------------------------------------------------------------------------------------------|
When the version to be used is Vtiger 5.1

<table>
<thead>
<tr>
<th><strong>Endpoint</strong></th>
<th>Type in the URL address of the invoked Web server.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Username</strong></td>
<td>Type in the user name to log in to the VtigerCRM.</td>
</tr>
<tr>
<td><strong>Access key</strong></td>
<td>Type in the access key for the user name.</td>
</tr>
<tr>
<td><strong>Action</strong></td>
<td>Insert or Update the data in the SugarCRM module.</td>
</tr>
<tr>
<td><strong>Module</strong></td>
<td>Select the relevant module in the list</td>
</tr>
</tbody>
</table>

**Schema and Edit Schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `LINE` when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

In this component the schema is related to the Module selected.

**Die on error**

This check box is clear by default to skip the row on error and complete the process for error-free rows.

**Advanced settings**

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

**Global Variables**

**Global Variables**

- **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>Used as an output component. An Input component is required.</th>
</tr>
</thead>
</table>

### Related scenarios

No scenario is available for the Standard version of this component yet.
tWaitForFile

Iterates on a directory and triggers the next component when the defined condition is met.

This component is used to put the component connected with it in waiting state. It then triggers that component when the defined file operation occurs in the specified directory.

**tWaitForFile Standard properties**

These properties are used to configure tWaitForFile running in the Standard Job framework.

The Standard tWaitForFile component belongs to the Orchestration family.

The component in this framework is available in all Talend products.

### Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Time (in seconds) between iterations</strong></td>
<td>Set the time interval in seconds between each two iterations.</td>
</tr>
<tr>
<td><strong>Max. number of iterations (infinite loop if empty)</strong></td>
<td>Set the maximum number of iterations on the specified directory.</td>
</tr>
<tr>
<td><strong>Directory to scan</strong></td>
<td>Specify the directory to iterate on.</td>
</tr>
<tr>
<td><strong>File mask</strong></td>
<td>Type in the file mask to filter the files to be monitored. To monitor a given file, type in the file name.</td>
</tr>
<tr>
<td><strong>Include subdirectories</strong></td>
<td>Select this check box to iterate also on the subdirectories.</td>
</tr>
<tr>
<td><strong>Case sensitive</strong></td>
<td>Select this check box to activate case sensitivity.</td>
</tr>
<tr>
<td><strong>Include present file</strong></td>
<td>Select this check box to include the file in use.</td>
</tr>
</tbody>
</table>
| **Trigger action when** | Select one of the following trigger conditions:  
  - **a file is created**: triggers the next component when a file is created.  
  - **a file is deleted**: triggers the next component when a file is removed.  
  - **a file is updated**: triggers the next component when a file is modified.  
  - **a file is created or updated or deleted**: triggers the next component when a file is created, or removed, or modified. |
| **Then** | Select what to do with the iteration loop after the next component is triggered:  
  - **continue loop**: continues iterating until the number of iterations reaches the defined maximum value.  
  - **exit loop**: stops iterating immediately. |
| **Schema** and **Edit Schema** | A schema is a row description, it defines the number of fields that will be processed and passed on to the next component. The schema of this component is **Built-in** and cannot be updated. |
### Advanced Settings

| Wait for file to be released Every (in ms) | Select this check box so that the next component is triggered only after the file operation is completed. |

### Global Variables

| Global Variables | \( \text{ERROR\_MESSAGE} \): the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. |
|\| \( \text{CURRENT\_ITERATION} \): the sequence number of the current iteration. This is a Flow variable and it returns an integer. |
|\| \( \text{PRESENT\_FILE} \): the path and name of the present file. This is a Flow variable and it returns a string. |
|\| \( \text{DELETED\_FILE} \): the path and name of the deleted file. This is a Flow variable and it returns a string. |
|\| \( \text{CREATED\_FILE} \): the path and name of the created file. This is a Flow variable and it returns a string. |
|\| \( \text{UPDATED\_FILE} \): the path and name of the updated file. This is a Flow variable and it returns a string. |
|\| \( \text{FILENAME} \): the name of the file being processed. This is a Flow variable and it returns a string. |
|\| \( \text{NOT\_UPDATED\_FILE} \): the path and name of the file that has not been updated. This is a Flow variable and it returns a string. |

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press \( \text{Ctrl} + \text{Space} \) to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

### Usage

| Usage rule | This component plays the role of triggering the next component based on the defined condition. Therefore this component requires another component to be connected to it via a link. |
| Connections | Outgoing links (from this component to another): |
|\| \( \text{Row} \): Main; Iterate. |
|\| \( \text{Trigger} \): On Subjob Ok; Run if; On Component Ok; On Component Error. |
|\| Incoming links (from one component to this one): |
|\| \( \text{Row} \): Iterate. |
|\| \( \text{Trigger} \): On Subjob Ok; Run if; On Component Ok; On Component Error; Synchronize; Parallelize. |
Waiting for a file to be created and stopping the iteration loop after a message is triggered

This scenario describes a Job that scans a directory and triggers a message showing file creation information on the console when a text file is created in that directory. Immediately after this, the scanning is ended, followed by another message showing the number of iterations finished.

Dropping and linking the components

Procedure

1. Drop three components from the Palette onto the design workspace: one tWaitForFile and two tJava components.
2. Connect tWaitForFile to the first tJava using a Row > Iterate connection.
3. Connect tWaitForFile to the second tJava using a Trigger > On Subjob Ok connection.

Configuring the components

Procedure

1. Double-click tWaitForFile to open its Basic settings view.
2. In the Directory to scan field, enter the directory to be scanned.
3. In the File mask field, enter "*.txt" to scan only text files.
4. From the Trigger action when drop-down list, select a file is created to trigger the first tJava when a text file is created.
5. From the Then drop-down list, select exit loop to stop the iteration loop immediately after the first tJava is triggered.
6. Double-click the first tJava to open its Basic settings view.

7. In the code area, type in the following code:

```java
System.out.println("A file was created at " + TalendDate.getCurrentDate());
System.out.println("Name of the created file: " + ((String)globalMap.get("tWaitForFile_1_CREATED_FILE")));
```

8. Double-click the second tJava to open its Basic settings view.
9. In the code area, type in the following code:

```java
System.out.println("\r\nIteration loop ended at " + TalendDate.getCurrentDate());
System.out.println("Number of iterations finished: " + ((Integer)globalMap.get("tWaitForFile_1_CURRENT_ITERATION")));
```

**Saving and executing the Job**

**Procedure**

1. Press Ctrl+S to save the Job.
2. Press F6 to execute the Job.
3. Create a text file exit.txt in the defined directory.
When a text file is created, a message about file creation is displayed on the Run console. The iteration loop is ended immediately after that, followed by another message showing the time the iteration loop is ended and the number of iterations executed.

**Waiting for a file to be created and continuing the iteration loop after a message is triggered**

Based on the previous scenario, this scenario describes a Job triggers a message on the console when a text file is created in the directory being scanned, without ending the scanning process immediately. The Job continues scanning the directory until the number of iterations reaches the defined maximum value.

**Procedure**

1. Double-click **tWaitForFile** to open its **Basic settings** view.

2. In the **Time (in seconds) between iterations** field, enter the time interval in seconds between each two iterations. In this example, it is set to 5.

3. In the **Max. number of iterations (infinite loop if empty)** field, enter the maximum number of iterations. In this example, it is set to 10.

4. From the **Then** drop-down list, select **continue loop** to continue the iteration loop after the message is triggered.

5. Press **Ctrl+S** to save the Job.

6. Press **F6** to execute the Job.
7. Create a text file `continue.txt` in the defined directory.

```
Starting job DOCTS124_tWaitForFile_501 at 14:35 18/03/2014.
[statistics] connecting to socket on port 3455
A file was created at Tue Mar 18 14:35:28 CST 2014
Name of the created file: E:\Studio\continue.txt

The iteration was ended at Tue Mar 18 14:36:03 CST 2014
Number of iterations finished: 10
[statistics] disconnected
Job DOCTS124_tWaitForFile_501 ended at 14:36 18/03/2014. [exit code=0]
```

When a text file is created, a message about file creation is displayed on the Run console. The iteration loop is ended until the number of iterations reaches ten, followed by another message showing the time the iteration loop is ended and the number of iterations executed.
tWaitForSocket

Triggers a Job based on a defined condition.

tWaitForSocket component makes a loop on a defined port, to look for data, and triggers a subjob when the condition is met.

**tWaitForSocket Standard properties**

These properties are used to configure tWaitForSocket running in the Standard Job framework.
The Standard tWaitForSocket component belongs to the Orchestration family.
The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Port</th>
<th>DB server listening port.</th>
</tr>
</thead>
<tbody>
<tr>
<td>End of line separator</td>
<td>Enter the end of line separator to be used.</td>
</tr>
<tr>
<td>Then</td>
<td>Select the action to be carried out: keep on listening or close socket</td>
</tr>
<tr>
<td>Print client/server data</td>
<td>Select this check box to display the client or server data.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect the log data at a component level. |

**Global Variables**

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. |
|-------------------| INPUT_DATA: the data transmitted by the client. This is a Flow variable and it returns a string. |
|                   | A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. |
|                   | To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. |
|                   | For further information about variables, see Talend Studio User Guide. |
Usage

**Usage rule**

This is an input, trigger component for the subjob executed depending on the condition set. Hence, it needs to be connected to a subjob via an Iterate link.

**Connections**

Outgoing links (from this component to another):
- **Row**: Iterate.
- **Trigger**: On Subjob Ok; On Subjob Error; Run if; On Component Ok; On Component Error.

Incoming links (from one component to this one):
- **Row**: Iterate.
- **Trigger**: On Subjob Ok; On Subjob Error; Run if; On Component Ok; On Component Error; Synchronize; Parallelize.

For further information regarding connections, see [Talend Studio User Guide](#).

Related scenarios

No scenario is available for the Standard version of this component yet.
tWaitForSqlData

Iterates on a given connection for insertion or deletion of rows and triggers a subJob when a condition linked to SQL data presence is met.

**tWaitForSqlData Standard properties**

These properties are used to configure tWaitForSqlData running in the Standard Job framework.

The Standard tWaitForSqlData component belongs to the Orchestration family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Wait at each iteration (in seconds)</td>
<td>Set the time interval in seconds between each check for the sql data.</td>
</tr>
<tr>
<td>Max. iterations (infinite if empty)</td>
<td>Number of checks for sql data before the Jobs times out.</td>
</tr>
<tr>
<td>Use an existing connection/Component List</td>
<td>A connection needs to be open to allow the loop to check for sql data on the defined DB.</td>
</tr>
<tr>
<td></td>
<td>When a Job contains the parent Job and the child Job, Component list presents only the connection components in the same Job level, so if you need to use an existing connection from the other level, you can</td>
</tr>
<tr>
<td></td>
<td>From the available database connection component in the level where the current component is, select the Use or register a shared DB connection check box. For more information about this check box, see tMysqlConnection on page 2436 for the connection components according to the database you are using.</td>
</tr>
<tr>
<td></td>
<td>Otherwise, still in the level of the current component, deactivate the connection components and use Dynamic settings of the component to specify the intended connection manually. In this case, make sure the connection name is unique and distinctive all over through the two Job levels. For more information about Dynamic settings, see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Table to scan</td>
<td>Name of the table to be checked for insert or deletion</td>

<tr>
<td></td>
<td>Equal to Not Equal to Greater than Lower than Greater or equal to Lower or equal to</td>
</tr>
<tr>
<td>Value</td>
<td>Define the value to take into account.</td>
</tr>
<tr>
<td>Then</td>
<td>Select the action to be carried out: either stop the iterations when the condition is met (exit loop) or continue the loop until the end of the max iteration number (continue loop).</td>
</tr>
</tbody>
</table>
Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERROR_MESSAGE</td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td>CURRENT_ITERATION</td>
<td>the sequence number of the current iteration. This is a Flow variable and it returns an integer.</td>
</tr>
<tr>
<td>ROW_COUNT</td>
<td>the number of rows detected in the table. This is a Flow variable and it returns an integer. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
</tbody>
</table>

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

| Usage rule | Although this component requires a Connection component to open the DB access, it plays also the role of the start (or trigger) component of the subjob which gets executed under the condition described. Therefore this component requires a subjob to be connected to via an Iterate link. |

Waiting for insertion of rows in a table

This scenario describes a Job reading a DB table and waiting for data to be put in this table in order for a subjob to be executed. When the condition of the data insertion in the table is met, then the subjob performs a Select* on the table and simply displays the content of the inserted data onto the standard console.

- Drop the following components from the Palette onto the design workspace: tMySqlConnection, tWaitForSqlData, tMysqlInput, tLogRow.
- Connect the tMySqlConnection component to the tWaitForSqlData using an OnSubjobOK link, available on the right-click menu.
- Then connect the tWaitForSqlData component to the subjob using an Iterate link as no actual data is transferred in this part. Indeed, simply a loop is implemented by the tWaitForSqlData until the condition is met.
- On the subjob to be executed if the condition is met, a tMySqlInput is connected to the standard console component, tLogRow. As the connection passes on data, use a Row main link.
- Now, set the connection to the table to check at regular intervals. On the Basic Settings view of the tMySqlConnection Component tab, set the DB connection properties.

![Diagram](image-url)
• Fill out the **Host**, **Port**, **Database**, **Username**, **Password** fields to open the connection to the Database table.
• Select the relevant **Encoding** if needed.
• Then select the **tWaitForSqlData** component, and on the **Basic Setting** view of the **Component** tab, set its properties.
• In the **Wait at each iteration** field, set the time in seconds you want to wait before the next iteration starts.

Wait at each iteration (in seconds) **5**
Max iterations (infinite loop if empty) **5**
Use an existing connection **Y**
Component List **MysqlConnection_1**

• In the **Max iterations** field, fill out the number of iterations max you want to have before the whole Job is forced to end.
• The **tWaitForSqlData** component requires a connection to be open in order to loop on the defined number of iteration. Select the relevant connection (if several) in the **Component List** combo box.
• In the **Table to scan** field, type in the name of the table in the DB to scan. In this example: **test_datatypes**.
• In the **Trigger action when rowcount is** and **Value** fields, select the condition to be met, for the sublob to be triggered. In this use case, the number of rows in the scanned table should **be greater or equal to 1**.
• In the **Then** field, select the action to be carried out when the condition is met before the number of iteration defined is reached. In this use case, as soon as the condition is met, the loop should be ended.
• Then set the sublob to be executed when the condition set is met. In this use case, the sublob simply selects the data from the scanned table and displays it on the console.
• Select the **tMySqlInput** component, and on the **Basic Setting** view of the **Component** tab, set the connection to the table.
If the connection is set in the Repository, select the relevant entry on the list. Or alternatively, select the Use an existing connection check box and select the relevant connection component on the list.

In this use case, the schema corresponding to the table structure is stored in the Repository.

Fill out the Table Name field with the table the data is extracted from, Test_datatypes.

Then in the Query field, type in the Select statement to extract the content from the table.

No particular setting is required in the tLogRow component for this use case.

Then before executing the Job, make sure the table to scan (test_datatypes) is empty, in order for the condition (greater or equal to 1) to be met. Then execute the Job by pressing the F6 key on your keyboard. Before the end of the iterating loop, feed the test_datatypes table with one or more rows in order to meet the condition.

The Job ends when this table insert is detected during the loop, and the table content is thus displayed on the console.
tWarn

Triggers a warning often caught by the tLogCatcher component for exhaustive log.

Both tDie and tWarn components are closely related to the tLogCatcher component. They generally make sense when used alongside a tLogCatcher in order for the log data collected to be encapsulated and passed on to the output defined.

This component provides a priority-rated message to the next component. It does not stop your Job in case of error. If you want to kill a Job in case of error, see tDie on page 637.

**tWarn Standard properties**

These properties are used to configure tWarn running in the Standard Job framework.

The Standard tWarn component belongs to the Logs & Errors family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Warn message</th>
<th>Type in your warning message.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Code</td>
<td>Define the code level.</td>
</tr>
<tr>
<td>Priority</td>
<td>Enter the priority level as an integer.</td>
</tr>
</tbody>
</table>

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>WARN_MESSAGES: the warning message. This is an After variable and it returns a string.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>WARN_CODE: the code level of the warning message. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>WARN_PRIORITY: the priority level of the warning message. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.
Usage

| Usage rule | Cannot be used as a start component. If an output component is connected to it, an input component should be preceding it. |

Related scenarios

For use cases in relation with tWarn, see tLogCatcher scenarios:

- Catching messages triggered by a tWarn component on page 1950
- Catching the message triggered by a tDie component on page 1952
**tWebService**

Calls a method via a Web service in order to retrieve the values of the parameters defined in the component editor.

**Warning:**

*This component requires a JDK to be functional. It should be noted that tWebservice will not run in the Talend Cloud.*

tWebservice calls the defined method from the invoked Web service and returns the class as defined, based on the given parameters.

### tWebService Standard properties

These properties are used to configure tWebService running in the Standard Job framework.

The Standard tWebService component belongs to the Internet family.

The component in this framework is available in all Talend products.

#### Basic settings

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either <strong>Built-in</strong> or <strong>Repository</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-in:</strong></td>
<td>No property data stored centrally. Enter properties manually</td>
</tr>
<tr>
<td><strong>Repository:</strong></td>
<td>Select the repository file where properties are stored. The fields that come after are pre-filled in using the fetched data.</td>
</tr>
</tbody>
</table>

**Service configuration**

Click the three-dot button next to the field to open the component editor.

In this editor, you can:

- select the Web service you want to use,
- configure the input parameters of the Web service,
- configure the output parameters of the Web service. These parameters will be used to retrieve and output specific data.

**Mapping links display as**

**Auto:** By default, the links between the input and output schemas and the Web service parameters are in the form of curves.

**Curves:** Links between the schema and the Web service parameters are in the form of curve.

**Lines:** Links between the schema and the Web service parameters are in the form of straight lines. This option slightly optimizes performance.

**Connection Time out**

Set a value in seconds for Web service connection time out.

**Receive Time out**

Set a value in seconds for server answer.
### Input schema

A schema is a row description. It defines the number of fields that will be processed and passed on to the next component. The schema is either built-in or remote in the Repository. This field is used to process the input schema. The option for this schema may be:

- **Built-in**: No property data stored centrally.
- **Repository**: Select the Repository file where properties are stored. The following fields are pre-filled in using fetched data.

### Edit Schema

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

### Sync columns

This button is available when an input link has been created. Click this button to retrieve the schema from the previous component connected in the Job.

### Output schema

This field is used to process the output schema. The schema is either built-in or remote in the Repository and is configured the same way as the input schema is.

**Warning:**

*The input schema is not necessarily identical with the output schema.*

### Use NTLM

Select this check box if you want to use the NTLM authentication protocol.

**Domain**: Name of the client domain,

**Host**: Client IP address.

### Need authentication

Select this check box and enter a username and a password in the corresponding fields if this is necessary to access the service.

To enter the password, click the `[...]` button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

### Use http proxy

Select this check box if you are using a proxy server and fill in the necessary information.

### Trust server with SSL

Select this check box to validate the server certificate to the client via an SSL protocol and fill in the corresponding fields:
TrustStore file: enter the path (including filename) to the certificate TrustStore file that contains the list of certificates that the client trusts.
TrustStore password: enter the password used to check the integrity of the TrustStore data.

**Die on error**
Clear this check box to skip the rows in error and to complete the process for the error free rows.

### Advanced settings

**Temporary folder (for wsdl2java)**
Set or browse to a temporary folder that you configured in order to store the wsdl files.

**tStatCatcher Statistics**
Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

### Global Variables

**Global Variables**

- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.
- **NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](https://docs.talend.com/).

### Usage

#### Usage rule
This component can be used as an input or as an intermediate component. It must be linked to an output component.

#### Limitation
A JDK is required for this component to operate.

### Getting country names using tWebService

This scenario describes a three-component Job that uses a Web service to retrieve the country name corresponding to a given country code.
Linking components

Procedure
1. Drop the following components from the Palette onto the design workspace: tFixedFlowInput, tWebService, and tLogRow.

![Diagram of component connections]

2. Connect the components together using Main Row links.

Configuring the input data

Procedure
1. Double-click tFixedFlowInput to open its Basic settings view and define the component properties.

![Screenshot of tFixedFlowInput Basic settings]

2. Click the three-dot button next to the Edit schema field to open a dialog box where you can define the input schema.
3. In the open dialog box, click the plus button to add a column to the schema.
4. Click in the column and type in a name, CountryCode in this example.
5. Click OK to close the schema definition dialog box. The CountryCode column displays in the Values table in the component Basic settings view.
6. In the Values table, click in the Value column and enter the value of the CountryCode column, cn in this example. This country code will be passed to the tWebService component to retrieve the country name corresponding to it.
Configuring the Web service

Selecting the WSDL

Procedure

1. Double-click **tWebService** to open the component editor, or select the component in the design workspace and in the **Basic settings** view, click the three-dot button next to **Service configuration**.

![Component editor with WSDL selection](image)

2. In the **WSDL** field, enter the Web service address or browse to it, if the WSDL is locally stored, by clicking the **Browse...** button. In this example, the WSDL URL is `http://www.webservicex.net/country.asmx?WSDL`.

3. Click the refresh button next to the **WSDL** field to retrieve the WSDL description and display it in the fields that follow.

4. In the **Port Name** list, select the port you want to use, `countrySoap` in this example.

5. In the **Operation** list, select the service you want to use. In this example, the selected service is `GetCountryByCountryCode(parameters):string`.

Configure the input mapping

Procedure

1. Click **Next** to open a new view in the editor.
2. In the panel to the right of the Input mapping view, select [+ parameters] and then click the plus button on top to display the Parameter Tree dialog box where you can select any of the listed parameters.

   The Web service in this example has only one input parameter, CountryCode.

   **Note:**

   If available, use the Auto map! button, located at the bottom left of the interface, to carry out the mapping operation automatically.

   You now need to create a connection between the input schema and the input parameter of the defined Web service.

3. In the Column list, drag the column in the input schema you want to link to the input parameter of the Web service to the corresponding parameter in the panel to the right.

   ![Configuring the output mapping](image)

   **Configuring the output mapping**

   **Procedure**

   1. Click Next to open a new view in the editor.
In the Element list to the left of the view, the output parameter of the web service displays automatically. However, you can add other parameters if you select [+ parameters] and then click the plus button on top to display the Parameter Tree dialog box where you can select any of the parameters listed.

The Web service in this example has only one output parameter: GetCountryByCountryCodeResult.

2. In the panel to the right of the view, click the three-dot button next to Edit Schema to open a dialog box in which you can define the output schema.

3. In the Output list to the right of the dialog box, click the plus button to add a column to the output schema.

4. Click in the column and type in a name, Result in this example. This will retrieve the names of the country.

5. Click OK to validate your changes and to close the schema definition dialog box.

You now need to create a connection between the output parameter of the defined Web service and the schema of the output component.

6. In the Element list to the right of the editor, drag parameters.GetCountryByCountryCodeResult to the field that corresponds to the Result column to the right of the editor.
7. Click **OK** to validate your changes and to close the editor.

8. Click the [...] button to open the **Schema** dialog box, and add a column to the output schema, *Result* in this example. Then click **OK** to validate the schema setting and close the dialog box.

9. Double-click the **tLogRow** component to open its **Basic settings** view, and click **Sync columns** to retrieve the schema from the proceeding component.

### Executing the Job

**Procedure**

Save your Job and press **F6** to execute it.
Results

The country name corresponding to the specified country code is returned from the Web service.
tWebServiceInput

Invokes a Method through a Web service.

This component calls the defined method from the invoked Web service, and returns the class as defined, based on the given parameters.

**tWebServiceInput Standard properties**

These properties are used to configure tWebServiceInput running in the Standard Job framework.

The Standard tWebServiceInput component belongs to the Internet family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-in or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Built-in</strong>: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: Select the Repository file where the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>![icon]</td>
<td>Click this icon to open a WSDL schema wizard and store your WSDL connection in the Repository tree view. For more information about setting up and storing database connection parameters, see <a href="#">Talend Studio User Guide</a>.</td>
</tr>
</tbody>
</table>

**Schema and Edit Schema**

A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either **Built-in** or stored remotely in the Repository.

Click [Edit schema](#) to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the [Repository Content](#) window.

<p>| Property type | <strong>Built-in</strong>: You create the schema and store it locally for the relevant component. Related topic: see <a href="#">Talend Studio User Guide</a>. |
|               | <strong>Repository</strong>: You have already created the schema and stored it in the Repository. You can reuse it in various projects and job flowcharts. Related topic: see <a href="#">Talend Studio User Guide</a>. |</p>
<table>
<thead>
<tr>
<th><strong>WSDL</strong></th>
<th>Description of Web service bindings and configuration.</th>
</tr>
</thead>
</table>
| **Need authentication / Username and Password** | Select this check box and:  
- enter a username and a password in the corresponding fields if this is necessary to access the service. Or,  
- select the **Windows authentication** check box and enter the windows domain in the corresponding field if this is necessary to access the service.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings. |
| **Use http proxy** | Select this check box if you are using a proxy server and fill in the necessary information. |
| **Trust server with SSL** | Select this check box to validate the server certificate to the client via an SSL protocol and fill in the corresponding fields:  
**TrustStore file**: enter the path (including filename) to the certificate TrustStore file that contains the list of certificates that the client trusts.  
**TrustStore password**: enter the password used to check the integrity of the TrustStore data. |
| **Time out (second)** | Set a value in seconds for Web service connection time out. |
| **Method Name** | Enter the exact name of the Method to be invoked.  
The Method name MUST match the corresponding method described in the Web Service. The Method name is also case-sensitive. |
| **Parameters** | Enter the parameters expected and the sought values to be returned. Make sure that the parameters entered fully match the names and the case of the parameters described in the method. |
| **Advanced Use** | Select this check box to display the fields dedicated for the advanced use of **tWebServiceInput**:  
**WSDL2Java**: click the three-dot button to generate **Talend** routines that hold the Java code necessary to connect and query the Web service.  
**Code**: replace the generated model Java code with the code necessary to connect and query the specified Web service using the code in the generated **Talend** routines.  
**Match Brackets**: select the number of brackets to be used to close the for loop based on the number of open brackets. |
| **tStatCatcher Statistics** | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

**Global Variables**

| **Global Variables** | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the... |

| 3983 |  |
**Usage**

| Usage rule | This component is generally used as a Start component. It must be linked to an output component. |

**Getting country names using tWebServiceInput**

This scenario describes a two-component Job which uses a Web service method to obtain the country name corresponding to a given country code and displays the output on the Run console view.

**Getting country names using tWebServiceInput**

**Procedure**

1. Drop a `tWebServiceInput` component and a `tLogRow` component from the Palette onto the design workspace.

2. Link the two components using a Row > Main connection.

3. Double-click the `tWebServiceInput` component to open its Basic settings view.
4. Click the [...] button next to Edit schema to open the Schema dialog box and define the schema for the response from the Web service.

   In this example, the schema is composed of only one column: Result.

5. In the WSDL field, specify the WSDL URL of the Web service to be used, http://www.webservicex.net/country.asmx?WSDL in this example.

6. If you are using a proxy server, select the Use http proxy check box and enter the necessary connection information.

7. In the Method name field, enter the method to be used. Note that the method name is case sensitive.

   In this example, we use the method GetCountryByCountryCode.

8. In the Parameters area, click the plus [+] button to add a row to the table, then enter a country code, fr in this example.

9. Then save your Job and press F6 to execute it.
The country information is returned from the Web service and displayed on the Run view.
tWriteJSONField

Transforms the incoming data into JSON fields and transfers them to a file, a database table, etc.

Configuring a JSON Tree

When configuring a JSON tree, the default type of an element is string. If an element is not of type `string`, you need to add an attribute for the element to set its type.

- For an `integer`, `double`, `float`, or `boolean` element, you need to add an attribute named `type` and set its static value to `integer`, `number`, `float`, or `boolean` respectively.
- For an `array` element, you need to add an attribute named `class` and set its static value to `array`, and then add a sub-element named `element` set as a loop.
- For an `object` element, you need to add an attribute named `class` and set its static value to `object`.

The following figure shows an example of JSON tree configuration:

![JSON Tree Configuration Example](image)

**tWriteJSONField Standard properties**

These properties are used to configure tWriteJSONField running in the Standard Job framework. The Standard tWriteJSONField component belongs to the Processing family. The component in this framework is available in all Talend products.
## Basic settings

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Output Column</strong></td>
<td>Select the column from the list for holding the JSON string generated. The columns in the list are defined in the output schema.</td>
</tr>
<tr>
<td><strong>Configure JSON Tree</strong></td>
<td>Opens the interface to create the JSON data structure. For more information, see Configuring a JSON Tree on page 3987.</td>
</tr>
</tbody>
</table>
| **Schema and Edit Schema**     | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Note: Among all the columns defined in the output schema, only the one selected from Output Column holds the JSON string generated. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
  - **View schema**: choose this option to view the schema only.  
  - **Change to built-in property**: choose this option to change the schema to Built-in for local changes.  
  - **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |
| **Sync columns**               | Click to synchronize the output file schema with the input file schema. The Sync function only displays once the Row connection is linked with the output component. |
| **Group by**                   | Define the aggregation set, the columns you want to use to regroup the data. Warning: Make sure that the data to be grouped is in sequential order. |
| **Remove root node**           | Select this check box to remove the root node from the JSON field generated. |
Advanced settings

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Quote all values</td>
<td>Select this check box to surround all values including number and boolean values in the generated JSON field with double quotation marks. Clear this check box to surround only string values in the generated JSON field with double quotation marks.</td>
</tr>
<tr>
<td>tStatCatcher Statistics</td>
<td>Select this check box to gather the Job processing metadata at a Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERROR_MESSAGE</td>
<td>The error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td>NB_LINE</td>
<td>The number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td></td>
<td>For further information about variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Preceded by an input component, this component wraps the incoming data into a JSON field.</td>
</tr>
</tbody>
</table>

Note: For any field with the null value, this component writes a pair of square brackets ([]). If needed, you can remove or replace them using a regular expression in a tJavaRow component next to the tWriteJSONField component. For example:

```java
output_row.rootNode = input_row.rootNode.replaceAll("\[\[\]", "");
```

Writing flat data into JSON fields

In this scenario, flat data is wrapped into JSON fields via tWriteJSONField.

Linking the components

Procedure

1. Drop the following components from the Palette onto the design workspace: tFixedFlowInput, tWriteJSONField and tLogRow.
2. Link `tFixedFlowInput` and `tWriteJSONField` using a Row > Main connection.
3. Link `tWriteJSONField` and `tLogRow` using a Row > Main connection.

![Diagram showing connections between components]

**Configuring the components**

**Procedure**

1. Double-click `tFixedFlowInput` to display its Basic settings view.

   ![Basic settings view]

   - **Schema**: Built-In
   - **Number of rows**: 1
   - **Mode**: Use Inline Content
   - **Row Separator**: `;`
   - **Field Separator**: `;`
   - **Content**: `Andrew;Wallace;Doc
   John;Smith;R&D
   Christian;Dior;Sales`

2. Click Edit schema to open the schema editor.

   ![Schema editor]

   Click the [+] button to add three columns, namely `firstname`, `lastname` and `dept`, with the type of string.
   Click OK to close the editor.

3. Select the Use Inline Content option and enter the data below in the Content box:

   Andrew;Wallace;Doc
   John;Smith;R&D
   Christian;Dior;Sales
4. Click **tWriteJSONField** to display its **Basic settings** view.

![tWriteJSONField](image)

Select the **Remove root node** option to remove the root node setting from the JSON fields generated.

5. Click **Configure JSON Tree** to open the XML tree editor.

![Configure JSON Tree](image)

The schema of **tFixedFlowInput** appears in the **Linker source** panel.

6. In the **Linker target** panel, click the default **rootTag** and type in **staff**, which is the root node of the JSON field to be generated.

7. Right-click **staff** and select **Add Sub-element** from the context menu.

8. In the pop-up box, enter the sub-node name, namely **firstname**.
Repeat the steps to add two more sub-nodes, namely lastname and dept.

9. Right-click firstname and select Set As Loop Element from the context menu.

10. Drop firstname from the Linker source panel to its counterpart in the Linker target panel.
    In the pop-up dialog box, select Add linker to target node.

    Click OK to close the dialog box.
    Repeat the steps to link the two other items.
    Click OK to close the XML tree editor.

11. Click Edit schema to open the schema editor.

12. Click the [+] button in the right panel to add one column, namely staff, which will hold the JSON data generated.
    Click OK to close the editor.

13. Double-click tLogRow to display its Basic settings view.
Select **Table (print values in cells of a table)** for a better display of the results.

**Executing the Job**

**Procedure**

1. Press **Ctrl + S** to save the Job.
2. Click **F6** to execute the Job.

```
<table>
<thead>
<tr>
<th>tLogRow_1</th>
</tr>
</thead>
<tbody>
<tr>
<td>staff</td>
</tr>
<tr>
<td>{&quot;first_name&quot;:&quot;Andrew&quot;, &quot;last_name&quot;:&quot;Wallace&quot;, &quot;dept&quot;:&quot;Doc&quot;}</td>
</tr>
<tr>
<td>{&quot;first_name&quot;:&quot;John&quot;, &quot;last_name&quot;:&quot;Smith&quot;, &quot;dept&quot;:&quot;R&amp;D&quot;}</td>
</tr>
<tr>
<td>{&quot;first_name&quot;:&quot;Christian&quot;, &quot;last_name&quot;:&quot;Dior&quot;, &quot;dept&quot;:&quot;Sales&quot;}</td>
</tr>
</tbody>
</table>
```

As shown above, the JSON fields have been generated correctly, with the root node settings removed.

**Related Scenarios**

For related scenarios, see:

- *Retrieving error messages while extracting data from JSON fields* on page 940.
- *Extracting the structure of an XML file and inserting it into the fields of a database table* on page 3996.
tWriteXMLField

Reads an input XML file and extracts the structure to insert it in defined fields of the output XML file.

**tWriteXMLField Standard properties**

These properties are used to configure tWriteXMLField running in the Standard Job framework.

The Standard tWriteXMLField component belongs to the XML family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Output Column</strong></td>
<td>Select the destination field in the output component where you want to write the XML structure.</td>
</tr>
<tr>
<td><strong>Configure XML Tree</strong></td>
<td>Opens the interface that supports the creation of the XML structure you want to write in a field. For more information about the interface, see Defining the XML tree on page 127.</td>
</tr>
</tbody>
</table>
| **Schema and Edit Schema**    | A schema is a row description, it defines the number of fields that will be processed and passed on to the next component. The schema is either built-in or remote in the Repository.  

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  

- **View schema**: choose this option to view the schema only.  
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No upon completion** and choose this schema metadata again in the **Repository Content** window.  

**Built-in**: You create the schema and store it locally for this component only. Related topic: see Talend Studio User Guide.  

**Repository**: You already created the schema and stored it in the Repository, hence can be reused in various projects and job flowcharts. Related topic: see Talend Studio User Guide.  

**Sync columns**             | Click to synchronize the output file schema with the input file schema. The Sync function only displays once the Row connection is linked with the input component.                                             |
| **Group by**                 | Define the aggregation set, the columns you want to use to regroup the data.                                                                                                                                |

3. If you have already stored the input schema in the **Repository** tree view, select **Repository** first from the **Property Type** list and then from the **Schema** list to display the **Repository Content** dialog box where you can select the relevant metadata.

   For more information about storing schema metadata in the **Repository** tree view, see *Talend Studio User Guide*.

4. If you have not stored the input schema locally, select **Built-in** in the **Property Type** and **Schema** fields and fill in the fields that follow manually. For more information about *tFileInputXML* properties, see *tFileInputXML* on page 1085.

   If you have selected **Built-in**, click the three-dot button next to the **Edit schema** field to open a dialog box where you can manually define the structure of your file.

5. In the **Look Xpath query** field, enter the node of the structure where the loop is based. In this example, the loop is based on the `customer` node. **Column** in the **Mapping** table will be automatically populated with the defined file content.

   In the **Xpath query** column, enter between inverted commas the node of the XML file that holds the data corresponding to each of the **Column** fields.

6. In the design workspace, click **tWriteXMLField** and then in the **Component** view, click **Basic settings** to open the relevant view where you can define the component properties.

```
<table>
<thead>
<tr>
<th>Output Column</th>
<th>CustomerDetails</th>
</tr>
</thead>
<tbody>
<tr>
<td>Configure Xml Tree</td>
<td>...</td>
</tr>
<tr>
<td>Schema</td>
<td>Built-In</td>
</tr>
<tr>
<td>Group by</td>
<td>Input column</td>
</tr>
</tbody>
</table>
```

7. Click the three-dot button next to the **Edit schema** field to open a dialog box where you can add a line by clicking the plus button.

```
<table>
<thead>
<tr>
<th>Column</th>
<th>Key</th>
<th>Type</th>
<th>N. D</th>
<th>Length</th>
</tr>
</thead>
<tbody>
<tr>
<td>CustomerDetails</td>
<td></td>
<td>String</td>
<td>✓</td>
<td>255</td>
</tr>
</tbody>
</table>
```

8. Click in the line and enter the name of the output column where you want to write the XML content, `CustomerDetails` in this example.

   Define the type and length in the corresponding fields, *String* and *255* in this example.

   Click **Ok** to validate your output schema and close the dialog box.
In the **Basic settings** view and from the **Output Column** list, select the column you already defined where you want to write the XML content.

9. Click the three-dot button next to **Configure Xml Tree** to open the interface that helps to create the XML structure.

10. In the **Link Target** area, click **rootTag** and rename it as **CustomerDetails**.

    In the **Linker source** area, drop **CustomerName** and **CustomerAddress** to **CustomerDetails**. A dialog box displays asking what type of operation you want to do.

    Select **Create as sub-element of target node** to create a sub-element of the **CustomerDetails** node.

    Right-click **CustomerName** and select from the contextual menu **Set As Loop Element**.

    Click **OK** to validate the XML structure you defined.

11. Double-click **tMysqlOutput** to open its **Basic settings** view and define its properties.

12. If you have already stored the schema in the **DB Connection** node in the **Repository** tree view, select **Repository** from the **Schema** list to display the **Repository Content** dialog box where you can select the relevant metadata.

    For more information about storing schema metadata in the **Repository** tree view, see [Talend Studio User Guide](#).

    If you have not stored the schema locally, select **Built-in** in the **Property Type** and **Schema** fields and enter the database connection and data structure information manually. For more information about **tMysqlOutput** properties, see [tMysqlOutput on page 2471](#).

    In the **Table** field, enter the name of the database table to be created, where you want to write the extracted XML data.
From the **Action on table** list, select **Create table** to create the defined table.

From the **Action on data** list, select **Insert** to write the data.

Click **Sync columns** to retrieve the schema from the preceding component. You can click the three-dot button next to **Edit schema** to view the schema.

**13.** Save your Job and click **F6** to execute it.

**Results**

<table>
<thead>
<tr>
<th>CustomerDetails</th>
</tr>
</thead>
</table>
| <xml version="1.0" encoding="ISO-8859-15"?>
  <CustomerDetails>
    <CustomerAddress>talend@apress.com</CustomerAddress>
    <CustomerName>John Doe</CustomerName>
  </CustomerDetails>
  ...
| <xml version="1.0" encoding="ISO-8859-15"?>
  <CustomerDetails>
    <CustomerAddress>Pine Tree Rd.</CustomerAddress>
    <CustomerName>Jane Smith</CustomerName>
  </CustomerDetails>
  ...
| <xml version="1.0" encoding="ISO-8859-15"?>
  <CustomerDetails>
    <CustomerAddress>123 Maple Ave.</CustomerAddress>
    <CustomerName>David Brown</CustomerName>
  </CustomerDetails>
  ...

**tWriteXMLField** fills every field of the **CustomerDetails** column with the XML structure of the input file: the XML processing instruction `<xml version="1.0" encoding="ISO-8859-15"?>`, the first node that separates each client `<CustomerDetails>` and finally customer information `<CustomerAddress>` and `<CustomerName>`.
tXMLMap

Transforms and routes data from single or multiple sources to single or multiple destinations.

tXMLMap is an advanced component fine-tuned for transforming and routing XML data flow (data of the **Document** type), especially when processing numerous XML data sources, with or without flat data to be joined.

## tXMLMap Standard properties

These properties are used to configure tXMLMap running in the Standard Job framework.

The Standard tXMLMap component belongs to the Processing and the XML families.

The component in this framework is available in all **Talend products**.

### Basic settings

| Map Editor | It allows you to define the **tXMLMap** routing and transformation properties. |

### Advanced settings

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |
| Keep order for document | Select this check box to output XML elements strictly in the order specified in the output XML schema. |

### Global Variables

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. |

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*. |

### Usage

| Usage rule | Possible uses are from a simple reorganization of fields to the most complex jobs of data multiplexing or demultiplexing transformation, concatenation, inversion, filtering and so on. |
When needs be, you can define sophisticated outputting strategy for the output XML flows using group element, aggregate element, empty element and many other features such as All in one. For further information about these features, see Talend Studio User Guide.

It is used as an intermediate component and fits perfectly the process requiring many XML data sources, such as, the ESB request-response processes.

<table>
<thead>
<tr>
<th>Limitation</th>
</tr>
</thead>
<tbody>
<tr>
<td>The limitations to be kept in mind are:</td>
</tr>
<tr>
<td>- The use of this component supposes minimum Java and XML knowledge in order to fully exploit its functionalities.</td>
</tr>
<tr>
<td>- This component is a junction step, and for this reason it cannot be a start nor an end component in the Job.</td>
</tr>
<tr>
<td>- At least one loop element is required for each XML data flow involved.</td>
</tr>
</tbody>
</table>

The following sections present several generic use cases about how to use the tXMLMap component, while if you need some specific examples using this component along with the ESB components to build data services, see the scenarios for the ESB components:

- Using tESBConsumer with custom SOAP Headers on page 826
- Requesting airport names based on country codes on page 838
- Sending a message without expecting a response on page 852
- Returning Hello world response on page 863

**Mapping and transforming XML data**

The following scenario creates a three-component Job that maps and transforms data from an XML source file *Customer.xml*, and generates an XML output flow which could be reused for various purposes, such as for an ESB request, in the future based on the XML tree structure of the file *Customer_State.xml*.

These three components are:

- **tFileInputXML**: provides the input data to tXMLMap.
- **tXMLMap**: maps and transforms the received XML data flows into one single XML data flow.
- **tLogRow**: displays the output data.
The content of the XML file *Customer.xml* is as follows:

```xml
<?xml version="1.0" encoding="ISO-8859-15"?>
<Customers>
  <Customer RegisterTime="2001-01-17 06:26:40.000">
    <Name>
      <id>1</id>
      <CustomerName>Griffith Paving and Sealcoating</CustomerName>
    </Name>
    <Address>
      <CustomerAddress>talend@apres91</CustomerAddress>
      <idState>2</idState>
    </Address>
    <Revenue>
      <Sum1>67852</Sum1>
    </Revenue>
  </Customer>
  <Customer RegisterTime="2002-06-07 09:40:00.000">
    <Name>
      <id>2</id>
      <CustomerName>Bill's Dive Shop</CustomerName>
    </Name>
    <Address>
      <CustomerAddress>511 Maple Ave. Apt. 1B</CustomerAddress>
      <idState>3</idState>
    </Address>
    <Revenue>
      <Sum1>88792</Sum1>
    </Revenue>
  </Customer>
  <Customer RegisterTime="1987-02-23 17:33:20.000">
    <Name>
      <id>3</id>
      <CustomerName>Glenn Oaks Office Supplies</CustomerName>
    </Name>
    <Address>
      <CustomerAddress>1859 Green Bay Rd.</CustomerAddress>
      <idState>2</idState>
    </Address>
    <Revenue>
      <Sum1>1225</Sum1>
    </Revenue>
  </Customer>
  <Customer RegisterTime="1992-04-28 23:26:40.000">
    <Name>
      <id>4</id>
      <CustomerName>DBN Bank</CustomerName>
    </Name>
    <Address>
      <CustomerAddress>456 Grossman Ln.</CustomerAddress>
      <idState>3</idState>
    </Address>
    <Revenue>
      <Sum1>64493</Sum1>
    </Revenue>
  </Customer>
</Customers>
```

The content of the XML file *Customer_State.xml* is as follows:

```xml
<?xml version="1.0" encoding="ISO-8859-15"?>
<customers>
  <customer id="1">
    <CustomerName>Griffith Paving and Sealcoating</CustomerName>
    <CustomerAddress>talend@apres91</CustomerAddress>
    <idState>2</idState>
  </customer>
  <customer id="2">
    <CustomerName>Bill's Dive Shop</CustomerName>
    <CustomerAddress>511 Maple Ave. Apt. 1B</CustomerAddress>
    <idState>3</idState>
  </customer>
</customers>
```
Adding and linking the components

Procedure

1. Create a new Job and add a **tFileInputXML** component, a **tXMLMap** component, a **tLogRow** component by typing their names in the design workspace or dropping them from the Palette.

2. Label the **tFileInputXML** component *Customers* to better identify its function.

   **Note:**
   A component used in the workspace can be labelled the way you need. For further information about how to label a component, see *Talend Studio User Guide*.

3. Link the **tFileInputXML** component labelled *Customers* to the **tXMLMap** component using a **Row > Main** connection.

4. Link the **tXMLMap** component to the **tLogRow** component using a **Row > *New Output* (Main)** connection. In the pop-up dialog box, enter the name of the output connection, *Customer* in this scenario.

![Image of tXMLMap_1Output](image)

Configuring the input flow

Procedure

1. Double-click the **tFileInputXML** component labelled *Customers* to open its **Basic settings** view.

   ![Image of Customers(tFileInputXML_1)](image)

2. Click the [...] button next to *Edit schema* and in the **Schema** dialog box define the schema by adding one column *Customer* of **Document** type.
Note that the **Document** data type is essential for making full use of **tXMLMap**. For further information about this data type, see *Talend Studio User Guide*.

3. Click **OK** to validate the changes and close the dialog box. One row is added automatically to the **Mapping** table.

4. In the **File name/Stream** field, browse to or type in between double quotation marks the path to the XML source file that provides the customer data. In this scenario, it is `E:/Customer.xml`.

5. In the **Loop XPath query** field, type in an XPath expression between double quotation marks to specify the node on which the loop is based. In this scenario, it is `/`, which means to perform look query from the root.

6. In the **XPath query** column of the **Mapping** table, type in the fields to be queried between double quotation marks. In this scenario, it is `.` , which means all fields under the current node (root) will be extracted.

7. In the **Get Nodes** column of the **Mapping** table, select the check box.

   In order to build the **Document** type data flow, it is necessary to get the nodes from this component.

**Configuring tXMLMap for transformation**

**Procedure**

1. Double-click the **tXMLMap** component to open its **Map Editor**.
Note that the input area is already filled with the default basic XML structure and the top table is the main input table.

2. In the row1 input table, right-click the Customer node and from the contextual menu select **Import From File**. In the pop-up dialog box, browse to the XML source file to import therefrom the XML tree structure used by the data to be received by tXMLMap. In this scenario, the XML source file is Customer.xml, which is the input data to the tFileInputXML component labelled Customers.

3. In the imported XML tree, right-click the Customer node and from the contextual menu select **As loop element** to set it as the loop element.

4. On the lower part of this map editor, click the Schema editor tab to display the corresponding view. Then on the right side of this view, add one column Customer_States of Document type to the Customer schema table. The corresponding XML root is added automatically to the Customer output table on the top right side which represents the output flow.

5. In the Customer output table, right-click the Customer_States node and from the contextual menu select **Import From File**. In the pop-up dialog box, browse to the XML file from which the XML tree structure is imported. In this scenario, it is Customer_State.xml.
6. Right-click the customer node and from the contextual menu select As loop element to set it as the loop element.

7. In the row1 input table, click the id node and drop it to the Expression column in the row of the @id node in the Customer output table.

Do the same to map CustomerName to CustomerName, CustomerAddress to CustomerAddress, and idState to idState from the input table to the output table.

**Note:**
In some circumstances, you may have to keep empty elements in your output XML tree. If so, you can use tXMLMap to manage them. For further information about how to manage empty elements using tXMLMap, see Talend Studio User Guide.

8. On the top of the Customer output table, click the wrench icon and set the value of the All in one property to true to generate a single XML flow. For further information about the All in one feature, see Talend Studio User Guide.
9. Click **OK** to validate the changes and close the **Map Editor**.

**Note:**

If you close the **Map Editor** without having set the required loop elements as described earlier in this scenario, the root element will be automatically set as the loop element.

**Configuring tLogRow to display the customer information**

**Procedure**

1. Double-click the **tLogRow** component to open its **Basic settings** view.
2. Click the **Sync columns** button to retrieve the schema from its preceding component.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl+S** to save the Job.
2. Press **F6** to execute the Job.

```xml
[statistics] connecting to socket on port 4025
[statistics] connected
<?xml version="1.0" encoding="UTF-8"?>
<customers>
  <customer id="1">
    <CustomerName>Griffith Paving and Sealcoating</CustomerName>
    <EmailAddress>talend@apress91</EmailAddress>
  </customer>
  <customer id="2">
    <CustomerName>Bill's Dive Shop</CustomerName>
    <CustomerAddress>511 Maple Ave. Apt. 1B</CustomerAddress>
  </customer>
  <customer id="3">
    <CustomerName>Glenn Oaks Office Supplies</CustomerName>
    <CustomerAddress>1859 Green Bay Rd</CustomerAddress>
  </customer>
  <customer id="4">
    <CustomerName>DDN Bank</CustomerName>
    <CustomerAddress>456 Grossmen Ln</CustomerAddress>
  </customer>
</customers>
[statistics] disconnected
```

As shown above, the transformed customer information is displayed on the console.

**Launching a lookup flow to join complementary data**

Based on the previous scenario, this scenario shows how to use a lookup flow to join data of interest in the XML file `USState.xml` to the main flow. Another **tFileInputXML** component is added to the Job to load data from the lookup file `USState.xml` to the processing component **tXMLMap**.
The content of the XML file USState.xml is as follows:

```xml
<?xml version="1.0" encoding="ISO-8859-15"?>
<USStates>
  <States>
    <idState>1</idState>
    <LabelState>Alabama</LabelState>
  </States>
  <States>
    <idState>2</idState>
    <LabelState>Connecticut</LabelState>
  </States>
  <States>
    <idState>3</idState>
    <LabelState>Ohio</LabelState>
  </States>
  <States>
    <idState>4</idState>
    <LabelState>Wyoming</LabelState>
  </States>
  <States>
    <idState>5</idState>
    <LabelState>Hawaii</LabelState>
  </States>
</USStates>
```

Adding and linking another input component

**Procedure**

1. In your Studio, open the Job used in the previous scenario to display it in the design workspace.
2. Add another `tFileInputXML` component to the Job by typing its name in the design workspace or dropping it from the Palette. Label the component `USStates` to better identify its function.
3. Link the `tFileInputXML` component labelled `USStates` to the `tXMLMap` component using a **Row > Main** connection, and the connection is automatically changed to a lookup flow.

Configuring the input flow for lookup

**Procedure**

1. Double-click the `tFileInputXML` component labelled `USStates` to open its **Basic settings** view.
2. Click the [...] button next to Edit schema and in the Schema dialog box define the schema by adding one column USState of Document type.

3. Click OK to validate the changes and close the dialog box. One row is added automatically to the Mapping table.

4. In the File name/Stream field, browse to or type in between double quotation marks the path to the XML source file that holds the complementary data. In this scenario, it is E:/USState.xml.

5. In the Loop XPath query field, type in an XPath expression between double quotation marks to specify the node on which the loop is based. In this scenario, it is /, which means to perform look query from the root.

6. In the XPath query column of the Mapping table, type in the fields to be queried between double quotation marks. In this scenario, it is ., which means all fields under the current node (root) will be extracted.

7. In the Get Nodes column of the Mapping table, select the check box. This retrieves the XML structure for the Document type data.

Configuring tXMLMap for transformation

Procedure

1. Double-click the tXMLMap component to open its Map Editor.
Note that the input area is already filled with the defined input tables and the top table is the main input table.

2. In the row2 input table, right-click the USState node and from the contextual menu select **Import From File**. In the pop-up dialog box, browse to the XML source file to import therefrom the XML tree structure used by the data to be received by **tXMLMap**. In this scenario, the XML source file is USState.xml, which is the input data to **tFileInputXML** labelled USStates.

3. In the imported XML tree, right-click the States node and from the contextual menu select **As loop element** to set it as the loop element.
4. In the row1 main input table, click the idState node and drop it to the Exp.key column in the row of the idState node in the row2 lookup input table. This creates a join between the two input tables on the idState data, among which the idState node from the main flow provides the lookup key.

5. In the row2 lookup input table, click the LabelState node and drop it on the customer node in the Customer output table. A dialog box pops up.

6. In the pop-up dialog box, select Create as sub-element of target node and click OK. A new LabelState sub-element is added to the output XML tree and mapped with the LabelState node in the lookup input table.
7. Click OK to validate the mappings and close the Map Editor.

**Saving and executing the Job**

**Procedure**

1. Press Ctrl+S to save the Job.
2. Press F6 to run the Job.

```
[statistics] connecting to socket on port 3667
[statistics] connected
<?xml version="1.0" encoding="UTF-8"?>
<customers><customer id="1"><CustomerName>Griffith Paving and Sealcoating</CustomerName><CustomerAddress>talend@apress.com</CustomerAddress><idState>2</idState><LabelState>Connecticut</LabelState><customer id="2"><CustomerName>Bill's Dive Shop</CustomerName><CustomerAddress>511 Maple Ave. Apt. 1B</CustomerAddress><idState>3</idState><LabelState>Ohio</LabelState><customer id="3"><CustomerName>Glenn Oaks Office Supplies</CustomerName><CustomerAddress>1859 Green Bay Rd.</CustomerAddress><idState>2</idState><LabelState>Connecticut</LabelState></customer><customer id="4"><CustomerName>LEN Bank</CustomerName><CustomerAddress>456 Grossman Ln.</CustomerAddress><idState>3</idState><LabelState>Ohio</LabelState></customer><customers>
```

As shown above, the state names from the lookup file with the state IDs matching those in the main input file are added to the data flow and the combined information is displayed on the console.

**Results**

Mapping data using a filter

Based on Launching a lookup flow to join complementary data on page 4007, this scenario presents how to apply filter condition(s) to select the data of interest using tXMLMap.

Procedure

1. In your Studio, open the Job used in the previous scenario to display it in the design workspace.

2. Double-click the tXMLMap component to open its Map Editor.

3. On the top of the Customer output table, click the button to open the filter area.
4. Drop the `idState` node in the main input table to the filter area. The XPath `[row1.Customer:/Customers/Customer/Address/idState]` of the `idState` node is added automatically to this filter area.

Enter `== 2` after the XPath of the `idState` node, and the complete filter condition becomes `[row1.Customer:/Customers/Customer/Address/idState] == 2`. This means only the customer data with the state id of 2 will be passed to the output flow.

5. Click **OK** to validate the changes and close the map editor.

6. Press **Ctrl + S** to save the Job and then **F6** to run the Job.

**Results**

As shown above, the customers **Griffith Paving and Sealcoating** and **Glenn Oaks Office Supplies**, whose state id is 2 are displayed on the console.

**Catching the data rejected by lookup and filter**

The data rejected by the lookup and filter conditions set in **tXMLMap** can be caught and outputted by this component itself.

Based on **Mapping data using a filter** on page 4013, this scenario presents how to catch the data rejected by the lookup and the filter set up in the previous scenarios. Another **tLogRow** component is added to the Job used in the previous scenario to display the rejected data.
Adding and linking another output component

**Procedure**

1. In your Studio, open the Job used in the previous scenario to display it in the design workspace.
2. Add another `tLogRow` component to the Job by typing its name in the design workspace or dropping it from the Palette.
3. Link the `tXMLMap` component to the second `tLogRow` using a Row > "New Output" (Main) connection. In the pop-up dialog box, enter the name of the output connection, `Reject` in this example.

Configuring `tXMLMap` for transformation

**Procedure**

1. Double-click the `tXMLMap` component to open its Map Editor. An empty `Reject` output table that carries the rejected data has been added to the output side to represent the output data flow carrying the rejected data.
2. In the row1 main input table, click the id node and drop it on the Reject output table. A column id is added to the Reject schema table in the Schema editor on the lower part of the map editor.

3. Do the same to drop CustomerName, CustomerAddress, and idState in the row1 main input table and LabelState in the row2 lookup input table on the Reject output table. Another four columns CustomerName, CustomerAddress, idState, and LabelState are added to the Reject schema table in the Schema editor.

Note:
In this scenario, the Reject output flow uses the flat data type. However, you can create an XML tree view for this flow similar to the Customer output flow using the Document data type. For further information about how to use the Document type, see Mapping and transforming XML data on page 4001.

4. On the top of the Reject output table, click the button to open the property setting area.
5. Set the value of the **Catch Output Reject** property to **true** to catch the data rejected by the filter set up in the previous scenario for the **Customer** output flow.

6. Set the value of the **Catch Lookup Inner Join Reject** property to **true** to catch the data rejected by the inner join operation.

7. Click **OK** to validate the changes and close the map editor.

**Configuring the output flow**

**Procedure**

1. Double-click the second **tLogRow** component to open its **Basic settings** view.
2. Click the **Sync columns** button to retrieve the schema from its preceding component.
3. In the **Mode** area, select **Table (print values in cells of a table)** for better readability of the result.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl+S** to save the Job.
2. Press **F6** to run the Job.

The captured data rejected by the filter and the lookup reads as follows in the **Run** view:

```
[statistics] connecting to socket on port 4058
[statistics] connected
<customers><customer id="1"><CustomerName>Griffith Paving and Sealcoating</CustomerName><CustomerAddress>tailend@apres91</CustomerAddress><idState>2</idState><LabelState>Connecticut</LabelState><customer id="3"><CustomerName>Glenn Oaks Office Supplies</CustomerName><CustomerAddress>1859 Green Bay Rd</CustomerAddress><idState>2</idState><LabelState>Connecticut</LabelState><customer id="1">CustomerName</CustomerAddress><idState>LabelState>
<table>
<thead>
<tr>
<th>id</th>
<th>CustomerName</th>
<th>CustomerAddress</th>
<th>idState</th>
<th>LabelState</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>Bill's Dive Shop</td>
<td>511 Maple Ave. Apt. 1E</td>
<td>3</td>
<td>Chic</td>
</tr>
<tr>
<td>4</td>
<td>DBR Bank</td>
<td>456 Grossman Ln.</td>
<td>3</td>
<td>Chic</td>
</tr>
</tbody>
</table>
```

[statistics] disconnected
As shown above, the data whose idState value is 2 is selected by the filter set up in the previous scenario and displayed in the upper part, and the data whose idState value is not 2 is rejected and displayed in the lower part.

Mapping data using a group element

Based on Launching a lookup flow to join complementary data on page 4007, this scenario presents how to set up an element as group element in the Map Editor of tXMLMap to group the output data. For more information about how to group the output data using tXMLMap, see Talend Studio User Guide.

The objective of this scenario is to group the customer id and the customer name information according to the states the customers come from. You need to reconstruct the XML tree view of the Customer output table by considering the following factors:

- The elements tagging the customer id and the customer name information should be located under the loop element. Thus they are the sub-elements of the loop element.
- The loop element and its sub-elements should be dependent directly on the group element.
- The element tagging the state information used as the grouping condition should be dependent directly on the group element.
- The group element cannot be the root element.

Based on this analysis, the XML structure of the output data should read as follows. The customers node is the root element, the customer node is set as the group element and the output data is grouped according to the LabelState element.

To put a group element into effect, the XML data to be processed should have been sorted, for example via your XML tools, around the element that will be used as the grouping condition. In this...
example, the customers possessing the same state id should be put together. The input data in the XML file Customer.xml should read as follows:

```xml
<?xml version="1.0" encoding="ISO-8859-15"?>
<Customers>
  <Customer RegisterTime="2001-01-17 06:26:40.000">
    <Name>
      <id>1</id>
      <CustomerName>Griffith Paving and Sealcoating</CustomerName>
    </Name>
    <Address>
      <CustomerAddress>talend@apres91</CustomerAddress>
      <idState>2</idState>
    </Address>
    <Revenue>
      <Sum1>67852</Sum1>
    </Revenue>
  </Customer>
  <Customer RegisterTime="1987-02-23 17:33:20.000">
    <Name>
      <id>3</id>
      <CustomerName>Glenn Oaks Office Supplies</CustomerName>
    </Name>
    <Address>
      <CustomerAddress>1859 Green Bay Rd.</CustomerAddress>
      <idState>2</idState>
    </Address>
    <Revenue>
      <Sum1>1225</Sum1>
    </Revenue>
  </Customer>
  <Customer RegisterTime="2002-06-07 09:40:00.000">
    <Name>
      <id>2</id>
      <CustomerName>Bill's Dive Shop</CustomerName>
    </Name>
    <Address>
      <CustomerAddress>511 Maple Ave. Apt. 1B</CustomerAddress>
      <idState>3</idState>
    </Address>
    <Revenue>
      <Sum1>88792</Sum1>
    </Revenue>
  </Customer>
  <Customer RegisterTime="1992-04-28 23:26:40.000">
    <Name>
      <id>4</id>
      <CustomerName>DBN Bank</CustomerName>
    </Name>
    <Address>
      <CustomerAddress>456 Grossman Ln.</CustomerAddress>
      <idState>3</idState>
    </Address>
    <Revenue>
      <Sum1>64493</Sum1>
    </Revenue>
  </Customer>
</Customers>
```

**Mapping data using a group element**

**Procedure**

1. In your Studio, open the Job used in Launching a lookup flow to join complementary data on page 4007 to display it in the design workspace, and double-click the tXMLMap component to open its Map Editor.
2. In the XML tree view of the Customer output table, right-click the customer (loop) node and select Delete from the contextual menu. Thus all of the elements under the customers root node are
removed, then you can reconstruct the XML tree view that can be used to group the output data of interest.

<table>
<thead>
<tr>
<th>Expression</th>
<th>Column</th>
</tr>
</thead>
<tbody>
<tr>
<td>[row1.Customer/Cus...</td>
<td>- customers</td>
</tr>
<tr>
<td>[row1.Customer/Cus...</td>
<td>Customer_Name</td>
</tr>
<tr>
<td>[row1.Customer/Cus...</td>
<td>Customer_Address</td>
</tr>
<tr>
<td>[row1.Customer/Cus...</td>
<td>idState</td>
</tr>
<tr>
<td>[row2.USState/USStates/State...</td>
<td>LabelState</td>
</tr>
</tbody>
</table>

3. Right-click the *customers* root node and select **Create Sub-Element** from the contextual menu. In the pop-up dialog box, enter the name of the new sub-element. In this example, it is *customer*.

4. Click **OK** to validate the changes and close the dialog box. A *customer* node is added under the *customers* root node in the output table.

5. In the *row2* lookup input table, select the *LabelState* node and drop it onto the *customer* node in the output table. In the pop-up dialog box, select **Create as sub-element of target node** and click **OK** to close the dialog box. A *LabelState* node is added under the *customer* node in the output table.

6. Right-click the *customer* node in the output table and select **Create Sub-Element** from the contextual menu. In the pop-up dialog box, enter the name of the new sub-element. In this example, it is *Name*.

7. Click **OK** to validate the changes and close the dialog box. A *Name* node is added under the *customer* node in the output table.

8. In the *row1* main input table, select the *id* and *CustomerName* nodes and drop them onto the *Name* node in the output table. In the pop-up dialog box, select **Create as sub-element of target node** and click **OK** to close the dialog box. A *id* node and a *CustomerName* node are added under the *Name* node in the output table.

9. In the output table, right-click the *Name* node and from the contextual menu select **As loop element** to set it as the loop element, then right-click the *customer* node and from the contextual menu select **As group element** to group the output data according to the *LabelState* element.
10. Click OK to validate the changes and close the map editor.
11. Press Ctrl+S to save the Job and then F6 to run the Job.

Results

As shown above, the id element and the CustomerName element contained in the loop are grouped according to the LabelState element. The group element customer tags the start and the end of each group.

Classifying the output data with aggregate element

Based on the previous scenarios, this scenario presents how to set up an element as aggregate element in the Map Editor of tXMLMap to classify the output data into separate XML flows. For more information about how to aggregate the output data using tXMLMap, see Talend Studio User Guide.

The objective of this scenario is to classify the customer id and the customer name information using an aggregate element in accordance with the states they come from and then to send these classes separately in different XML flows to the next component.

To put an aggregate element into effect, the XML data to be processed should have been sorted, for example via your XML tools, around the element that will be used as the aggregating condition. In
this example, the customers possessing the same state id should be put together. The input data in the XML file Customer.xml should be same as the input data in.

**Classifying the output data with aggregate element**

**Procedure**

1. In your Studio, open the Job used in , and double-click the tXMLMap component to open its Map Editor.
2. Right-click the customer element in the output table and select Remove group element from the contextual menu.
3. On the top of the output table, click the wrench icon and set the value of the All in one property to false.
4. Right-click the LabelState element and select As aggregate element from the contextual menu. The LabelState element tags the state information of each customer and the customer information will be classified according to the state information.

To make the aggregate element available, ensure that the value of the All in one property is set to false. For further information about the All in one feature, see Talend Studio User Guide.

5. Click OK to validate the changes and close the Map Editor.
6. Press Ctrl+S to save the Job and then F6 to run the Job.
Results

As shown above, **tXMLMap** outputs two separate XML flows, each of which carries the information of one state and the customers from that state.

### Restructuring products data using multiple loop elements

The following scenario creates a four-component Job that restructures the products data from an XML source file *ProductsIn.xml* using multiple loop elements.

![Diagram](image)

These four components are:

- **tFileInputXML**: reads the source products data and passes it to the **tXMLMap** component.
- **tXMLMap**: transforms the input flow to the expected structure streamlined.
- **tLogRow**: presents the execution result on the console.
- **tFileOutputXML**: writes the output flow into an XML file.

```xml
<results version="1.0" encoding="UTF-8">
  <customers>
    <customer>
      <LabelState>Connecticut</LabelState>
      <Name id="1"/>
      <CustomerName>Griffith Paving and Sealing</CustomerName>
      <Name id="3"/>
      <CustomerName>Glenn Oaks Office Supplies</CustomerName>
    </customer>
    <customer>
      <LabelState>Ohio</LabelState>
      <Name id="2"/>
      <CustomerName>Bill’s Dive Shop</CustomerName>
      <Name id="4"/>
      <CustomerName>DBN Bank</CustomerName>
    </customer>
  </customers>
</results>
```
The content of the source XML file *ProductsIn.xml* is as follows:

```xml
<?xml version="1.0" encoding="ISO-8859-15"?>
<products category="1" name="laptop">
    <!-- Summary -->
    <summary>
        <company>DELL, HP</company>
        <sales unit="Dollars">12345678910.12345</sales>
        <model>business</model>
    </summary>

    <!-- Loop1 manufacture -->
    <manufacture id="manu_1" date="2012-10-30">
        <name>DELL</name>
    </manufacture>
    <manufacture id="manu_2" date="2012-10-28">
        <name>HP</name>
    </manufacture>

    <!-- Loop2 types -->
    <types model="business1">
        <type>DELL123</type>
        <manufacture_id>manu_1</manufacture_id>
    </types>
    <types model="business2">
        <type>HP123</type>
        <manufacture_id>manu_2</manufacture_id>
    </types>

    <!-- Loop3 sale -->
    <sales>
        <sale unit="Dollars" type="DELL123">
            <quater>1</quater>
            <income>12345</income>
        </sale>
        <sale unit="Dollars" type="HP123">
            <quater>1</quater>
            <income>12345.123</income>
        </sale>
    </sales>
</products>
```

The objective of this scenario is to restructure the products data to streamline the presentation of the products information to serve the manufacturing operations. The expected output data is as follows.
The root element is changed to *manufacturers*, the sales information is consolidated into the *sale* element, and the *manufacturer* element is reduced to one single level.

```xml
<?xml version="1.0" encoding="ISO-8859-15"?>
<manufacturers category="1" name="laptop">
  <sales unit="Dollars">
    <sale sales_type="DELL123">12345.0</sale>
    <sale sales_type="HP123">12345.123</sale>
  </sales>
  <manufacturer id="manu_1" date="03-04-0036" name="DELL"/>
  <manufacturer id="manu_2" date="04-04-0034" name="HP"/>
  <types>
    <type>DELL123</type>
    <manufacturer_id>manu_1</manufacturer_id>
  </types>
  <types>
    <type>DELL123</type>
    <manufacturer_id>manu_2</manufacturer_id>
  </types>
  <types>
    <type>HP123</type>
    <manufacturer_id>manu_1</manufacturer_id>
  </types>
  <types>
    <type>HP123</type>
    <manufacturer_id>manu_2</manufacturer_id>
  </types>
</manufacturers>
```

**Adding and linking the components**

**Procedure**

1. Create a new Job and add a tFileInputXML component, a tXMLMap component, a tLogRow component, and a tFileOutputXML component by typing their names in the design workspace or dropping them from the Palette.
2. Link the tFileInputXML component to the tXMLMap component using a Row > Main connection.
3. Link the tXMLMap component to the tLogRow component using a Row > *New Output* (Main) connection. In the pop-up dialog box, enter the name of the output connection, *outDoc* in this example.
4. Link the tLogRow component to the tFileOutputXML component using a Row > Main connection.

**Configuring the input flow**

**Procedure**

1. Double-click the tFileInputXML component to open its Basic settings view.
2. Click the [...] button next to Edit schema and in the Schema dialog box define the schema by adding one column doc of Document type.

3. Click OK to validate the changes and close the dialog box. One row is added automatically to the Mapping table.

4. In the File name/Stream field, browse to or type in between double quotation marks the path to the XML source file that provides the products data. In this scenario, it is E:/ProductsIn.xml.

5. In the Loop XPath query field, type in an XPath expression between double quotation marks to specify the node on which the loop is based. In this scenario, it is /, which means to perform look query from the root.

6. In the XPath query column of the Mapping table, type in the fields to be queried between double quotation marks. In this scenario, it is ., which means all fields under the current node (root) will be extracted.

7. In the Get Nodes column of the Mapping table, select the check box.

Configuring tXMLMap with multiple loops

Procedure

1. Double-click the tXMLMap component to open its Map Editor.
2. In the \texttt{row1} input table, right-click the \texttt{doc} node and from the contextual menu select \textbf{Import From File}. In the pop-up dialog box, browse to the XML source file to import therefrom the XML structure used by the data to be received by \texttt{tXMLMap}. In this scenario, the XML source file is \textit{ProductsIn.xml}, which contains the input data to \texttt{tFileInputXML}.

3. In the imported XML tree, right-click the \textit{manufacturer} node and from the contextual menu select \textbf{As loop element} to set it as the loop element. Then do the same to set the \textit{types} node and the \textit{sale} node as loop elements respectively.
4. On the lower part of the map editor, click the **Schema editor** tab to display the corresponding view. Then on the right side of this view, add one column `outDoc` of **Document** type to the schema table. The corresponding XML root is added automatically to the output table on the top right side which represents the output flow.

5. In the `outDoc` output table, import the XML data structure to be used from the XML file that contains the expected output data and provides the expected XML structure.

   Right-click the `sale` node in the output table and select **As loop element** from the contextual menu. Then do the same to set the `manufacturer` node and the `types` node as loop elements respectively.
6. In the row1 input table, click the `@category` node and drop it to the **Expression** field of the `@category` node in the `outDoc` output table.

Do the same to map other nodes from the input table to the output table:

- the `@name` node to the `@name` node,
- the `@unit` node under the `summary` node to the `@unit` node,
- the `@id` node to the `@id` node and to the `manufacturer_id` node respectively,
- the `@date` node to the `@date` node,
- the `name` node to the `@name` node,
- the `type` node to the `type` node,
• the @type node to the @sales_type node, and
• the income node to the sale (loop) node.

7. On the top of the outDoc output table, click the wrench icon and set the value of the All in one property to true to generate a single XML flow. For further information about the All in one feature, see Talend Studio User Guide.

8. Click the [...] button next to the manufacturer loop element and in the pop-up Configure source loops dialog box click the [+] button to add one source loop manufacturer. Do the same to add one source loop sale for the sale loop element.

9. Click the [...] button next to the types loop element and in the pop-up Configure source loops dialog box add two source loops types and manufacturer. Make sure the sequence number of the types source loop is 0 so that the relative part of the output flow will be sorted based on the values of the type element.

Note:
When a loop element receives mappings from more than one loop element of the input flow, it allows you to set the sequence of the input loops. For example, the types loop element of the output flow in this scenario is mapped with the @id node which belongs to the manufacturer loop element and the type node which belongs to the types loop element of the input flow. The output flow will be sorted according to the primary types loop.

10. Click OK to validate the mappings and close the Map Editor.
Configuring the output flow

Procedure

1. Double-click the tLogRow component to open its Basic settings view.
2. Click the Sync columns button to retrieve the schema from its preceding component and accept the propagation prompted by the pop-up dialog box.
3. Double-click the tFileOutputXML component to open its Basic settings view.

4. In the File Name field, browse to or enter the path to the file in which the output data will be written. In this scenario, it is E:/ProductsOut.xml.
5. Select the Incoming record is a document check box.

Saving and executing the Job

Procedure

1. Press Ctrl+S to save the Job.
2. Press F6 to execute the Job.
As shown above, the input products data is restructured as expected and the output data is displayed on the console and written into the XML file ProductsOut.xml.
tXMLRPCInput

Invokes a Method through a Web service and for the described purpose.
This component calls the defined method from the invoked RPC service, and returns the class as defined, based on the given parameters.

tXMLRPCInput Standard properties

These properties are used to configure tXMLRPCInput running in the Standard Job framework.
The Standard tXMLRPCInput component belongs to the Internet family.
The component in this framework is available in all Talend products.

Basic settings

| Schema and Edit Schema | A schema is a row description, it defines the number of fields that will be processed and passed on to the next component. The schema is either Built-in or remote in the Repository.
Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:
• View schema: choose this option to view the schema only.
• Change to built-in property: choose this option to change the schema to Built-in for local changes.
• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.
In the RPC context, the schema corresponds to the output parameters. If two parameters are meant to be returned, then the schema should contain two columns. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Server URL</td>
<td>URL of the RPC service to be accessed</td>
</tr>
<tr>
<td>Need authentication / Username and Password</td>
<td>Select this check box and fill in a username and password if required to access the service.</td>
</tr>
</tbody>
</table>
| Method Name | Enter the exact name of the Method to be invoked.
The Method name MUST match the corresponding method described in the RPC Service. The Method name is also case-sensitive. |
| Return class | Select the type of data to be returned by the method. Make sure it fully matches the one defined in the method. |
| Parameters | Enter the parameters expected by the method as input parameters. |
### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
<td></td>
</tr>
<tr>
<td>NB_LINE: the number of rows processed. This is an After variable and it returns an integer.</td>
<td></td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>This component is generally used as a Start component. It requires to be linked to an output component.</td>
<td></td>
</tr>
</tbody>
</table>

### Guessing the State name from an XMLRPC

This scenario describes a two-component Job aiming at using a RPC method and displaying the output on the console view.

- Drop the `tXMLRPCInput` and a `tLogRow` components from the Palette to the design workspace.
- Set the `tXMLRPCInput` basic settings.

- Define the Schema type as Built-in for this use case.
• Set a single-column schema as the expected output for the called method is only one parameter: 
  **StateName.**

  ![XMLRPCInput Schema](image)

<table>
<thead>
<tr>
<th>Column</th>
<th>Key</th>
<th>Type</th>
<th>N.</th>
<th>Date P...</th>
<th>Length</th>
<th>P...</th>
<th>D...</th>
</tr>
</thead>
<tbody>
<tr>
<td>StateName</td>
<td></td>
<td>String</td>
<td></td>
<td></td>
<td>255</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

• Then set the **Server url**. For this demo, use: `http://phpxmlrpc.sourceforge.net/server.php`
• No authentication details are required in this use case.
• The **Method** to be called is: `examples.getStateName`
• The **return class** is not compulsory for this method but might be strictly required for another. Leave the default setting for this use case.
• Then set the input **Parameters** required by the method called. The **Name** field is not used in the code but the value should follow the syntax expected by the method. In this example, the Name used is `State Nr` and the value randomly chosen is `42`.
• The class has not much impact using this demo method but could have with another method, so leave the default setting.
• On the **tLogRow** component **Component** view, check the box: **Print schema column name in front of each value.**
• Then save the Job and press **F6** to execute it.

```
StateName: South Dakota
Job xmlrpc ended at 16:25 21/09/2007 [exit code=0]
```

*South Dakota* is the state name found using the *GetStateName* RPC method and corresponds the 42nd State of the United States as defined as input parameter.
tXSDValidator

Helps at controlling data and structure quality of the file or flow to be processed.

tXSDValidator validates an input XML file or an input XML flow against an XSD file and sends the validation log to the defined output.

**tXSDValidator Standard properties**

These properties are used to configure tXSDValidator running in the Standard Job framework.

The Standard tXSDValidator component belongs to the XML family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th><strong>Mode</strong></th>
<th>Select the validation mode from the drop-down list.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• <strong>File Mode</strong>: to validate an input file.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Flow Mode</strong>: to validate an input flow.</td>
</tr>
</tbody>
</table>

| **Schema and Edit schema** | A schema is a row description. It defines the number of fields to be processed and passed on to the next component. Note that when **File Mode** is selected from the **Mode** list, the schema of this component is read-only and it contains standard information regarding the file validation. |

| **XSD file** | Specify the path to the XSD reference file. The HTTP URL is also supported, for example, http://localhost:8080/book.xsd. This field is available only when **File Mode** is selected from the **Mode** drop-down list. |

| **XML file** | Specify the path to the XML file to be validated. This field is available only when **File Mode** is selected from the **Mode** drop-down list. |

| **If XML is valid, display** | Type in the message to be displayed on the console if the XML file is valid. This field is available only when **File Mode** is selected from the **Mode** drop-down list. |

| **If XML is invalid, display** | Type in the message to be displayed on the console if the XML file is invalid. This field is available only when **File Mode** is selected from the **Mode** drop-down list. |

| **Print to console** | Select this check box to display the validation message on the console. This check box is available only when **File Mode** is selected from the **Mode** drop-down list. |

| **Allocate** | Click the [+] button to add as many rows as needed, and in each row set the value of the following columns: |
- **Input Column**: click the cell and select a column to be validated.
- **XSD File**: enter the path to the corresponding XSD reference file.

This table is available only when **Flow Mode** is selected from the **Mode** drop-down list.

### Advanced settings

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Enable Features</strong></td>
<td>Click the [+ ] button to add as many rows as needed, and in each row enter the feature to be enabled on the underlying parser between double quotation marks, for example, “<a href="http://apache.org/xml/features/honour-all-schemaLocations%E2%80%9D">http://apache.org/xml/features/honour-all-schemaLocations”</a>. For more information about the features, see <a href="https://xerces.apache.org/xerces2-j/features.html">https://xerces.apache.org/xerces2-j/features.html</a>.</td>
</tr>
<tr>
<td><strong>Encoding</strong></td>
<td>Enter the encoding type between double quotation marks.</td>
</tr>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to gather the Job processing metadata at the Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

### Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>ERROR_MESSAGE</strong></td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td><strong>DIFFERENCE</strong></td>
<td>the result of the validation. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td><strong>VALID</strong></td>
<td>the validation result. This is a Flow variable and it returns a boolean.</td>
</tr>
<tr>
<td><strong>XSD_ERROR_MESSAGE</strong></td>
<td>the xsd error message generated by the component. This is a Flow variable and it returns a string. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Usage rule</strong></td>
<td>When <strong>File Mode</strong> is selected, this component can be used as a standalone component but it is usually linked to an output component to gather the log data.</td>
</tr>
</tbody>
</table>
Validating data flows against an XSD file

This scenario describes a Job that validates an XML column in the input file *ShipOrder.csv* against the XSD reference file *ShipOrder.xsd* and then outputs valid rows into the delimited file *ShipOrder_Valid.csv* and invalid rows and error messages into the delimited file *ShipOrder_Invalid.csv*. For a similar use case that validates an XML file, see Validating XML files on page 662.

The content of the input file *ShipOrder.csv* that includes the XML column *ShipOrder* to be validated is as follows:

```
ID;ShipOrder
000001;<shiporder orderid="000001"><orderperson>George Bush</orderperson><shipto><name>John Adams</name><address>Oxford Street</address></shipto><item><title>Empire Burlesque</title><note>Special Edition</note><quantity>1</quantity><price>10.90</price></item></shiporder>
000002;<shiporder orderid="000002"><orderperson>Judy Liu</orderperson><shipto><name>Jack Liu</name><address>Wangfujing Street</address></shipto><item><title>Hide Your Heart</title><quantity>1</quantity><price>9.90</price></item></shiporder>
000003;<shiporder><orderperson>Thomas Wang</orderperson><shipto><name>Wangfujing Street</name></shipto><item><title>The Power of Habit</title><quantity>1</quantity><price>8.99</price></item></shiporder>
```
The content of the XSD reference file *ShipOrder.xsd* is as follows:

```xml
<?xml version="1.0" encoding="ISO-8859-1" ?>
<xs:schema xmlns:xs="http://www.w3.org/2001/XMLSchema">
  <xs:element name="shiporder">
    <xs:complexType>
      <xs:sequence>
        <xs:element name="orderperson" type="xs:string"/>
        <xs:element name="shipto">
          <xs:complexType>
            <xs:sequence>
              <xs:element name="name" type="xs:string"/>
              <xs:element name="address" type="xs:string"/>
            </xs:sequence>
          </xs:complexType>
        </xs:element>
        <xs:element name="item" maxOccurs="unbounded">
          <xs:complexType>
            <xs:sequence>
              <xs:element name="title" type="xs:string"/>
              <xs:element name="note" type="xs:string" minOccurs="0"/>
              <xs:element name="quantity" type="xs:positiveInteger"/>
              <xs:element name="price" type="xs:decimal"/>
            </xs:sequence>
          </xs:complexType>
        </xs:element>
      </xs:sequence>
      <xs:attribute name="orderid" type="xs:string" use="required"/>
    </xs:complexType>
  </xs:element>
</xs:schema>
```

**Adding and linking components**

**Procedure**

1. Create a new Job and add a `tFileInputDelimited` component, a `tXSDValidator` component, and two `tFileOutputDelimited` components by typing their names in the design workspace or dropping them from the Palette.

2. Double-click the `tXSDValidator` component to open its Basic settings view and select Flow Mode from the Mode drop-down list.

3. Link the `tFileInputDelimited` component to the `tXSDValidator` component using a Row > Main connection.

4. Link the `tXSDValidator` component to the first `tFileOutputDelimited` component using a Row > Main connection to output valid rows.

5. Link the `tXSDValidator` component to the second `tFileOutputDelimited` component using a Row > Rejects connection to output invalid rows.

**Configuring the components**

**Procedure**

1. Double-click the `tFileInputDelimited` component to open its Basic settings view on the Component tab.
2. In the **File name/Stream** field, specify the path to the input file. In this example, it is `E:/ShipOrder.csv`.

In the **Header** field, enter `1` to skip the first header row of the input file.

Click the `[...]` button next to **Edit schema** and define the schema by adding two columns `ID` and `ShipOrder` of **String** type.

3. Double-click the **tXSDValidator** component to open its **Basic settings** view on the **Component** tab.

4. Click the **Sync columns** button to retrieve the schema from the preceding **tFileInputDelimited** component, and in the pop-up dialog box, click **Yes** to propagate the schema to the two **tFileOutputDelimited** components.
Add a row in the **Allocate** table by clicking the [+]-button. Then click the **Input Column** cell and select the XML column **ShipOrder** to be validated from the drop-down list. And in the **XSD File** cell, enter the path to the XSD reference file, *E:/ShipOrder.xsd* in this example.

5. Double-click the first **tFileOutputDelimited** component to open its **Basic settings** view on the **Component** tab.

6. In the **File Name** field, specify the path to the output file that will store valid rows. In this example, it is *E:/ShipOrder_Valid.csv*.

   Select the **Include Header** check box to include column headers in the output file.

7. Double-click the second **tFileOutputDelimited** component to open its **Basic settings** view on the **Component** tab.

8. Click the [...] button next to **Edit schema** to view its schema.

   ![Schema view](image)

   You can see an extra column **errorMessage** that holds the error information for invalid rows is added automatically into the schema in addition to the two propagated columns.
9. In the **File Name** field, specify the path to the output file that will store invalid rows and error messages. In this example, it is *E:/ShipOrder_Invalid.csv*. Select the **Include Header** check box to include column headers in the output file.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl+S** to save the Job.
2. Press **F6** to run the Job.

As shown above, the output file *ShipOrder_Valid.csv* contains two valid rows, and the output file *ShipOrder_Invalid.csv* contains one invalid row that doesn’t define the *orderid* attribute and the error message.
tXSLT

Helps to transform data structure to another structure.
This component refers to an XSL stylesheet, to transform an XML source file into a defined output file.

**tXSLT Standard properties**

These properties are used to configure tXSLT running in the Standard Job framework.
The Standard tXSLT component belongs to the XML family.
The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>XML file</td>
<td>File path to the XML file to be validated.</td>
</tr>
<tr>
<td>XSL file</td>
<td>File path to the reference XSL transformation file.</td>
</tr>
<tr>
<td>Output file</td>
<td>File path to the output file. If the file does not exist, it will be created. The output file can be any structured or unstructured file such as html, xml, txt or even pdf or edifact depending on your xsl.</td>
</tr>
<tr>
<td>Parameters</td>
<td>Click the plus button to add new lines in the Parameters list and define the transformation parameters of the XSLT file. Click in each line and enter the key in the name list and its associated value in the value list.</td>
</tr>
</tbody>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tStatCatcher Statistics</td>
<td>Select this check box to gather the processing metadata at the Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

**Global Variables**

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERROR_MESSAGE</td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td>OUTPUT_FILEPATH</td>
<td>the output file path. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td>OUTPUT_FILENAME</td>
<td>the output file name. This is a Flow variable and it returns a string.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.
Transforming XML to html using an XSL stylesheet

This scenario describes a two-component Job that converts xml data into an html document using an xsl stylesheet. It as well defines a transformation parameter of the xsl stylesheet to change the background color of the header of the created html document.

Procedure

1. Drop the tXSLT and tMsBox components from the Palette to the design workspace.

2. Double-click tXSLT to open its Basic settings view where you can define the component properties.
3. In the **XML file** field, set the path or browse to the xml file to be transformed. In this example, the xml file holds a list of MP3 song titles and related information including artist names, company etc.

```xml
<catalog>
  <cd>
    <title>Empire Burlesque</title>
    <artist>Bob Dylan</artist>
    <country>USA</country>
    <company>Columbia</company>
    <price>10.90</price>
    <year>1983</year>
  </cd>
  ...
</catalog>
```

4. In the **XSL file** field in the **Basic settings** view, set the path or browse to the relevant xsl file.

5. In the **Output file** field, set the path or browse to the output html file.

In this example, we want to convert the xml data into an html file holding a table heading followed by a table listing artists' names next to song titles.

```xml
<xsl:stylesheet version="1.0" encoding="ISO-8859-1">
  
  <xsl:param name="bgcolor" />

  <xsl:template match="/">
    <html>
      <body>
        <h2>My CD Collection</h2>
        <table border="1">
          <tr bgcolor="${bgcolor}">
            <th>Title</th>
            <th>Artist</th>
          </tr>
          <xsl:for-each select="catalog/cd">
            <tr>
              <td><xsl:value-of select="title" /></td>
              <td><xsl:value-of select="artist" /></td>
            </tr>
          </xsl:for-each>
        </table>
      </body>
    </html>
  </xsl:template>
</xsl:stylesheet>
```
6. In the **Parameters** area of the **Basic settings** view, click the plus button to add a line where you can define the name and value of the transformation parameter of the xsl file. In this example, the name of the transformation parameter we want to use is **bgcolor** and the value is **green**.

7. Double-click the **tMsgBox** to display its **Basic settings** view and define its display properties as needed.

8. Save the Job and press **F6** to execute it. The message box displays confirming that the output html file is created and stored in the defined path.

9. Click **OK** to close the message box.

**Results**

You can now open the output html file to check the transformation of the xml data and that of the background color of the table heading.

**My CD Collection**

<table>
<thead>
<tr>
<th>Title</th>
<th>Artist</th>
</tr>
</thead>
<tbody>
<tr>
<td>Empire Burlesque</td>
<td>Bob Dylan</td>
</tr>
<tr>
<td>Hide your heart</td>
<td>Bonnie Tyler</td>
</tr>
<tr>
<td>Greatest Hits</td>
<td>Dolly Parton</td>
</tr>
<tr>
<td>Still got the blues</td>
<td>Gary Moore</td>
</tr>
</tbody>
</table>
