<td>Select this check box to use the ActiveMQ failover transport. For more information about the failover transport, see <strong>Failover Transport Reference</strong>. This check box is available only when <strong>ActiveMQ</strong> is selected from the <strong>MQ server</strong> list and the <strong>Static Discovery</strong> check box is cleared.</td>
</tr>
<tr>
<td><strong>Static Discovery</strong></td>
<td>Select this check box to use the ActiveMQ static transport discovery mechanism. For more information about the static transport, see <strong>Static Transport Reference</strong>. This check box is available only when <strong>ActiveMQ</strong> is selected from the <strong>MQ server</strong> list and the <strong>Failover</strong> check box is cleared.</td>
</tr>
<tr>
<td><strong>URI parameters</strong></td>
<td>Enter the URI parameters. This field is available only when the <strong>Failover</strong> or <strong>Static Discovery</strong> check box is selected.</td>
</tr>
<tr>
<td><strong>MQ Server</strong></td>
<td>Select the type of the <strong>MQ server(s)</strong> to be connected from the list: <strong>ActiveMQ</strong>, <strong>JBoss Messaging</strong>, or <strong>WebSphere MQ</strong>. According to the server type selected, the parameters required differ slightly.</td>
</tr>
<tr>
<td><strong>Use SSL Transport</strong></td>
<td>Select this check box to use the ActiveMQ SSL transport. For more information about the SSL transport, see <strong>SSL Transport Reference</strong>. This check box is available only when <strong>ActiveMQ</strong> is selected from the <strong>MQ server</strong> list.</td>
</tr>
<tr>
<td><strong>Host</strong></td>
<td>Enter the host name or IP address of the MQ server.</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Enter the listening port of the MQ server.</td>
</tr>
</tbody>
</table>
| **Username and Password** | Enter the user authentication credentials.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings. |
| **Channel** | Specify the name of the channel through which the connection is established. The default value is **DC.SVRCONN**.  
This field is available only when **WebSphere MQ** is selected from the **MQ server** list. |
| **To** | Type in the message destination, respecting the syntax required by the server; this must include the type and name of the target folder, e.g.: queue/A or topic/testtopic. Note that this field is case-sensitive.  
This field is available only when **ActiveMQ** or **JBoss Messaging** is selected from the **MQ Server** list. |
| **Message Type** | Select the message type: either **Topic** or **Queue**.  
This list is available only when **ActiveMQ** or **JBoss Messaging** is selected from the **MQ Server** list. |
| **Message Body Type** | Select the message body type: **Text Message**, **Bytes Message** or **Map Message**. |
| **Schema and Edit Schema** | A schema is a row description, it defines the number of fields that will be processed and passed on to the next component.  
In the context of **tMomOutput** usage, the schema is read-only but will change according to the incoming schema.  
Only one-column schema is expected by the server to contain the **Messages**. |
| **QueueManager** | Specify the name of the queue manager to which the connection is established.  
This field is available only when **WebSphere MQ** is selected from the **MQ server** list. |
| **MessageQueue** | Enter the name of the message queue into which message queueing applications can put messages.  
This field is available only when **WebSphere MQ** is selected from the **MQ server** list. |
| **Set Transacted** | Select this check box to transact the session. For further information about this parameter, see [https://publib.boulder.ibm.com/series/v5r2/ic2924/books/csqzaw07.pdf](https://publib.boulder.ibm.com/series/v5r2/ic2924/books/csqzaw07.pdf).  
Note that selecting this check box will ignore the settings in the **Acknowledgement Mode** list in the **Advanced settings** view of **tMomInput**. |
| **Is using message id to set** | Select this check box to set messages according to their ids. |
### Advanced settings

<table>
<thead>
<tr>
<th>Additional options</th>
<th>Define the additional transport options in the table. This table is available only if you select the Failover or Static Discovery check box in the Basic settings view.</th>
</tr>
</thead>
</table>
|                    | • **Option name**: the name of the option.  
|                    | • **Option value**: the value of the option.  
|                    | For example, enter `maxReconnectAttempts` in the Option name field and then `0` in the Option value field so that no attempt is made to retry the connection when no server is available.  
|                    | For more information about the failover transport options, see Failover Transport Reference.  
|                    | For more information about the static discovery transport options, see Static Transport Reference. |

| Delivery Mode | Select a delivery mode supported by JMS:  
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               | **Not Persistent**: This delivery mode does not require that the message be logged to stable storage.  
|               | **Persistent**: This delivery mode requires that the message be logged to stable storage as part of the client’s send operation.  
|               | For further information about the delivery modes, see https://publib.boulder.ibm.com/iseries/v5r2/ic2924/books/csqzaw07.pdf.  
|               | (Available when ActiveMQ or JBoss Messaging is selected in the MQ Server list.) |

| Set Jms Header | Select this check box to send the Jms headers through the mapping from Jms fields onto MQ Series fields on the MQ server. When this check box is checked, you can specify the header name and the header value in the line(s) you added by clicking the plus button in the Parameters table. For further information about the usage of Jms headers, see https://publib.boulder.ibm.com/iseries/v5r2/ic2924/books/csqzaw07.pdf.  
<table>
<thead>
<tr>

</tbody>
</table>

| Use format | Select this check box to specify the WebSphere message format in the WebSphere Message Format field. The default format is MQSTR. |

(Available when WebSphere MQ is selected in the MQ Server list.)

<table>
<thead>
<tr>
<th>Set MQMD Fields</th>
<th>Select this check box to enable the Parameters table in which you can specify the value of the MQMD fields. This check box is available only when WebSphere MQ is selected from the MQ Server list.</th>
</tr>
</thead>
</table>
| Parameters      | Specify the value of the MQMD fields.  
|                 | • **Field Name**: Select an MQMD field from the list.  
|                 | • **Field Value**: Enter the value of the corresponding MQMD field.  
|                 | This table is available only when the Set MQMD Fields check box is selected.  
|                 | For more information about the MQMD fields, see [Fields for MQMD](http://publib.boulder.ibm.com/infocenter/wmbhelp/v6r1m0/index.jsp?topic=%2Fcom.ibm.etools.mft.doc%2Faq06920_.htm). |

| Include Header | Select this check box to specify the header of the message:  
|                | **MQRFH2 fixed Portion**: Select this check box and click the plus button to add one or more lines to specify the Version, Encoding, Format, Flags, NameValueCCSID and CodedCharSetId as needed for the fixed portion of MQRFH2 header.  
|                | **MCD folder**: Select this check box and click the plus button to add one or more lines to specify the field name and the value for the properties that describe the format of the message.  
|                | **JMS folder**: Select this check box and click the plus button to add one or more lines to specify the field name and the value for the transportation of JMS header fields and JMSX properties.  
|                | **USR folder**: Select this check box and click the plus button to add one or more lines to specify the field name and the value for the transportation of application-defined properties associated with the message.  
|                | Available when WebSphere MQ is selected in the MQ Server list. |

| Set Cipher Suite | Select this check box to enable the Cipher Suite list from which you can specify the Cipher Suite to be used with WebSphere MQ SSL.  
|                 | For further information about Cipher Suite, see [CipherSpecs and their equivalent CipherSuites supported by IBM WebSphere MQ](http://publib.boulder.ibm.com/infocenter/wtmrdoc/v7r2m0/index.jsp?topic=%2Fcom.ibm.etools.mft.doc%2Faq06920_.htm).  
|                 | Available when WebSphere MQ is selected in the MQ Server list. |
### Custom Cipher Suite

Select this check box to allow you to customize Cipher Suite.

**IBM Cipher Mappings**: Use the IBM Java Cipher Suite to IBM MQ Cipher Spec Mappings.

**Oracle Cipher Mappings**: Use the Oracle Cipher Suite to IBM MQ Cipher Spec Mappings.

### tStatCatcher Statistics

Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>NB_LINE</strong>: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press <strong>Ctrl + Space</strong> to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td></td>
<td>For further information about variables, see <strong>Talend Studio User Guide</strong>.</td>
</tr>
</tbody>
</table>

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component must be linked to an input or intermediary component.</th>
</tr>
</thead>
</table>

**Usage rule**

Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your MQ Server connection dynamically from multiple connections planned in your Job.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see **Reading data from databases through context-based dynamic connections** on page 2457 and **Reading data from different MySQL databases using dynamically loaded connection parameters** on page 491. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

### Limitation

Make sure the relevant Websphere MQ, JBoss Messaging, or ActiveMQ server is launched.

This component requires installation of its related jar files.
Related scenario

For a related scenario, see tMomInput on page 2241.
tMomRollback

Cancels the transaction committed in the MQ Server.

**tMomRollback Standard properties**

These properties are used to configure tMomRollback running in the Standard Job framework.

The Standard tMomRollback component belongs to the Internet family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Component List</th>
<th>Select the component used in your Job.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Backout messages to backout queue (WebsphereMQ)</td>
<td>Select this check box to backout the messages to the backout queue defined in the Websphere MQ manager when the backout count reaches the configured threshold which is a property of the queue in the Websphere MQ server.</td>
</tr>
</tbody>
</table>

- If a tMomConnection component is selected from Component List, the messages processed by all tMomInput components that reuses the connection created by the selected tMomConnection component will be backouted.
- If a tMomInput component is selected from Component List and the Use existing connection check box in the Basic settings view of the tMomInput component is cleared, the messages processed by the selected tMomInput component will be backouted.
- If a tMomInput component is selected from Component List and the Use existing connection check box in the Basic settings view of the tMomInput component is selected, the messages processed by all tMomInput components that reuses the same connection the selected tMomInput component reused will be backouted.
- If a tMomOutput component is selected from Component List and the Use existing connection check box in the Basic settings view of the tMomOutput component is cleared, no messages will be backouted.
- If a tMomOutput component is selected from Component List and the Use existing connection check box in the Basic settings view of the tMomOutput component is selected, the messages processed by all tMomInput components that reuses the same connection the selected tMomOutput component reused will be backouted.

Note that this check box works only when the Commit (delete message after read from the queue), Backout messages to input queue, Backout messages to backout queue (when backoutCount of message reach the threshold value), and Browse message check boxes of all tMomInput components in the same Job are cleared.
Close Connection

Clear this check box to continue to use the selected connection once the component has performed its task.

Advanced settings

**tStatCatcher Statistics**

Select this check box to collect log data at the component level.

Global Variables

**Global Variables**

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

Usage

**Usage rule**

This component is more commonly used with other tMom* components, especially with the **tMomConnection** and **tMomCommit** components.

Related scenario

For a similar scenario, see *Rollback from inserting data in mother/daughter tables* on page 2440.
tMondrianInput

Executes a multi-dimensional expression (MDX) query corresponding to the dataset structure and schema definition.

tMondrianInput reads data from relational databases and produces multidimensional data sets based on an MDX query. Then it passes on the multidimensional dataset to the next component via a Main row link.

### tMondrianInput Standard properties

These properties are used to configure tMondrianInput running in the Standard Job framework.
The Standard tMondrianInput component belongs to the Business Intelligence family.
The component in this framework is available in all Talend products.

#### Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mondrian Version</td>
<td>Select the Mondrian version you are using.</td>
</tr>
<tr>
<td>DB type</td>
<td>Select the relevant type of relational database</td>
</tr>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-in</strong>: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: Select the Repository file where Properties are stored. The following fields are pre-filled in using fetched data.</td>
</tr>
<tr>
<td>Datasource</td>
<td>Name and path of the file containing the data.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <code>line</code> when naming the fields. Click <strong>Edit schema</strong> to make changes to the schema. If the current schema is of the <strong>Repository</strong> type, three options are available:</td>
</tr>
<tr>
<td></td>
<td>• <strong>View schema</strong>: choose this option to view the schema only.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Change to built-in property</strong>: choose this option to change the schema to <strong>Built-in</strong> for local changes.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Update repository connection</strong>: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select <strong>No</strong> upon</td>
</tr>
</tbody>
</table>

2266
**MondrianInput**

Completion and choose this schema metadata again in the **Repository Content** window.

<table>
<thead>
<tr>
<th><strong>Built-in</strong>: The schema is created and stored locally for this component only. Related topic: see <em>Talend Studio User Guide</em>.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Repository</strong>: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see <em>Talend Studio User Guide</em>.</td>
</tr>
</tbody>
</table>

**Catalog**

Path to the catalog (structure of the data warehouse).

**MDX Query**

Type in the MDX query paying particularly attention to properly sequence the fields in order to match the schema definition and the data warehouse structure.

**Encoding**

Select the encoding from the list or select Custom and define it manually. This field is compulsory for DB data handling.

### Advanced settings

**tStat Catcher Statistics**

Select this check box to collect log data at the component level.

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th><strong>NB_LINE</strong>: the number of rows read by an input component or transferred to an output component. This is a Flow variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>QUERY</strong>: the query statement being processed. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td></td>
<td><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press <strong>Ctrl + Space</strong> to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td></td>
<td>For further information about variables, see <em>Talend Studio User Guide</em>.</td>
</tr>
</tbody>
</table>

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component covers MDX queries for multi-dimensional datasets.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limitation</td>
<td>This component requires installation of its related jar files.</td>
</tr>
</tbody>
</table>
Cross-join tables

This Job extracts multi-dimensional datasets from relational database tables stored in a MySQL base. The data are retrieved using a multidimensional expression (MDX query). Obviously you need to have to know the structure of your data, or at least have a structure description (catalog) as a reference for the dataset to be retrieved in the various dimensions.

Setting up the Job

Procedure

1. Drop tMondrianInput and tLogRow from the Palette to the design workspace.
2. Connect the Mondrian connector to the output component using a Row Main connection.

Setting up the DB connection

Procedure

1. Double-click the tMondrianInput component to display its Basic settings view.

   - In DB type field, select the relational database you are using with Mondrian.
   - Select the relevant Repository entry as Property type, if you store your DB connection details centrally. In this example the properties are built-in.
   - Fill out the details of connection to your DB: Host, Port, Database name, User Name and Password.
   - Select the relevant Schema in the Repository if you store it centrally. In this example, the schema is to be set (built-in).
Configuring the DB query

Procedure

1. The relational database we want to query contains five columns: media, drink, unit_sales, store_cost and store_sales.

2. The query aims at retrieving the unit_sales, store_cost and store_sales figures for various media / drink using an MDX query such as in the example below:

   **CrossJoin Example 1**

   The current slicer is 1997.

<table>
<thead>
<tr>
<th>Radio</th>
<th>Alcoholic Beverages</th>
<th>75</th>
<th>70.40</th>
<th>160.62</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Beverages</td>
<td>97</td>
<td>75.70</td>
<td>196.03</td>
</tr>
<tr>
<td></td>
<td>Dairy</td>
<td>54</td>
<td>36.75</td>
<td>99.03</td>
</tr>
<tr>
<td>TV</td>
<td>Alcoholic Beverages</td>
<td>76</td>
<td>70.99</td>
<td>132.38</td>
</tr>
<tr>
<td></td>
<td>Beverages</td>
<td>188</td>
<td>167.00</td>
<td>419.14</td>
</tr>
<tr>
<td></td>
<td>Dairy</td>
<td>68</td>
<td>45.19</td>
<td>119.55</td>
</tr>
<tr>
<td>Sunday Paper</td>
<td>Alcoholic Beverages</td>
<td>148</td>
<td>128.97</td>
<td>316.88</td>
</tr>
<tr>
<td></td>
<td>Beverages</td>
<td>197</td>
<td>161.81</td>
<td>399.58</td>
</tr>
<tr>
<td></td>
<td>Dairy</td>
<td>85</td>
<td>54.75</td>
<td>140.27</td>
</tr>
<tr>
<td>Street Handout</td>
<td>Alcoholic Beverages</td>
<td>158</td>
<td>121.14</td>
<td>294.55</td>
</tr>
<tr>
<td></td>
<td>Beverages</td>
<td>270</td>
<td>201.20</td>
<td>520.55</td>
</tr>
<tr>
<td></td>
<td>Dairy</td>
<td>84</td>
<td>50.25</td>
<td>128.32</td>
</tr>
</tbody>
</table>

3. Back on the Basic settings tab of the tMondrianInput component, set the Catalog path to the data warehouse. This catalog describes the structure of the warehouse.
4. Then type in the MDX query such as:

```mdx
"select
    { [Measures].[Unit Sales], [Measures].[Store Cost], [Measures].[Store Sales] } on columns,
    CrossJoin(
        { [Promotion Media].[All Media].[Radio],
          [Promotion Media].[All Media].[TV],
          [Promotion Media].[All Media].[Sunday Paper],
          [Promotion Media].[All Media].[Street Handout] },
        [Product].[All Products].[Drink].children) on rows
from Sales
where ([Time].[1997])"
```

5. Eventually, select the **Encoding** type on the list.

**Job execution**

**Procedure**

1. Select the **tLogRow** component and select the **Print header** check box to display the column names on the console.

2. Then press **F6** to run the Job.

```plaintext
Starting job Mondrian at 15:31 08-07-2005
media  drink  unit sales  store cost  store sales
Promotion Media [All Media] [Radio] [Product] [All Products] [Drink] [Alcoholic beverages] 75.070.3977100.62
Promotion Media [All Media] [Radio] [Product] [All Products] [Drink] [Beverages] 97.075.7016186.03
Promotion Media [All Media] [Radio] [Product] [All Products] [Drink] [Dairy] 34.036.747485.03
Promotion Media [All Media] [TV] [Product] [All Products] [Drink] [Alcoholic beverages] 76.070.3989112.58
Promotion Media [All Media] [TV] [Product] [All Products] [Drink] [Beverages] 189.0167.0025419.14
Promotion Media [All Media] [TV] [Product] [All Products] [Drink] [Dairy] 48.045.1904113.65
Promotion Media [All Media] [Sunday Paper] [Product] [All Products] [Drink] [Alcoholic beverages] 148.0129.4796136.63
Promotion Media [All Media] [Sunday Paper] [Product] [All Products] [Drink]. [Beverages] 137.0151.8067393.56
Promotion Media [All Media] [Sunday Paper] [Product] [All Products] [Drink]. [Dairy] 95.054.746140.27
Promotion Media [All Media] [Street Handout] [Product] [All Products] [Drink] [Alcoholic beverages] 158.0121.1384204.55
Promotion Media [All Media] [Street Handout] [Product] [All Products] [Drink]. [Beverages] 270.0201.2125520.95
Promotion Media [All Media] [Street Handout] [Product] [All Products] [Drink]. [Dairy] 185.0150.2605128.32

Job Mondrian ended at 15:33 08-07-2005. [exit code=0]
```

**Results**

The console shows the result of the **unit_sales**, **store_cost** and **store_sales** for each type of **Drink (Beverages, Dairy, Alcoholic beverages)** crossed with each media (TV, Sunday Paper, Street handout) as shown previously in a table form.
tMongoDBBulkLoad

Imports data files in different formats (CSV, TSV or JSON) into the specified MongoDB database so that the data can be further processed.

### tMongoDBBulkLoad Standard properties

These properties are used to configure tMongoDBBulkLoad running in the Standard Job framework.

The Standard tMongoDBBulkLoad component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

#### Basic settings

| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:
| | • **View schema**: choose this option to view the schema only.
| | • **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
<p>| | • <strong>Update repository connection</strong>: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select <strong>No</strong> upon completion and choose this schema metadata again in the <strong>Repository Content</strong> window. |
| <strong>MongoDB directory</strong> | Fill in this field with the MongoDB home directory. |
| <strong>Use local DB path</strong> | Select this check box to provide the information of the local database that you want to use. MongoDB V3.0 and onward versions do not support this feature. |
| | • <strong>Local DB path</strong>: type in the path to the local database specified when starting the MongoDB server. |
| <strong>Use replica set address</strong> | Select this check box to define a replica set to be connected. |
| | • <strong>Replica set name</strong>: specify the name of the replica set. |
| | • <strong>Replica address</strong>: specify multiple MongoDB database servers for failover as needed. Note that if you leave the replica host or replica port unspecified, their default values localhost and 27017 will be used. |
| <strong>Server</strong> | Hostname or IP address of the database server. Note that the default value localhost will be used if the server is not specified. |</p>
<table>
<thead>
<tr>
<th><strong>Port</strong></th>
<th>Listening port of the database server. Note that the default value 27017 will be used if the port is not specified. This field is available only when the Use replica set address check box is not selected.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Type in the name of the database to import data to.</td>
</tr>
<tr>
<td><strong>Collection</strong></td>
<td>Type in the name of the collection to import data to.</td>
</tr>
<tr>
<td><strong>Use SSL connection</strong></td>
<td>Select this check box to enable the SSL or TLS encrypted connection. Then you need to use the tSetKeystore component in the same Job to specify the encryption information. For further information about tSetKeystore, see tSetKeystore on page 3464. Note that the SSL connection is available only for the version 2.4 + of MongoDB.</td>
</tr>
<tr>
<td><strong>Drop collection if exist</strong></td>
<td>Select this check box to remove the collection if it already exists.</td>
</tr>
<tr>
<td><strong>Required authentication</strong></td>
<td>Select this check box to enable the database authentication. Among the mechanisms listed on the Authentication mechanism drop-down list, the NEGOTIATE one is recommended if you are not using Kerberos, because it automatically select the authentication mechanism the most adapted to the MongoDB version you are using. For details about the other mechanisms in this list, see MongoDB Authentication from the MongoDB documentation.</td>
</tr>
<tr>
<td><strong>Set Authentication database</strong></td>
<td>If the username to be used to connect to MongoDB has been created in a specific Authentication database of MongoDB, select this check box to enter the name of this Authentication database in the Authentication database field that is displayed. For further information about the MongoDB Authentication database, see User Authentication database.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. Available when the Required authentication check box is selected. If the security system you have selected from the Authentication mechanism drop-down list is Kerberos, you need to enter the User principal, the Realm and the KDC server fields instead of the Username and the Password fields.</td>
</tr>
</tbody>
</table>
| Data file | Type in the full path of the file from which the data will be imported or click the [...] button to browse to the desired data file.
Make sure that the data file is in standard format. For example, the fields in CSV files should be separated with commas. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>File type</td>
<td>Select the proper file type from the list. CSV, TSV and JSON are supported.</td>
</tr>
</tbody>
</table>
| The JSON file starts with an array | Select this check box to allow tMongoDBBulkload to read the JSON files starting with an array.
This check box appears when the File type you have selected is JSON. |
| Action on data | Select the action that you want to perform on the data.
- **Insert**: Insert the data into the database.
  Note that when inserting data from CSV or TSV files into the MongoDB database, you need to specify fields either by selecting the *First line is header* check box or defining them in the schema.
- **Upsert**: Insert the data if they do not exist or update the existing data.
  Note that when upserting data into the MongoDB database, you need to specify a list of fields for the query portion of the upsert operation. |
| Upsert fields | Customize the fields that you want to upsert as needed.
This table is available when you select Upsert from the Action on data list. |
| First line is header | Select this check box to use the first line in CSV or TSV files as a header.
This check box is available only when you select CSV or TSV from the File type list. |
| Ignore blanks | Select this check box to ignore the empty fields in CSV or TSV files.
This check box is available only when you select CSV or TSV from the File type list. |
| Print log | Select this check box to print logs. |

**Advanced settings**

| Additional arguments | Complete this table to use the additional arguments as required.
For example, you can use the argument `--jsonArray` to accept the import of data expressed with multiple MongoDB documents within a single JSON array. For more information about the additional arguments, go to [http://docs.mongodb.org/manual/reference/program/mongoimport/](http://docs.mongodb.org/manual/reference/program/mongoimport/) and read the description of options. |
tMongoDBBulkLoad

| tStatCatcher Statistics | Select this check box to collect the log data at a component level. |

Global Variables

| Global Variables | NB_LINE: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer. ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | This component can be used together with the tMongoDBInput component to check if the data is imported as expected. |
| Limitation | The MongoDB client tool needs to be installed on the machine where Jobs using this component are executed. |

Importing data into MongoDB database

This scenario applies only to Talend products with Big Data.

The following scenario describes a Job that firstly imports data from a CSV file into the specified MongoDB collection, then reads data from the MongoDB collection to check if the import is successful, next continues to import data from a JSON file with the same data structure into the same MongoDB collection, and finally displays the data from the MongoDB collection to demonstrate that the data from the JSON file is also imported successfully.
Dropping and linking the components

Procedure

1. Drop the following components from the Palette onto the design workspace: two tMongoDBBulkLoad components, two tMongoDBInput components, and two tLogRow components.

2. Connect the first tMongoDBBulkLoad to the first tMongoDBInput using a Trigger > OnSubjobOk link.

3. Connect the first tMongoDBInput to the first tLogRow using a Row > Main link.

4. Repeat the two steps above to connect the second tMongoDBBulkLoad to the second tMongoDBInput, and the second tMongoDBInput to the second tLogRow.

5. Connect the first tMongoDBInput to the second tMongoDBBulkLoad using a Trigger > OnSubjobOk link.

6. Label the two tLogRow components to better identify the data displayed on the console.
Configuring the components

Importing data from a CSV file

Procedure

1. Double-click the first tMongoDBBulkLoad component to open its Basic settings view in the Component tab.

2. In the MongoDB directory field, type in the MongoDB home directory. In this example, it is D:/MongoDB.

3. In the Server and Port fields, fill in the information required for the connection to MongoDB. In this example, type in localhost and 27017.

4. In the Database field, type in the database to import data to, bookstore in this example.

5. In the Collection field, type in the collection to import data to, books in this example.

6. Select the Drop collection if exist check box to remove the specified collection if it already exists.

7. Browse to the desired data file from which you want to import data. In this example, it is D:/Input/books.csv, which is a standard CSV file containing four columns: id, title, author, and category.

8. Select CSV from the File type list.

9. Select Insert from the Action on data list.

10. Select the First line is header check box to use the first line in the CSV file as a header.

11. Select the Ignore blanks check box to ignore the blank fields (if any) in the CSV file.
Validating that the CSV file is imported successfully

Procedure

1. Double-click the first `tMongoDBInput` component to open its Basic settings view in the Component tab.

2. From the DB Version list, select the MongoDB version you are using.

3. In the Server and Port fields, fill in the information required for the connection to MongoDB. In this example, type in `localhost` and `27017`.

4. In the Database field, type in the database from which the data will be read, `bookstore` in this example.

5. In the Collection field, type in the collection from which the data will be read, `books` in this example.

6. Click Edit schema to define the data structure to be read from the MongoDB collection.
7. In the Mapping table, the Column field is automatically populated with the defined schema. You do not need to fill in the Parent node path column.

8. Double-click the first tLogRow component to open its Basic settings view in the Component tab.

9. In the Mode area, select Table (print values in cells of a table).

Importing data from a JSON file

Procedure

1. Double-click the second tMongoDBBulkLoad component to open its Basic settings view in the Component tab.
2. In the **MongoDB directory** field, type in the MongoDB home directory. In this example, it is `D:/MongoDB`.

3. In the **Server** and **Port** fields, fill in the information required for the connection to MongoDB. In this example, type in `localhost` and `27017`.

4. In the **Database** field, type in the target database to import data, `bookstore` in this example.

5. In the **Collection** field, type in the target collection to import data, `books` in this example.

6. Browse to the desired data file from which you want to import data. Here, select `books.json`.

   ```json
   { "id": "4", "title": "Les Miserables", "author": "Victor Hugo", "category": "Language&Literature" } 
   { "id": "5", "title": "Advanced Database Systems", "author": "Carlo Zaniolo", "category": "Database" }
   ```

7. Select **JSON** from the **File type** list.

8. Select **Insert** from the **Action on data** list.

9. Click the **Advanced settings** tab to define the additional arguments as needed.

   ```
   Additional arguments
<table>
<thead>
<tr>
<th>Argument</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>--jsonArray</td>
<td></td>
</tr>
</tbody>
</table>
   ```

In this example, add the argument `--jsonArray` to accept the imported data within a single JSON array.
Validating that the JSON file is imported successfully

Procedure

1. Repeat Step 1 through Step 7 described in the procedure Validating that the CSV file is imported successfully on page 2277 to configure the second `tMongoDBInput` component.

2. Repeat Step 8 through Step 9 described in the procedure Validating that the CSV file is imported successfully on page 2277 to configure the second `tLogRow` component.

Saving and executing the Job

Procedure

1. Press Ctrl + S to save the Job.
2. Execute the Job by pressing F6 or clicking Run on the Run tab.
Results

The data from the collection *books* in the MongoDB database *bookstore* is displayed on the console, which contains the data imported from both the CSV file *books.csv* and the JSON file *books.json*.

Job MongoDB_scenario ended at 10:51 13/08/2013. [exit code=0]
```
**tMongoDBClose**

Closes a connection to the MongoDB database.

**tMongoDBClose Standard properties**

These properties are used to configure tMongoDBClose running in the Standard Job framework.

The Standard tMongoDBClose component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| Component list | Select the tMongoDBConnection component in the list if more than one connection is created for the current Job. |

**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

**Global Variables**

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

**Usage**

| Usage rule | This component is to be used along with other MongoDB components, especially tMongoDBConnection. |

**Related scenario**

For a related scenario, see Creating a collection and writing data to it on page 2325.
tMongoDBConnection

Creates a connection to a MongoDB database and reuse that connection in other components. tMongoDBConnection opens a connection to a database in order that a transaction may be made.

**tMongoDBConnection Standard properties**

These properties are used to configure tMongoDBConnection running in the Standard Job framework. The Standard tMongoDBConnection component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th><strong>DB Version</strong></th>
<th>List of the database versions.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Use replica set address</strong></td>
<td>Select this check box to show the Replica address table. In the Replica address table, you can define multiple MongoDB database servers for failover.</td>
</tr>
<tr>
<td><strong>Server and Port</strong></td>
<td>IP address and listening port of the database server. Available when the Use replica set address check box is not selected.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database.</td>
</tr>
<tr>
<td><strong>Use SSL connection</strong></td>
<td>Select this check box to enable the SSL or TLS encrypted connection. Then you need to use the tSetKeystore component in the same Job to specify the encryption information. For further information about tSetKeystore, see tSetKeystore on page 3464. Note that the SSL connection is available only for the version 2.4 + of MongoDB.</td>
</tr>
<tr>
<td><strong>Required authentication</strong></td>
<td>Select this check box to enable the database authentication. Among the mechanisms listed on the Authentication mechanism drop-down list, the NEGOTIATE one is recommended if you are not using Kerberos, because it automatically select the authentication mechanism the most adapted to the MongoDB version you are using. For details about the other mechanisms in this list, see MongoDB Authentication from the MongoDB documentation.</td>
</tr>
<tr>
<td><strong>Set Authentication database</strong></td>
<td>If the username to be used to connect to MongoDB has been created in a specific Authentication database of MongoDB, select this check box to enter the name of this Authentication database in the Authentication database field that is displayed.</td>
</tr>
</tbody>
</table>
For further information about the MongoDB Authentication database, see User Authentication database.

**Username and Password**

DB user authentication data.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

Available when the Required authentication check box is selected.

If the security system you have selected from the Authentication mechanism drop-down list is Kerberos, you need to enter the User principal, the Realm and the KDC server fields instead of the Username and the Password fields.

**Advanced settings**

**tStatCatcher Statistics**

Select this check box to collect the log data at a component level.

**No query timeout**

Select this check box to prevent MongoDB servers from stopping idle cursors at the end of 10-minute inactivity of these cursors. In this situation, an idle cursor will stay open until either the results of this cursor are exhausted or you manually close it using the cursor.close() method.

A cursor for MongoDB is a pointer to the result set of a query. By default, that is to say, with this check box being clear, a MongoDB server automatically stops idle cursors after a given inactivity period to avoid excess memory use. For further information about MongoDB cursors, see https://docs.mongodb.org/manual/core/cursors/.

**Global Variables**

**Global Variables**

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

**Usage**

**Usage rule**

This component is generally used with other MongoDB components, particularly tMongoClose.
Related scenario

For a related scenario, see Creating a collection and writing data to it on page 2325.
tMongoDBGridFSDelete

Automates the delete action over specific files in MongoDB GridFS.

tMongoDBGridFSDelete connects to a given MongoDB GridFS system, executes a user-defined query to select specific files and deletes these files from this system.

**tMongoDBGridFSDelete Standard properties**

These properties are used to configure tMongoDBGridFSDelete running in the Standard Job framework.

The Standard tMongoDBGridFSDelete component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| Property type | Either Built-In or Repository.  
|---------------|--------------------------------|
|               | Built-In: No property data stored centrally.  
|               | Repository: Select the repository file where the properties are stored.  

**Use an existing connection**

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level.

**Use replica set address or multiple query routers**

Select this check box to show the Server addresses table.

In the Server addresses table, define the sharded MongoDB databases or the MongoDB replica sets you want to connect to.

**Server and Port**

IP address and listening port of the database server.

Available when the Use replica set address check box is not selected.

Note that if you use the authentication mechanisms to connect to this MongoDB database, you must enter the name, rather than the IP address, of the host of the database server.

**Database**

Name of the database.

**Use SSL connection**

Select this check box to enable the SSL or TLS encrypted connection.

Then you need to use the tSetKeystore component in the same Job to specify the encryption information.

For further information about tSetKeystore, see tSetKeystore on page 3464.
<table>
<thead>
<tr>
<th><strong>Set read preference</strong></th>
<th>Note that the SSL connection is available only for the version 2.4+ of MongoDB.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Use authentication</strong></td>
<td>Set this check box and from the Read preference drop-down list that is displayed, select the member to which you need to direct the read operations. If you leave this check box clear, the Job uses the default Read preference, that is to say, uses the primary member in a replica set. For further information, see MongoDB’s documentation about Replication and its Read preferences.</td>
</tr>
<tr>
<td><strong>Set Authentication database</strong></td>
<td>Select this check box to enable the database authentication. Among the mechanisms listed on the Authentication mechanism drop-down list, the NEGOTIATE one is recommended if you are not using Kerberos, because it automatically select the authentication mechanism the most adapted to the MongoDB version you are using. For details about the other mechanisms in this list, see MongoDB Authentication from the MongoDB documentation.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>If the username to be used to connect to MongoDB has been created in a specific Authentication database of MongoDB, select this check box to enter the name of this Authentication database in the Authentication database field that is displayed. For further information about the MongoDB Authentication database, see User Authentication database.</td>
</tr>
<tr>
<td><strong>Bucket</strong></td>
<td>Enter the name of the bucket from which you need to delete files. A bucket of GridFS is similar to a folder.</td>
</tr>
<tr>
<td><strong>Query type</strong></td>
<td>Select the type of the query you want to perform to select the files to be deleted.</td>
</tr>
<tr>
<td></td>
<td><strong>Filename</strong>: you need to enter the name of the file to be deleted. This name is the value of the filename attribute of this file. Note that only one name is allowed. In GridFS, a file is identified only by its unique identifier (its object ID); its file name is not necessarily unique.</td>
</tr>
<tr>
<td></td>
<td><strong>Mongo Query</strong>: enter the query to be used to select the files to be deleted.</td>
</tr>
</tbody>
</table>
The example query, `{}` within double quotation marks provided with `tMongoDBGridFSDelete`, means to select all of the files in a bucket. You can put `{ 'filename': {$regex': 'REGEX_PATTERN'} }` to apply a regular expression to defining the file names to be used.

</tr>
</tbody>
</table>
Related scenario

For a scenario using **tMongoDBGridFSDelete**, see *Managing files using MongoDB GridFS* on page 2304.
tMongoDBGridFSGet

Connects to a MongoDB GridFS system to copy files from it.

**tMongoDBGridFSGet copies files from a given MongoDB GridFS system to a local directory and if needs be, renames these files.**

**tMongoDBGridFSGet Standard properties**

These properties are used to configure tMongoDBGridFSGet running in the Standard Job framework.

The Standard tMongoDBGridFSGet component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| Property type | Either Built-In or Repository.  
|---------------|--------------------------------|
|               | **Built-In**: No property data stored centrally.  
|               | **Repository**: Select the repository file where the properties are stored. |

**Use an existing connection**

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level.

**Use replica set address or multiple query routers**

Select this check box to show the Server addresses table. In the Server addresses table, define the sharded MongoDB databases or the MongoDB replica sets you want to connect to.

**Server and Port**

IP address and listening port of the database server.

Available when the Use replica set address check box is not selected.

Note that if you use the authentication mechanisms to connect to this MongoDB database, you must enter the name, rather than the IP address, of the host of the database server.

**Database**

Name of the database.

**Use SSL connection**

Select this check box to enable the SSL or TLS encrypted connection.

Then you need to use the tSetKeystore component in the same Job to specify the encryption information.

For further information about tSetKeystore, see tSetKeystore on page 3464.
Note that the SSL connection is available only for the version 2.4 + of MongoDB.

**Set read preference**
Select this check box and from the Read preference drop-down list that is displayed, select the member to which you need to direct the read operations.
If you leave this check box clear, the Job uses the default Read preference, that is to say, uses the primary member in a replica set.
For further information, see MongoDB's documentation about Replication and its Read preferences.

**Required authentication**
Select this check box to enable the database authentication.
Among the mechanisms listed on the Authentication mechanism drop-down list, the NEGOTIATE one is recommended if you are not using Kerberos, because it automatically select the authentication mechanism the most adapted to the MongoDB version you are using.
For details about the other mechanisms in this list, see MongoDB Authentication from the MongoDB documentation.

**Set Authentication database**
If the username to be used to connect to MongoDB has been created in a specific Authentication database of MongoDB, select this check box to enter the name of this Authentication database in the Authentication database field that is displayed.
For further information about the MongoDB Authentication database, see User Authentication database.

**Username and Password**
DB user authentication data.
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.
Available when the Required authentication check box is selected.
If the security system you have selected from the Authentication mechanism drop-down list is Kerberos, you need to enter the User principal, the Realm and the KDC server fields instead of the Username and the Password fields.

**Bucket**
Enter the name of the bucket you need to read files from. A bucket of GridFS is similar to a folder.

**Query type**
Select the type of the query you want to perform to select the data to be copied.
- **Filename**: you need to enter the name of the file to be copied. This name is the value of the filename attribute used by this file. Note that only one name is allowed.
  In GridFS, a file is identified only by its unique identifier (its object ID); its file name is not necessarily unique.
- **Mongo Query**: enter the query to be used to select the files to be copied.
The default query, `{}` within double quotation marks provided with this component, means to select all of the files. You can also apply a regular expression by putting `{'filename': {'$regex': 'REGEX_PATTERN'}}` to define the file names to be used.

It is recommended to use your query along with the Overwrite local files and the Use Document ID as output filename check boxes to avoid any file name conflict issue.

<table>
<thead>
<tr>
<th>Component</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Local Folder</td>
<td>Enter the path to the folder in which the data copied from GridFS is to be written.</td>
</tr>
<tr>
<td>Overwrite local files</td>
<td>Select this check box to overwrite the file using the same file name in the local folder being used. Otherwise, an exception will be returned in this type of situation.</td>
</tr>
<tr>
<td>Use Document ID as output filename</td>
<td>Select this box to rename the incoming files on the fly using the values of their object IDs. This allows you to keep the files that have the same file names.</td>
</tr>
</tbody>
</table>

### Advanced settings

<table>
<thead>
<tr>
<th>Component</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tStatCatcher Statistics</td>
<td>Select this check box to collect the log data at the component level.</td>
</tr>
<tr>
<td>No query timeout</td>
<td>Select this check box to prevent MongoDB servers from stopping idle cursors at the end of 10-minute inactivity of these cursors. In this situation, an idle cursor will stay open until either the results of this cursor are exhausted or you manually close it using the <code>cursor.close()</code> method.</td>
</tr>
</tbody>
</table>

A cursor for MongoDB is a pointer to the result set of a query. By default, that is to say, with this check box being clear, a MongoDB server automatically stops idle cursors after a given inactivity period to avoid excess memory use. For further information about MongoDB cursors, see [https://docs.mongodb.org/manual/core/cursors/](https://docs.mongodb.org/manual/core/cursors/).

### Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NB_FILE</td>
<td>the number of files processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>ERROR_MESSAGE</td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](https://docs.talend.com/current/user-guide/).
### Usage

| Usage rule | This component combines MongoDB GridFS connection and data extraction, thus usually used as a single-component subjob to copy data from GridFS to a user-defined local directory. It is often connected to the Job using `OnSubjobOk` or `OnComponentOk` link, depending on the context. |

#### Related scenario

For a scenario using `tMongoDBGridFSGet`, see Managing files using MongoDB GridFS on page 2304.
tMongoDBGridFSList

Retrieves a list of files based on a query.
tMongoDBGridFSList iterates on files of a bucket in MongoDB GridFS.

**tMongoDBGridFSList Standard properties**

These properties are used to configure tMongoDBGridFSList running in the Standard Job framework.
The Standard tMongoDBGridFSList component belongs to the Big Data and the Databases NoSQL families.
The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| Property type | Either **Built-In** or **Repository**.  
|              | **Built-In**: No property data stored centrally.  
|              | **Repository**: Select the repository file where the properties are stored.  
| Use an existing connection | Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined.  
|              | Note that when a Job contains the parent Job and the child Job, **Component List** presents only the connection components in the same Job level.  
| Use replica set address or multiple query routers | Select this check box to show the **Server addresses** table.  
|              | In the **Server addresses** table, define the sharded MongoDB databases or the MongoDB replica sets you want to connect to.  
| Server and Port | IP address and listening port of the database server.  
|              | Available when the **Use replica set address** check box is not selected.  
|              | Note that if you use the authentication mechanisms to connect to this MongoDB database, you must enter the name, rather than the IP address, of the host of the database server.  
| Database | Name of the database.  
| Use SSL connection | Select this check box to enable the SSL or TLS encrypted connection.  
|              | Then you need to use the **tSetKeystore** component in the same Job to specify the encryption information.  
|              | For further information about **tSetKeystore**, see **tSetKeystore** on page 3464.  
|              | Note that the SSL connection is available only for the version 2.4 + of MongoDB.  

Set read preference | Select this check box and from the Read preference drop-down list that is displayed, select the member to which you need to direct the read operations.

If you leave this check box clear, the Job uses the default Read preference, that is to say, uses the primary member in a replica set.

For further information, see MongoDB’s documentation about Replication and its Read preferences.

Use authentication | Select this check box to enable the database authentication.

Among the mechanisms listed on the Authentication mechanism drop-down list, the NEGOTIATE one is recommended if you are not using Kerberos, because it automatically select the authentication mechanism the most adapted to the MongoDB version you are using.

For details about the other mechanisms in this list, see MongoDB Authentication from the MongoDB documentation.

Set Authentication database | If the username to be used to connect to MongoDB has been created in a specific Authentication database of MongoDB, select this check box to enter the name of this Authentication database in the Authentication database field that is displayed.

For further information about the MongoDB Authentication database, see User Authentication database.

Username and Password | DB user authentication data.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

Available when the Required authentication check box is selected.

If the security system you have selected from the Authentication mechanism drop-down list is Kerberos, you need to enter the User principal, the Realm and the KDC server fields instead of the Username and the Password fields.

Bucket | Enter the name of the bucket in which the files to be listed are stored. A bucket of GridFS is similar to a folder.

Query | Enter the query to be used to select the files to be listed. You need to define how these files are sorted in the list by selecting:

- **Sort by**: these files can be sorted by their filename attributes, uploadDate attributes or length (the File Size option) attributes.
- **Sort order**: these files can be sorted in the Ascending or Descending order.

Advanced settings

| tStatCatcher Statistics | Select this check box to collect the log data at the component level. |
No query timeout

Select this check box to prevent MongoDB servers from stopping idle cursors at the end of 10-minute inactivity of these cursors. In this situation, an idle cursor will stay open until either the results of this cursor are exhausted or you manually close it using the `cursor.close()` method.

A cursor for MongoDB is a pointer to the result set of a query. By default, that is to say, with this check box being clear, a MongoDB server automatically stops idle cursors after a given inactivity period to avoid excess memory use. For further information about MongoDB cursors, see [https://docs.mongodb.org/manual/core/cursors/](https://docs.mongodb.org/manual/core/cursors/).

Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_FILE: the number of files processed. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td></td>
<td>CURRENT_FILEID: the value of the ObjectID (the file ID) attribute of the current file. This is an Flow variable and it returns a string.</td>
</tr>
<tr>
<td></td>
<td>CURRENT_FILENAME: the value of the filename attribute of the current file. This is an Flow variable and it returns a string.</td>
</tr>
<tr>
<td></td>
<td>CURRENT_FILEUPLOADDATE: the value of the uploadDate attribute of the current file. This is an Flow variable and it returns a date.</td>
</tr>
<tr>
<td></td>
<td>CURRENT_FILELENGTH: the value of the length (the size) attribute of the current file. This is an Flow variable and it returns a length.</td>
</tr>
<tr>
<td></td>
<td>CURRENT_FILEMD5: the value of the md5 attribute of the current file. This is an Flow variable and it returns a string.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press `Ctrl + Space` to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](https://docs.talend.com/)

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component combines MongoDB GridFS connection and data iteration, thus usually used as a single-component subjob to list files stored in a given bucket in MongoDB GridFS.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Different lists are returned, each representing an attribute of these files and being stored in a specific global variable as explained above regarding the global variables provided by <code>tMongoDBGridFSList</code>.</td>
</tr>
</tbody>
</table>
Related scenario

For a scenario using `tMongoDBGridFSList`, see Managing files using MongoDB GridFS on page 2304.
tMongoDBGridFSProperties

Obtains information about the properties of given files selected based on a query.

tMongoDBGridFSProperties iterates on files of a bucket in MongoDB GridFS to extract the attributes of these files.

**tMongoDBGridFSProperties Standard properties**

These properties are used to configure tMongoDBGridFSProperties running in the Standard Job framework.

The Standard tMongoDBGridFSProperties component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-In or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-In</strong>: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td><strong>Repository</strong>: Select the repository file where</td>
<td></td>
</tr>
<tr>
<td>the properties are stored.</td>
<td></td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level.

**Use replica set address or multiple query routers**

Select this check box to show the Server addresses table.

In the Server addresses table, define the sharded MongoDB databases or the MongoDB replica sets you want to connect to.

**Server and Port**

IP address and listening port of the database server.

Available when the Use replica set address check box is not selected.

Note that if you use the authentication mechanisms to connect to this MongoDB database, you must enter the name, rather than the IP address, of the host of the database server.

**Database**

Name of the database.

**Use SSL connection**

Select this check box to enable the SSL or TLS encrypted connection.

Then you need to use the tSetKeystore component in the same Job to specify the encryption information.

For further information about tSetKeystore, see tSetKeystore on page 3464.
<table>
<thead>
<tr>
<th><strong>tMongoDBGridFSProperties</strong></th>
<th>Note that the SSL connection is available only for the version 2.4 + of MongoDB.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Set read preference</strong></td>
<td>Select this check box and from the Read preference dropdown list that is displayed, select the member to which you need to direct the read operations. If you leave this check box clear, the Job uses the default Read preference, that is to say, uses the primary member in a replica set. For further information, see MongoDB's documentation about Replication and its Read preferences.</td>
</tr>
<tr>
<td><strong>Use authentication</strong></td>
<td>Select this check box to enable the database authentication. Among the mechanisms listed on the Authentication mechanism drop-down list, the NEGOTIATE one is recommended if you are not using Kerberos, because it automatically select the authentication mechanism the most adapted to the MongoDB version you are using. For details about the other mechanisms in this list, see MongoDB Authentication from the MongoDB documentation.</td>
</tr>
<tr>
<td><strong>Set Authentication database</strong></td>
<td>If the username to be used to connect to MongoDB has been created in a specific Authentication database of MongoDB, select this check box to enter the name of this Authentication database in the Authentication database field that is displayed. For further information about the MongoDB Authentication database, see User Authentication database.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. Available when the Required authentication check box is selected. If the security system you have selected from the Authentication mechanism drop-down list is Kerberos, you need to enter the User principal, the Realm and the KDC server fields instead of the Username and the Password fields.</td>
</tr>
<tr>
<td><strong>Bucket</strong></td>
<td>Enter the name of the bucket in which the files to be used are stored. A bucket of GridFS is similar to a folder.</td>
</tr>
<tr>
<td><strong>Schema and Edit schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. The columns of the predefined schema of tMongoDBGridFS Properties represent the default attributes of a GridFS file and the column names are already identical with the attribute names. • If you want to exclude some attributes from the data flow to be processed in your Job, you can remove the columns corresponding to those attributes from this schema.</td>
</tr>
</tbody>
</table>
- Do not change the names of the columns to be used, because the names of each column must be identical with the name of the file attribute it represents.
- If the files to be processed contain some custom attributes you want to extract, you need to add their representative columns accordingly and ensure that these columns and these custom attributes are using identical names.

**Query type**

Select the type of the query you want to perform to select the files from which you need to extract the attributes.

- **Filename**: you need to enter the name of the file to be used. This name is the value of the `filename` attribute of this file. Note that only one name is allowed.
  
  In GridFS, a file is identified only by its unique identifier (its object ID); its file name is not necessarily unique.
- **Mongo Query**: enter the query to be used to select the files to be used.
  
  The example query, `{}` within double quotation marks provided with `tMongoDBGridFSProperties`, means to select all of the files in a bucket. You can put `{'filename': {'$regex': 'REGEX_PATTERN'}}` to apply a regular expression to defining the file names to be used.

**Advanced settings**

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
<th>Select this check box to collect the log data at the component level.</th>
</tr>
</thead>
<tbody>
<tr>
<td>No query timeout</td>
<td>Select this check box to prevent MongoDB servers from stopping idle cursors at the end of 10-minute inactivity of these cursors. A cursor for MongoDB is a pointer to the result set of a query. By default, that is to say, with this check box being clear, a MongoDB server automatically stops idle cursors after a given inactivity period to avoid excess memory use. For further information about MongoDB cursors, see <a href="https://docs.mongodb.org/manual/core/cursors/">https://docs.mongodb.org/manual/core/cursors/</a>.</td>
</tr>
</tbody>
</table>

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th><strong>NB_FILE</strong>: the number of files processed. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
</tbody>
</table>
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

**Usage**

| Usage rule | This component combines MongoDB GridFS connection and data extraction and needs to use a Main link to connect to its following component in order to send data to this component. |

**Related scenario**

For a scenario using tMongoDBGridFSProperties, see Managing files using MongoDB GridFS on page 2304.
tMongoDBGridFSPut

Connects to a MongoDB GridFS system to load files into it.

tMongoDBGridFSPut copies files from a local directory, pastes them into a given MongoDB GridFS system and if needs be, renames these files.

**tMongoDBGridFSPut Standard properties**

These properties are used to configure tMongoDBGridFSPut running in the Standard Job framework.

The Standard tMongoDBGridFSPut component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| Property type | Either **Built-In** or **Repository**.  
**Built-In**: No property data stored centrally.  
**Repository**: Select the repository file where the properties are stored. |
|----------------|---------------------------------------------|
| **Use an existing connection** | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.  
Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level. |
| **Use replica set address or multiple query routers** | Select this check box to show the Server addresses table.  
In the Server addresses table, define the sharded MongoDB databases or the MongoDB replica sets you want to connect to. |
| **Server and Port** | IP address and listening port of the database server.  
Available when the Use replica set address check box is not selected.  
Note that if you use the authentication mechanisms to connect to this MongoDB database, you must enter the name, rather than the IP address, of the host of the database server. |
| **Database** | Name of the database. |
| **Use SSL connection** | Select this check box to enable the SSL or TLS encrypted connection.  
Then you need to use the tSetKeystore component in the same Job to specify the encryption information.  
For further information about tSetKeystore, see tSetKeystore on page 3464. |
Note that the SSL connection is available only for the version 2.4 + of MongoDB.

### Set read preference
Select this check box and from the Read preference drop-down list that is displayed, select the member to which you need to direct the read operations.

If you leave this check box clear, the Job uses the default Read preference, that is to say, uses the primary member in a replica set.

For further information, see MongoDB’s documentation about Replication and its Read preferences.

### Required authentication
Select this check box to enable the database authentication.

Among the mechanisms listed on the Authentication mechanism drop-down list, the NEGOTIATE one is recommended if you are not using Kerberos, because it automatically select the authentication mechanism the most adapted to the MongoDB version you are using.

For details about the other mechanisms in this list, see MongoDB Authentication from the MongoDB documentation.

### Set Authentication database
If the username to be used to connect to MongoDB has been created in a specific Authentication database of MongoDB, select this check box to enter the name of this Authentication database in the Authentication database field that is displayed.

For further information about the MongoDB Authentication database, see User Authentication database.

### Username and Password
DB user authentication data.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

Available when the Required authentication check box is selected.

If the security system you have selected from the Authentication mechanism drop-down list is Kerberos, you need to enter the User principal, the Realm and the KDC server fields instead of the Username and the Password fields.

### Bucket
Enter the name of the bucket you need to write files in. A bucket of GridFS is similar to a folder.

### Local Folder
Browse to, or enter the path to the folder in which the files to be copied and written to GridFS are stored.

### Use Perl5 Regex Expression as Filemask
Select this check box if you want to use Perl5 regular expressions in the Files field as file filters. This is useful when the name of the file to be used contains special characters such as parentheses.

For information about Perl5 regular expression syntax, see Perl5 Regular Expression Syntax.

### Files
In the Files area, the fields to be completed are:
- **File mask**: type in the file name to be selected from the local directory. Regular expression is available.
- **New name**: give a new name to the loaded file.

### Advanced settings

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
<th>Select this check box to collect the log data at the component level.</th>
</tr>
</thead>
<tbody>
<tr>
<td>No query timeout</td>
<td>Select this check box to prevent MongoDB servers from stopping idle cursors at the end of 10-minute inactivity of these cursors. In this situation, an idle cursor will stay open until either the results of this cursor are exhausted or you manually close it using the <code>cursor.close()</code> method. A cursor for MongoDB is a pointer to the result set of a query. By default, that is to say, with this check box being clear, a MongoDB server automatically stops idle cursors after a given inactivity period to avoid excess memory use. For further information about MongoDB cursors, see <a href="https://docs.mongodb.org/manual/core/cursors/">https://docs.mongodb.org/manual/core/cursors/</a>.</td>
</tr>
</tbody>
</table>

### Global Variables

| Global Variables | **NB_FILE**: the number of files processed. This is an After variable and it returns an integer. **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press `Ctrl + Space` to access the variable list and choose the variable to use from it. For further information about variables, see [Talend Studio User Guide](https://docs.talend.com/talend-studio-user-guide). |

### Usage

| Usage rule | This component combines MongoDB GridFS connection and data extraction, thus usually used as a single-component subJob to copy data from a user-defined local directory to GridFS. It is often connected to the Job using **OnSubjobOk** or **OnComponentOk** link, depending on the context. |

### Managing files using MongoDB GridFS

This scenario applies only to [Talend products with Big Data](https://www.talend.com/products/big-data/).
In this scenario, the MongoDB GridFS components are used to create a Job to manage video files in MongoDB GridFS.

For further information about the GridFS system of MongoDB, see When to use GridFS.

For demonstration purposes, only one video file, called `custom_hadoop.mp4`, is used; you can use any of your own video files to replicate this scenario.

### Linking the components

**Procedure**

1. In the Integration perspective of the Studio, create an empty Job, named `FS_video` for example, from the Job Designs node in the Repository tree view.
   
   For further information about how to create a Job, see Talend Studio User Guide.

2. In the workspace, enter the name of the component to be used and select this component from the list that appears. In this scenario, the components are `tMongoDBConnection`, `tMongoDBGridFSPut`, `tMongoDBGridFSList`, `tMongoDBGridFSProperties`, `tFilterColumns`, `tLogRow`, `tMongoDBGridFSGet`, and `tMongoDBGridFSDelete`.

3. Connect `tMongoDBConnection` to `tMongoDBGridFSPut` using the Trigger > On Subjob Ok link.

4. Repeat this operation to connect `tMongoDBGridFSPut` to `tMongoDBGridFSList`, `tMongoDBGridFSGet`, and then `tMongoDBGridFSGet` to `tMongoDBGridFSDelete`.

5. Connect `tMongoDBGridFSList` to `tMongoDBGridFSProperties` using the Row > Iterate link. This link allows `tMongoDBGridFSList` to send data to `tMongoDBGridFSProperties` iteratively.

6. Connect `tMongoDBGridFSProperties` to `tFilterColumns` using the Row > Main link.
7. Do the same to connect tFilterColumns to tLogRow.

**Connecting to MongoDB**

**Procedure**

1. Double-click tMongoDBConnection to open its Component view.

2. From the DB version list, select the MongoDB version you are using.

3. In the Server and Port fields, enter the authentication information required for the connection to MongoDB.
   
   If you use the host name of the MongoDB server, ensure that you have added the mapping between this host name and its IP address in the hosts file of the operating system in which the current Job is executed.

4. In the Database field, enter the name of the database hosting GridFS. This database is created on the fly if it dose not exist.

**Copying data to MongoDB GridFS**

**Procedure**

1. Double-click tMongoDBGridFSPut to open its Component view.
2. Select the **Use existing connection** check box and from the **Connection** list, select the component in which the MongoDB connection to be used is defined.

3. In the **Bucket** field, enter the bucket to be used to store files in GridFS. In this example, it is `talend_channel/61`.

4. In the **Local folder** field, enter the path, or browse to the folder where the files to be uploaded to GridFS are stored. As explained previously, it is a video file called `custom_hadoop.mp4`.

5. In the **Files** table, add one row by clicking the `[+]` button and in the **Filemask** column, enter `*.mp4` within the double quotation marks. This allows `tMongoDBGridFSPut` to copy all the files with the `.mp4` extension from the local folder you have specified to the bucket to be used in GridFS.

6. Leave the **New name** column empty, that is to say, leave the double quotation marks in this column as is, so as to keep the name of this video unchanged after being copied to GridFS.

**Listing files stored in MongoDB GridFS**

**Iterating on the files**

**Procedure**

1. Double-click `tMongoDBGridFSList` to open its **Component** view.
2. Select the **Use existing connection** check box and from the **Connection** list, select the component in which the MongoDB connection to be used is defined.

3. In the **Bucket** field, enter the bucket in which the files to be listed are stored. In this example, it is `talend_channel/61`.

4. In the **Query** field, enter the query to select the files you want `tMongoDBGridFSList` to iterate on to generate different file lists. In this example, leave the default one in order to iterate on all of the files stored in this `talend_channel/61` bucket.

   As explained previously, only one file, `custom_hadoop.mp4`, is expected.

### Extracting file metadata

**Procedure**

1. Double-click `tMongoDBGridFSProperties` to open its **Component** view.

2. Select the **Use existing connection** check box and from the **Connection** list, select the component in which the MongoDB connection to be used is defined.
3. In the **Bucket** field, enter the bucket in which the files to be used are stored. In this example, it is `talend_channel/61`.

4. From the **Query type** list, select the approach you want to use to select the files about which you need to extract the metadata. In this example, select **Filename** to use the `filename` attribute of each GridFS file for query.

5. In the **Filename** field, press Ctrl + Space to display the variable list and choose the variable to be used. In this example, select `tMongoDBGridFSList.CURRENT_FILENAME` from the list. Then the expression to use the `CURRENT_FILENAME` variable is automatically added. This allows `tMongoDBGridFSProperties` to read each file name returned by `tMongoDBGridFSList`.

### Filtering attributes

**Procedure**

1. Double-click `tFilterColumns` to open its **Component** view.

2. Click the [...] button next to **Edit schema** to open the schema editor.

3. On the left side (the input side), select the column to be used and click the button to move this column to the right side (the output side). In this example, move every column to the right side except the `contentType` column.

   Each column represents a file attribute and the pre-defined schema of `tMongoDBGridFSProperties` automatically contains these columns.

4. Click **OK** to validate these changes and accept the propagation prompted by the pop-up dialog box.
Downloading files from MongoDB GridFS

Procedure

1. Double-click `tMongoDBGridFSPut` to open its Component view.

2. Select the **Use existing connection** check box and from the **Connection** list, select the component in which the MongoDB connection to be used is defined.

3. In the **Bucket** field, enter the bucket in which the files to be retrieved are stored. In this example, it is `talend_channel/61`.

4. In the **Local folder** field, enter the path to the local folder in which you want to store the downloaded files. In this scenario, it is `C:/tmp/output`.

5. Select the **Use Document ID as output filename** check box to rename each downloaded file using the value of its **ObjectID** attribute.

   Since a file in GridFS is distinct by ID rather than by name, it is possible that several files are using the same file name. For this reason, when downloading this kind of files into the same directory without renaming them differently, an exception is returned to alert that the file being downloaded already exists. In order to avoid this error, you can either select the **Overwrite local files** check box to replace the existing one with the latest downloaded file or rename these files on the fly using their IDs. In this example, the strategy of renaming these files is adopted.

Remove files from MongoDB GridFS

Procedure

1. Double-click `tMongoDBGridFSDelete` to open its Component view.
2. Select the **Use existing connection** check box and from the **Connection** list, select the component in which the MongoDB connection to be used is defined.

3. In the **Bucket** field, enter the bucket in which the files to be deleted are stored. In this example, it is `talend_channel/61`.

4. From the **Query type** list, select the approach you want to use to select the files to be deleted. In this example, select **Filename** to use the *filename* attribute of each GridFS file for query.

5. In the **Filename** field, enter the name of the file to be deleted.

### Executing the Job

**About this task**

Then you can run this Job.

The **tLogRow** component is used to present the execution result of the Job.

**Procedure**

1. If you want to configure the presentation mode on its **Component** view, double-click the **tLogRow** component to open the **Component** view and in the **Mode** area, then, select the **Table (print values in cells of a table)** radio box.

2. Press **F6** to run this Job.

**Results**

Once done, the **Run** view is opened automatically, where the metadata of the video `custom_hadoop.mp4` in GridFS is displayed.
The downloaded file can be found in the directory $C/tmp/output$, using its ID as its file name.
tMongoDBInput

Retrieves records from a collection in the MongoDB database and transfers them to the following component for display or storage.
tMongoDBInput retrieves certain documents from a MongoDB database collection by supplying a query document containing the fields the desired documents should match.

**tMongoDBInput Standard properties**

These properties are used to configure tMongoDBInput running in the Standard Job framework.
The Standard tMongoDBInput component belongs to the Big Data and the Databases NoSQL families.
The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use existing connection</td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td>DB Version</td>
<td>List of the database versions. Available when the <strong>Use existing connection</strong> check box is not selected.</td>
</tr>
<tr>
<td>Use replica set address</td>
<td>Select this check box to show the <strong>Replica address</strong> table. In the <strong>Replica address</strong> table, you can define multiple MongoDB database servers for failover. Available when the <strong>Use existing connection</strong> check box is not selected.</td>
</tr>
<tr>
<td>Server and Port</td>
<td>IP address and listening port of the database server. Available when the <strong>Use existing connection</strong> or <strong>Use replica set address</strong> check box is not selected.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database.</td>
</tr>
<tr>
<td>Use SSL connection</td>
<td>Select this check box to enable the SSL or TLS encrypted connection.</td>
</tr>
<tr>
<td></td>
<td>Then you need to use the <strong>tSetKeystore</strong> component in the same Job to specify the encryption information. For further information about <strong>tSetKeystore</strong>, see <strong>tSetKeystore</strong> on page 3464. Note that the SSL connection is available only for the version 2.4+ of MongoDB.</td>
</tr>
<tr>
<td>Set read preference</td>
<td>Select this check box and from the <strong>Read preference</strong> dropdown list that is displayed, select the member to which you need to direct the read operations.</td>
</tr>
</tbody>
</table>
If you leave this check box clear, the Job uses the default Read preference, that is to say, uses the primary member in a replica set.

For further information, see MongoDB’s documentation about Replication and its Read preferences.

**Required authentication**

Select this check box to enable the database authentication. Among the mechanisms listed on the Authentication mechanism drop-down list, the NEGOTIATE one is recommended if you are not using Kerberos, because it automatically select the authentication mechanism the most adapted to the MongoDB version you are using.

For details about the other mechanisms in this list, see [MongoDB Authentication](https://docs.mongodb.com/manual/reference/reading-operations/#sec-read-preference) from the MongoDB documentation.

**Set Authentication database**

If the username to be used to connect to MongoDB has been created in a specific Authentication database of MongoDB, select this check box to enter the name of this Authentication database in the Authentication database field that is displayed.

For further information about the MongoDB Authentication database, see [User Authentication database](https://docs.mongodb.com/manual/core/api-reference/auth/).

**Username and Password**

DB user authentication data.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

Available when the Required authentication check box is selected.

If the security system you have selected from the Authentication mechanism drop-down list is Kerberos, you need to enter the User principal, the Realm and the KDC server fields instead of the Username and the Password fields.

**Collection**

Name of the collection in the MongoDB database.

**Schema and Edit Schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.
If a column in the database is a JSON document and you need to read the entire document, put an asterisk (*) in the DB column column, without quotation marks around.

### Query
Specify the query condition. This field is available only when you have selected Find query from the Query type drop-down list.

For example, type in "{id:4}" to retrieve the record whose id is 4 from the collection specified in the Collection field.

**Note:**
Different from the query statements required in the MongoDB client software, the query here refers to the contents inside `find()`, such as the query here `{id:4}` versus the MongoDB client query `db.blog.find({id:4})`.

### Aggregation stages
Create a MongoDB aggregation pipeline by adding the stages you want the documents to pass through so as to obtain aggregated results from these documents. This table is available only when you have selected Aggregation pipeline query from the Query type drop-down list.

Only one stage is allowed per row in this Aggregation stages table and the stages are executed one by one in the order you place them in this table.

For example, if you want to aggregate documents about your customers using the `$match` and the `$group` stages, you need to add two rows to this Aggregation stages table and define the two stages as follows:

```
"{$match : {status : 'A'}}"
"{$group : { _id : '$cust_id', total : { $sum : '$amount' } }}"
```

In this aggregation, the customer documents with status A are selected; then among the selected customers, those using the same customer id are grouped and the values from the amount fields of the same customer are summed up.

For a full list of the stages you can use and their related operators, see Aggregation pipeline operators.

For further information about MongoDB aggregation pipeline, see Aggregation pipeline.

### Mapping
Each column of the schema defined for this component represents a field of the documents to be read. In this table, you need to specify the parent nodes of these fields, if any.

For example, in the document reading as follows

```json
{
   _id: ObjectId("5099803df3f4948bd2f98391"),
   person: { first: "Joe", last: "Walker" }
}
```

The first and the last fields have person as their parent node but the _id field does not have any parent node. So once completed, this Mapping table should read as follows:
<table>
<thead>
<tr>
<th>Column</th>
<th>Parent node path</th>
</tr>
</thead>
<tbody>
<tr>
<td>_id</td>
<td></td>
</tr>
<tr>
<td>first</td>
<td>&quot;person&quot;</td>
</tr>
<tr>
<td>last</td>
<td>&quot;person&quot;</td>
</tr>
</tbody>
</table>

**Sort by**

Specify the column and choose the order for the sort operation.

This field is available only when you have selected Find query from the Query type drop-down list.

**Limit**

Type in the maximum number of records to be retrieved.

This field is available only when you have selected Find query from the Query type drop-down list.

---

**Advanced settings**

**tStatCatcher Statistics**

Select this check box to collect the log data at the component level.

**No query timeout**

Select this check box to prevent MongoDB servers from stopping idle cursors at the end of 10-minute inactivity of these cursors. In this situation, an idle cursor will stay open until either the results of this cursor are exhausted or you manually close it using the cursor.close() method.

A cursor for MongoDB is a pointer to the result set of a query. By default, that is to say, with this check box being clear, a MongoDB server automatically stops idle cursors after a given inactivity period to avoid excess memory use. For further information about MongoDB cursors, see [https://docs.mongodb.org/manual/core/cursors/](https://docs.mongodb.org/manual/core/cursors/).

**Enable external sort**

Since the aggregation pipeline stages have a maximum memory use limit (100 megabytes) and a stage exceeding this limit will produce errors, when handling large datasets, select this check box to avoid aggregation stages exceeding this limit.

For further information about this external sort, see Large sort operation with external sort.

---

**Global Variables**

**Global Variables**

**NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.
For further information about variables, see Talend Studio User Guide.

Usage

Usage rule

As a start component, tMongoDBInput allows you to retrieve records from a collection in the MongoDB database and transfer them to the following component for display or storage.

Retrieving data from a collection by advanced queries

This scenario applies only to Talend products with Big Data.

In this scenario, advanced MongoDB queries are used to retrieve the post by the author Anderson.

There are such posts in the collection blog of the MongoDB database talend:

```javascript
> db.blog.find()
{ "id" : ObjectId("5226d25e675f26b4a2876888"), "id" : 1, "post" : { "author" : "Andy", "title" : "Open Source Outlook", "keywords" : "Open Source,Talend", "content" : "Talend, the leader of the open source world..." } } 
{ "id" : ObjectId("5226d25e675f26b4a2876889"), "id" : 2, "post" : { "author" : "Andy", "title" : "Data Integration Overview", "keywords" : "Data Integration,Talend", "content" : "Talend, the leading player in the DI field..." } } 
{ "id" : ObjectId("5226d25e675f26b4a287688a"), "id" : 3, "post" : { "author" : "Anderson", "title" : "ELT Overview", "keywords" : "ELT,Talend", "content" : "Talend, the big name in the ELT circle..." } } 
{ "id" : ObjectId("5226d25e675f26b4a287688b"), "id" : 4, "post" : { "author" : "Andy", "title" : "Big Data Bang", "keywords" : "Big Data,Talend", "content" : "Talend, the driving force for Big Data applications..." } } 
```

To insert data into the database, see Creating a collection and writing data to it on page 2325.

Linking the components

Procedure

1. Drop tMongoDBConnection, tMongoDBClose, tMongoDBInput and tLogRow onto the workspace.
2. Link tMongoDBConnection to tMongoDBInput using the OnSubjobOk trigger.
3. Link tMongoDBInput to tMongoDBClose using the OnSubjobOk trigger.
4. Link tMongoDBInput to tLogRow using a Row > Main connection.
Configuring the components

Procedure

1. Double-click `tMongoDBConnection` to open its Basic settings view.

2. From the DB Version list, select the MongoDB version you are using.

3. In the Server and Port fields, enter the connection details.

4. In the Database field, enter the name of the MongoDB database.

5. Double-click `tMongoDBInput` to open its Basic settings view.
Select the **Use existing connection** option.

In the **Collection** field, enter the name of the collection, namely blog.

Click the [...] button next to **Edit schema** to open the schema editor.

Click the [+] button to add five columns, namely id, author, title, keywords and contents, with the type as Integer and String respectively.

Click **OK** to close the editor.

The columns now appear in the left part of the **Mapping** area.

For columns author, title, keywords and contents, enter their parent node post so that the data can be retrieved from the correct positions.
13. In the **Query** box, enter the advanced query statement to retrieve the posts whose author is Anderson:

```
"{post.author : 'Anderson'}"
```

This statement requires that the sub-node of `post`, the node `author`, should have the value “Anderson”.

14. Double-click **tLogRow** to open its **Basic settings** view.

Select **Table (print values in cells of a table)** for a better display of the results.

**Executing the Job**

**Procedure**

1. Press **Ctrl+S** to save the Job.
2. Press **F6** to run the Job.

<table>
<thead>
<tr>
<th>id</th>
<th>author</th>
<th>title</th>
<th>keywords</th>
<th>contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>Anderson</td>
<td>ELT Overview</td>
<td>ELT,Talend,Talend, the big name in the ELT circle...</td>
<td></td>
</tr>
</tbody>
</table>

As shown above, the post by Anderson is retrieved.

**Related scenarios**

For related scenarios, see:

- Creating a collection and writing data to it on page 2325
- Using MongoDB functions to create a collection and write data to it on page 2341
tMongoDBOutput

Executes the action defined on the collection in the MongoDB database.

tMongoDBOutput inserts, updates, upserts or deletes documents in a MongoDB database collection based on the incoming flow from the preceding component in the Job.

**tMongoDBOutput Standard properties**

These properties are used to configure tMongoDBOutput running in the Standard Job framework.
The Standard tMongoDBOutput component belongs to the Big Data and the Databases NoSQL families.
The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td>DB Version</td>
<td>List of the database versions.</td>
</tr>
<tr>
<td></td>
<td>Available when the Use existing connection check box is not selected.</td>
</tr>
<tr>
<td>Use replica set address</td>
<td>Select this check box to show the Replica address table.</td>
</tr>
<tr>
<td></td>
<td>In the Replica address table, you can define multiple MongoDB database servers for failover.</td>
</tr>
<tr>
<td></td>
<td>Available when the Use existing connection check box is not selected.</td>
</tr>
<tr>
<td>Server and Port</td>
<td>IP address and listening port of the database server.</td>
</tr>
<tr>
<td></td>
<td>Available when the Use existing connection or Use replica set address check box is not selected.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database.</td>
</tr>
<tr>
<td>Use SSL connection</td>
<td>Select this check box to enable the SSL or TLS encrypted connection.</td>
</tr>
<tr>
<td></td>
<td>Then you need to use the tSetKeystore component in the same Job to specify the encryption information.</td>
</tr>
<tr>
<td></td>
<td>For further information about tSetKeystore, see tSetKeystore on page 3464.</td>
</tr>
<tr>
<td></td>
<td>Note that the SSL connection is available only for the version 2.4 + of MongoDB.</td>
</tr>
<tr>
<td>Set write concern</td>
<td>Select this check box to set the level of acknowledgement requested from for write operations. Then you need to select the level of this operation.</td>
</tr>
<tr>
<td>Feature</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| **Bulk write**       | Select this check box to insert, update or remove data in bulk. Note this feature is available only when the version of MongoDB you are using is 2.6+. Then you need to select **Ordered** or **Unordered** to define how the MongoDB database processes the data sent by the Studio.  
- If you select **Ordered**, MongoDB processes the queries sequentially.  
- If you select **Unordered**, MongoDB optimizes the bulk write operations without keeping the order in which the individual operations were inserted in the bulk write.  
In the **Bulk write size** field, enter the size of each query group to be processed by MongoDB. In the documentation of MongoDB, some restrictions and expected behaviors as to this size are explained. You can find the details on [http://docs.mongodb.org/manual/core/bulk-write-operations/](http://docs.mongodb.org/manual/core/bulk-write-operations/). |
| **Required authentication** | Select this check box to enable the database authentication. Among the mechanisms listed on the Authentication mechanism drop-down list, the NEGOTIATE one is recommended if you are not using Kerberos, because it automatically select the authentication mechanism the most adapted to the MongoDB version you are using.  
For details about the other mechanisms in this list, see MongoDB Authentication from the MongoDB documentation. |
| **Set Authentication database** | If the username to be used to connect to MongoDB has been created in a specific Authentication database of MongoDB, select this check box to enter the name of this Authentication database in the Authentication database field that is displayed.  
For further information about the MongoDB Authentication database, see User Authentication database. |
| **Username and Password** | DB user authentication data.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.  
Available when the **Required authentication** check box is selected.  
If the security system you have selected from the Authentication mechanism drop-down list is Kerberos, you need to enter the User principal, the Realm and the KDC server fields instead of the Username and the Password fields. |
| **Collection**        | Name of the collection in the MongoDB database. |
| **Drop collection if exist** | Select this check box to drop the collection if it already exists. |
### Action on data

The following operations are available:

- **Insert**: insert documents.
- **Set**: modifies the existing fields of an existing document and appends a field if it does not exist in this document.

If you need to apply this action on all the documents in the collection to be used, select the *Update all document* check box that is displayed; otherwise, only the first document is updated.

- **Update**: replaces the existing documents with the incoming data but keeps the technical ID of these documents.
- **Upsert**: inserts a document if it does not exist otherwise it applies the same rules as **Update**.
- **Upsert with set**: inserts a document if it does not exist otherwise it applies the same rules as **Set**.

If you need to apply this action on all the documents in the collection to be used, select the *Update all document* check box that is displayed; otherwise, only the first document is updated.

- **Delete**: delete documents.

### Schema and Edit Schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

Click **Sync columns** to retrieve the schema from the previous component connected in the Job.

### Built-In

You create and store the schema locally for this component only.

### Repository

You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).
Each column of the schema defined for this component represents a field of the documents to be read. In this table, you need to specify the parent nodes of these fields, if any.

For example, in the document reading as follows:

```json
{
   _id: ObjectId("5099803df3f4948bd2f98391"),
   person: { first: "Joe", last: "Walker" }
}
```

The `first` and the `last` fields have `person` as their parent node but the `_id` field does not have any parent node. So once completed, this Mapping table should read as follows:

<table>
<thead>
<tr>
<th>Column</th>
<th>Parent node path</th>
</tr>
</thead>
<tbody>
<tr>
<td>_id</td>
<td></td>
</tr>
<tr>
<td>first</td>
<td>&quot;person&quot;</td>
</tr>
<tr>
<td>last</td>
<td>&quot;person&quot;</td>
</tr>
</tbody>
</table>

Not available when the Generate JSON Document check box is selected in Advanced settings.

**Die on error**

This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

### Advanced settings

**Generate JSON Document**

Select this check box for JSON configuration:

- **Configure JSON Tree**: click the [...] button to open the interface for JSON tree configuration. For more information, see Configuring a JSON Tree on page 3987.
- **Group by**: click the [+ ] button to add lines and choose the input columns for grouping the records.
- **Remove root node**: select this check box to remove the root node.
- **Data node** and **Query node** (available for update and upsert actions): type in the name of data node and query node configured on the JSON tree.

**Warning:**

These nodes are mandatory for update and upsert actions. They are intended to enable the update and upsert actions though will not be stored in the database.

**No query timeout**

Select this check box to prevent MongoDB servers from stopping idle cursors at the end of 10-minute inactivity of these cursors. In this situation, an idle cursor will stay open until either the results of this cursor are exhausted or you manually close it using the cursor.close() method.

A cursor for MongoDB is a pointer to the result set of a query. By default, that is to say, with this check box being clear, a MongoDB server automatically stops idle cursors after a given inactivity period to avoid excess memory use. For further information about MongoDB cursors, see https://docs.mongodb.org/manual/core/cursors/.
Global Variables

**NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

**tMongoDBOutput** executes the action defined on the collection in the MongoDB database based on the flow incoming from the preceding component in the Job.

Limitation

- The "multi" parameter, which allows to update multiple documents at a time, is not supported. Therefore, if two documents have the same key, the first is always updated, but the second never will.
- For the update operation, the key cannot be a JSON array.

Creating a collection and writing data to it

This scenario applies only to Talend products with Big Data.

This scenario creates the collection blog and writes post data to it.

Linking the components

Procedure

1. Drop tMongoDBConnection, tFixedFlowInput, tMongoDBOutput, tMongoDBClose, tMongoDBInput and tLogRow onto the workspace.
2. Rename tFixedFlowInput as blog_post_data, tMongoDBOutput as write_data_to_collection, tMongoDBInput as read_data_from_collection and tLogRow as show_data_from_collection.
3. Link tMongoDBConnection to tFixedFlowInput using the OnSubjobOk trigger.
4. Link tFixedFlowInput to tMongoDBOutput using a Row > Main connection.
5. Link tFixedFlowInput to tMongoDBInput using the OnSubjobOk trigger.
7. Link tMongoDBInput to tLogRow using a Row > Main connection.

Configuring the components

Procedure

1. Double-click tMongoDBConnection to open its Basic settings view.

2. From the DB Version list, select the MongoDB version you are using.
3. In the Server and Port fields, enter the connection details.
   In the Database field, enter the name of the MongoDB database.
4. Double-click tFixedFlowInput to open its Basic settings view.
Select **Use Inline Content (delimited file)** in the **Mode** area.

In the **Content** field, enter the data to write to the MongoDB database, for example:

```
1;Andy;Open Source Outlook;Open Source, Talend, Talend, the leader of the open source world...
3;Andy;ELT Overview;ELT, Talend, Talend, the big name in the ELT circle...
2;Andy;Data Integration Overview;Data Integration, Talend, Talend, the leading player in the DI field...
```

5. **Double-click** `tMongoDBOutput` to open its **Basic settings** view.

Select the **Use existing connection** and **Drop collection if exist** check boxes.

In the **Collection** field, enter the name of the collection, namely `blog`.

6. Click the `[...]` button next to **Edit schema** to open the schema editor.
7. Click the [+] button to add five columns in the right part, namely \textit{id}, \textit{author}, \textit{title}, \textit{keywords} and \textit{contents}, with the type as \textit{Integer} and \textit{String} respectively.

   Click \includegraphics[scale=0.1]{arrow.png} to copy all the columns to the input table.
   Click \textit{Ok} to close the editor.

8. The columns now appear in the left part of the \textbf{Mapping} area.
   For columns \textit{author}, \textit{title}, \textit{keywords} and \textit{contents}, enter their parent node \textit{post}. By doing so, those nodes reside under the node \textit{post} in the MongoDB collection.

9. Double-click \textbf{tMongoDBInput} to open its \textbf{Basic settings} view.
Select the **Use existing connection** check box.

In the **Collection** field, enter the name of the collection, namely *blog*.

10. Click the [...] button next to **Edit schema** to open the schema editor.

11. Click the [+ ] button to add five columns, namely *id*, *author*, *title*, *keywords* and *contents*, with the type as *Integer* and *String* respectively.

   Click **OK** to close the editor.

12. The columns now appear in the left part of the **Mapping** area.
For columns *author*, *title*, *keywords* and *contents*, enter their parent node *post* so that the data can be retrieved from the correct positions.

13. In the **Sort by** area, click the [*+] button to add one line and enter *id* under **Column**. Select **asc** from the **Order asc or desc?** column to the right of the *id* column. This way, the retrieved records will appear in ascending order of the *id* column.

**Executing the Job**

**Procedure**

1. Press **Ctrl+S** to save the Job.
2. Press **F6** to run the Job.

```
[statistics] connecting to socket on port 3638
[statistics] connected
[show_data_from_collection]
<table>
<thead>
<tr>
<th>id</th>
<th>author</th>
<th>title</th>
<th>keywords</th>
<th>contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Andy</td>
<td>Open Source Outlook</td>
<td>Open Source.Talend; Talend, the leader of the open source world...</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>Andy</td>
<td>Data Integration Overview</td>
<td>Data Integration.Talend; Talend, the leading player in the DI field...</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>Andy</td>
<td>ELT Overview</td>
<td>ELT.Talend;</td>
<td></td>
</tr>
</tbody>
</table>

[statistics] disconnected
Job The_MongoDB_components ended at 11:45 14-09-2012  [exit code=0]
```

3. Switch to the database *talend* and read data from the collection *blog* in the MongoDB command line client. You can find that *author*, *title*, *keywords* and *contents* all reside under the node *post*. Meanwhile, the records are stored in the same order as the source input.

```
MongoDB shell version: 2.2.0
connecting to: test
> use talend
> db.blog.find()
{ "id" : ObjectId("5052d1e10dada579241c8332"), "id" : 1, "post" : { "author" : "Andy", "title" : "Open Source Outlook", "keywords" : "Open Source.Talend; Talend, the leader of the open source world..." } } |
{ "id" : ObjectId("5052d1e10dada579241c8333"), "id" : 3, "post" : { "author" : "Andy", "title" : "ELT Overview", "keywords" : "ELT.Talend, contents" : "Talend, the leading player in the DI field..." } } |
```

**Upserting records in a collection**

This scenario applies only to Talend products with Big Data.

This scenario upserts the collection *blog* as an existing record has its author changed and a new record is added. Before the upsert, the collection *blog* looks like:

1;Andy;Open Source Outlook;Open Source,Talend;Talend, the leader of the open source world...
2;Andy;Data Integration Overview;Data Integration,Talend;Talend, the leading player in the DI field...
3;Andy;ELT Overview;ELT,Talend;Talend, the big name in the ELT circle...

Such records can be inserted to the database following the instructions of Creating a collection and writing data to it on page 2325.
Linking the components

Procedure

1. Drop `tMongoDBConnection`, `tFixedFlowInput`, `tMongoDBOutput`, `tMongoDBClose`, `tMongoDBInput` and `tLogRow` from the Palette onto the design workspace.
2. Rename `tFixedFlowInput` as `blog_post_data`, `tMongoDBOutput` as `write_data_to_collection`, `tMongoDBInput` as `read_data_from_collection` and `tLogRow` as `show_data_from_collection`.
3. Link `tMongoDBConnection` to `tFixedFlowInput` using the `OnSubjobOk` trigger.
4. Link `tFixedFlowInput` to `tMongoDBOutput` using a Row > Main connection.
5. Link `tFixedFlowInput` to `tMongoDBInput` using the `OnSubjobOk` trigger.
7. Link `tMongoDBInput` to `tLogRow` using a Row > Main connection.

Configuring the components

Procedure

1. Double-click `tMongoDBConnection` to open its Basic settings view.
   
   ![Diagram](attachment:diagram.png)

   - **Connection**
     - **DB Version**: MongoDB 2.1.X
     - **Use replica set address**: False
     - **Server**: localhost
     - **Port**: 27017
     - **Database**: talend
     - **Authentication**: Required authentication

2. From the DB Version list, select the MongoDB version you are using.
3. In the Server and Port fields, enter the connection details.
   In the Database field, enter the name of the MongoDB database.
4. Double-click `tFixedFlowInput` to open its Basic settings view.
Select **Use Inline Content (delimited file)** in the **Mode** area.

In the **Content** field, enter the data for upserting the MongoDB database, for example:

<table>
<thead>
<tr>
<th>Record</th>
<th>Author</th>
<th>Title</th>
<th>Organization</th>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Andy</td>
<td>Open Source Outlook</td>
<td>Open Source</td>
<td>Talend, the leader of the open source world...</td>
</tr>
<tr>
<td>2</td>
<td>Andy</td>
<td>Data Integration Overview</td>
<td>Data Integration, Talend, the leading player in the DI field...</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>Anderson</td>
<td>ELT Overview</td>
<td>ELT</td>
<td>Talend, the big name in the ELT circle...</td>
</tr>
<tr>
<td>4</td>
<td>Andy</td>
<td>Big Data Bang</td>
<td>Big Data</td>
<td>Talend, the driving force for Big Data applications...</td>
</tr>
</tbody>
</table>

As shown above, the 3rd record has its author changed and the 4th record is new.

5. Double-click **tMongoDBOutput** to open its **Basic settings** view.

Select the **Use existing connection** and **Die on error** check boxes.

In the **Collection** field, enter the name of the collection, namely *blog*.

Select **Upsert** from the **Action on data** list.

6. Click the [...] button next to **Edit schema** to open the schema editor.
7. Click the [+] button to add five columns in the right part, namely `id`, `author`, `title`, `keywords` and `contents`, with the type as `Integer` and `String` respectively.

Click to copy all the columns to the input table.
Click Ok to close the editor.

8. In the Advanced Settings view, select the Generate JSON Document check box.
Select the Remove root node check box.
In the Data node and Query node fields, enter “data” and “query”.

9. Click the [...] button next to Configure JSON Tree to open the configuration interface.
10. Right-click the node *rootTag* and select **Add Sub-element** from the contextual menu. In the dialog box that appears, type in *data* for the **Data node**: 

![Input element's label](image)

Click **OK** to close the window.

Repeat this operation to define *query* as the **Query node**. Right-click the node *data* and select **Set As Loop Element** from the contextual menu.

**Warning:**

These nodes are mandatory for update and upsert actions. They are intended to enable the update and upsert actions though will not be stored in the database.

11. Select all the columns under the **Schema list** and drop them to the *data node*. In the window that appears, select **Create as sub-element of target node**.
Click **OK** to close the window.

Repeat this operation to drop the *id* column from the **Schema list** under the **Query** node.

12. Right-click the node *id* under *data* and select **Add Attribute** from the contextual menu.

In the dialog box that appears, type in *type* as the attribute name:

Click **OK** to close the window.

Right-click the node *@type* under *id* and select **Set A Fix Value** from the contextual menu.

In the dialog box that appears, type in *integer* as the attribute value, ensuring the *id* values are stored as integers in the database.

Click **OK** to close the window.

Repeat this operation to set this attribute for the *id* node under **Query**.

Click **OK** to close the JSON Tree configuration interface.

13. Double-click **tMongoDBInput** to open its **Basic settings** view.
Select the **Use existing connection** check box.

In the **Collection** field, enter the name of the collection, namely *blog*.

Click the [...] button next to **Edit schema** to open the schema editor.

Click the [+ ] button to add five columns, namely *id, author, title, keywords* and *contents*, with the type as **Integer** and **String** respectively.

Click **OK** to close the editor.

The columns now appear in the left part of the **Mapping** area.

For columns *author, title, keywords* and *contents*, enter their parent node *post* so that the data can be retrieved from the correct positions.

14. Double-click **tLogRow** to open its **Basic settings** view.
In the **Mode** area, select **Table (print values in cells of a table)** for better display.

### Executing the Job

**Procedure**

1. Press **Ctrl+S** to save the Job.
2. Press **F6** to run the Job.

<table>
<thead>
<tr>
<th>id</th>
<th>author</th>
<th>title</th>
<th>keywords</th>
<th>contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Andy</td>
<td>Open Source Outlook</td>
<td>Open Source, Talend</td>
<td>Talend, the leader of the open source world...</td>
</tr>
<tr>
<td>2</td>
<td>Andy</td>
<td>Data Integration Overview</td>
<td>Data Integration, Talend</td>
<td>Talend, the leading player in the BI field...</td>
</tr>
<tr>
<td>3</td>
<td>Anderson</td>
<td>ELT Overview</td>
<td>ELT, Talend</td>
<td>Talend, the big name in the ELT circle...</td>
</tr>
<tr>
<td>4</td>
<td>Andy</td>
<td>Big Data Hug</td>
<td>Big Data, Talend</td>
<td>Talend, the driving force for Big Data applications...</td>
</tr>
</tbody>
</table>

As shown above, the 3rd record has its author updated and the 4th record is inserted.
tMongoDBRow

Executes the commands and functions of the MongoDB database.

**tMongoDBRow Standard properties**

These properties are used to configure tMongoDBRow running in the Standard Job framework.

The Standard tMongoDBRow component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td>DB Version</td>
<td>List of the database versions. Available when the Use existing connection check box is not selected.</td>
</tr>
<tr>
<td>Use replica set address</td>
<td>Select this check box to show the Replica address table. In the Replica address table, you can define multiple MongoDB database servers for failover. Available when the Use existing connection check box is not selected.</td>
</tr>
<tr>
<td>Server and Port</td>
<td>Address and listening port of the database server. Available when the Use existing connection or Use replica set address check box is not selected.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database.</td>
</tr>
<tr>
<td>Use SSL connection</td>
<td>Select this check box to enable the SSL or TLS encrypted connection. Then you need to use the tSetKeystore component in the same Job to specify the encryption information. For further information about tSetKeystore, see tSetKeystore on page 3464. Note that the SSL connection is available only for the version 2.4 + of MongoDB.</td>
</tr>
<tr>
<td>Required authentication</td>
<td>Select this check box to enable the database authentication. Among the mechanisms listed on the Authentication mechanism drop-down list, the NEGOTIATE one is recommended if you are not using Kerberos, because it automatically select the authentication mechanism the most adapted to the MongoDB version you are using. For details about the other mechanisms in this list, see MongoDB Authentication from the MongoDB documentation.</td>
</tr>
<tr>
<td>Set Authentication database</td>
<td>If the username to be used to connect to MongoDB has been created in a specific Authentication database of MongoDB, select this check box to enter the name of this Authentication database in the Authentication database field that is displayed. For further information about the MongoDB Authentication database, see User Authentication database.</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. Available when the Required authentication check box is selected. If the security system you have selected from the Authentication mechanism drop-down list is Kerberos, you need to enter the User principal, the Realm and the KDC server fields instead of the Username and the Password fields.</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available: • View schema: choose this option to view the schema only. • Change to built-in property: choose this option to change the schema to Built-in for local changes. • Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. Click Sync columns to retrieve the schema from the previous component connected in the Job.</td>
</tr>
<tr>
<td>Execute command</td>
<td>Select this check box to enter MongoDB commands in the Command field for execution. • Command: in this field, enter the command to be executed, if this command contains one single variable. For example, if you need to construct the command {&quot;isMaster&quot;: 1} You need simply enter isMaster within quotation marks. • Construct command from keys and values: if the command to be executed contains multiple variables, select this check box and in the Command keys and values table, add the variables and their respective values to be used.</td>
</tr>
</tbody>
</table>
For example, if you need to construct the following command

```javascript
{ renameCollection : "<source_namespace>" , to : "<target_namespace>" , dropTarget : < true | false > }
```

You need to add three rows to the **Command keys and values** table and enter one variable-value pair to each row within quotation marks:

| renameCollection | old_name | to | new_name | dropTarget | false |

- **Construct command from a JSON string**: if you want to directly enter the command to be used, select this check box and enter this command in the **JSON string command** field that is displayed. Only one command is allowed per **tMongoDBRow**.

For example:

```json
"{createIndexes: 'restaurants', indexes : [{key : {restaurant_id : 1}, name: 'id_index_2', unique: true})]
```

Note that you must use single quotation marks to surround the string values used in the command and double quotation marks to surround the command itself.

For further information about the MongoDB commands you can use in this field, see [https://docs.mongodb.org/manual/reference/command/](https://docs.mongodb.org/manual/reference/command/).

| Function | Enter MongoDB functions in the **Function** field for execution. Not available when the **Execute command** check box is selected. |
| Parameters value | Click the [+] button to add lines as needed and then define the parameter values in the form of variables or constant values, for example row1.author or 'Andy'. Note that the parameter values correspond to the parameters defined in the **Function** field, in the same order. Not available when the **Execute command** check box is selected. |
| Die on error | This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows. |

**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect the log data at the component level. |
**Global Variables**

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

**Usage**

| Usage rule | **tMongoDBRow** allows you to manipulate the MongoDB database through the MongoDB commands and functions. |

**Using MongoDB functions to create a collection and write data to it**

This scenario applies only to Talend products with Big Data.

This scenario creates the collection *blog* and writes post data to it through the MongoDB functions.

**Linking the components**

**Procedure**

1. Drop **tMongoDBConnection**, **tFixedFlowInput**, **tMongoDBRow**, **tMongoDBClose**, **tMongoDBInput** and **tLogRow** onto the workspace.
2. Rename **tFixedFlowInput** as **blog_post_data**, **tMongoDBRow** as **write_data_to_collection**, **tMongoDBInput** as **read_data_from_collection** and **tLogRow** as **show_data_from_collection**.
3. Link **tMongoDBConnection** to **tFixedFlowInput** using the **OnSubjobOk** trigger.
4. Link **tFixedFlowInput** to **tMongoDBRow** using a **Row > Main** connection.
5. Link **tFixedFlowInput** to **tMongoDBInput** using the **OnSubjobOk** trigger.
6. Link **tMongoDBInput** to **tMongoDBClose** using the **OnSubjobOk** trigger.
7. Link **tMongoDBInput** to **tLogRow** using a **Row > Main** connection.
Configuring the components

Procedure

1. Double-click tMongoDBConnection to open its Basic settings view.

2. From the DB Version list, select the MongoDB version you are using.

3. In the Server and Port fields, enter the connection details.
   In the Database field, enter the name of the MongoDB database.

4. Double-click tFixedFlowInput to open its Basic settings view.
Select **Use Inline Content (delimited file)** in the **Mode** area.

In the **Content** field, enter the data to write to the MongoDB database, for example:

```
Andy;Open Source Outlook;Open Source,Talend;Talend, the leader of the open source world...
Andy;Data Integration Overview;Data Integration,Talend;Talend, the leading player in the DI field...
Andy;ELT Overview;ELT,Talend;Talend, the big name in the ELT circle...
```

5. **Double-click** **tMongoDBRow** to open its **Basic settings** view.
Select the **Use existing connection** check box.

In the **Function** field, enter the MongoDB function to create the collection `blog` and insert data to it:

```javascript
"function(author,title,keywords,contents) {
return db.blog.save({
author:author,title:title,keywords:keywords,contents:contents}
});
"
```

6. Click the [...] button next to **Edit schema** to open the schema editor.
7. Click the [+] button to add four columns in the right part, namely *author*, *title*, *keywords* and *contents*, with the type of *String*.

Click ![image](image) to copy all the columns to the input table.

Click OK to close the editor.

8. In the **Parameters value** table, click the [+] button to add four lines and enter the values in sequence: *row1.author*, *row1.title*, *row1.keywords* and *row1.contents*. By doing so, data of *row1* will be transferred to the parameters defined in the function.

9. Double-click **tMongoDBInput** to open its **Basic settings** view.

![Basic settings](image)

Select the **Use existing connection** check box.

In the **Collection** field, enter the name of the collection, namely *blog*.

10. Click the [...] button next to **Edit schema** to open the schema editor.

![Schema editor](image)

11. Click the [+] button to add four columns, namely *author*, *title*, *keywords* and *contents*, with the type as *String*. 
Click **OK** to close the editor.

12. Double-click **tLogRow** to open its **Basic settings** view.

In the **Mode** area, select **Table (print values in cells of a table)** for better display.

### Executing the Job

**Procedure**

1. Press **Ctrl+S** to save the Job.
2. Press **F6** to run the Job.

<table>
<thead>
<tr>
<th>author</th>
<th>title</th>
<th>keywords</th>
<th>contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>Andy</td>
<td>Open Source Outlook</td>
<td></td>
<td>Talend, the leader of the open source world.</td>
</tr>
<tr>
<td>Andy</td>
<td>Data Integration Overview</td>
<td></td>
<td>Talend, the leading player in the DI field...</td>
</tr>
<tr>
<td>Andy</td>
<td>EIT Overview</td>
<td>EIT.Talend</td>
<td>Talend, the big name in the ELI circle...</td>
</tr>
</tbody>
</table>
tMSAXInput

Extracts data from a MicrosoftAX server based on a query.

**tMSAXInput Standard properties**

These properties are used to configure tMSAXInput running in the Standard Job framework.

The Standard tMSAXInput component belongs to the Business family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-in or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Built-in</strong>: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: Select the Repository file where properties are stored. The fields that come after are pre-filled in using the fetched data.</td>
</tr>
</tbody>
</table>

**Version**

Select the type of the business connector to be used. The type may be:

- Dynamics AX 4.0
- Dynamics AX 2012

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

**Global Variables**

**Global Variables**

| **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer. |
| **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. |
| A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. |
| To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it. |
| For further information about variables, see **Talend Studio User Guide**. |
**Usage**

Inserting data in a defined table in a MicrosoftAX server

Warning:
Before being able to use this component, make sure that you install and launch the MicrosoftAX server correctly.

This Java scenario describes a two-component Job that uses tMSAXOutput to insert four columns in a defined table in a MicrosoftAX server after it alters values in one of the inserted columns.

Setting up the Job

Procedure
1. Drop tFixedFlowInput and tMSAXOutput from the Palette to the design workspace.
2. Connect the two components together using a Row > Main connection.

Configuring tFixedFlowInput

Procedure
1. Double-click tFixedFlowInput to display its Basic settings view and define the component properties.
2. Set Schema type to Built-in and click the three-dot button next to Edit schema to display a dialog box where you can define the input schema.
3. Click the plus button and add the input schema columns, three in this example: name, city and street.
4. Click **OK** to close the dialog box and accept propagating the changes when prompted by the system. The three schema columns display automatically in the **Values** list.

5. Click in the **Value** column and enter a value for each of the input columns.

### Configuring tMSAXOutput

#### Procedure

1. Double-click **tMSAXOutput** to open its **Basic settings** view and define the component properties.

2. Set **Property type** to **Built-in**.

3. In the **Host** field, type in the IP address of the MicrosoftAX server and type in the domain name on which the MicrosoftAX server is hosted in the **Domain** field.

4. Enter your username and password for the server in the corresponding fields and enter the name of the table you want to write data in the **Table Name** field, **ADDRESS** in this example.

5. In the **Action on data** list, select the action you want to carry on, **Insert** in this example.

6. Click **Sync columns** to retrieve the schema from the preceding component.

   In this example, we want to retrieve the three input columns: **name**, **city** and **street** and write the data included in the three input columns in the MicrosoftAX server without any changes.

   If needed, click the three-dot button next to **Edit Schema** to verify the retrieved schema.

7. In the **Additional columns** list, click the plus button to add one line where you can define parameters for the new column to add to the row you want to write in the **ADDRESS** table.

8. Set a name, a data type, a position and a reference column in the corresponding columns for the line you added.

   In this example, we want to add a new column we call **"address"** after the **street** column.

9. Click in the **Local expression** column and press **Ctrl + space** on your keyboard to open the context variable list and select: ```StringHandling.UPCASE(row2.city)"-"+row2.street```.

   This expression will write the city name initially capped followed by the street name to form the address of **Bryant park**. Thus the address column in this example will contain the string: **New York-Midtown Manhattan**.
Job execution

Procedure

Save your Job and press F6 to execute it.

tMSAXOutput inserts in the ADDRESS table in the MicrosoftAX server a row that holds the three input columns, name, city and street in addition to the new address column that combines the city name and the street name.

Deleting data from a defined table in a MicrosoftAX server

Warning:
Before being able to use this component, make sure that you install and launch the MicrosoftAX server correctly.

This Java scenario describes a two-component Job that uses tMSAXOutput to delete from a defined table in a MicrosoftAX server all rows that do not match the data included in a key column.

In this example, the input schema we use is an address column that holds the following data: New York-Midtown Manhattan. We want to delete from the MicrosoftAX server all addresses that are not identical with this one.

Setting up the Job

Procedure

1. Drop tFixedFlowInput and tMSAXOutput from the Palette to the design workspace.
2. Connect the two components together using a Row > Main connection.

Configuring tFixedFlowInput

Procedure

1. Double-click tFixedFlowInput to display its Basic settings view and define the component properties.
2. Set Schema type to Built-in and click the three-dot button next to Edit schema to display a dialog box where you can define the input schema.
3. Click the plus button and add the input schema columns, address in this example.
4. Click OK to close the dialog box. The schema column displays automatically in the Values list.
5. Click in the Value column and enter a value for the input column.

**Setting up the connection to the MicrosoftAX server**

**Procedure**
1. Double-click tMSAXOutput to open its Basic settings view and define the component properties.

2. Set Property type to Built-in.
3. In the Host field, type in the IP address of the MicrosoftAX server.
4. In the Domain field, type in the domain name on which the MicrosoftAX server is hosted.
5. Enter your username and password for the server in the corresponding fields.
6. In the Table Name field, enter the name of the table you want to delete data from, ADDRESS in this example.
Defining the action on data

Procedure

1. In the Action on data list, select the action you want to carry on, Delete in this example.
2. Click Sync columns to retrieve the schema from the preceding component. In this example, we want to retrieve the input column: address.
3. Click the three-dot button next to Edit Schema to open a dialog box where you can verify the retrieved schema.

![Schema dialog box for tMSAXOutput_2](image)

4. In the output schema, select the Key check box next to the column name you want to define as a key column, and then click OK to validate your changes and close the dialog box.

**Note:**
When you select Delete as an action on data, you must always define the Reference column as a key column in order for tMSAXOutput to delete rows based on this key column.

5. In the Additional columns list, click the plus button to add one line and define the parameters the component will use as basis for the delete operation.
6. Set a name, an operator, a data type, a local expression, a position and a reference column in the corresponding columns for the line you added.

In this example, we want to delete from the ADDRESS table in the MicrosoftAX server all rows in which the address column is not equal to the address in the key address column and that reads as the following: New York-Midtown Manhattan.

**Note:**
When you select Delete as an action on data, you must always set Position to Replace. Otherwise, all settings in the Additional columns will not be taken into account when executing your Job.

Job execution

Procedure

Save your Job and press F6 to execute it.

**tMSAXOutput** deletes from the ADDRESS table in the MicrosoftAX server all rows where the address string is not equal to the address in the key column.
tMsgBox

Opens a dialog box with an OK button requiring action from the user.
tMsgBox is a graphical break in the Job execution progress.

tMsgBox Standard properties

These properties are used to configure tMsgBox running in the Standard Job framework.
The Standard tMsgBox component belongs to the Misc family.
The component in this framework is available in all Talend products.

Basic settings

<table>
<thead>
<tr>
<th>Title</th>
<th>Text entered shows on the title bar of the dialog box created.</th>
</tr>
</thead>
</table>
| Buttons | Listbox of buttons you want to include in the dialog box. The button combinations are restricted and cannot be changed.  
The Question button displays the Mask Answer check box. Select this check box if you want to mask the answer you type in the pop-up window that opens when you run the Job. |
| Icon | Icon shows on the title bar of the dialog box. |
| Message | Free text to display as message on the dialog box. Text can be dynamic (for example: retrieve and show a file name). |

Global Variables

| Global Variables | RESULT: the return value of the component. This is an After variable and it returns a string.  
ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.  
For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | This component can be used as intermediate step in a data flow or as a start or an end object in the Job flowchart. |
'Hello world!' type test

The following scenario creates a single-component Job, where tMsgBox is used to display the pid (process id) in place of the traditional “Hello World!” message.

Setting up the Job

Procedure
1. Drop a tMsgBox component from the Palette to the design workspace.
2. Define the dialog box display properties:

   ![Screenshot of tMsgBox settings]

   'Title' is the message box title, it can be any variable.

3. In the Message field, enter "Current date is: " between double quotation marks. Then click CTRL+Space to display the autocompletion list and select the following system routine, Talend Date.getCurrentDate. Put brackets around this routine.

Executing the Job

Procedure

Switch to the Run tab to execute the Job defined.

Results

The Message box displays the message and requires the user to click OK to go to the next component or end the Job.

After the user clicked OK, the Run log is updated accordingly.
Related topic: see *Talend Studio User Guide*. 
tMSSqlBulkExec

Offers gains in performance while executing the Insert operations to a Microsoft SQL Server database. The tMSSqlOutputBulk and tMSSqlBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tMSSqlOutputBulkExec component, detailed in a separate section. The advantage of using a two step process is that the data can be transformed before it is loaded in the database.

**tMSSqlBulkExec Standard properties**

These properties are used to configure tMSSqlBulkExec running in the Standard Job framework.

The Standard tMSSqlBulkExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>

<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in: No property data is stored centrally.</td>
<td></td>
</tr>
<tr>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
<td></td>
</tr>
<tr>
<td>JDBC Provider</td>
<td>Select the provider of the JDBC driver to be used, either Microsoft (recommended) or Open source JTDS.</td>
</tr>
<tr>
<td>When using this component with Datasource in Talend Runtime, you need to use the Open source JTDS driver.</td>
<td></td>
</tr>
<tr>
<td>Note that when Microsoft is selected, you need to download the Microsoft JDBC Driver for SQL Server on Microsoft Download Center, unpack the downloaded zip file, choose a jar in the unzipped folder based on your JRE version, rename the jar to mssql-jdbc.jar and install it manually. For more information about choosing the jar, see the System Requirements information on Microsoft Download Center.</td>
<td></td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.
Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th><strong>Host</strong></th>
<th>Database server IP address</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database.</td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>Name of the schema.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Table</strong></td>
<td>Name of the table to be written. Note that only one table can be written at a time and that the table must exist for the insert operation to succeed.</td>
</tr>
</tbody>
</table>
| **Action on table** | On the table defined, you can perform one of the following operations:

  - **None**: No operation is carried out.
  - **Drop and create table**: The table is removed and created again.
  - **Create table**: The table does not exist and gets created.
  - **Create table if not exists**: The table is created if it does not exist.
  - **Drop table if exists and create**: The table is removed if it already exists and created again.
  - **Clear table**: The table content is deleted.
  - **Truncate table**: The table content is deleted. You do not have the possibility to rollback the operation. |
| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. |
| **Built-In** | You create and store the schema locally for this component only. |
Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

Remote File Name

Name of the file to be loaded.

**Warning:**
This file is located on the machine specified by the URI in the Host field so it should be on the same machine as the database server.

Advanced settings

| Action | Select the action to be carried out.  
| Bulks insert, Bulk update and Bcp query out, depending on the action selected, the required information varies. |
| Additional JDBC parameters | Specify additional JDBC parameters for the database connection being created.  
| This property is not available when the Use an existing connection check box is selected. |
| Fields terminated by | Character, string or regular expression to separate fields. |
| Rows terminated | String (ex: "\n" on Unix) to distinguish rows. |
| First row | Type in the number of the row where the action should start. |
| Code page | OEM code pages used to map a specific set of characters to numerical code point values. |
| Data file type | Select the type of data being handled. |
### Output

Select the type for the standard output of the Microsoft SQL Server database:

- **to console**
- **to global variable**

This property is available when **BCP query out** is selected from the **Action** drop-down list.

### Fire Triggers

Select this check box to execute any insert trigger defined on the table into which data will be loaded during the bulk insert operation.

This property is available when **Bulk insert** is selected from the **Action** drop-down list.

### tStatCatcher Statistics

Select this check box to collect log data at the component level.

### Enable parallel execution

Select this check box to perform high-speed data processing, by treating multiple data flows simultaneously. Note that this feature depends on the database or the application ability to handle multiple inserts in parallel as well as the number of CPU affected. In the **Number of parallel executions** field, either:

- Enter the number of parallel executions desired.
- Press **Ctrl + Space** and select the appropriate context variable from the list. For further information, see *Talend Studio User Guide*.

Note that when parallel execution is enabled, it is not possible to use global variables to retrieve return values in a subjob.

- The **Action on table** field is not available with the parallelization function. Therefore, you must use a **tCreateTable** component if you want to create a table.
- When parallel execution is enabled, it is not possible to use global variables to retrieve return values in a subjob.

### Usage

#### Usage rule

This component is to be used along with **tMSSqlBulkOutputBu lk** component. Used together, they can offer gains in performance while feeding a MSSql database.

#### Dynamic settings

Click the [+][1] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.
For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

<td></td>
<td>CHARACTER_OCTET_LENGTH: the maximum length in bytes of the column currently iterated upon. This is a Flow variable, and it returns a numeric string for binary or character data types and NULL for other types.</td>
</tr>
</tbody>
</table>
**Usage**

**Usage rule**
This component is to be used along with MSSql components, especially with `tMSSqlConnection`.

**Dynamic settings**
Click the `[*]` button to add a row in the table and fill the `Code` field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the `Component List` box in the `Basic settings` view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic...
Related scenario

For `tmSSqlColumnList` related scenario, see Iterating on a DB table and listing its column names on page 2430.
tMSSqlCommit

Commits in one go, using a unique connection, a global transaction instead of doing that on every row or every batch and thus provides gain in performance.

TmMSSqlCommit validates the data processed through the job into the connected DB.

TmMSSqlCommit Standard properties

These properties are used to configure TmMSSqlCommit running in the Standard Job framework.

The Standard tMSSqlCommit component belongs to the Databases family.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tMSSqlConnection component in the list if more than one connection are planned for the current Job.</td>
</tr>
<tr>
<td>Close connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

Warning:

If you want to use a Row > Main connection to link TmMSSqlCommit to your Job, your data will be committed row by row. In this case, do not select the Close connection check box or your connection will be closed before the end of your first row commit.

Advanced settings

| tStatCatcher Statistics | Select this check box to gather the job processing metadata at a job level as well as at each component level. |

Usage

| Usage rule | This component is more commonly used with other TmMSSql* components, especially with the TmMSSqlConnection and TmMSSqlRollback components. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to acces |
s database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenarios

For a tMSSqlCommit related scenario, see Inserting data in mother/daughter tables on page 2437.
tMSSqlConnection

Opens a connection to the specified database that can then be reused in the subsequent subjob or subjobs.

tMSSqlConnection opens a connection to a Microsoft SQL Server database or a Microsoft Azure SQL database.

**tMSSqlConnection Standard properties**

These properties are used to configure tMSSqlConnection running in the Standard Job framework.

The Standard tMSSqlConnection component belongs to the Databases and the ELT families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

</tr>
</tbody>
</table>
password between double quotes and click **OK** to save the settings.

### Additional JDBC parameters
Specify additional connection properties for the database connection you are creating. The properties are separated by semicolon and each property is a key-value pair. For example, `encrypt=true;trustServerCertificate=false;hostNameInCertificate=*.database.windows.net;loginTimeout=30;` for Azure SQL database connection.

### Use or register a shared DB Connection
Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the **Shared DB Connection Name** field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child.

This option is incompatible with the **Use dynamic job** and **Use an independent process to run subjob** options of the `tRunJob` component. Using a shared connection together with a `tRunJob` component with either of these two options enabled will cause your Job to fail.

This check box is not available when the **Specify a data source alias** check box is selected.

### Specify a data source alias
Select this check box and specify the alias of a data source created on the **Talend Runtime** side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in **Talend Runtime**.

This check box is not visible when the **Use or register a shared DB Connection** check box is selected.

### Data source alias
Enter the alias of the data source created on the **Talend Runtime** side.

This field is available only when the **Specify a data source alias** check box is selected.

### Advanced settings

#### Auto Commit
Select this check box to commit any changes to the database automatically upon the transaction.

With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component.

Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component.
**Share identity insert in multi table**

Select this check box to share `IDENTITY_INSERT` among multiple Microsoft SQL tables that accept data through the same database connection.

This option prevents errors caused by setting `IDENTITY_INSERT` to `ON` (or `OFF`) repeatedly when writing Microsoft SQL tables through a database connection. It is necessary to check this option when the component is used along with multiple `tMSSqlOutput` components with their Turn on Identity insert options checked in the Basic settings tab.

Note that checking this option may decrease the execution performance.

**tStatCatcher Statistics**

Select this check box to gather the job processing metadata at a Job level as well as at each component level.

---

**Usage**

**Usage rule**

This component is more commonly used with other `tMSSql*` components, especially with the `tMSSqlCommit` and `tMSSqlRollback` components.

**Limitation**

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

---

**Inserting data into a database table and extracting useful information from it**

The scenario describes a Job that reads the employee data from a text file, inserts the data into a table of an MSSQL database, then extracts useful data from the table, and displays the information on the console.
This scenario involves the following components:

- **tMSSqlConnection**: establishes a connection to the MSSQL server.
- **tFileInputDelimited**: reads the input file, defines the data structure and sends it to the next component.
- **tMSSqlOutput**: writes data it receives from the preceding component into a table of an MSSQL database.
- **tMSSqlInput**: extracts data from the table based on an SQL query.
- **tLogRow**: displays the information it receives from the preceding component on the console.
- **tMSSqlCommit**: commits the transaction in the connected MSSQL server.

**Setting up the Job**

**Procedure**

1. Drop the following components from the Palette onto the design workspace: tMSSqlConnection, tFileInputDelimited, tMSSqlOutput, tMSSqlInput, tLogRow, and tMSSqlCommit.
2. Connect tMSSqlConnection to tFileInputDelimited using a Trigger > OnSubjobOk link.
3. Do the same to connect tFileInputDelimited to tMSSqlInput and tMSSqlInput to tMSSqlCommit.
4. Connect tFileInputDelimited to tMSSqlOutput using a Row > Main link.
5. Do the same to connect tMSSqlInput to tLogRow.
Configuring the components

Opening a connection to the MSSQL server

Procedure

1. Double-click the tMSSqlConnection component to open its Basic settings view in the Component tab.

2. In the Host field, type in the IP address or hostname of the MSSQL server, 192.168.30.47 in this example.

3. In the Port field, type in the port number of the database server, 1433 in this example.

4. In the Schema field, type in the schema name, dbo in this example.

5. In the Database field, type in the database name, talend in this example.

6. In the Username and Password fields, enter the credentials for the MSSQL connection.

Reading the input data

Procedure

1. Double-click the tFileInputDelimited component to open its Component view.

2. Click the [...] button next to the File Name/Stream field to browse to the input file. In this example, it is D:/Input/Employee_Wage.txt. This text file holds three columns: id, name and wage.

id;name;wage 51;Harry;2300 40;Ronald;3796 17;Theodore;2174 21;James;19
3. In the **Header** field, type in 1 to skip the first row of the input file.

4. Click **Edit schema** to define the data to pass on to the **tMSSqlOutput** component. In this example, we define `id` as the key, and specify the length and precision for each column respectively. Click **OK** to close the schema editor. A dialog box opens, and you can choose to propagate the schema to the next component.

![Schema of tFileInputDelimited 1](image)

Related topic: **tFileInputDelimited** on page 1008.

### Writing the data into the database table

**Procedure**

1. Double-click the **tMSSqlOutput** component to open its **Basic settings** view in the **Component** tab.

   ![tMSSqlOutput](image)

2. Type in required information for the connection or use the existing connection you have configured before. In this example, we select the **Use an existing connection** check box. If multiple connections are available, select the connection you want to use from the **Component List** dropdown list.

3. In the **Table** field, type in the name of the table you want to write the data to: **Wage_Info** in this example. You can also click the [...] button next to the **Table** field to open a dialog box and select a proper table.

4. Select **Create table if not exists** from the **Action on table** dropdown list.

5. Select **Insert if not exists** from the **Action on data** dropdown list.

6. Click **Sync columns** to retrieve the schema from the preceding component.
Extracting useful information from the table

Procedure

1. Double-click the tMSSqlInput component to open its Basic settings view in the Component tab.

2. Select the Use an existing connection check box. If multiple connections are available, select the connection you want to use from the Component List drop-down list.

3. Click Edit schema to define the data structure to be read from the table. In this example, we need to read all three columns from the table.

4. In the Table Name field, type in the name of the table you want to read the data from: Wage_Info in this example.

5. In the Query field, fill in the SQL query to be executed on the table specified. To obtain the data of employees whose wages are above the average value and order them by id, enter the SQL
query as follows: SELECT * FROM Wage_Info WHERE wage > (SELECT avg(wage) FROM Wage_Info) ORDER BY id

Displaying information on the console

Procedure

1. Double-click the tLogRow component to open its Basic settings view.
2. In the Mode area, select Table (print values in cells of a table).

Committing the transaction and closing the connection

Procedure

1. Double-click the tMSSqlCommit component to open its Basic settings view.
2. Select the Close Connection check box.

Saving and executing the Job

Procedure

1. Press Ctrl+S to save your Job.
2. Execute the Job by pressing F6 or clicking Run on the Run tab.

The information of employees whose wages are above the average value ordered by id is displayed on the console.
tMSSqlInput

Executes a DB query with a strictly defined order which must correspond to the schema definition. tMSSqlInput reads data and extracts fields based on a query from a Microsoft SQL Server database or a Microsoft Azure SQL database. Then it passes on the field list to the next component via a Main row link.

**tMSSqlInput Standard properties**

These properties are used to configure tMSSqlInput running in the Standard Job framework.

The Standard tMSSqlInput component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Click this icon to open a database connection wizard and store the database connection parameters you set in the component Basic settings view. For more information about setting up and storing database connection parameters, see Talend Studio User Guide.</td>
<td></td>
</tr>
<tr>
<td>JDBC Provider</td>
<td>Select the provider of the JDBC driver to be used, either Microsoft (recommended) or Open source JTDS. When using this component with Datasource in Talend Runtime, you need to use the Open source JTDS driver. Note that when Microsoft is selected, you need to download the Microsoft JDBC Driver for SQL Server on Microsoft Download Center, unpack the downloaded zip file, choose a jar in the unzipped folder based on your JRE version, rename the jar to mssql-jdbc.jar and install it manually. For more information about choosing the jar, see the System Requirements information on Microsoft Download Center.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>

</table>

**Global Variables**

| **Global Variables** | **NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.  
**QUERY**: the query statement being processed. This is a Flow variable and it returns a string.  
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
An After variable functions after the execution of the component.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it. |
|----------------------|------------------------------------------------------------------------------------------------------------------|

2381
**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component covers all possible SQL queries for MS SQL server databases.</th>
</tr>
</thead>
</table>

**Dynamic settings**

Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

**Limitation**

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

**Related scenarios**

For related topics, see:

- tMSSqlConnection on page 2371

For related topic in tContextLoad, see Reading data from different MySQL databases using dynamically loaded connection parameters on page 491.
tMSSqlLastInsertId

Retrieves the last primary keys added by a user to a MSSql table.

`tMSSqlLastInsertId` displays the last IDs added to a table from a MSSql specified connection.

**tMSSqlLastInsertId Standard properties**

These properties are used to configure `tMSSqlLastInsertId` running in the Standard Job framework.

The Standard `tMSSqlLastInsertId` component belongs to the Databases family.

The component in this framework is available in all **Talend products**.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Schema and Edit Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <strong>line</strong> when naming the fields.</td>
</tr>
<tr>
<td><strong>Built-In:</strong></td>
<td>You create and store the schema locally for this component only.</td>
</tr>
<tr>
<td><strong>Repository:</strong></td>
<td>You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
</tr>
</tbody>
</table>

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema:** choose this option to view the schema only.
- **Change to built-in property:** choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection:** choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

| Component list | Select the **tMSSqlConnection** component on the **Component list** to reuse the connection details you already defined, if there are more than one component in this list. |
Advanced settings

| tStat | Catcher Statistics | Select this check box to collect log data at the component level. |

Global Variables

| Global Variables | NB_LINE: the number of rows processed. This is an After variable and it returns an integer. ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | This component offers the flexibility of the DB query and covers all possible SQL queries. |

Dynamic settings

Click the [+ button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).
Related scenario

For a related scenario, see Getting the ID for the last inserted record with tMysqlLastInsertId on page 2466
tMSSqlOutput

Executes the action defined on the table and/or on the data contained in the table, based on the flow incoming from the preceding component in the Job.

tMSSqlOutput writes, updates, makes changes or suppresses entries in a Microsoft SQL Server database or a Microsoft Azure SQL database.

**tMSSqlOutput Standard properties**

These properties are used to configure tMSSqlOutput running in the Standard Job framework.

The Standard tMSSqlOutput component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-in:</strong> No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository:</strong> Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td></td>
<td><img src="icon.png" alt="Icon" /> Click this icon to open a database connection wizard and store the database connection parameters you set in the component Basic settings view.</td>
</tr>
<tr>
<td></td>
<td>For more information about setting up and storing database connection parameters, see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

**JDBC Provider**

Select the provider of the JDBC driver to be used, either Microsoft (recommended) or Open source JTDS.

When using this component with Datasource in Talend Runtime, you need to use the Open source JTDS driver.

Note that when Microsoft is selected, you need to download the Microsoft JDBC Driver for SQL Server on Microsoft Download Center, unpack the downloaded zip file, choose a jar in the unzipped folder based on your JRE version, rename the jar to mssql-jdbc.jar and install it manually. For more information about choosing the jar, see the System Requirements information on Microsoft Download Center.

**Host**

Database server IP address.

**Port**

Listening port number of DB server.

**Schema**

Name of the schema.

**Database**

Name of the database.

**Username and Password**

DB user authentication data.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

**Table**

Name of the table to be written. Note that only one table can be written at a time.

**Action on table**

On the table defined, you can perform one of the following operations:

- **Default**: No operation is carried out.
- **Drop and create table**: The table is removed and created again.
- **Create table**: The table does not exist and gets created.
- **Create table if not exists**: The table is created if it does not exist.
- **Drop table if exists and create**: The table is removed if it already exists and created again.
- **Clear table**: The table content is deleted.
<table>
<thead>
<tr>
<th><strong>Truncate table</strong>: The table content is deleted. You do not have the possibility to rollback the operation.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Turn on identity insert</strong></td>
</tr>
<tr>
<td>Select this check box to use your own sequence for the identity value of the inserted records (instead of having the SQL Server pick the next sequential value).</td>
</tr>
<tr>
<td><strong>Action on data</strong></td>
</tr>
<tr>
<td>On the data of the table defined, you can perform:</td>
</tr>
<tr>
<td><strong>Insert</strong>: Add new entries to the table. If duplicates are found, job stops.</td>
</tr>
<tr>
<td><strong>Single Insert Query</strong>: Add entries to the table in a batch</td>
</tr>
<tr>
<td><strong>Update</strong>: Make changes to existing entries</td>
</tr>
<tr>
<td><strong>Insert or update</strong>: Insert a new record. If the record with the given reference already exists, an update would be made.</td>
</tr>
<tr>
<td><strong>Update or insert</strong>: Update the record with the given reference. If the record does not exist, a new record would be inserted.</td>
</tr>
<tr>
<td><strong>Delete</strong>: Remove entries corresponding to the input flow.</td>
</tr>
<tr>
<td><strong>Insert if not exist</strong>: Add new entries to the table if they do not exist.</td>
</tr>
</tbody>
</table>

**Warning:**

It is necessary to specify at least one column as a primary key on which the Update and Delete operations are based. You can do that by clicking *Edit Schema* and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the *Advanced settings* view where you can simultaneously define primary keys for the Update and Delete operations. To do that: Select the *Use field options* check box and then in the *Key in update column*, select the check boxes next to the column names you want to use as a base for the Update operation. Do the same in the *Key in delete column* for the Delete operation.

| **Specify identity field** |
| Select this check box to specify the identity field, which is made up of an automatically incrementing identification number. |
| When this check box is selected, three other fields are displayed: |
| **Identity field**: select the column you want to define as the identity field from the list. |
| **Start value**: type in a start value, used for the very first row loaded into the table. |
| **Step**: type in an incremental value, added to the value of the previous row that was loaded. |
| This check box is available only when you select *Drop and create table*, *Create table*, *Create table if not exists*, or *Drop table if exists and create* from the *Action on table* list, and will disappear if you select the *Enable parallel execution* check box in the *Advanced settings* view. If you select this check box with the *Turn on identity insert* check box cleared and the *Create table if not exists* option selected from the *Action on table* list and if the specified table does not exist, only a table will be created without inserting data into it. |
### Schema and Edit schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `LINE` when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

### Built-In

- **Built-In**: You create and store the schema locally for this component only.

### Repository

- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

### Specify a data source alias

Select this check box and specify the alias of a data source created on the **Talend Runtime** side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in **Talend Runtime**.

This check box is not available when the **Use an existing connection** check box is selected.

### Data source alias

Enter the alias of the data source created on the **Talend Runtime** side.

This field is available only when the **Specify a data source alias** check box is selected.
| **Die on error** | This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a **Row > Rejects** link. |

**Advanced settings**

| **Additional JDBC parameters** | Specify additional connection properties for the database connection you are creating. The properties are separated by semicolon and each property is a key-value pair. For example, `encrypt=true,trustServerCertificate=false;hostNameInCertificate=*.database.windows.net;loginTimeout=30;` for Azure SQL database connection. This field is not available if the **Use an existing connection** check box is selected. |

| **Commit every** | Enter the number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and, above all, better performance at execution. |

| **Additional Columns** | This option is not offered if you create (with or without drop) the DB table. This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing. |

- **Name:** Type in the name of the schema column to be altered or inserted as new column
- **SQL expression:** Type in the SQL statement to be executed in order to alter or insert the relevant column data.
- **Position:** Select **Before,** **Replace** or **After** following the action to be performed on the reference column.
- **Reference column:** Type in a column of reference that the tDBOutput can use to place or replace the new or altered column. |

| **Use field options** | Select this check box to customize a request, especially when there is double action on data. |

| **Ignore date validation** | Select this check box to ignore the date validation and insert the data directly into the database for the data types of DATE, DATETIME, DATETIME2 and DATETIMEOFFSET. |

| **Enable debug mode** | Select this check box to display each step during processing entries in a database. |

| **Support null in **SQL WHERE** statement** | Select this check box if you want to deal with the Null values contained in a DB table. |

**Note:**

Make sure that the **Nullable** check box is selected for the corresponding columns in the schema.
| Use Batch | Use this check box to activate the batch mode for data processing.  
This check box is available only when you have selected the Insert, the Update, the Single Insert Query or the Delete option in the Action on data list.  

**Note:**  
If you select the Single Insert Query option in the Action on data list, be aware that the batch size must be lower than or equal to the limit of parameter markers authorized by the JDBC driver (generally 2000) divided by the number of columns. For more information, see Limitation below. |
| --- | --- |
| **Batch Size** | Specify the number of records to be processed in each batch..  
This field appears only when the Use batch mode check box is selected.  |
| **tStatCatcher Statistics** | Select this check box to collect log data at the component level.  |

### Global Variables

| Global Variables |  
| --- | --- |
| **NB_LINE** | the number of rows processed. This is an After variable and it returns an integer.  
**NB_LINE_UPDATED** | the number of rows updated. This is an After variable and it returns an integer.  
**NB_LINE_INSERTED** | the number of rows inserted. This is an After variable and it returns an integer.  
**NB_LINE_DELETED** | the number of rows deleted. This is an After variable and it returns an integer.  
**NB_LINE_REJECTED** | the number of rows rejected. This is an After variable and it returns an integer.  
**QUERY** | the query statement processed. This is an After variable and it returns a string.  
**ERROR_MESSAGE** | the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.  
For further information about variables, see Talend Studio User Guide. |
Usage

Usage rule

This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible.

This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in a MSSql database. It also allows you to create a reject flow using a Row > Rejects link to filter data in error. For an example of tMysqlOutput in use, see Retrieving data in error with a Reject link on page 2485.

Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Limitation

When the Single Insert Query option is selected in the Action on data list, an SQL Prepared Statement is generated, for example, INSERT INTO table (col1, col2, col3) VALUES (?,?,?,?) , (?,?,?,?) , (?,?,?,?) , (?,?,?,?) . Within brackets are the groups of parameters the number of which cannot exceed 2000, generally, depending on the JDBC driver. Therefore, the batch size should be set so that this limit is respected.

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

Related scenarios

For tMSSqlOutput related topics, see:

• tMSSqlConnection on page 2371.
• Inserting a column and altering data using tMysqlOutput on page 2477.
tMSSqlOutputBulk

Prepares the file to be used as parameter in the INSERT query to feed the MSSql database.

The tMSSqlOutputBulk and tMSSqlBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tMSSqlOutputBulkExec component, detailed in a separate section. The advantage of using a two step process is that the data can be transformed before it is loaded in the database.

tMSSqlOutputBulk writes a file with columns based on the defined delimiter and the MSSql standards.

tMSSqlOutputBulk Standard properties

These properties are used to configure tMSSqlOutputBulk running in the Standard Job framework.
The Standard tMSSqlOutputBulk component belongs to the Databases family.
The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
<tr>
<td><strong>Property type</strong></td>
<td>Either Built-in or Repository. Built-in: No property data stored centrally. Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><strong>File Name</strong></td>
<td>Name of the file to be generated.</td>
</tr>
<tr>
<td><strong>Append</strong></td>
<td>Select this check box to add the new rows at the end of the records.</td>
</tr>
<tr>
<td><strong>Schema and Edit Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
</tbody>
</table>
Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the jobs upon completion. If you just want to propagate the changes to the current job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

### Advanced settings

<table>
<thead>
<tr>
<th><strong>Row separator</strong></th>
<th>String (ex: “\n” on Unix) to distinguish rows.</th>
</tr>
</thead>

<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

- **Database**
  - Select a type of database from the list and click **Apply**.

- **Action**
  - Select the action to be carried out:
    - **Bulk insert**
    - **Bulk update**

- **Property type**
  - Either **Built-in** or **Repository**.

  - **Built-in**: No property data stored centrally.

  - **Repository**: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.

- **Use an existing connection**
  - Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.
**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

| **JDBC Provider** | Select the provider of the JDBC driver to be used, either **Microsoft** (recommended) or **Open source JTDS**.
| **Microsoft** | When using this component with Datasource in Talend Runtime, you need to use the **Open source JTDS** driver.
| **Open source JTDS** | Note that when **Microsoft** is selected, you need to download the Microsoft JDBC Driver for SQL Server on Microsoft Download Center, unpack the downloaded zip file, choose a jar in the unzipped folder based on your JRE version, rename the jar to *mssql-jdbc.jar* and install it manually. For more information about choosing the jar, see the System Requirements information on Microsoft Download Center.

| **Host** | Database server IP address.
| **localhost, 127.0.0.1** | Currently, only localhost, 127.0.0.1 or the exact IP address of the local machine is allowed for proper functioning. In other words, the database server must be installed on the same machine where the Studio is installed or where the Job using tMSSqlOutputBulkExec is deployed.

| **Port** | Listening port number of DB server.

| **DB name** | Name of the database.

| **Schema** | Name of the schema.

| **Username and Password** | DB user authentication data.
| **Click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.**

| **Table** | Name of the table to be written.
| **Note that only one table can be written at a time and that the table must exist for the insert operation to succeed.**

| **Action on table** | On the table defined, you can perform one of the following operations:
| **None:** No operation is carried out.
| **Drop and create a table:** The table is removed and created again.
| **Create a table:** The table does not exist and gets created.
| **Create a table if not exists**: The table is created if it does not exist. |
|-------------------------|-----------------------------|
| **Truncate table**: The table content is deleted. You do not have the possibility to rollback the operation. |
| **Clear a table**: The table content is deleted. You have the possibility to rollback the operation. |

**Schema and Edit schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

**Built-In**: You create and store the schema locally for this component only.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**File Name**

Name of the file to be generated and loaded.

**Warning:**
This file is generated on the machine specified by the URI in the **Host** field so it should be on the same machine as the database server.

**Append**

Select this check box to add the new rows at the end of the records.

**Advanced settings**

**Additional JDBC parameters**

Specify additional connection properties for the database connection you are creating. The properties are separated by semicolon and each property is a key-value pair. For example, `encrypt=true,trustServerCertificate=false;`
<table>
<thead>
<tr>
<th>Field separator</th>
<th>Character, string or regular expression to separate fields.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Row separator</td>
<td>String (ex: \n on Unix) to distinguish rows.</td>
</tr>
<tr>
<td>First row</td>
<td>Type in the number of the row where the action should start.</td>
</tr>
<tr>
<td>Include header</td>
<td>Select this check box to include the column header.</td>
</tr>
<tr>
<td>Code page</td>
<td>OEM code pages used to map a specific set of characters to numerical code point values.</td>
</tr>
<tr>
<td>Data file type</td>
<td>Select the type of data being handled.</td>
</tr>
<tr>
<td>Encoding</td>
<td>Select the encoding from the list or select Custom and define it manually. This field is compulsory for DB data handling.</td>
</tr>
<tr>
<td>tStatCatcher statistics</td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is mainly used when no particular transformation is required on the data to be loaded onto the database.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic settings</td>
<td>Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

| Limitation | The database server must be installed on the same machine where the Studio is installed or where the Job using tMSSqlOutputBulkExec is deployed, so that the component functions properly. |
Related scenarios

For use cases in relation with `tMSSqlOutputBulkExec`, see the following scenarios:

- Inserting transformed data in MySQL database on page 2493
- Inserting data in bulk in MySQL database on page 2500
tMSSqlRollback

Cancels the transaction commit in the MSSql database and thus avoids to commit part of a transaction involuntarily.

**tMSSqlRollback Standard properties**

These properties are used to configure tMSSqlRollback running in the Standard Job framework.

The Standard tMSSqlRollback component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tMSSqlConnection component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is more commonly used with other tMSSql* components, especially with the tMSSqlConnection and tMSSqlCommit components.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic settings</td>
<td>Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection.</td>
</tr>
</tbody>
</table>
Related scenario

For **tMSSqlRollback** related scenario, see *Rollback from inserting data in mother/daughter tables* on page 2440.
tMSSqlRow

Acts on the actual DB structure or on the data (although without handling data).

tMSSqlRow executes the SQL query stated onto the specified Microsoft SQL Server or Azure SQL database, depending on the nature of the query and the database. The row suffix means the component implements a flow in the job design although it doesn’t provide output.

The SQLBuilder tool helps you write easily your SQL statements.

**tMSSqlRow Standard properties**

These properties are used to configure tMSSqlRow running in the Standard Job framework.

The Standard tMSSqlRow component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Property</th>

<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-in:</strong> No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository:</strong> Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined.

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see **Talend Studio User Guide**.

| JDBC Provider          | Select the provider of the JDBC driver to be used, either **Microsoft** (recommended) or **Open source JTDS**. |
When using this component with Datasource in Talend Runtime, you need to use the Open source JTDS driver. Note that when Microsoft is selected, you need to download the Microsoft JDBC Driver for SQL Server on Microsoft Download Center, unpack the downloaded zip file, choose a jar in the unzipped folder based on your JRE version, rename the jar to mssql-jdbc.jar and install it manually. For more information about choosing the jar, see the System Requirements information on Microsoft Download Center.

<table>

<td><strong>Propagate QUERY’s recordset</strong></td>
<td>Select this check box to insert the result of the query into a COLUMN of the current flow. Select this column from the use column list.</td>
</tr>
<tr>
<td><strong>Use PreparedStatement</strong></td>
<td>Select this check box if you want to query the database using a PreparedStatement. In the Set PreparedStatement Parameter table, define the parameters represented by &quot;?&quot; in the query.</td>
</tr>
</tbody>
</table>
the SQL instruction of the **Query** field in the **Basic Settings** tab.

**Parameter Index**: Enter the parameter position in the SQL instruction.

**Parameter Type**: Enter the parameter type.

**Parameter Value**: Enter the parameter value.

### Note:
This option is very useful if you need to execute the same query several times. Performance levels are increased.

<table>
<thead>
<tr>
<th>Commit every</th>
<th>Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions.</th>
</tr>
</thead>
<tbody>
<tr>
<td>tStat Catcher Statistics</td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

### Global Variables

**Global Variables**

| Global Variables | **QUERY**: the query statement being processed. This is a Flow variable and it returns a string.  
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
For further information about variables, see *Talend Studio User Guide*. |

### Usage

**Usage rule**

This component offers the flexibility of the DB query and covers all possible SQL queries.

**Dynamic settings**

Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic**
settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

Related scenarios

For related topics, see:

- Combining two flows for selective output on page 2514
- Procedure on page 625.
- Removing and regenerating a MySQL table index on page 2508.
Tracks and reflects changes in a dedicated SCD table in a Microsoft SQL Server or Azure SQL database.

tmSSqISCD addresses Slowly Changing Dimension needs, reading regularly a source of data and logging the changes into a dedicated SCD table.

**tmSSqISCD Standard properties**

These properties are used to configure tmSSqISCD running in the Standard Job framework.

The Standard tmSSqISCD component belongs to the Business Intelligence and the Databases families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>

</tr>
<tr>
<td>Built-in:</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository:</td>
<td>Select the Repository file where Properties are stored. The following fields are pre-filled in using fetched data.</td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined.

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

### JDBC Provider

Select the provider of the JDBC driver to be used, either **Microsoft** (recommended) or **Open source JTDS**.

When using this component with Datashow in Talend Runtime, you need to use the **Open source JTDS** driver.
Note that when **Microsoft** is selected, you need to download the Microsoft JDBC Driver for SQL Server on **Microsoft Download Center**, unpack the downloaded zip file, choose a jar in the unzipped folder based on your JRE version, rename the jar to `mssql-jdbc.jar` and install it manually. For more information about choosing the jar, see the System Requirements information on **Microsoft Download Center**.

<table>
<thead>
<tr>

2410
Usage

Usage rule
This component is used as Output component. It requires an Input component and Row main link as input.

Dynamic settings
Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Limitation
This component does not support using SCD type 0 together with other SCD types.

Related scenario
For related topics, see tMysqlSCD on page 2519.
tMSSqISP

Offers a convenient way to centralize multiple or complex queries in a database and calls them easily. tMSSqISP calls the stored procedure in a Microsoft SQL Server or Azure SQL database.

**tMSSqISP Standard properties**

These properties are used to configure tMSSqISP running in the Standard Job framework.

The Standard tMSSqISP component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

that the SP schema can hold more columns than there are parameters used in the procedure.

Select the Type of parameter:

**IN**: Input parameter

**OUT**: Output parameter/return value

**IN OUT**: Input parameters is to be returned as value, likely after modification through the procedure (function).

**RECORDSET**: Input parameters is to be returned as a set of values, rather than single value.

**Note:**
Check Inserting data in mother/daughter tables on page 2437, if you want to analyze a set of records from a database table or DB query and return single records.

---

**Specify a data source alias**

Select this check box and specify the alias of a data source created on the **Talend Runtime** side to use the shared connection pool defined in the data source configuration.

This option works only when you deploy and run your Job in **Talend Runtime**.

This check box is not available when the **Use an existing connection** check box is selected.

**Data source alias**

Enter the alias of the data source created on the **Talend Runtime** side.

This field is available only when the **Specify a data source alias** check box is selected.

---

**Advanced settings**

**Additional JDBC parameters**

Specify additional connection properties for the database connection you are creating. The properties are separated by semicolon and each property is a key-value pair. For example, `encrypt=true;trustServerCertificate=false;hostNameInCertificate=*.database.windows.net;loginTimeout=30;` for Azure SQL database connection.

This field is not available if the **Use an existing connection** check box is selected.

**tStatCatcher Statistics**

Select this check box to collect log data at the component level.

---

**Usage**

**Usage rule**

This component is used as intermediary component. It can be used as start component but only input parameters are thus allowed.

**Dynamic settings**

Click the `[+]` button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for
example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see **Reading data from databases through context-based dynamic connections** on page 2457 and **Reading data from different MySQL databases using dynamically loaded connection parameters** on page 491. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

| Limitation | The Stored Procedures syntax should match the Database syntax.

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

---

### Retrieving personal information using a stored procedure

This scenario describes a Job that retrieves a personal information record from a specified table using a stored procedure according to the **id** value defined in the input flow.

In this scenario, the table to retrieve data from contains the personal information. To reproduce this scenario, you can write the data into the table from a CSV file like the following. For how to write data into a MS SQL table, see **Inserting data into a database table and extracting useful information from it** on page 2373.

```plaintext
id;name;sex;age
1;Ford;Male;25
2;Rose;Female;30
3;Sabrina;Female;28
4;Teddy;Male;32
5;Kate;Male;35
```
In this scenario, the stored procedure used to retrieve the personal information is as follows:

```sql
CREATE PROCEDURE [dbo].[QueryPerson]
@id int,
@name varchar(50)
AS
BEGIN
SET NOCOUNT ON
SELECT * FROM dbo.person where id=@id
END
```

**Dropping and linking the components**

**Procedure**

1. Create a new Job and add the following components by typing their names in the design workspace or dropping them from the Palette: a `tFixedFlowInput` component, a `tMSSqlSP` component, a `tParseRecordSet` component, and two `tLogRow` components.
2. Connect `tFixedFlowInput` to `tMSSqlSP` using a Row > Main link.
3. Do the same to connect `tMSSqlSP` to the first `tLogRow`, the first `tLogRow` to `tParseRecordSet`, and `tParseRecordSet` to the second `tLogRow`.

**Configuring the components**

**Configuring the input component**

**Procedure**

1. Double-click `tFixedFlowInput` to open its Basic settings view.

![Basic settings view](image)

2. Click the [...] button next to Edit schema to open the schema editor.
Click the [+] button to add two columns: *id* of the integer type and *name* of the string type. Click OK to close the schema editor.

3. In the **Mode** area, fill each column with respective value. In this example, the *id* value is set to 4, and the *name* value is null since it is not used in the select SQL statement in the stored procedure.

**Configuring the tMSSqlSP component**

**Procedure**

1. Double-click **tMSSqlSP** to open its **Basic settings** view.

2. Fill in the **Host**, **Port**, **Schema**, **Database**, **Username**, and **Password** fields with your MS SQL Server connection details.

3. In the **SP Name** field, enter the name of the stored procedure to be used. In this example, it is *QueryPerson*.
4. Click the [...] button next to Edit schema to open the schema editor.

![Schema editor](image)

Click the button to copy all columns from the input schema to the output schema, and then click the [+ ] button in the right panel to add a new column person of the object type to hold the personal information to be retrieved from the database. 

Click OK to close the schema editor and accept the propagation prompted by the pop-up dialog box.

5. In the Parameters area, click the [+] button to add three rows and select a schema column and its type for each row. In this example, the id and name columns are of type IN, and the person column is of type RECORD SET.

**Configuring the tParseRecordSet component**

**Procedure**

1. Double-click tParseRecordSet to open its Basic settings view.

![Basic settings](image)

2. From the Prev. Comp. Column list drop-down list, select the column that holds the personal information to be parsed. In this example, it is person.

3. Click the [...] button next to Edit schema to open the schema editor.
Click the [+ ] button in the right panel to add four columns: id and age of the integer type, and name and sex of the string type.

Click OK to close the schema editor and accept the propagation prompted by the pop-up dialog box.

4. In the Attribute table area, fill in each Value column with the corresponding column name in the MS SQL Server table that holds the personal information.

Configuring the output components

Procedure

1. Double-click the first tLogRow to open its Basic settings view.

In the Mode area, select Vertical (each row is a key/value list) for a better display of the result.

2. Do the same to configure the second tLogRow.

Saving and executing the Job

Procedure

1. Press Ctrl + S to save the Job.

2. Press F6 to run the Job.
The personal information with the id of 4 in the MS SQL table is displayed in the lower table on the console. Note that the values of the id and name columns shown in the upper table are the input data.

Related scenarios

For related scenarios, see:

- Using tMysqlSP to find a State Label using a stored procedure on page 2539.
- Checking number format using a stored procedure on page 2754.
- Executing a stored procedure using tMDMSP on page 2159.

Check as well inserting data in mother/daughter tables on page 2437 to analyze a set of records from a database table or DB query and return single records.
tMSSqlTableList

Lists the names of a given set of MSSql tables using a select statement based on a Where clause.

**tMSSqlTableList Standard properties**

These properties are used to configure tMSSqlTableList running in the Standard Job framework.

The Standard tMSSqlTableList component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tMSSqlConnection component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Where clause for table name selection</td>
<td>Enter the Where clause to identify the tables to iterate on.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th><strong>CURRENT_TABLE</strong>: the name of the table currently iterated upon. This is a Flow variable and it returns a string.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>NB_TABLE</strong>: the number of tables iterated upon so far. This is a Flow variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press <strong>Ctrl + Space</strong> to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td></td>
<td>For further information about variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>
### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is to be used along with MSSql components, especially with tMSSqlConnection.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic settings</td>
<td>Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

### Related scenario

For tMSSqlTableList related scenario, see Iterating on a DB table and listing its column names on page 2430.
**tMysqlBulkExec**

Offers gains in performance while executing the Insert operations on a MySQL or Aurora database.

The tMysqlOutputBulk and tMysqlBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT statement used to feed a database. These two steps are fused together in the tMysqlOutputBulkExec component, detailed in a separate section. The advantage of using two separate steps is that the data can be transformed before it is loaded in the database.

**tMysqlBulkExec Standard Properties**

These properties are used to configure tMysqlBulkExec running in the Standard Job framework.

The Standard tMysqlBulkExec component belongs to the Databases family.

The component in this framework is available in all **Talend products**.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see **Dynamic database components** on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th><strong>Database</strong></th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Property type</strong></td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><strong>DB Version</strong></td>
<td>Select the version of the database that you are using.</td>
</tr>
<tr>
<td><strong>Use an existing connection</strong></td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>Host</th>
<th>Database server IP address</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
</tbody>
</table>
| Action on table | On the table defined, you can perform one of the following operations:

  - **None**: No operation is carried out.
  - **Drop and create table**: The table is removed and created again.
  - **Create table**: The table does not exist and gets created.
  - **Create table if not exists**: The table is created if it does not exist.
  - **Drop table if exists and create**: The table is removed if it already exists and created again.
  - **Clear table**: The table content is deleted. You have the possibility to rollback the operation.
  - **Truncate table**: The table content is deleted. You do not have the possibility to rollback the operation. |
| Table | Name of the table to be written. Note that only one table can be written at a time and that the table must exist for the insert operation to succeed. |
| Local file Name | Name of the file to be loaded. This file should be located on the same machine where the Studio is installed or where the Job using tMysqlBulkExec is deployed. |
| Schema and Edit Schema | A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either **Built-in** or stored remotely in the Repository. |
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

---

**Built-In**: You create and store the schema locally for this component only.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

---

### Advanced settings

<table>
<thead>
<tr>
<th><strong>Additional JDBC parameters</strong></th>
<th>Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the <strong>Use an existing connection</strong> check box in the <strong>Basic settings</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Lines terminated by</strong></td>
<td>Character or sequence of characters used to separate lines.</td>
</tr>

<td>Replace existing records with new ones. <strong>Ignore records in table</strong>: Ignore the existing records, or insert the new ones.</td>
</tr>
<tr>
<td><strong>Records contain NULL value</strong></td>
<td>Check this box if you want to retrieve the null values from the input data flow. If you do not check this box, the null values from the input data flow will be considered as empty fields in the output data flow.</td>
</tr>
<tr>
<td><strong>Encoding</strong></td>
<td>Select the encoding from the list or select <strong>Custom</strong> and define it manually. This field is compulsory for DB data handling.</td>
</tr>
<tr>
<td>tStatCatcher Statistics</td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

## Usage

| Usage rule | This component is to be used along with tMysqlOutputBulk component. Used together, they can offer gains in performance while feeding a MySQL or Aurora database. |

| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |

| Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |

## Related scenarios

For use cases in relation with tMysqlBulkExec, see the following scenarios:

- Inserting transformed data in MySQL database on page 2493.
- Inserting data in bulk in MySQL database on page 2500.
- Truncating and inserting file data into an Oracle database on page 2700.
**tMysqlClose**

Closes the transaction committed in a Mysql database.

**tMysqlClose Standard properties**

These properties are used to configure tMysqlClose running in the Standard Job framework.

The Standard tMysqlClose component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>

</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tMysqlConnection component in the list if more than one connection are planned for the current Job.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is to be used along with Mysql components, especially with tMysqlConnection and tMysqlCommit. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |
Related scenario

This component is closed related to `tMysqlConnection` and `tMysqlRollback`. It is often used along with a `tMysqlConnection` component since it closes an ongoing transaction.

For a scenario related to `tMysqlClose`, see `tMysqlConnection` on page 2436.
tMysqlColumnList

Iterates on all columns of a given Mysql table and lists column names.

**tMysqlColumnList Standard properties**

These properties are used to configure tMysqlColumnList running in the Standard Job framework.

The Standard tMysqlColumnList component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tMysqlConnection component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Table name</td>
<td>Enter the name of the table.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>COLUMN_NAME: the name of the column currently iterated upon. This is a Flow variable and it returns a string.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>DATA_TYPE: the data type of the column currently iterated upon. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td></td>
<td>COLUMN_DEFAULT: the default value of the column currently iterated upon. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td></td>
<td>IS_NULLABLE: nullability of the column currently iterated upon. This is a Flow variable and it returns YES if the column allows NULL; otherwise, NO.</td>
</tr>
<tr>
<td></td>
<td>COLUMN_KEY: the key indicator of the column currently iterated upon. This is a Flow variable and it returns a string if the column is set to Key; otherwise it returns nothing.</td>
</tr>
<tr>
<td></td>
<td>CHARACTER_MAXIMUM_LENGTH: the maximum length in number of characters of the column currently iterated upon. This is a Flow variable, and it returns a numeric string for binary or character data types and NULL for other types.</td>
</tr>
<tr>
<td></td>
<td>NUMERIC_PRECISION: the data precision of the column currently iterated upon. This is a Flow variable, and it returns a numeric string for approximate numeric data.</td>
</tr>
</tbody>
</table>
exact numeric data, integer data, or monetary data and NULL for other data types.

**NUMERIC_SCALE**: the scale in digits allowed in the column currently iterated upon. This is a Flow variable, and it returns a numeric string for approximate numeric data, exact numeric data, integer data, or monetary data and NULL for other data types.

**NB_COLUMN**: the number of columns iterated upon so far. This is an After variable and it returns an integer.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is to be used along with Mysql components, especially with <strong>tMysqlConnection</strong>.</th>
</tr>
</thead>
</table>

**Dynamic settings**

Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see [Reading data from databases through context-based dynamic connections](#) on page 2457 and [Reading data from different MySQL databases using dynamically loaded connection parameters](#) on page 491. For more information on **Dynamic settings** and context variables, see [Talend Studio User Guide](#).

**Iterating on a DB table and listing its column names**

The following Java scenario creates a five-component job that iterates on a given table name from a Mysql database using a Where clause and lists all column names present in the table.

- Drop the following components from the Palette onto the design workspace: **tMysqlConnection**, **tMysqlTableList**, **tMysqlColumnList**, **tFixedFlowInput**, and **tLogRow**.
- Connect **tMysqlConnection** to **tMysqlTableList** using an **OnSubjobOk** link.
• Connect `tMysqlTableList`, `tMysqlColumnList`, and `tFixedFlowInput` using `Iterate` links.
• Connect `tFixedFlowInput` to `tLogRow` using a `Row Main` link.

In the design workspace, select `tMysqlConnection` and click the `Component` tab to define its basic settings.
• In the `Basic settings` view, set the database connection details manually or select them from the context variable list, through a `Ctrl+Space` click in the corresponding field if you have stored them locally as Metadata DB connection entries.
For more information about Metadata, see *Talend Studio User Guide*.

In this example, we want to connect to a Mysql database called *customers*.

• In the design workspace, select `tMysqlTableList` and click the `Component` tab to define its basic settings.

• On the `Component list`, select the relevant Mysql connection component if more than one connection is used.
• Enter a Where clause using the right syntax in the corresponding `field` to iterate on the table name(s) you want to list on the console.
In this scenario, the table we want to iterate on is called customer.

- In the design workspace, select **tMysqlColumnList** and click the **Component** tab to define its basic settings.

  ![tMysqlColumnList_1](image)

  - On the **Component list**, select the relevant Mysql connection component if more than one connection is used.
  - In the **Table name** field, enter the name of the DB table you want to list its column names.

    In this scenario, we want to list the columns present in the DB table called **customer**.
  - In the design workspace, select **tFixedFlowInput** and click the **Component** tab to define its basic settings.
  - Set the **Schema** to **Built-In** and click the three-dot `[...]` button next to **Edit Schema** to define the data you want to use as input. In this scenario, the schema is made of two columns, the first for the table name and the second for the column name.

  ![Schema of tFixedFlowInput_1](image)

    - Click **OK** to close the dialog box, and accept propagating the changes when prompted by the system. The defined columns display in the **Values** panel of the **Basic settings** view.
    - Click in the **Value** cell for each of the two defined columns and press **Ctrl+Space** to access the global variable list.
    - From the global variable list, select `((String)globalMap.get("tMysqlTableList_1_CURRENT_TABLE"))` and `((String)globalMap.get("tMysqlColumnList_1_COLUMN_NAME"))` for the **TableName** and **ColumnName** respectively.
• In the design workspace, select **tLogRow**.
• Click the **Component** tab and define the basic settings for **tLogRow** as needed.
• Save your job and press **F6** to execute it.

```
Starting job Column_Table_List at 00:55 17/11/2008.
customer|id
customer|First_Name
customer|Last_Name
customer|Address
customer|id_State
Job Column_Table_List ended at 00:55 17/11/2008. [exit code=0]
```

The name of the DB table is displayed on the console along with all its column names.
tMysqlCommit

Commits in one go, using a unique connection, a global transaction instead of doing that on every row or every batch and thus provides gain in performance.

tMysqlCommit validates the data processed through the Job into the connected DB.

**tMysqlCommit Standard properties**

These properties are used to configure tMysqlCommit running in the Standard Job framework.

The Standard tMysqlCommit component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tMysqlConnection component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Warning:**

If you want to use a Row > Main connection to link tMysqlCommit to your Job, your data will be committed row by row. In this case, do not select the Close connection check box or your connection will be closed before the end of your first row commit.

### Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

### Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. |
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

| Usage rule | This component is more commonly used with other tMysql* components, especially with the tMysqlConnection and tMysqlRollback components. |

| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |

Related scenario

For tMysqlCommit related scenario, see Inserting data in mother/daughter tables on page 2437.
tMysqlConnection

Opens a connection to the specified MySQL database for reuse in the subsequent subJob or subJobs.

**tMysqlConnection Standard properties**

These properties are used to configure tMysqlConnection running in the Standard Job framework.

The Standard tMysqlConnection component belongs to the Databases and the ELT families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
<tr>
<td><strong>Property type</strong></td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><strong>Host</strong></td>
<td>Database server IP address.</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database.</td>
</tr>
<tr>
<td><strong>Additional JDBC parameters</strong></td>
<td>Specify additional connection properties for the DB connection you are creating.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Use or register a shared DB Connection</strong></td>
<td>Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the Shared DB Connection Name field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child.</td>
</tr>
<tr>
<td></td>
<td>This option is incompatible with the Use dynamic job and Use an independent process to run subJob options of the tRunJob component. Using a shared connection together</td>
</tr>
</tbody>
</table>
with a **tRunJob** component with either of these two options enabled will cause your Job to fail.

This check box is not available when the **Specify a data source alias** check box is selected.

### Specify a data source alias

Select this check box and specify the alias of a data source created on the **Talend Runtime** side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in **Talend Runtime**.

### Advanced settings

#### Auto Commit

Select this check box to commit any changes to the database automatically upon the transaction.

With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component.

Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component.

#### tStatCatcher Statistics

Select this check box to gather the job processing metadata at a Job level as well as at each component level.

### Usage

#### Usage rule

This component is more commonly used with other tMysql* components, especially with the **tMysqlCommit** and **tMysqlRollback** components.

### Inserting data in mother/daughter tables

The following Job is dedicated to advanced database users, who want to carry out multiple table insertions using a parent table id to feed a child table.

As a prerequisite to this Job, follow the steps described below to create the relevant tables using an engine such as *innodb*:

1. In a command line editor, connect to your Mysql server.
2. Once connected to the relevant database, type in the following command to create the parent table:
   ```sql
   create table f1090_mum(id int not null auto_increment, name varchar(10), primary key(id)) engine=innodb;
   ```
3. Then create the second table:
create table f1090_baby (id_baby int not null, years int)
engine=innodb;

Back in *Talend Studio*, the Job requires seven components including *tMysqlConnection* and *tMysqlCommit*.

**Linking the components**

**Procedure**

1. Drag and drop the following components from the Palette: a *tFileList*, a *tFileInputDelimited*, a *tMap*, a *tMysqlConnection*, a *tMysqlCommit* and two *tMysqlOutput*.
2. Connect *tMysqlConnection* to *tFileList* using an *OnComponentOk* link.
3. Connect *tFileList* to *tMysqlCommit* using an *OnComponentOk* link.
4. Connect the *tFileList* component to the input file component using an *Iterate* link as the name of the file to be processed will be dynamically filled in from the *tFileList* directory using a global variable.
5. Connect the *tFileInputDelimited* component to the *tMap* and dispatch the flow between the two output Mysql DB components. Use a *Row* link for each for these connections representing the main data flow.

![Diagram](image)

**Configuring the components**

**Procedure**

1. Set the *tFileList* component properties, such as the directory name where files will be fetched from.
2. In the *tMysqlConnection* Component view, set the connection details manually or fetch them from the Repository if you centrally stored them as a Metadata DB connection entry. For more information about Metadata, see *Talend Studio User Guide*.
3. On the *tFileInputDelimited* component’s *Basic settings* panel, press *Ctrl+Space* bar to access the variable list. Set the *File Name* field to the global variable: *tFileList_1.CURRENT_FILEPATH*
4. Set the rest of the fields as usual, defining the row and field separators according to your file structure.

5. Then set the schema manually through the Edit schema feature or select the schema from the Repository. In Java version, make sure the data type is correctly set, in accordance with the nature of the data processed.

6. In the tMap Output area, add two output tables, one called mum for the parent table, the second called baby, for the child table.

   Drag the Name column from the Input area, and drop it to the mum table.

   Drag the Years column from the Input area and drop it to the baby table.

7. Make sure the mum table is on the top of the baby table as the order is determining for the flow sequence hence the DB insert to perform correctly.

   Connect the output row link to distribute correctly the flow to the relevant DB output component.

8. In the Basic settings tab of the two tMysqlOutput components, select the Use an existing connection check box to retrieve the tMysqlConnection details.

9. Set the Table name, making sure it corresponds to the correct table, in this example either f1090_mum or f1090_baby.
There is no action on the table as they are already created.
Select Insert as Action on data for both output components.
Click on Sync columns to retrieve the schema set in the tMap.

10. Switch to the Advanced settings tab of the DB output component corresponding to the child table (that is, f1090_baby).
   - In the id-baby row of the Additional columns table, fill the SQL expression field with "(Select Last_Insert_id())".
   - Set the Position field to Before.
   - Set the Reference column field to years.

These settings allow the f1090_baby table to use the ID key of the f1090_mum as its key.

11. Clear the Extend insert table to use the ID key of the f1090_mum as its key.

**Executing the Job**

**Procedure**

1. Press Ctrl + S to save your Job.
2. Press F6 to execute it.

The parent table id has been reused to feed the id_baby column.

**Rollback from inserting data in mother/daughter tables**

**About this task**

Based on Inserting data in mother/daughter tables on page 2437, insert a rollback function in order to prevent unwanted commit.
Procedure
1. Drag and drop **tMysqlRollback** to the design workspace. **tMysqlRollback** ensures that the transaction will not be partly committed.
2. Connect **tFileList** to **tMysqlRollback** with an **OnSubjobError** trigger.
3. Double-click **tMysqlRollback** to enter its **Basic settings** view.
4. From the **Component List**, select the connection component.

Sharing a database connection between a parent Job and child Job

This scenario shows how a database connection is shared between a parent Job and a child Job. The parent Job first calls the child Job to write some randomly generated data to a MySQL database, and then reads the data from the MySQL database and displays it on the console. A connection to the MySQL database is set up only once and used in both Jobs.

Setting up the child Job

Adding and linking components

Procedure
1. Add the following components by typing the component names on the design workspace or dropping them from the **Palette**:
   - a **tMysqlConnection** component, to open a connection to the MySQL database,
   - a **tRowGenerator**, to generate random input data,
   - a **tMysqlOutput** component, to write data to the MySQL database.
2. Connect the **tRowGenerator** component to the **tMysqlOutput** component using a **Row > Main** connection.
3. Connect the **tMysqlConnection** component to the **tRowGenerator** using a **Trigger > OnSubjobOk** connection.
Configuring the database connection

Procedure

1. Double-click the `tMysqlConnection` component to open its `Basic settings` view.

   ![tMysqlConnection component](image)

   **tMysqlConnection_1**

   **OnSubjobOk**

   ![Flowchart](image)

   - **tRowGenerator_1**
   - **row1 (Main)**
   - **tMysqlOutput_1**

2. With the **Property Type** set to **Built-In**, specify the connection details in the relevant fields, including:
   - the host name or IP address of your database server
   - the listening port number
   - the database name
   - the user name and password for your database authentication.

   If you have stored your connection details under the **Metadata** node in the **Repository** tree view, you can simply drop your centralized metadata item onto the `tMysqlConnection` component. For information on how to centralize a database connection, see the chapter on managing metadata of the **Talend Studio User Guide**.

3. Select the **Use or register a shared DB Connection** check box so that the database connection open by this component can be shared across different Jobs. Then, enter a name for the shared connection between double quotes in the **Shared DB Connection Name** field, `shared_mysql_connection` in this example.
Configuring the input data

Procedure

1. Double-click the **tRowGenerator** component to open the Row Generator editor.

2. Click the [+] button to add four columns and set their properties:
   - **id**, type Integer, 2 characters long.
   - **firstName**, type String, 15 characters long
   - **lastName**, type String, 15 characters long
   - **city**, type String, 15 characters long

3. Define the function for each column:
   - For the **id** column, select **Numeric.sequence** from the **Function** list to generate sequence numbers.
   - For the **firstName** column, select **TalendDataGenerator.getFirstName** from the **Function** list to generate random first names.
   - For the **lastName** column, select **TalendDataGenerator.getLastName** from the **Function** list to generate random family names.
   - For the **city** column, select **TalendDataGenerator.getUsCity** from the **Function** list to generate random city names.

4. In the **Number of Rows for RowGenerator** field, specify the number of data rows you want to generate, 10 in this example.

5. Click the **Preview** button on the **Preview** tab to validate the generator settings.

6. When done, click **OK** to close the editor and click **Yes** when prompted to propagate the schema to the next component.
Configuring the database output

Procedure

1. Double-click the tMysqlOutput component to open its Basic settings view.

2. Select the Use an existing connection check box and, in case you have more than one connection component in the Job, select the connection component to be used from the Component List drop-down list.

3. In the Table field, enter the name of the database table you are going to write data to, customers in this example.

4. From the Action on table list, select the Drop table if exists and create option to ensure a clean table is created.

5. From the Action on data list, select Insert.

6. Click the [...] button next to Edit schema to check the output schema. If needed, click Sync columns to retrieve the schema from the preceding component.

7. Press Ctrl+S to save the Job.

Setting up the parent Job

Arranging data flow for the parent Job

Procedure

1. Add the following components by typing the component names on the design workspace or dropping them from the Palette:
   - a tRunJob component, to call the child Job,
   - a tMysqlConnection component, to open the MySQL database connection,
   - a tMysqlInput component, to read the data written to the MySQL database by the child Job.
   - a tLogRow component to display the data on the console,
   - a tMysqlCommit component to commit data upon transation and close the database connection.

2. Connect the tRunJob component to the tMysqlConnection component using a Trigger > OnSubjobOk connection.

3. Connect the tMysqlConnection component to the tMysqlInput component using a Trigger > OnSubjobOk connection.

4. Connect the tMysqlInput component to the tLogRow component using a Row > Main connection.

5. Connect the tMysqlInput component to the tMysqlCommit component using a Trigger > OnSubjobOk connection.
Configuring the components

Procedure

1. Double-click the tRunJob component to open its Basic settings view.
   If a child Job has been already specified in the component, you can open its Basic settings view by right-clicking it and selecting Settings from the contextual menu, or by clicking the component and then selecting the Component tab.

2. Click the [...] button next to the Job field and select the child Job from the Repository Content dialog box. Leave all the other parameters as default.

3. In the Basic settings view of the tMysqlConnection component, select the Use or register a shared DB Connection check box. Then, in the Shared DB Connection Name field, enter the name of the shared connection defined in the child Job, shared_mysql_connection in this example. Leave all the other parameters blank or as default.
4. Double-click the tMysqlInput component to open its Basic settings view.

5. Select the Use an existing connection check box and, in case you have more than one connection component in the Job, select the connection component to be used from the Component List drop-down list.

6. Click the [...] button next to Edit schema to open the Schema editor, and define the same data structure as in the child Job.
When done, click **OK** to close the dialog and click **Yes** when prompted to propagate the schema to the next component.

7. Specify the table name in the **Table Name** list, and click **Guess Query** to get the query statement automatically filled in the **Query** field.

8. In the **Basic settings** view of the **tLogRow** component, select the **Table** mode to display the execution result in table cells.
   Leave the settings of the **tMysqlCommit** component unchanged.

### Execute the Job

**Procedure**

1. Press **Ctrl+S** to save the Job.
2. Press **F6** or click the **Run** button on the **Run** console to execute the Job.

<table>
<thead>
<tr>
<th>id</th>
<th>firstName</th>
<th>lastName</th>
<th>city</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Franklin</td>
<td>Quincy</td>
<td>Bisnarck</td>
</tr>
<tr>
<td>2</td>
<td>Theodore</td>
<td>Coolidge</td>

</tbody>
</table>

The Job first calls the child Job to write data to the database and then reads the data from the database and displays it on the console.
tMysqlInput

Executes a DB query with a strictly defined order which must correspond to the schema definition. tMysqlInput reads a database and extracts fields based on a query. Then it passes on the field list to the next component via a Main row link.

**tMysqlInput Standard properties**

These properties are used to configure tMysqlInput running in the Standard Job framework. The Standard tMysqlInput component belongs to the Databases family. The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
<tr>
<td>Property type</td>
<td>Either Built-In or Repository. Built-In: No property data stored centrally. Repository: Select the repository file where the properties are stored.</td>
</tr>
<tr>
<td><img src="image" alt="Icon" /></td>
<td>Click this icon to open a database connection wizard and store the database connection parameters you set in the component Basic settings view. For more information about setting up and storing database connection parameters, see Talend Studio User Guide.</td>
</tr>
<tr>
<td>DB version</td>
<td>Select the version of the database to be used.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the *Basic settings* view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th>Host</th>
<th>Database server IP address.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td><strong>Built-In</strong></td>
<td>You create and store the schema locally for this component only.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
</tr>
<tr>
<td>Click <strong>Edit schema</strong> to make changes to the schema. If the current schema is of the <strong>Repository</strong> type, three options are available:</td>
<td></td>
</tr>
<tr>
<td>• <strong>View schema</strong>: choose this option to view the schema only.</td>
<td></td>
</tr>
<tr>
<td>• <strong>Change to built-in property</strong>: choose this option to change the schema to <strong>Built-in</strong> for local changes.</td>
<td></td>
</tr>
<tr>
<td>• <strong>Update repository connection</strong>: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select <strong>No</strong> upon completion and choose this schema metadata again in the <strong>Repository Content</strong> window.</td>
<td></td>
</tr>
<tr>
<td>Table Name</td>
<td>Name of the table to be read.</td>
</tr>
</tbody>
</table>
**Query type and Query**
Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.

**Specify a data source alias**
Select this check box and specify the alias of a data source created on the *Talend Runtime* side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in *Talend Runtime*.

**Warning:**
If you use the component’s own DB configuration, your data source connection will be closed at the end of the component. To prevent this from happening, use a shared DB connection with the data source alias specified.

This check box is not available when the **Use an existing connection** check box is selected.

**Advanced settings**

**Additional JDBC parameters**
Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the **Use an existing connection** check box in the **Basic settings**.

**Note:** When you need to handle data of the time-stamp type 0000-00-00 00:00:00 using this component, set the parameter as: noDateTimeStringSync=true&zeroDateTimeBehavior=convertToNull.

**Enable stream**
Select this check box to enables streaming over buffering which allows the code to read from a large table without consuming a large amount of memory in order to optimize the performance.

This check box is available only when MySQL 4 or MySQL 5 is selected from the **DB Version** drop-down list.

**Trim all the String/Char columns**
Select this check box to remove leading and trailing whitespace from all the String/Char columns.

**Trim column**
Remove leading and trailing whitespace from defined columns.

**Note:** Clear **Trim all the String/Char columns** to enable **Trim columns in this field**.

**tStatCatcher Statistics**
Select this check box to collect log data at the component level.

**Global Variables**

**Global Variables**
**NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.
Writing columns from a MySQL database to an output file using tMysqlInput

In this scenario we will read certain columns from a MySQL database, and then write them to a table in a local output file.

Dragging and dropping components and linking them together

Procedure

1. Drop tMysqlInput and tFileOutputDelimited from the Palette onto the workspace.
2. Link tMysqlInput to tFileOutputDelimited using a Row > Main connection.

![Diagram](image)

**Configuring the components**

**Procedure**

1. Double-click tMysqlInput to open its Basic Settings view in the Component tab.

   ![Component Tab](image)

2. From the Property Type list, select Repository if you have already stored the connection to database in the Metadata node of the Repository tree view. The property fields that follow are automatically filled in.

   For more information about how to store a database connection, see *Talend Studio User Guide*. If you have not defined the database connection locally in the Repository, fill in the details manually after selecting Built-in from the Property Type list.

3. Set the Schema as Built-in and click Edit schema to define the desired schema.

   The schema editor opens:
4. Click the [+ ] button to add the rows that you will use to define the schema, four columns in this example  *id, first_name, city* and *salary*. Under *Column*, click in the fields to enter the corresponding column names. Click the field under *Type* to define the type of data. Click *OK* to close the schema editor.

5. Next to the *Table Name* field, click the [...] button to select the database table of interest. A dialog box displays a tree diagram of all the tables in the selected database:

6. Click the table of interest and then click *OK* to close the dialog box.

7. Set the *Query Type* as *Built-In*.

8. In the *Query* box, enter the query required to retrieve the desired columns from the table.

```
"SELECT "employees".id, "employees".first_name, "employees".city, "employees".salary
FROM employees"
```

9. Double-click *tFileOutputDelimited* to set its *Basic settings* in the *Component* tab.
10. Next to the **File Name** field, click the [...] button to browse your directory to where you want to save the output file, then enter a name for the file. Select the **Include Header** check box to retrieve the column names as well as the data.

11. Save the Job.

**Executing the Job**

The results below can be found after F6 is pressed to run the Job.

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>id;first_name;city;salary</td>
</tr>
<tr>
<td>2</td>
<td>1;Martin;Sacramento;9011</td>
</tr>
<tr>
<td>3</td>
<td>2;Zachary;Atlanta;8118</td>
</tr>
<tr>
<td>4</td>
<td>3;James;Hartford;5087</td>
</tr>
<tr>
<td>5</td>
<td>4;Herbert;Charleston;9233</td>
</tr>
<tr>
<td>6</td>
<td>5;Herbert;Hartford;6289</td>
</tr>
<tr>
<td>7</td>
<td>6;Ulysses;Nashville;6269</td>
</tr>
</tbody>
</table>

As shown above, the output file is written with the desired column names and corresponding data, retrieved from the database:

**Note:**
The Job can also be run in the **Traces Debug** mode, which allows you to view the rows as they are being written to the output file, in the workspace.

**Using context parameters when reading a table from a database**

In this scenario, MySQL is used for demonstration purposes. We will read a table from a MySQL database, using a context parameter to refer to the table name.

**Dragging and dropping components and linking them together**

**Procedure**

1. Drop **tMysqlInput** and **tLogRow** from the Palette onto the workspace.
2. Link **tMysqlInput** to **tLogRow** using a **Row > Main** connection.
Configuring the components

Procedure

1. Double-click `tMysqlInput` to open its **Basic Settings** view in the **Component** tab.

2. From the **Property Type** list, select **Repository** if you have already stored the connection to database in the **Metadata** node of the **Repository** tree view. The property fields that follow are automatically filled in.

   For more information about how to store a database connection, see *Talend Studio User Guide*. If you have not defined the database connection in the **Repository**, fill in the details manually after selecting **Built-in** from the **Property Type** list.

3. Set the **Schema** as **Built-In** and click **Edit schema** to define the desired schema.

   The schema editor opens:
4. Click the [+] button to add the rows that you will use to define the schema, seven columns in this example: *id, first_name, last_name, city, state, date_of_birth* and *salary.*

Under **Column**, click the fields to enter the corresponding column names. Click the fields under **Type** to define the type of data.

Click **OK** to close the schema editor.

5. Put the cursor in the **Table Name** field and press **F5** for context parameter setting.

For more information about context settings, see *Talend Studio User Guide.*

6. Keep the default setting in the **Name** field and type in the name of the database table in the **Default value** field, *employees* in this case.

7. Click **Finish** to validate the setting.

The context parameter *context.TABLE* automatically appears in the **Table Name** field.

8. In the **Query type** list, select **Built-In.** Then, click **Guess Query** to get the query statement.

In this use case, we want to read the records with the salary above 8000. Therefore, we add a **Where** clause and the final query statement is as follows:

```
"SELECT "+context.TABLE+.`id`,
  "+context.TABLE+.`first_name`,
  "+context.TABLE+.`last_name`,
  "+context.TABLE+.`city`,
  "+context.TABLE+.`state`,
  "+context.TABLE+.`date_of_birth`,
  "+context.TABLE+.`salary`
FROM "+context.TABLE+
WHERE "+context.TABLE+.`salary` > 8000"
```

9. Double-click **tLogRow** to set its **Basic Settings** in the **Component** tab.
10. In the Mode area, select **Table (print values in cells of a table)** for a better display of the results.
11. Save the Job.

### Executing the Job

The results below can be found after **F6** is pressed to run the Job.

<table>
<thead>
<tr>
<th>id</th>
<th>first_name</th>
<th>last_name</th>
<th>city</th>
<th>state</th>
<th>date_of_birth</th>
<th>salary</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Martin</td>
<td>Roosevelt</td>
<td>Sacramento</td>
<td>ND</td>
<td>18-10-1950</td>
<td>9011</td>
</tr>
<tr>
<td>2</td>
<td>Zachary</td>
<td>Johnson</td>
<td>Atlanta</td>
<td>ND</td>
<td>14-11-1978</td>
<td>8118</td>
</tr>
<tr>
<td>4</td>
<td>Herbert</td>
<td>Harrison</td>
<td>Charleston</td>
<td>AE</td>
<td>15-08-1963</td>
<td>9233</td>
</tr>
</tbody>
</table>

As shown above, the records with the salary greater than 8000 are retrieved.

### Reading data from databases through context-based dynamic connections

In this scenario, MySQL is used for demonstration purposes. We will read data from database tables with the same data structure but in two different MySQL databases named **project_q1** and **project_q2** respectively. We will specify the connections to these databases dynamically at runtime, without making any modification to the Job.

### Dropping and linking the components

**Procedure**

1. Drop two **tMysqlConnection**, a **tMysqlInput**, a **tLogRow**, and a **tMysqlClose** components onto the design workspace.
2. Link the first **tMysqlConnection** to the second **tMysqlConnection** and the second **tMysqlConnection** to **tMysqlInput** using **Trigger > On Subjob Ok** connections.
3. Link **tMysqlInput** to **tLogRow** using a **Row > Main** connection.
4. Link **tMysqlInput** to **tMysqlClose** using a **Trigger > On Subjob Ok** connection.
Creating a context variable

About this task

To be able to choose a database connection dynamically at runtime, we need to define a context variable, which will then be configured in the Dynamic settings of the database input component.

Procedure

1. In the Contexts view, click the [+] button to add a row in the table, click in the Name field and enter a name for the variable, myConnection in this example.

2. From the Type list field, select List Of Value.

3. Click in the Value field and then click the button that appears in the field to open the Configure value of list dialog box.
4. In the Configure value of list dialog box, click the New... button to open the New Value dialog box, and enter the name of one of the connection components in the text field, tMysqlConnection_1 in this example. Then click OK to close the dialog box.

Repeat this step to specify the other connection component name as another list item, tMysqlConnection_2 in this example.

When done, click OK to close the Configure Values dialog box.

5. Select the check box next to the variable value field, and fill the Prompt field with the message you want to display at runtime, Select a connection component: in this example.
Configuring the components

Procedure

1. Double-click the first `tMysqlConnection` component to show its Basic settings view, and set the connection details. For more information on the configuration of `tMysqlConnection`, see `tMysqlConnection` on page 2436.

   Note that we use this component to open a connection to a MySQL database named `project_q1`.

   ![tMysqlConnection_1](image)

   - **Property Type**: Built-In
   - **DB Version**: Mysql 5
   - **Host**: localhost
   - **Database**: project_q1
   - **Username**: root
   - **Password**: ********
   - **Port**: 3306
   - **Additional JDBC Parameters**: "noDatet imeStrin gSync=true"

2. Configure the second `tMysqlConnection` component in the same way, but fill the Database field with `project_q2` because we want to use this component to open a connection to another MySQL database, `project_q2`.

   ![tMysqlConnection_2](image)

   - **Property Type**: Built-In
   - **DB Version**: Mysql 5
   - **Host**: localhost
   - **Database**: project_q2
   - **Username**: root
   - **Password**: ********
   - **Port**: 3306
   - **Additional JDBC Parameters**: "noDatet imeStrin gSync=true"

3. Double-click the `tMysqlInput` component to show its Basic settings view.

   ![tMysqlInput_1](image)

   - **Scheme**: Built-In
   - **Table Name**: customers
   - **Query Type**: `SELECT customers.id, customers.firstName, customers.lastName, customers.city FROM customers`
5. Click the [...] button next to Edit schema to open the Schema dialog box and define the data structure of the database table to read data from.

![Schema of tMysqlInput_1](image)

In this example, the database table structure is made of four columns, `id` (type Integer, 2 characters long), `firstName` (type String, 15 characters long), `lastName` (type String, 15 characters long), and `city` (type String, 15 characters long). When done, click OK to close the dialog box and propagate the schema settings to the next component.

6. Fill the Table field with the database table name, *customers* in this example, and click Guess Query to generate the query statement corresponding to your table schema in the Query field.

7. In the Dynamic settings view, click the [+] button to add a row in the table, and fill the Code field with the code script of the context variable you just created, " + context.myConnection + " in this example.

![tMysqlInput_1](image)

8. In the Basic settings view of the tLogRow component, select the Table option for better display effect of the Job execution result.
9. In the Dynamic settings view of the tMysqlClose component, do exactly the same as in the Dynamic settings view of the tMysqlInput component.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl+S** to save your Job and press **F6** or click **Run** to launch it.
   
   A dialog box appears prompting you to specify the connection component you want to use.

2. Select the connection component, **tMysqlConnection_1**, and click **OK**.

The data read from database *project_q1* is displayed in the Run console.
3. Press **F6** or click **Run** to launch your Job again. When prompted, select the other connection component, **tMysqlConnection_2**, to read data from the other database, **project_q2**. The data read from database **project_q2** is displayed in the **Run** console.

tMysqlLastInsertId

Obtains the primary key value of the record that was last inserted in a Mysql table by a user.
tMysqlLastInsertId fetches the last inserted ID from a selected MySQL Connection.

**tMysqlLastInsertId Standard properties**

These properties are used to configure tMysqlLastInsertId running in the Standard Job framework.
The Standard tMysqlLastInsertId component belongs to the Databases family.
The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td><strong>Built-In:</strong></td>
<td>You create and store the schema locally for this component only.</td>
</tr>
<tr>
<td><strong>Repository:</strong></td>
<td>You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
</tr>

</tr>
<tr>
<td></td>
<td>• Change to built-in property: choose this option to change the schema to Built-in for local changes.</td>
</tr>
<tr>
<td></td>
<td>• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.</td>
</tr>
</tbody>
</table>

| Component list | Select the relevant tMysqlConnection component in the list if more than one connection is planned for the current job. |
Advanced settings

**tStatCatcher Statistics**
Select this check box to collect log data at the component level.

Global Variables

Global Variables

**NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

**Usage rule**
This component is to be used as an intermediary component.

*Warning:*
If you use this component with **tMySqlOutput**, verify that the **Extend Insert** check box in the **Advanced Settings** tab is not selected. **Extend Insert** allows you to make a batch insertion, however, if the check box is selected, only the ID of the last line in the last batch will be returned.

**Dynamic settings**
Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.
Getting the ID for the last inserted record with `tMysqlLastInsertId`

The following Java scenario creates a job that opens a connection to Mysql database, writes the defined data into the database, and finally fetches the last inserted ID on the existing connection.

- Drop the following components from the Palette onto the design workspace: `tMySqlConnection`, `tMySqlCommit`, `tFileInputDelimited`, `tMySqlOutput`, `tMysqlLastInsertId`, and `tLogRow`.
- Connect `tMySqlConnection` to `tFileInputDelimited` using an OnSubjobOk link.
- Connect `tFileInputDelimited` to `tMySqlCommit` using an OnSubjobOk link.
- Connect `tFileInputDelimited` to the three other components using Row Main links.

- In the design workspace, select `tMysqlConnection`.
- Click the Component tab to define the basic settings for `tMysqlConnection`.
- In the Basic settings view, set the connection details manually or select them from the context variable list, through a Ctrl+Space click in the corresponding field if you stored them locally as Metadata DB connection entries. For more information about Metadata, see Talend Studio User Guide.
- In the design workspace, select **tMysqlCommit** and click the **Component** tab to define its basic settings.
- On the **Component List**, select the relevant **tMysqlConnection** if more than one connection is used.
- In the design workspace, select **tFileInputDelimited**.
- Click the **Component** tab to define the basic settings of **tFileInputDelimited**.

```
<table>
<thead>
<tr>
<th>tFileInputDelimited_1</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Basic settings</strong></td>
</tr>
<tr>
<td>Property Type</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>Advanced settings</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>Dynamic settings</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>View</td>
</tr>
<tr>
<td>CSV options</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>Documentation</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>
```

- Fill in a path to the processed file in the **File Name** field. The file used in this example is *Customers*.
- Define the **Row separator** that allow to identify the end of a row. Then define the **Field separator** used to delimit fields in a row.
- Set the header, the footer and the number of processed rows as necessary. In this scenario, we have one header.
- Click the three-dot button next to **Edit Schema** to define the data to pass on to the next component.

Related topics: *Talend Studio  User Guide*.

```
<table>
<thead>
<tr>
<th>Schema of tFileInputDelimited_1</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Column</strong></td>
</tr>
<tr>
<td>name</td>
</tr>
<tr>
<td>age</td>
</tr>
</tbody>
</table>
```

In this scenario, the schema consists of two columns, *name* and *age*. The first holds three employees' names and the second holds the corresponding age for each.

- In the design workspace, select **tMySqlOutput**.
- Click the **Component** tab to define the basic settings of **tMySqlOutput**.
• Select the **Use an existing connection** check box.
• In the **Table** field, enter the name of the table where to write the employees’ list, in this example: *employee*.
• Select relevant actions on the **Action on table** and **Action on data** lists. In this example, no action is carried out on table, and the action carried out on data is *Insert*.
• Click **Sync columns** to synchronize columns with the previous component. In this example, the schema to be inserted into the MySql database table consists of the two columns *name* and *age*.

![Schema of tMySqlOutput_1](image)

• In the design workspace, select **tMySqlLastInsertId**.
• Click the **Component** tab to define the basic settings of **tMySqlLastInsertId**.

![tMySqlLastInsertId_1](image)

• On the **Component List**, select the relevant **tMysqlConnection**, if more than one connection is used.
• Click **Sync columns** to synchronize columns with the previous component. In the output schema of **tMySqlLastInsertId**, you can see the read-only column *last_insert_id* that will fetch the last inserted ID on the existing connection.
You can select the data type *Long* from the *Type* drop-down list in case of a huge number of entries.

- In the design workspace, select **tLogRow** and click the **Component** tab to define its basic settings. For more information, see **tLogRow** on page 1956.
- Save your job and press **F6** to execute it.

```
Starting job lastinserted at 11:12 01/09/2008.

<table>
<thead>
<tr>
<th>name</th>
<th>age</th>
<th>last_insert_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>Marie</td>
<td>24</td>
<td>40</td>
</tr>
<tr>
<td>Patrick</td>
<td>22</td>
<td>41</td>
</tr>
<tr>
<td>Pierrick</td>
<td>27</td>
<td>42</td>
</tr>
</tbody>
</table>

Job lastinserted ended at 11:12 01/09/2008. [exit code=0]
```

**tMysqlLastInsertId** fetched the last inserted ID for each line on the existing connection.
tMysqlLookupInput

Reads a MySQL database and extracts fields based on a query.

It passes on the extracted data to tMap in order to provide the lookup data to the main flow. It must be directly connected to a tMap component and requires this tMap to use *Reload at each row* or *Reload at each row (cache)* for the lookup flow.

This component also allows you to connect and read data from a RDS Aurora or a RDS MySQL database.
**tMysqlOutput**

Writes, updates, makes changes or suppresses entries in a database.

`tMysqlOutput` executes the action defined on the table and/or on the data contained in the table, based on the flow incoming from the preceding component in the Job.

**tMysqlOutput Standard properties**

These properties are used to configure `tMysqlOutput` running in the Standard Job framework.

The `tMysqlOutput` component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
</tbody>
</table>

| DB Version             | Select the MySQL version you are using. |

| Use an existing connection | Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined. |

Click this icon to open a database connection wizard and store the database connection parameters you set in the component **Basic settings** view.

For more information about setting up and storing database connection parameters, see **Talend Studio User Guide**.
Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>Host</th>
<th>Database server IP address.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Table</td>
<td>Name of the table to be written. Note that only one table can be written at a time</td>
</tr>
<tr>
<td>Action on table</td>
<td>On the table defined, you can perform one of the following operations: Default: No operation is carried out. Drop and create a table: The table is removed and created again. Create a table: The table does not exist and gets created. Create a table if not exists: The table is created if it does not exist. Drop a table if exists and create: The table is removed if it already exists and created again. Clear a table: The table content is deleted. Truncate table: The table content is quickly deleted. However, you will not be able to rollback the operation.</td>
</tr>
<tr>
<td>Action on data</td>
<td>On the data of the table defined, you can perform: Insert: Add new entries to the table. If duplicates are found, the job stops. Update: Make changes to existing entries. Insert or update: Insert a new record. If the record with the given reference already exists, an update would be made. Update or insert: Update the record with the given reference. If the record does not exist, a new record would be inserted. Delete: Remove entries corresponding to the input flow.</td>
</tr>
</tbody>
</table>
Replace: Add new entries to the table. If an old row in the table has the same value as a new row for a PRIMARY KEY or a UNIQUE index, the old row is deleted before the new row is inserted.

Insert or update on duplicate key or unique index: Add entries if the inserted value does not exist or update entries if the inserted value already exists and there is a risk of violating a unique index or primary key.

Insert Ignore: Add only new rows to prevent duplicate key errors.

Warning:
You must specify at least one column as a primary key on which the Update and Delete operations are based. You can do that by clicking Edit Schema and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the Advanced settings view where you can simultaneously define primary keys for the update and delete operations. To do that: Select the Use field options check box and then in the Key in update column, select the check boxes next to the column name on which you want to base the update operation. Do the same in the Key in delete column for the deletion operation.

### Schema and Edit schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

Built-In: You create and store the schema locally for this component only.

Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- View schema: choose this option to view the schema only.
- Change to built-in property: choose this option to change the schema to Built-in for local changes.
- Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.
<table>
<thead>
<tr>
<th><strong>Die on error</strong></th>
<th>This check box is selected by default. Clear the check box to skip the row in error and complete the process for error-free rows. If needed, you can retrieve the rows in error via a Row &gt; Rejects link.</th>
</tr>
</thead>
</table>
| **Specify a data source alias** | Select this check box and specify the alias of a data source created on the Talend Runtime side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in Talend Runtime.  

**Warning:**  
If you use the component’s own DB configuration, your data source connection will be closed at the end of the component. To prevent this from happening, use a shared DB connection with the data source alias specified.  

This check box is not available when the **Use an existing connection** check box is selected. |

## Advanced settings

| **Additional JDBC parameters** | Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the **Use an existing connection** check box in the **Basic settings**.  

**Note:**  
You can press Ctrl+Space to access a list of predefined global variables. |
|-------------------|----------------------------------------------------------------------------------------------------------|
| **Extend Insert** | Select this check box to carry out a bulk insert of a defined set of lines instead of inserting lines one by one. The gain in system performance is considerable.  

**Number of rows per insert**: enter the number of rows to be inserted per operation. Note that the higher the value specified, the lower performance levels shall be due to the increase in memory demands.  

**Note:**  
This option is not compatible with the Reject link. You should therefore clear the check box if you are using a Row > Rejects link with this component.  

**Warning:**  
If you are using this component with tMysqlLastInsertID, ensure that the **Extend Insert** check box in **Advanced Settings** is not selected. **Extend Insert** allows for batch loading, however, if the check box is selected, only the ID of the last line of the last batch will be returned. |
<p>| <strong>Use Batch</strong> | Select this check box to activate the batch mode for data processing. |</p>
<table>
<thead>
<tr>
<th><strong>Note:</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>This check box is available only when you have selected, the Update or the Delete option in the Action on data field.</td>
</tr>
</tbody>
</table>

| **Batch Size** | Specify the number of records to be processed in each batch. This field appears only when the Use batch mode check box is selected. |
| **Commit every** | Number of rows to be included in the batch before it is committed to the DB. This option ensures transaction quality (but not rollback) and, above all, a higher performance level. |
| **Additional Columns** | This option is not available if you have just created the DB table (even if you delete it beforehand). This option allows you to call SQL functions to perform actions on columns, provided that these are not insert, update or delete actions, or actions that require pre-processing. |

| **Name:** | Type in the name of the schema column to be altered or inserted. |
| **SQL expression:** | Type in the SQL statement to be executed in order to alter or insert the data in the corresponding column. |
| **Position:** | Select Before, Replace or After, depending on the action to be performed on the reference column. |
| **Reference column:** | Type in a reference column that tMySqlOutput can use to locate or replace the new column, or the column to be modified. |

| **Use field options** | Select this check box to customize a request, particularly if multiple actions are being carried out on the data. |
| **Use Hint Options** | Select this check box to activate the hint configuration area which helps you optimize a query's execution. In this area, parameters are: | - **HINT**: specify the hint you need, using the syntax /*+ */. | - **POSITION**: specify where you put the hint in a SQL statement. | - **SQL STMT**: select the SQL statement you need to use. |
| **Enable debug mode** | Select this check box to display each step involved in the process of writing data in the database. |
| **Use duplicate key update mode insert** | Updates the values of the columns specified, in the event of duplicate primary keys.: | - **Column**: Between double quotation marks, enter the name of the column to be updated. | - **Value**: Enter the action you want to carry out on the column. |
**tStatCatcher Statistics**

Select this check box to collect log data at the component level.

---

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_LINE: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>NB_LINE_UPDATED: the number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>NB_LINE_INSERTED: the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>NB_LINE_DELETED: the number of rows deleted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>NB_LINE_REJECTED: the number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>QUERY: the query statement processed. This is an After variable and it returns a string.</td>
</tr>
</tbody>
</table>

To fill up a field or expression with a variable, press `Ctrl + Space` to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

---

### Usage

**Usage rule**

This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible.

This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in a MySQL database. It also allows you to create a reject flow using a Row > Rejects link to filter data in error.

For an example of tMySqlOutput in use, see [Retrieving data in error with a Reject link on page 2485](#).

**Dynamic settings**

Click the `[+]` button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic Settings** view.
settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Inserting a column and altering data using tMysqlOutput

This Java scenario is a three-component job that aims at creating random data using a tRowGenerator, duplicating a column to be altered using the tMap component, and eventually altering the data to be inserted based on an SQL expression using the tMysqlOutput component.

- Drop the following components from the Palette onto the design workspace: tRowGenerator, tMap and tMySQLOutput.
- Connect tRowGenerator, tMap, and tMysqlOutput using the Row Main link.

- In the design workspace, select tRowGenerator to display its Basic settings view.

- Click the Edit schema three-dot button to define the data to pass on to the tMap component, two columns in this scenario, name and random_date.
• Click OK to close the dialog box.
• Click the RowGenerator Editor three-dot button to open the editor and define the data to be generated.

  ![RowGenerator Editor](image)

  - Click in the corresponding Functions fields and select a function for each of the two columns, getFirstName for the first column and getRandomDate for the second column.
  - In the Number of Rows for Rowgenerator field, enter 10 to generate ten first name rows and click Ok to close the editor.
  - Double-click the tMap component to open the Map editor. The Map editor opens displaying the input metadata of the tRowGenerator component.
• In the **Schema editor** panel of the Map editor, click the plus button of the output table to add two rows and define the first as `random_date` and the second as `random_date1`.

In this scenario, we want to duplicate the `random_date` column and adapt the schema in order to alter the data in the output component.

• In the Map editor, drag the `random_date` row from the input table to the `random_date` and `random_date1` rows in the output table.
- Click **OK** to close the editor.
- In the design workspace, double-click the **tMysqlOutput** component to display its **Basic settings** view and set its parameters.

  ![tMysqlOutput Component](image)

- Set **Property Type** to **Repository** and then click the three-dot button to open the **Repository content** dialog box and select the correct DB connection. The connection details display automatically in the corresponding fields.

  ![Repository Content Dialog](image)

  **Note:**
  
  If you have not stored the DB connection details in the **Metadata** entry in the **Repository**, select **Built-in** on the property type list and set the connection detail manually.

- Click the three-dot button next to the **Table** field and select the table to be altered, `Dates` in this scenario.
On the **Action on table** list, select **Drop table if exists and create**, select **Insert** on the **Action on data** list.

- If needed, click **Sync columns** to synchronize with the columns coming from the **tMap** component.
- Click the **Advanced settings** tab to display the corresponding view and set the advanced parameters.

- In the **Additional Columns** area, set the alteration to be performed on columns.
  
  In this scenario, the **One_month_later** column replaces **random_date_1**. Also, the data itself gets altered using an SQL expression that adds one month to the randomly picked-up date of the **random_date_1** column. ex: 2007-08-12 becomes 2007-09-12.

  - Enter **One_Month_Later** in the **Name** cell.
  
  - In the **SQL expression** cell, enter the relevant addition script to be performed, "**adddate(Random_date, interval 1 month)**" in this scenario.
  
  - Select **Replace** on the **Position** list.
  
  - Enter **Random_date1** on the **Reference column** list.

**Note:**

For this job we duplicated the **random_date_1** column in the DB table before replacing one instance of it with the **One_Month_Later** column. The aim of this workaround was to be able to view upfront the modification performed.

- Save your job and press **F6** to execute it.

The new **One_month_later** column replaces the **random_date1** column in the DB table and adds one month to each of the randomly generated dates.
Updating data using `tMysqlOutput`

This Java scenario describes a two-component Job that updates data in a MySQL table according to that in a delimited file.

- Drop `tFileInputDelimited` and `tMysqlOutput` from the Palette onto the design workspace.
- Connect the two components together using a Row Main link.

Double-click `tFileInputDelimited` to display its Basic settings view and define the component properties.

- From the Property Type list, select Repository if you have already stored the metadata of the delimited file in the Metadata node in the Repository tree view. Otherwise, select Built-In to define manually the metadata of the delimited file.

For more information about storing metadata, see Talend Studio User Guide.
In the **File Name** field, click the three-dot button and browse to the source delimited file that contains the modifications to propagate in the MySQL table.

In this example, we use the `customer_update` file that holds four columns: `id`, `CustomerName`, `CustomerAddress` and `idState`. Some of the data in these four columns is different from that in the MySQL table.

<table>
<thead>
<tr>
<th>id</th>
<th>CustomerName</th>
<th>CustomerAddress</th>
<th>idState</th>
</tr>
</thead>
<tbody>
<tr>
<td>858</td>
<td>Froggy’s Gourmet Catering</td>
<td>1831 Beverly Place #9D</td>
<td>4</td>
</tr>
<tr>
<td>859</td>
<td>Dependable Plumbing and Sewer</td>
<td>1550 Ridge Rd.</td>
<td>25</td>
</tr>
<tr>
<td>860</td>
<td>Lickmen Restoration</td>
<td>1235 Easton Rd.</td>
<td>40</td>
</tr>
<tr>
<td>861</td>
<td>Actuarial Enterprises Ltd.</td>
<td>3148 cottonwood Ct.</td>
<td>18</td>
</tr>
<tr>
<td>862</td>
<td>Rythmics Ltd.</td>
<td>857 Woodbine Rd.</td>
<td>30</td>
</tr>
<tr>
<td>863</td>
<td>Actuarial Enterprises Ltd.</td>
<td>1482 Concorde Circle</td>
<td>48</td>
</tr>
<tr>
<td>864</td>
<td>Crossstracks Car Wash</td>
<td>218 Oakridge Ave.</td>
<td>39</td>
</tr>
<tr>
<td>865</td>
<td>Meonits &amp; Mogigni Inc.</td>
<td>616 Cobblestone Cir.</td>
<td>17</td>
</tr>
<tr>
<td>866</td>
<td>Foy Aviation</td>
<td>2220 Grant Blvd.</td>
<td>50</td>
</tr>
<tr>
<td>867</td>
<td>Ebert Music Center</td>
<td>12 Broadview Lane</td>
<td>29</td>
</tr>
<tr>
<td>868</td>
<td>Janice Mann Accounting Service</td>
<td>1660 Park Ave.</td>
<td>9</td>
</tr>
<tr>
<td>869</td>
<td>Johnson, Erico &amp; Co CPA’s</td>
<td>2922 Twin Oaks Drive</td>
<td>40</td>
</tr>
<tr>
<td>870</td>
<td>Corbins, Rodriguez, &amp; Savacochi</td>
<td>115 Pleasant Ave.</td>
<td>18</td>
</tr>
<tr>
<td>871</td>
<td>Nina’s Snow Plowing</td>
<td>3385 University Ave.</td>
<td>20</td>
</tr>
<tr>
<td>872</td>
<td>Darcy Frame and Matting Servic</td>
<td>1101 Deerfield Place</td>
<td>47</td>
</tr>
<tr>
<td>873</td>
<td>Marks, Marks, and Kaplan Ltd.</td>
<td>1949 Cloverdale Rd.</td>
<td>9</td>
</tr>
</tbody>
</table>

- Define the row and field separators used in the source file in the corresponding fields.
- If needed, set **Header**, **Footer** and **Limit**.

In this example, **Header** is set to 1 since the first row holds the names of columns, therefore it should be ignored. Also, the number of processed lines is limited to 2000.

- Click the three-dot button next to **Edit Schema** to open a dialog box where you can describe the data structure of the source delimited file that you want to pass to the component that follows.

<table>
<thead>
<tr>
<th>Column</th>
<th>Key</th>
<th>Type</th>
<th>Nullable</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>✓</td>
<td>Integer</td>
<td>✓</td>
</tr>
<tr>
<td>CustomerName</td>
<td></td>
<td>String</td>
<td>✓</td>
</tr>
<tr>
<td>CustomerAddress</td>
<td></td>
<td>String</td>
<td>✓</td>
</tr>
<tr>
<td>idState</td>
<td></td>
<td>Integer</td>
<td>✓</td>
</tr>
</tbody>
</table>

- Select the **Key** check box(es) next to the column name(s) you want to define as key column(s).

**Note:**

It is necessary to define at least one column as a key column for the Job to be executed correctly. Otherwise, the Job is automatically interrupted and an error message displays on the console.

- In the design workspace, double-click **tMysqlOutput** to open its **Basic settings** view where you can define its properties.
Click **Sync columns** to retrieve the schema of the preceding component. If needed, click the three-dot button next to **Edit schema** to open a dialog box where you can check the retrieved schema.

From the **Property Type** list, select **Repository** if you have already stored the connection metadata in the **Metadata** node in the **Repository** tree view. Otherwise, select **Built-In** to define manually the connection information.

For more information about storing metadata, see *Talend Studio User Guide*.

Fill in the database connection information in the corresponding fields.

In the **Table** field, enter the name of the table to update.

From the **Action on table** list, select the operation you want to perform, **Default** in this example since the table already exists.

From the **Action on data** list, select the operation you want to perform on the data, **Update** in this example.

Save your Job and press **F6** to execute it.
Using your DB browser, you can verify if the MySQL table, `customers`, has been modified according to the delimited file.

In the above example, the database table has always the four columns `id`, `CustomerName`, `CustomerAddress` and `idState`, but certain fields have been modified according to the data in the delimited file used.

**Retrieving data in error with a Reject link**

This scenario describes a four-component Job that carries out migration from a customer file to a MySQL database table and redirects data in error towards a CSV file using a **Reject** link.
• In the **Repository**, select the customer file metadata that you want to migrate and drop it onto the workspace. In the **Components** dialog box, select **tFileInputDelimited** and click **OK**. The component properties will be filled in automatically.

• If you have not stored the information about your customer file under the **Metadata** node in the **Repository**, drop a **tFileInputDelimited** component from the family **File > Input**, in the **Palette**, and fill in its properties manually in the **Component** tab.

• From the **Palette**, drop a **tMap** from the **Processing** family onto the workspace.

• In the **Repository**, expand the **Metadata** node, followed by the **Db Connections** node and select the connection required to migrate your data to the appropriate database. Drop it onto the workspace. In the **Components** dialog box, select **tMysqlOutput** and click **OK**. The database connection properties will be automatically filled in.

• If you have not stored the database connection details under the **Db Connections** node in the **Repository**, drop a **tMysqlOutput** from the **Databases** family in the **Palette** and fill in its properties manually in the **Component** tab.

For more information, see *Talend Studio User Guide*.

• From the **Palette**, select a **tFileOutputDelimited** from the **File > Output** family, and drop it onto the workspace.

• Link the **customers** component to the **tMap** component, and the **tMap** and **Localhost** with a **Row Main** link. Name this second link **out**.

• Link the **Localhost** to the **tFileOutputDelimited** using a **Row > Reject** link.

• Double-click the **customers** component to display the **Component** view.

  ![customers(tFileInputDelimited_1)](image)

• In the **Property Type** list, select **Repository** and click the **[...] button** in order to select the metadata containing the connection to your file. You can also select the **Built-in** mode and fill in the fields manually.

• Click the **[...] button** next to the **File Name** field, and fill in the path and the name of the file you want to use.

• In the **Row** and **Field Separator** fields, type in between inverted commas the row and field separator used in the file.

• In the **Header**, **Footer** and **Limit** fields, type in the number of headers and footers to ignore, and the number of rows to which processing should be limited.

• In the **Schema** list, select **Repository** and click the **[...] button** in order to select the schema of your file, if it is stored under the **Metadata** node in the **Repository**. You can also click the **[...] button** next to the **Edit schema** field, and set the schema manually.

The schema is as follows:
• Double-click the **tMap** component to open its editor.

![Diagram of tMap component](image)

<table>
<thead>
<tr>
<th>Column</th>
<th>Expression</th>
<th>Column</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>row1.id</td>
<td>id</td>
</tr>
<tr>
<td>CustomerName</td>
<td>row1.CustomerName</td>
<td>CustomerName</td>
</tr>
<tr>
<td>CustomerAddress</td>
<td>row1.CustomerAddress</td>
<td>CustomerAddress</td>
</tr>
<tr>
<td>idState</td>
<td>row1.idState</td>
<td>idState</td>
</tr>
<tr>
<td>id2</td>
<td>row1.id2</td>
<td>id2</td>
</tr>
<tr>
<td>RegTime</td>
<td>row1.RegTime</td>
<td>RegTime</td>
</tr>
<tr>
<td>RegisterTime</td>
<td>row1(RegisterTime)</td>
<td>RegisterTime</td>
</tr>
</tbody>
</table>

• Select the **id, CustomerName, CustomerAddress, idState, id2, RegTime and RegisterTime** columns on the table on the left and drop them on the **out** table, on the right.
In the Schema editor area, at the bottom of the tMap editor, in the right table, change the length of the CustomerName column to 28 to create an error. Thus, any data for which the length is greater than 28 will create errors, retrieved with the Reject link.

Click OK.

In the workspace, double-click the output Localhost component to display its Component view.

In the Property Type list, select Repository and click the [...] button to select the connection to the database metadata. The connection details will be automatically filled in. You can also select the Built-in mode and set the fields manually.

In the Table field, type in the name of the table to be created. In this scenario, we call it customers_data.

In the Action on data list, select the Create table option.

Click the Sync columns button to retrieve the schema from the previous component.

Make sure the Die on error check box isn’t selected, so that the Job can be executed despite the error you just created.

Click the Advanced settings tab of the Component view to set the advanced parameters of the component.
• Deselect the **Extend Insert** check box which enables you to insert rows in batch, because this option is not compatible with the **Reject** link.
• Double-click the **tFileOutputDelimited** component to set its properties in the **Component** view.

• Click the [...] button next to the **File Name** field to fill in the path and name of the output file.
• Click the **Sync columns** button to retrieve the schema of the previous component.
• Save your Job and press **F6** to execute it.
The data in error are sent to the delimited file, as well as the error type met. Here, we have: **Data truncation**.

<table>
<thead>

</tbody>
</table>
tMysqlOutputBulk

Writes a file with columns based on the defined delimiter and the MySQL or Aurora standards.

The tMysqlOutputBulk and tMysqlBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT statement used to feed a database. These two steps are fused together in the tMysqlOutputBulkExec component, detailed in a separate section. The advantage of using two separate steps is that the data can be transformed before it is loaded in the database.

tMysqlOutputBulk Standard properties

These properties are used to configure tMysqlOutputBulk running in the Standard Job framework.

The Standard tMysqlOutputBulk component belongs to the Databases family.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>File Name</td>
<td>Name of the file to be generated. This file is generated on the same machine where the Studio is installed or where the Job using tMysqlOutputBulk is deployed.</td>
</tr>
<tr>
<td>Append</td>
<td>Select this check box to add the new rows at the end of the file.</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td></td>
<td>Built-In: You create and store the schema locally for this component only.</td>
</tr>
<tr>
<td></td>
<td>Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. When the schema to be reused has default values that are integers or functions, ensure that these default values are...</td>
</tr>
</tbody>
</table>
not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

### Advanced settings

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Row separator</strong></td>
<td>String (ex: &quot;\n&quot; on Unix) to distinguish rows.</td>
</tr>
<tr>
<td><strong>Field separator</strong></td>
<td>Character, string or regular expression to separate fields.</td>
</tr>
<tr>
<td><strong>Text enclosure</strong></td>
<td>Character used to enclose the text.</td>
</tr>
<tr>
<td><strong>Create directory if does not exist</strong></td>
<td>This check box is selected by default. It creates a directory to hold the output table if required.</td>
</tr>
<tr>
<td><strong>Custom the flush buffer size</strong></td>
<td>Customize the amount of memory used to temporarily store output data. In the <strong>Row number field</strong>, enter the number of rows after which the memory is to be freed again.</td>
</tr>
<tr>
<td><strong>Records contain NULL value</strong></td>
<td>This check box is selected by default. It allows you to take account of NULL value fields. If you clear the check box, the NULL values will automatically be replaced with empty values.</td>
</tr>
<tr>
<td><strong>Check disk space</strong></td>
<td>Select the this check box to throw an exception during execution if the disk is full.</td>
</tr>
<tr>
<td><strong>Encoding</strong></td>
<td>Select the encoding from the list or select <strong>Custom</strong> and define it manually. This field is compulsory for DB data handling.</td>
</tr>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to collect the log data at the component level.</td>
</tr>
</tbody>
</table>

### Global Variables

| Global Variables | **NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.  
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the |
Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is to be used along with tMySQLBulkExec component. Used together they offer gains in performance while feeding a MySQL or Aurora database.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component family</td>
<td>Databases/MySQL</td>
</tr>
<tr>
<td>Limitation</td>
<td>Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
</tbody>
</table>

Inserting transformed data in MySQL database

This scenario describes a four-component job which aims at fueling a database with data contained in a file, including transformed data. Two steps are required in this job, first step is to create the file, that will then be used in the second step. The first step includes a transformation phase of the data included in the file.
## Dropping and linking components

**Procedure**

1. Drag and drop a `tRowGenerator`, a `tMap`, a `tMysqlOutputBulk` as well as a `tMysqlBulkExec` component.
2. Connect the main flow using **row Main** links.
3. And connect the start component (`tRowgenerator` in this example) to the `tMysqlBulkExec` using a **trigger** connection, of type **OnComponentOk**.

## Configuring the components

**Procedure**

1. A `tRowGenerator` is used to generate random data. Double-click on the `tRowGenerator` component to launch the editor.
2. Define the schema of the rows to be generated and the nature of data to generate. In this example, the `clients` file to be produced will contain the following columns: **ID**, **First Name**, **Last Name**, **Address**, **City** which all are defined as string data but the **ID** that is of integer type.

<table>
<thead>
<tr>
<th>Column</th>
<th>Key</th>
<th>Type</th>
<th>N.</th>
<th>Length</th>
<th>Functions</th>
<th>Preview</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>FirstName</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>LastName</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Address</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>City</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Some schema information don’t necessarily need to be displayed. To hide them away, click on **Columns** list button next to the toolbar, and uncheck the relevant entries, such as **Precision** or **Parameters**.

Use the plus button to add as many columns to your schema definition.

Click the Refresh button to preview the first generated row of your output.

3. Then select the `tMap` component to set the transformation.
4. Drag and drop all columns from the input table to the output table.
5. Apply the transformation on the LastName column by adding `.toUpperCase()` in its expression field. Then, click OK to validate the transformation.

6. Double-click on the tMysqlOutputBulk component.

7. Define the name of the file to be produced in File Name field. If the delimited file information is stored in the Repository, select it in Property Type field, to retrieve relevant data. In this use case the file name is clients.txt. The schema is propagated from the tMap component, if you accepted it when prompted.

8. In this example, don’t include the header information as the table should already contain it.

9. Click OK to validate the output.

10. Then double-click on the tMysqlBulkExec component to set the INSERT query to be executed.

11. Define the database connection details. We recommend you to store this type of information in the Repository, so that you can retrieve them at any time for any Job.

12. Set the table to be filled in with the collected data, in the Table field.

13. Fill in the column delimiters in the Field terminated by area.

14. Make sure the encoding corresponds to the data encoding.

**Saving and executing the Job**

**Procedure**

1. Press Ctrl+S to save your Job.

2. Press F6 or click Run on the Run tab to execute the Job.
<table>
<thead>
<tr>
<th>ID</th>
<th>First Name</th>
<th>Last Name</th>

<td>Calvin</td>
<td>COOLIDGE</td>
<td>Harbor Dr</td>
<td>Franklin</td>
</tr>
</tbody>
</table>

The clients database table is filled with data from the file including upper-case last name as transformed in the job.

**Results**

For simple Insert operations that don't include any transformations, the use of `tMysqlOutputBulkExec` allows you to skip a step in the process and thus improves performance.

Related topic: `tMysqlOutputBulkExec Standard properties` on page 2497
tMysqlOutputBulkExec

Executes the Insert action in the specified MySQL or Aurora database.

As a dedicated component, tMysqlBulkExec improves performance when performing Insert operations to a MySQL or Aurora database.

The tMysqlOutputBulk and tMysqlBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT statement used to feed a database. These two steps are fused together in the tMysqlOutputBulkExec component.

### tMysqlOutputBulkExec Standard properties

These properties are used to configure tMysqlOutputBulkExec running in the Standard Job framework.

The Standard tMysqlOutputBulkExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

<tr>
<td>Database</td>
<td>Name of the database</td>
</tr>
</tbody>
</table>
| Username and Password | DB user authentication data.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings. |
| Action on table| On the table defined, you can perform one of the following operations:  
**None:** No operation is carried out.  
**Drop and create table:** The table is removed and created again. |
<table>
<thead>
<tr>
<th>tMysqlOutputBulkExec</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Create table</strong>: The table does not exist and gets created.</td>
</tr>
<tr>
<td><strong>Create table if not exists</strong>: The table is created if it does not already exist.</td>
</tr>
<tr>
<td><strong>Drop table if exists and create</strong>: The table is removed if it already exists and created again.</td>
</tr>
<tr>
<td><strong>Clear table</strong>: The table content is deleted.</td>
</tr>
</tbody>
</table>

**Table**

Name of the table to be written.

**Note:**

Note that only one table can be written at a time and that the table must already exist for the insert operation to succeed

**Local FileName**

Name of the file to be generated and loaded.

This file is generated on the same machine where the Studio is installed or where the Job using tMysqlOutputBulkExec is deployed. Then it is loaded to the database specified by Host field.

**Append**

Select the check box for this option to append new rows to the end of the file.

**Schema and Edit Schema**

A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either Built-in or stored remotely in the Repository.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

**Built-In**

You create and store the schema locally for this component only.

**Repository**

You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).
## Advanced settings

</thead>
<tbody>
<tr>
<td><strong>Usage rule</strong></td>
<td>This component is mainly used when no particular transformation is required on the data to be loaded onto the database.</td>
</tr>
</tbody>
</table>
Inserting data in bulk in MySQL database

This scenario describes a two-component Job which carries out the same operation as the one described for tMysqlOutputBulk Standard properties on page 2491 and tMysqlBulkExec Standard Properties on page 2423, although no data is transformed.

- Drop a tRowGenerator and a tMysqlOutputBulkExec component from the Palette to the design workspace.
- Connect the components using a link such as Row > Main.
- Set the tRowGenerator parameters the same way as in Inserting transformed data in MySQL database on page 2493. The schema is made of four columns including: ID, First Name, Last Name, Address and City.
- In the workspace, double-click the tMysqlOutputBulkExec to display the Component view and set the properties.

![tMysqlOutputBulkExec_1]

- Define the database connection details in the corresponding fields, if necessary. Consult the recommendations detailed in Inserting transformed data in MySQL database on page 2493, concerning the conservation of connection details in the Repository, under the Metadata node. In the component view, select Repository in the Property Type field and then select the appropriate connection in the adjacent field. The following fields will be filled in automatically.

For further information, see Talend Studio User Guide.

- In the Action on table field, select the None option as you want to insert the data into a table which already exists.
- In the Table field, enter the name of the table you want to populate, the name being clients in this example.
- In the Local filename field, indicate the access path and the name of the file which contains the data to be added to the table. In this example, the file is clients.txt.
- Click on the Advanced settings tab to define the component’s advanced parameters.
In the **Action on data** list, select the **Insert records in table** to insert the new data in the table.

- Press **F6** to run the Job.

The result should be pretty much the same as in Inserting transformed data in MySQL database on page 2493, but the data might differ as these are regenerated randomly everytime the Job is run.
tMysqlRollback

Cancels the transaction commit in the connected MySQL database to avoid committing part of a transaction involuntarily.

tMysqlRollback Standard properties

These properties are used to configure tMysqlRollback running in the Standard Job framework.
The Standard tMysqlRollback component belongs to the Databases family.
The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tMysqlConnection component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

Usage

| Usage rule | This component is more commonly used with other tMysql* components, especially with the tMysqlConnection and tMysqlCommit components. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection |
parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.
tMysqlRow

Executes the stated SQL query on the specified MySQL database.

Depending on the nature of the query and the database, tMysqlRow acts on the actual DB structure or on the data (although without handling data). The SQLBuilder tool helps you write easily your SQL statements.

tMysqlRow is the specific component for MySQL database query. It implements a flow in the Job design although it doesn’t provide output.

**tMysqlRow Standard properties**

These properties are used to configure tMysqlRow running in the Standard Job framework.

The Standard tMysqlRow component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
<td></td>
</tr>
<tr>
<td>DB Version</td>
<td>Select the MySQL version that you are using.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>Host</th>
<th>Database server IP address</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td>Built-In</td>
<td>You create and store the schema locally for this component only.</td>
</tr>
<tr>
<td>Repository</td>
<td>You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually. You can find more details about how to verify default values in retrieved schema in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
</tbody>
</table>

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate
If you want to change the current job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

<table>
<thead>
<tr>
<th><strong>Table Name</strong></th>
<th>Name of the table to be processed.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Query type</strong></td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in:</strong></td>
<td>Fill in manually the query statement or build it graphically using SQLBuilder</td>
</tr>
<tr>
<td><strong>Repository:</strong></td>
<td>Select the relevant query stored in the Repository. The Query field gets accordingly filled in.</td>
</tr>
<tr>
<td><strong>Guess Query</strong></td>
<td>Click the <strong>Guess Query</strong> button to generate the query which corresponds to your table schema in the <strong>Query</strong> field.</td>
</tr>
<tr>
<td><strong>Query</strong></td>
<td>Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.</td>
</tr>
<tr>
<td><strong>Die on error</strong></td>
<td>This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a <strong>Row &gt; Rejects</strong> link.</td>
</tr>
<tr>
<td><strong>Specify a data source alias</strong></td>
<td>Select this check box and specify the alias of a data source created on the <strong>Talend Runtime</strong> side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in <strong>Talend Runtime</strong>. If you use the component’s own DB configuration, your data source connection will be closed at the end of the component. To prevent this from happening, use a shared DB connection with the data source alias specified. This check box is not available when the <strong>Use an existing connection</strong> check box is selected.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| **Additional JDBC parameters** | Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the **Use an existing connection** check box in the **Basic settings**. |
| **Propagate QUERY’s recordset** | Select this check box to insert the result of the query in a COLUMN of the current flow. Select this column from the **use column** list. **Note:** This option allows the component to have a different schema from that of the preceding component. Moreover, the column that holds the QUERY’s recordset should be set to the type of **Object** and this component is usually followed by **tParseRecordSet**. |
| **Use PreparedStatement**     | Select this check box if you want to query the database using a PreparedStatement. In the **Set PreparedStatement**... |
Parameter table, define the parameters represented by '?' in the SQL instruction of the Query field in the Basic Settings tab.

**Parameter Index**: Enter the parameter position in the SQL instruction.

**Parameter Type**: Enter the parameter type.

**Parameter Value**: Enter the parameter value.

**Note**: This option is very useful if you need to execute the same query several times. Performance levels are increased.

<table>
<thead>
<tr>
<th>Commit every</th>
<th>Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
<th>Select this check box to collect log data at the component level.</th>
</tr>
</thead>
</table>

**Global Variables**

| Global Variables | **QUERY**: the query statement being processed. This is a Flow variable and it returns a string.  
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
For further information about variables, see *Talend Studio User Guide*. |
| --- | --- |

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component offers the flexibility of the DB query and covers all possible SQL queries.</th>
</tr>
</thead>
</table>

| Dynamic settings | Click the [*] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. |
The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

### Removing and regenerating a MySQL table index

This scenario describes a four-component job that removes a table index, applies a select insert action onto a table then regenerates the index.

**Linking the components**

**Procedure**

1. Select and drop the following components onto the design workspace: **tMysqlRow** (x2), **tRowGenerator**, and **tMysqlOutput**.
2. Link the first **tMysqlRow** to **tRowGenerator** using an **OnComponentOk** connection.
3. Link **tRowGenerator** to **tMysqlOutput** using a **Row > Main** connection.
4. Link **tRowGenerator** to the second **tMysqlRow** using an **OnSubjobOk** connection.

![Diagram of components](image)

**Configuring the components**

**Procedure**

1. Select the **tMysqlRow** to fill in the DB **Basic settings**.
2. In **Property type** as well in **Schema**, select the relevant DB entry in the list.
   The DB connection details and the table schema are accordingly filled in.
3. Propagate the properties and schema details onto the other components of the Job.
The query being stored in the Metadata area of the Repository, you can also select Repository in the Query type field and the relevant query entry.

4. If you didn’t store your query in the Repository, type in the following SQL statement to alter the database entries: drop index <index_name> on <table_name>

5. Select the second tMysqlRow component, check the DB properties and schema.

6. Type in the SQL statement to recreate an index on the table using the following statement: create index <index_name> on <table_name>  (<column_name>)

   The tRowGenerator component is used to generate automatically the columns to be added to the DB output table defined.

7. Select the tMysqlOutput component and fill in the DB connection properties either from the Repository or manually the DB connection details are specific for this use only. The table to be fed is named: comprehensive.

8. The schema should be automatically inherited from the data flow coming from the tLogRow. Edit the schema to check its structure and check that it corresponds to the schema expected on the DB table specified.

   The Action on table is None and the Action on data is Insert.

   No additional Columns is required for this job.

**Executing the Job**

**Procedure**

1. Press Ctrl+S to save the Job.
2. Press F6 to run the job.

   If you manage to watch the action on DB data, you can notice that the index is dropped at the start of the job and recreated at the end of the insert action.

   Related topics: tDBSQLRow Standard properties on page 622.

**Using PreparedStatement objects to query data**

This scenario describes a four component job which allows you to link a table column with a client file. The MySQL table contains a list of all the American States along with the State ID, while the file contains the customer information including the ID of the State in which they live. We want to retrieve the name of the State for each client, using an SQL query. In order to process a large volume of data quickly, we use a PreparedStatement object which means that the query is executed only once rather than against each row in turn. Then each row is sent as a parameter. Note that PreparedStatement object can also be used in avoiding SQL injection.

For this scenario, we use a file and a database for which we have already stored the connection and properties in the Repository metadata. For further information concerning the creation of metadata in delimited files, the creation of database connection metadata and the usage of metadata, see Talend Studio User Guide.

**Linking the components**

**Procedure**

1. In the Repository, expand the Metadata and File delimited nodes.
2. Select the metadata which corresponds to the client file and slide the metadata onto the workspace. Here, we are using the *customers* metadata.

3. Double-click **tFileInputDelimited** in the **Components** dialog box to add **tFileInputDelimited** to the workspace, with the relevant fields filled by the metadata file.

4. Drop **tMysqlRow**, **tParseRecordSet** and **tFileOutputDelimited** onto the workspace.

5. Link **tFileInputDelimited** to **tMysqlRow** using a **Row > Main** connection.

6. Link **tMysqlRow** to **tParseRecordSet** using a **Row > Main** connection.

7. Link **tParseRecordSet** to **tFileOutputDelimited** using a **Row > Main** connection.

---

**Configuring the components**

**Procedure**

1. Double-click **tFileInputDelimited** to open its **Basic settings** view.

![Basic settings view](image)

- **Property Type**: Repository
- **File name/Stream**: "D:\J04_bbbc\Files\customer.csv"
- **Row Separator**: "\n"
- **Field Separator**: ";"
- **Header**: 6
- **Footer**: 0
- **Limit**: 0
- **Repository**: DELIM:customers
- **Uncompress as zip file**: No
- **Die on error**: No

2. In the **Schema** list, select **Built-in** so that you can modify the component's schema. Then click on [...] next to the **Edit schema** field to add a column into which the name of the State will be inserted.
3. Click on the [+] button to add a column to the schema. Rename this column `LabelStateRecordSet` and select `Object` from the `Type` list. Click `OK` to save your modifications.

4. From the Palette, select the `tMysqlRow`, `tParseRecordSet` and `tFileOutputDelimited` components and drop them onto the workspace.

5. Double click `tMysqlRow` to set its properties in the Basic settings tab of the Component view.
6. In the Property Type list, select Repository and click on the [...] button to select a database connection from the metadata in the Repository. The DB Version, Host, Port, Database, Username and Password fields are completed automatically. If you are using the Built-in mode, complete these fields manually.

7. From the Schema list, select Built-in to set the schema properties manually and add the LabelStateRecordSet column, or click directly on the Sync columns button to retrieve the schema from the preceding component.

8. In the Query field, enter the SQL query you want to use. Here, we want to retrieve the names of the American States from the LabelState column of the MySQL table, us_state: "SELECT LabelState FROM us_state WHERE idState=?". The question mark, "?", represents the parameter to be set in the Advanced settings tab.

9. Click Advanced settings to set the components advanced properties.

10. Select the Propagate QUERY’s recordset check box and select the LabelStateRecordSet column from the use column list to insert the query results in that column.

11. Select the Use PreparedStatement check box and define the parameter used in the query in the Set PreparedStatement Parameters table.

12. Click on the [+] button to add a parameter.
   a) In the Parameter Index cell, enter the parameter position in the SQL instruction. Enter "1" as we are only using one parameter in this example.
   b) In the Parameter Type cell, enter the type of parameter. Here, the parameter is a whole number, hence, select Int from the list.
   c) In the Parameter Value cell, enter the parameter value. Here, we want to retrieve the name of the State based on the State ID for every client in the input file. Hence, enter "row1.idState".

13. Double click tParseRecordSet to set its properties in the Basic settings tab of the Component view.
a) From the **Prev. Comp. Column list**, select the preceding components column for analysis. In this example, select **LabelStateRecordSet**.

b) Click on the **Sync columns** button to retrieve the schema from the preceding component. The **Attribute table** is automatically completed with the schema columns.

c) In the **Attribute table**, in the **Value** field which corresponds to the **LabelStateRecordSet**, enter the name of the column containing the State names to be retrieved and matched with each client, within double quotation marks. In this example, enter "**LabelState**".

14. Double click **tFileOutputDelimited** to set its properties in the **Basic settings** tab of the **Component** view.

a) In the **File Name field**, enter the access path and name of the output file.

b) Click **Sync columns** to retrieve the schema from the preceding component.

**Executing the Job**

**Procedure**

1. Press **Ctrl+S** to save the Job.
2. Press **F6** to run it.

**Results**

A column containing the name of the American State corresponding to each client is added to the file.
Combining two flows for selective output

In this scenario, a flow generated by `tFixedFlowInput` is combined with a flow from the Mysql database. The source flow contains `id` and `age` fields while the Mysql table contains `id` and `name`. We want to retrieve the `age` data of the source flow and combine it with the `id` and `name` records from the Mysql table based on `id` matching. One thing that is worth noting is that the input schema is different from the output one at `tMysqlRow` in the Job.

Linking the components

Procedure

1. Drop `tFixedFlowInput`, `tMysqlRow`, `tParseRecordSet` and `tLogRow` onto the workspace.
2. Rename `tFixedFlowInput` as `source_flow`, `tMysqlRow` as `insert_recordset`, `tParseRecordSet` as `parse_recordset` and `tLogRow` as `show_combined_flow`.
3. Link `tFixedFlowInput` to `tMysqlRow` using a Row > Main connection.
4. Link `tMysqlRow` to `tParseRecordSet` using a Row > Main connection.
5. Link `tParseRecordSet` to `tLogRow` using a Row > Main connection.

Configuring the components

Procedure

1. Double-click `tFixedFlowInput` to open its Basic settings view.
2. Select **Use Inline Content (delimited file)** in the **Mode** area.

   In the **Content** field, enter the data to be transferred:

   
   
   
   
   | 1; 30 |
   | 2; 20 |

3. Double-click the [...] button next to **Edit schema** to open the schema editor.

   Click the [+ ] button to add two columns, namely **id** and **age**, with the type of **Integer**. Click **Ok** to close the editor.

4. Double-click **tMysqlRow** to open its **Basic settings** view.
5. In the **Host** and **Port** fields, enter the connection details.
   In the **Database** field, enter the database name.
   In the **Username** and **Password** fields, enter the authentication details.
   In the **Query** field, enter the SQL query to retrieve the `id` and `name` data from the Mysql table `employee`:
   
   ```sql
   select id, name from employee WHERE id=?
   ```
   
   The question mark, `?`, represents the parameter to be set in the **Advanced settings** tab.

6. Click the `[...]` button next to **Edit schema** to open the schema editor.

![Schema of insert_recordset](image)

7. Click the `[+]` button to add two columns in the right part, namely `recordset` and `age`, with the type of **Object** and **Integer**. Note that `recordset` is intended to hold the query results of the Mysql table, namely the `id` and `name` fields.
   
   Click **OK** to close the editor.

8. Click the **Advanced settings** tab for further setup.
9. Select the Propagate QUERY’s recordset check box and choose recordset from the use column list to insert the query results in that column. Select the Use PreparedStatement check box and define the parameter used in the query in the Set PreparedStatement Parameters table.

10. Click on the [+] button to add a line.

   In the Parameter Index cell, enter the parameter position in the SQL instruction. Enter “1” as we are only using one parameter in this example.

   In the Parameter Type cell, enter the type of parameter. Here, the parameter is an integer. Hence, select Int from the list.

   In the Parameter Value cell, enter the parameter value. Here, we want to retrieve the id and name from the employee table based on the id value from the source flow. Hence, enter row3.id.

11. Double-click tParseRecordSet to open its Basic settings view.

   From the Prev. Comp. Column list, select the column to parse, namely recordset.

12. Click the [...] button next to Edit schema to open the schema editor.
Click the [+] button to add three columns in the right part, namely id, name and age, with the type of Integer, String and Integer. Note that the id and name fields are intended to hold the parsed data of recordset.

Click OK to close the editor.

In the Attribute table, in the Value fields which correspond to id and name, enter the name of the column in the Mysql table to be retrieved, namely “id” and “name”.

13. Double-click tLogRow to open its Basic settings view.

In the Mode area, select Table (print values in cells of a table) for better display.

## Executing the Job

### Procedure

1. Press Ctrl+S to save the Job.
2. Press F6 to run the Job.

```
[statistics] connecting to socket on port 4030
[statistics] connected
show_combined_flow
+--------+--------+--------+
| id     | name   | age    |
|--------+--------+--------+
| 1      | Andy   | 30     |
| 2      | Anderson | 20    |
```

[statistics] disconnected
tMysqlSCD

Reflects and tracks changes in a dedicated MySQL SCD table.

tMysqlSCD addresses Slowly Changing Dimension needs, reading regularly a source of data and logging the changes into a dedicated SCD table.

tMysqlSCD Standard properties

These properties are used to configure tMysqlSCD running in the Standard Job framework.
The Standard tMysqlSCD component belongs to the Business Intelligence and the Databases families.
The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the Repository file where properties are stored. The following fields are pre-filled in using fetched data.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<p>| DB Version | Select the Mysql version you are using. |
| Host | Database server IP address. |</p>
<table>
<thead>
<tr>
<th><strong>Port</strong></th>
<th>Listening port number of DB server.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Table</strong></td>
<td>Name of the table to be written. Note that only one table can be written at a time.</td>
</tr>
</tbody>
</table>
| **Action on table** | On the table defined, you can perform one of the following operations:  
  **None**: No operation is carried out.  
  **Create a table**: The table does not exist and gets created.  
  **Create a table if not exists**: The table is created if it does not exist. |
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.  
  Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
  • **View schema**: choose this option to view the schema only.  
  • **Change to built-in property**: choose this option to change the schema to Built-in for local changes.  
  • **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.  
  **Built-in**: The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide.  
  **Repository**: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide. |
| **SCD Editor** | The SCD editor helps to build and configure the data flow for slowly changing dimension outputs.  
  For more information, see SCD management methodology on page 2522. |
| **Use memory saving mode** | Select this check box to maximize system performance. |
| **Source keys include Null** | Select this check box to allow the source key columns to have Null values. |
Warning:
Special attention should be paid to the uniqueness of the source key(s) values when this option is selected.

**Die on error**
This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

## Advanced settings

<table>
<thead>
<tr>
<th><strong>Advanced settings</strong></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Additional JDBC Parameters</strong></td>
<td>Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the <strong>Use an existing connection</strong> check box in the <strong>Basic settings</strong>.</td>
</tr>
<tr>
<td><strong>End date time details</strong></td>
<td>Specify the time value of the SCD end date time setting in the format of <strong>HH:mm:ss</strong>. The default value for this field is <strong>12:00:00</strong>.</td>
</tr>
<tr>
<td></td>
<td>This field appears only when SCD Type 2 is used and <strong>Fixed year value</strong> is selected for creating the SCD end date.</td>
</tr>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
<tr>
<td><strong>Debug mode</strong></td>
<td>Select this check box to display each step during processing entries in a database.</td>
</tr>
</tbody>
</table>

## Global Variables

<table>
<thead>
<tr>
<th><strong>Global Variables</strong></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Global Variables</strong></td>
<td><strong>NB_LINE_UPDATED</strong>: the number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td><strong>NB_LINE_INSERTED</strong>: the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td><strong>NB_LINE_REJECTED</strong>: the number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press <strong>Ctrl + Space</strong> to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td></td>
<td>For further information about variables, see <a href="#">Talend Studio User Guide</a>.</td>
</tr>
</tbody>
</table>

## Usage

<table>
<thead>
<tr>
<th><strong>Usage rule</strong></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Usage rule</strong></td>
<td>This component is used as Output component. It requires an Input component and Row main link as input.</td>
</tr>
</tbody>
</table>
**Dynamic settings**

Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

| Limitation                                                                 | This component does not support using SCD type 0 together with other SCD types. |

## SCD management methodology

Slowly Changing Dimensions (SCDs) are dimensions that change slowly over time.

The SCD editor offers the simplest method of building the data flow for the SCD outputs. In the SCD editor, you can map columns, select surrogate key columns, and set column change attributes through combining SCD types. The following figure illustrates an example of the SCD editor.
SCD keys

You must choose one or more source keys columns from the incoming data to ensure its unicity.

You must set one surrogate key column in the dimension table and map it to an input column in the source table. The value of the surrogate key links a record in the source to a record in the dimension table. The editor uses this mapping to locate the record in the dimension table and to determine whether a record is new or changing. The surrogate key is typically the primary key in the source, but it can be an alternate key as long as it uniquely identifies a record and its value does not change.

**Source keys**: Drag one or more columns from the Unused panel to the Source keys panel to be used as the key(s) that ensure the unicity of the incoming data.

**Surrogate keys**: Set the column where the generated surrogate key will be stored. A surrogate key can be generated based on a method selected on the Creation list.

**Creation**: Select any of the below methods to be used for the key generation.

- **Auto increment**: auto-incremental key.
- **Input field**: key is provided in an input field.

When selected, you can drag the appropriate field from the Unused panel to the complement field.
• **Routine**: from the complement field, you can press **Ctrl+Space** to display the autocompletion list and select the appropriate routine.
• **Table max +1**: the maximum value from the SCD table is incremented to create a surrogate key.
• **DB Sequence**: from the complement field, you can enter the name of the existing database sequence that will automatically increment the column indicated in the name field.

Note that this option is only available through the SCD Editor of the tOracleSCD.

**Slowly Changing Dimensions types**

The Slowly Changing Dimensions support four types of changes: **Type 0** through **Type 3**. You can apply any of the SCD types to any column in a source table by a simple drag-and-drop operation.

• **Type 0**: is not used frequently. Some dimension data may be overwritten and other may stay unchanged over time. This is most appropriate when no effort has been made to deal with the changing dimension issues.
• **Type 1**: no history is kept in the database. New data overwrites old data. Use this type if tracking changes is not necessary. This is most appropriate when correcting certain typos, for example the spelling of a name.
• **Type 2**: the whole history is stored in the database. This type tracks historical data by inserting a new record in the dimensional table with a separate key each time a change is made. This is most appropriate to track updates, for example.
• **Type 3**: only the information about a previous value of a dimension is written into the database. This type tracks changes using separate columns. This is most appropriate to track only the previous value of a changing column.

SCD **Type 2** principle lies in the fact that a new record is added to the SCD table when changes are detected on the columns defined. Note that although several changes may be made to the same record on various columns defined as SCD **Type 2**, only one additional line tracks these changes in the SCD table.

The SCD schema in this type should include SCD-specific extra columns that hold standard log information such as:

• **start**: adds a column to your SCD schema to hold the start date. You can select one of the input schema columns as a start date in the SCD table.
• **end**: adds a column to your SCD schema to hold the end date value for a record. When the record is currently active, the end date is **NULL** or you can select **Fixed Year Value** and fill in a fictive year to avoid having a null value in the end date field.

Since the **end** column is used to identify the active record, you should set the **Fixed year value** parameter to the same value as the records that were created previously.
• **version**: adds a column to your SCD schema to hold the version number of the record.
• **active**: adds a column to your SCD schema to hold the **true** or **false** status value. This column helps to easily spot the active record.

**Tracking data changes using Slowly Changing Dimensions (type 0 through type 3)**

This scenario describes a Job that stores and manages both the current and historical employee data in a MySQL table using SCD (Slowly Changing Dimensions).
The input data contains various employee details including name, age, role, and salary, and another id column is added to help ensuring the unicity of the input data.

At first, the following employee data is inserted to a new MySQL table using SCD:

<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
<th>age</th>
<th>role</th>
<th>salary</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Mark Smith</td>
<td>30</td>
<td>tester</td>
<td>11000.00</td>
</tr>
<tr>
<td>2</td>
<td>Thomas Johnson</td>
<td>32</td>
<td>developer</td>
<td>12000.00</td>
</tr>
<tr>
<td>3</td>
<td>Teddy Brown</td>
<td>33</td>
<td>tester</td>
<td>13000.00</td>
</tr>
</tbody>
</table>

Then the table is updated using SCD with the following renewed employee data.

<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
<th>age</th>
<th>role</th>
<th>salary</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Mark Smith</td>
<td>31</td>
<td>tester</td>
<td>11000.00</td>
</tr>
<tr>
<td>2</td>
<td>Thomas Johnson</td>
<td>32</td>
<td>developer</td>
<td>12000.00</td>
</tr>
<tr>
<td>3</td>
<td>Teddy Brown</td>
<td>33</td>
<td>writer</td>
<td>13500.00</td>
</tr>
</tbody>
</table>

You can see the age of Mark Smith is updated from 30 to 31, the role of Teddy Brown is changed from tester to writer, and his salary is raised from 13000.00 to 13500.00. In this scenario,

- we don’t want to track the data changes for the name field, so we will perform Type 0 SCD on it,
- we want the new age data to overwrite the existing data, so we will perform Type 1 SCD on it,
- we want to retain the full history of the role data, and always create a new record with the changed data and close the previous record, so we will perform Type 2 SCD on it,
- we want to keep the current and previous dimension values for the salary field, so we will perform Type 3 SCD on it.

For more information about SCD types, see SCD management methodology on page 2522.

**Creating a Job for tracking data changes in MySQL using SCD**

Create a Job to open a connection to a MySQL database, insert the employee data into a MySQL database table using SCD (Slowly Changing Dimensions)

This Job retrieves and displays the inserted data on the console, then updates the employee data in MySQL using SCD, retrieves and displays the updated data on the console, finally closes the connection to the MySQL database.
Procedure

1. Create a new Job and add a `tMysqlConnection` component, two `tFixedFlowInput` components, two `tMysqlSCD` components, two `tMysqlInput` components, two `tLogRow` components, and a `tMysqlClose` component by typing their names in the design workspace or dropping them from the Palette.

2. Link the first `tFixedFlowInput` component to the first `tMysqlSCD` component using a `Row > Main` connection.

3. Do the same to link the first `tMysqlInput` component to the first `tLogRow` component, the second `tFixedFlowInput` component to the second `tMysqlSCD` component, and the second `tMysqlInput` component to the second `tLogRow` component.

4. Link the `tMysqlConnection` component to the first `tFixedFlowInput` component using a `Trigger > OnSubjobOk` connection.

5. Do the same to link the first `tFixedFlowInput` component to the first `tMysqlInput` component, the first `tMysqlInput` component to the second `tFixedFlowInput` component, the second `tFixedFlowInput` component to the second `tMysqlInput` component, and the second `tMysqlInput` component to the `tMysqlClose` component.
Opening a connection to a MySQL database

Configure the tMysqlConnection component to open a connection to a MySQL database.

Procedure

1. Double-click the tMysqlConnection component to open its Basic settings view.

   ![tMysqlConnection component settings](image)

2. In the Host, Port, Database, Username, and Password fields, enter the information required for the connection to the MySQL database.

Inserting the employee data into a MySQL table using SCD

Configure the first tFixedFlowInput component and the first tMysqlSCD component to insert the employee data into a MySQL database table using SCD (Slowly Changing Dimensions).

Procedure

1. Double-click the first tFixedFlowInput component to open its Basic settings view.

   ![tFixedFlowInput component settings](image)

2. Click the button next to Edit schema and in the pop-up window define the schema by adding five columns: id and age of Integer type, name and role of String type, and salary of Double type.
When done, click OK to save the changes. In the pop-up dialog box, click Yes to propagate the schema to the next component.

3. In the Mode area, select Use Inline Content (delimited file). Then in the Content field displayed, enter the following input employee data.

4. Click the first tMysqlSCD component to open its Basic settings view.

5. Select the Use an existing connection check box and from the Component List drop-down list displayed, select the connection component you have configured.

6. In the Table field, enter the name of employee_scd.

7. Click the button next to SCD Editor to open the SCD editor. All schema columns are listed on the Unused panel.

8. In the name field on the Surrogate keys panel, enter the name for the surrogate key, SK in this example.

9. From the Unused panel, drag and drop
   • id to the Source keys panel to use it as the key to ensure the unicity of the input data,
   • name to the Type 0 fields panel and no special action will be performed upon dimension changes of it,
• age to the **Type 1 fields** panel to perform Type 1 SCD on it,
• role to the **Type 2 fields** panel to perform Type 2 SCD on it, and
• salary to the **Type 3 fields** panel to perform Type 3 SCD on it.

10. In the **Versioning** panel, select the **version** check box to hold the version numbers for the historical and current records in the SCD table, and select also the **active** check box to add the column that will hold the **True** value for the current active record or the **False** value for the historical records in the SCD table.

When done, click **OK** to save the changes and close the SCD editor.

**Retrieving the inserted employee data from MySQL**

Configure the first **tMysqlInput** component and the first **tLogRow** component to retrieve the inserted employee data from the MySQL SCD table and display it on the console.

**Procedure**

1. Double-click the **tMysqlInput** component to open its **Basic settings** view.
2. Select the **Use an existing connection** check box and from the **Component List** drop-down list displayed, select the connection component you have configured.

3. In the **Table Name** field, enter the name of the table from which the employee data will be retrieved. In this example, it is `employee_scd`.

4. Open the schema editor of the **tMysqlSCD** component, select and copy all its schema columns, then open the schema editor of the **tMysqlInput** component, define its schema by pasting those schema columns you have copied from the **tMysqlSCD** component.

When done, click **OK** to save the changes. In the pop-up dialog box, click **Yes** to propagate the schema to the next component.

5. Click the **Guess Query** button to fill the **Query** field with the automatically generated SQL query that will extract data of all columns from the specified table.
Double-click the first **tLogRow** component to open its **Basic settings** view. In the **Mode** area, select **Table (print values in cells of a table)** for better readability of the result displayed on the console.

### Updating the employee data in MySQL using SCD

Configure the second **tFixedFlowInput** component and the second **tMysqlSCD** component to update the employee data in MySQL using SCD (Slowly Changing Dimensions).

**Procedure**

1. Double-click the second **tFixedFlowInput** component to open its **Basic settings** view.
2. Click the **Edit schema** button next to **Edit schema** and in the pop-up window define the schema by copying and pasting the schema of the first **tFixedFlowInput** component.
3. In the **Mode** area, select **Use Inline Content (delimited file)**. Then in the **Content** field displayed, enter the following updated employee data.

   ```
   1; Mark Smith; 31; tester; 11000.00
   2; Thomas Johnson; 32; developer; 12000.00
   3; Teddy Brown; 33; writer; 13500.00
   ```

4. Repeat 4 on page 2528 through 10 on page 2529 in the procedure **Inserting the employee data into a MySQL table using SCD** on page 2527 to configure the second **tMysqlSCD** component.

### Retrieving the updated employee data from MySQL

Configure the second **tMysqlInput** component and the second **tLogRow** component to retrieve the updated employee data from the MySQL SCD table and display it on the console.

**Procedure**

1. Repeat 1 on page 2529 through 5 on page 2530 in the procedure **Retrieving the inserted employee data from MySQL** on page 2529 to configure the second **tMysqlInput** component.
2. Repeat 6 on page 2531 in the procedure **Retrieving the inserted employee data from MySQL** on page 2529 to configure the second **tLogRow** component.

### Closing the connection to the MySQL database

Configure the **tMysqlClose** component to close the connection to the MySQL database.

**Procedure**

1. Double-click the **tMysqlClose** component to open its **Basic settings** view.
2. From the **Component List** drop-down list, select the connection component that opens the connection you want to close. In this example, it is **tMysqlConnection_1**.

### Executing the Job to track data changes in MySQL using SCD

After setting up the Job and configuring the components used in the Job for tracking data changes in MySQL using SCD, you can then execute the Job and verify the Job execution result.

**Procedure**

1. Press **Ctrl + S** to save the Job.
2. **Press F6 to execute the Job.**

As shown above, the new age data 31 for Mark Smith the old age data 30, a new record with the SK value set to 4 is created for the role change for Teddy Brown from tester to writer, and the values of the previous salary and the current salary for Teddy Brown are both kept in the newly created record.
tMysqlSCDELT

Reflects and tracks changes in a dedicated MySQL SCD table through SQL queries.

tMysqlSCDELT addresses Slowly Changing Dimension needs through SQL queries (server-side processing mode), and logs the changes into a dedicated MySQL SCD table.

**tMysqlSCDELT Standard properties**

These properties are used to configure tMysqlSCDELT running in the Standard Job framework.

The Standard tMysqlSCDELT component belongs to the Business Intelligence and the Databases families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in:</strong></td>
<td>No property data stored centrally. Enter properties manually.</td>
</tr>
<tr>
<td><strong>Repository:</strong></td>
<td>Select the repository file where Properties are stored. The fields that come after are pre-filled in using the fetched data.</td>
</tr>
<tr>
<td>DB Version</td>
<td>Select the Mysql version you are using.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see **Talend Studio User Guide**.
| **Host** | The IP address of the database server. |
| **Port** | Listening port number of database server. |
| **Database** | Name of the database. |
| **Username and Password** | User authentication data for a dedicated database. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings. |
| **Source table** | Name of the input MySQL SCD table. |
| **Table** | Name of the table to be written. Note that only one table can be written at a time. |
| **Action on table** | Select to perform one of the following operations on the table defined:  
  - **None**: No action carried out on the table.  
  - **Drop and create the table**: The table is removed and created again.  
  - **Create a table**: A new table gets created.  
  - **Create a table if not exists**: A table gets created if it does not exist.  
  - **Clear a table**: The table content is deleted. You have the possibility to rollback the operation.  
  - **Truncate a table**: The table content is deleted. You do not have the possibility to rollback the operation. |
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word **line** when naming the fields. Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
  - **View schema**: choose this option to view the schema only.  
  - **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
  - **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.  
  - **Built-in**: The schema is created and stored locally for this component only. Related topic: see **Talend Studio User Guide**.  
  - **Repository**: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see **Talend Studio User Guide**. |
### Surrogate Key
Select the surrogate key column from the list.

### Creation
Select the method to be used for the surrogate key generation.
For more information regarding the creation methods, see SCD management methodology on page 2522.

### Source Keys
Select one or more columns to be used as keys, to ensure the unicity of incoming data.

### Use SCD Type 1 fields
Use type 1 if tracking changes is not necessary. SCD Type 1 should be used for typos corrections for example. Select the columns of the schema that will be checked for changes.

### Use SCD Type 2 fields
Use type 2 if changes need to be tracked down. SCD Type 2 should be used to trace updates for example. Select the columns of the schema that will be checked for changes.

### Start date
Specify the column that holds the start date for type 2 SCD.
This list is available only when the **Use SCD type 2 fields** option is selected.

### End date
Specify the column that holds the end date for type 2 SCD.
This list is available only when the **Use SCD type 2 fields** option is selected.

### Log active status
Select this check box and from the **Active field** drop-down list displayed, select the column that holds the true or false status value, which helps to spot the active record for type 2 SCD.
This option is available only when the **Use SCD type 2 fields** option is selected.

### Log versions
Select this check box and from the **Version field** drop-down list displayed, select the column that holds the version number of the record for type 2 SCD.
This option is available only when the **Use SCD type 2 fields** option is selected.

### Advanced settings

<table>
<thead>
<tr>
<th>Debug mode</th>
<th>Select this check box to display each step during processing entries in a database.</th>

<tr>
<th>Usage rule</th>
<th>This component is used as an output component. It requires an input component and Row main link as input.</th>
</tr>
</thead>
</table>

Dynamic settings

Click the ++ button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenario

For related scenarios, see:

- Tracking data changes in a Snowflake table using the tJDBCSCDELT component on page 1859.
- Tracking data changes in a PostgreSQL table using the tPostgreSQLSCDELT component on page 3039.
tMysqlSP

Calls a MySQL database stored procedure.
tMysqlSP offers a convenient way to centralize multiple or complex queries in a database and call them easily.

**tMysqlSP Standard properties**

These properties are used to configure tMysqlSP running in the Standard Job framework.
The Standard tMysqlSP component belongs to the Databases family.
The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>

<tr>
<td>Host</td>
<td>Database server IP address</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td></td>
<td>Built-In: You create and store the schema locally for this component only.</td>
</tr>
<tr>
<td></td>
<td>Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
</tr>
</tbody>
</table>
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

### SP Name
Type in the exact name of the Stored Procedure

### Is Function / Return result in
Select this check box, if a value only is to be returned. Select on the list the schema column, the value to be returned is based on.

### Parameters
Click the Plus button and select the various **Schema Columns** that will be required by the procedures. Note that the SP schema can hold more columns than there are parameters used in the procedure.

Select the **Type** of parameter:

- **IN**: Input parameter.
- **OUT**: Output parameter/return value.
- **IN OUT**: Input parameters is to be returned as value, likely after modification through the procedure (function).
- **RECORDSET**: Input parameters is to be returned as a set of values, rather than single value.

**Note:**
Check **Inserting data in mother/daughter tables** on page 2437 if you want to analyze a set of records from a database table or DB query and return single records.

### Usage
This component is used as intermediary component. It can be used as start component but only input parameters are thus allowed.

### Dynamic settings
Click the [+ ] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic**
settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

**Limitation**
The Stored Procedures syntax should match the Database syntax.

### Using tMysqlSP to find a State Label using a stored procedure

The following job aims at finding the State labels matching the odd State IDs in a Mysql two-column table. A stored procedure is used to carry out this operation.

- Drag and drop the following components used in this example: tRowGenerator, tMysqlSP, tLogRow.
- Connect the components using the Row Main link.
- The tRowGenerator is used to generate the odd id number. Double-click on the component to launch the editor.

<table>
<thead>
<tr>
<th>Column</th>
<th>Key</th>
<th>Type</th>
<th>Nullable</th>
<th>Length</th>
<th>Functions</th>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td></td>
<td>int</td>
<td></td>
<td>2</td>
<td>sequence</td>
<td>sequence i...</td>
</tr>
</tbody>
</table>

- Click on the **Plus** button to add a column to the schema to generate.
- Select the **Key** check box and define the **Type to Int**.
- The **Length** equals to 2 digits max.

- Drag and drop the following components used in this example: tRowGenerator, tMysqlSP, tLogRow.
- Connect the components using the Row Main link.
- The tRowGenerator is used to generate the odd id number. Double-click on the component to launch the editor.

Here is the function parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>sequence identifier</td>
<td>'s1'</td>
<td></td>
</tr>
<tr>
<td>start value</td>
<td>1</td>
<td></td>
</tr>
<tr>
<td>step</td>
<td>2</td>
<td></td>
</tr>
</tbody>
</table>
• Use the preset function called **sequence** but customize the Parameters in the lower part of the window.

<table>
<thead>
<tr>
<th>Column</th>
<th>Key</th>
<th>Type</th>
<th>Nullable</th>
<th>Length</th>
<th>Functions</th>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td>✓</td>
<td>INT</td>
<td></td>
<td>2</td>
<td>sequence</td>
<td>sequence i...</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Column</th>
<th>Key</th>
<th>Type</th>
<th>Nullable</th>
<th>Length</th>
<th>Functions</th>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Function parameters

- **sequence identifier**: 's1'
- **start value**: 1
- **step**: 2

- Change the **Value** of **step** from 1 to 2 for this example, still starting from 1.
- Set the **Number of generated rows** to 25 in order for all the odd State id (of 50 states) to be generated.
- Click **OK** to validate the configuration.
- Then select the **tMysqlSP** component and define its properties.

![tMysqlSP_1](image)

**Property Type**: Built-In

- **DB Version**: Mysql 5
- **Use an existing connection**
- **Host**: localhost
- **Port**: 3306
- **Database**: taend
- **Username**: root
- **Password**: ********
- **Schema**: Built-In
- **SP Name**: getscale

**Parameters**

<table>
<thead>
<tr>
<th>Schema Column</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td>IN</td>
</tr>
<tr>
<td>State</td>
<td>OUT</td>
</tr>
</tbody>
</table>

- Set the **Property type** field to **Repository** and select the relevant entry on the list. The connection details get filled in automatically.
- Else, set manually the connection information.
- Click **Sync Column** to retrieve the generated schema from the preceding component.
• Then click **Edit Schema** and add an extra column to hold the State Label to be output, in addition to the ID.

• Type in the name of the procedure in the **SP Name** field as it is called in the Database. In this example, *getstate*. The procedure to be executed states as follows:

```
DROP PROCEDURE IF EXISTS `talend`.`getstate` $$
CREATE DEFINER=`root`@`localhost` PROCEDURE `getstate`(IN pid INT, OUT pstate VARCHAR(50))
BEGIN
  SELECT LabelState INTO pstate FROM us_states WHERE idState = pid;
END $$
```

• In the **Parameters** area, click the plus button to add a line to the table.

• Set the **Column** field to *ID*, and the **Type** field to *IN* as it will be given as input parameter to the procedure.

• Add a second line and set the **Column** field to *State* and the **Type** to *Out* as this is the output parameter to be returned.

• Eventually, set the **tLogRow** component properties.

```
<table>
<thead>
<tr>
<th>ID</th>
<th>State</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Alabama</td>
</tr>
<tr>
<td>3</td>
<td>Arizona</td>
</tr>
<tr>
<td>5</td>
<td>California</td>
</tr>
<tr>
<td>7</td>
<td>Connecticut</td>
</tr>
<tr>
<td>9</td>
<td>Florida</td>
</tr>
<tr>
<td>11</td>
<td>Hawaii</td>
</tr>
<tr>
<td>13</td>
<td>Illinois</td>
</tr>
<tr>
<td>15</td>
<td>Iowa</td>
</tr>
<tr>
<td>17</td>
<td>Kentucky</td>
</tr>
<tr>
<td>19</td>
<td>Maine</td>
</tr>
<tr>
<td>21</td>
<td>Massachusetts</td>
</tr>
<tr>
<td>23</td>
<td>Minnesota</td>
</tr>
<tr>
<td>25</td>
<td>Missouri</td>
</tr>
<tr>
<td>27</td>
<td>Nebraska</td>
</tr>
<tr>
<td>29</td>
<td>New Hampshire</td>
</tr>
<tr>
<td>31</td>
<td>New Mexico</td>
</tr>
<tr>
<td>33</td>
<td>North Carolina</td>
</tr>
</tbody>
</table>
```

The output shows the state labels corresponding to the odd state ids as defined in the procedure.
Note:
Check Inserting data in mother/daughter tables on page 2437 if you want to analyze a set of records from a database table or DB query and return single records.

Related scenarios

For related scenarios, see:

- Retrieving personal information using a stored procedure on page 2415.
- Checking number format using a stored procedure on page 2754.
- Executing a stored procedure using tMDMSP on page 2159.
tMysqlTableList

Lists the names of a given set of Mysql tables using a select statement based on a Where clause. tMysqlTableList iterates on a set of table names through a defined Mysql connection.

**tMysqlTableList Standard properties**

These properties are used to configure tMysqlTableList running in the Standard Job framework.

The Standard tMysqlTableList component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tMysqlConnection component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Where clause for table name selection</td>
<td>Enter the Where clause to identify the tables to iterate on.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>CURRENT_TABLE: the name of the table currently iterated upon. This is a Flow variable and it returns a string.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>NB_TABLE: the number of tables iterated upon so far. This is a Flow variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td></td>
<td>For further information about variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

| Error Message | This error message is generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. |

| Error Code | This error code is generated by the component when an error occurs. This is an After variable and it returns an integer. |

| Query | This query is the SQL statement used to list the tables. This is a Flow variable and it returns a string. |

For further information about variables, see Talend Studio User Guide.
### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is to be used along with Mysql components, especially with <strong>tMysqlConnection</strong>.</th>
</tr>
</thead>
</table>
| Dynamic settings | Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.
Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.
For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide. |

### Iterating on DB tables and deleting their content using a user-defined SQL template

The following Java scenario creates a three-component job that iterates on given table names from a MySQL database using a WHERE clause. It then deletes the content of the tables directly on the DBMS using a user-defined SQL template.

For advanced use, start with creating a connection to the database that contains the tables you want to empty of their content.

- In the **Repository** tree view, expand **Metadata** and right click **DB Connections** to create a connection to the relevant database and to store the connection information locally.
  
  For more information about Metadata, see *Talend Studio User Guide*.

  Otherwise, drop a **tMySQLConnection** component in the design workspace and fill the connection details manually.

  - Drop the database connection you created from the **Repository** onto the design workspace.

  - The **Components** dialog box displays.

  - Select **tMySQLConnection** and click **OK**.

    The **tMySQLConnection** components displays on the design workspace with all connection details automatically filled in its **Basic settings** view.

  - Drop the following two components from the **Palette** onto the design workspace: **tMysqlTableList** and **tELT**.

  - Connect **tMySQLConnection** to **tMysqlTableList** using an **OnSubjobOk** link.
• Connect `tMysqlTableList` to `tELT` using an Iterate link.
• If needed, double-click `tMysqlConnection` to display its Basic settings view and verify the connection details.

In this example, we want to connect to a MySQL database called `examples`.

• In the design workspace, double-click `tMysqlTableList` to display its Basic settings view and define its settings.

• On the Component list, select the relevant MySQL connection component if more than one connection is used.

• Enter a WHERE clause using the right syntax in the corresponding field to iterate on the table name(s) you want to delete the content of.

  In this scenario, we want the job to iterate on all the tables which names start with "ex".

• In the design workspace, double-click `tELT` to display its Basic settings view and define its settings.
• In **Database Name**, enter the name of the database containing the tables you want to process.
• On the **Component list**, select the relevant MySQL connection component if more than one connection is used.
• Click in the **Table name** field and press **Ctrl+Space** to access the global variable list.
• From the global variable list, select `((String)globalMap.get("tMysqlTableList_1_CURRENT_TABLE"))`.

To create the user-defined SQL template:

• In the **Repository** tree view, expand **SQL Templates** and **MySQL** in succession.

• Right-click **UserDefined** and select **Create SQLTemplate** from the drop-down list.
  The **New SQLTemplate** wizard opens.
• Enter a name for the new SQL template and fill in the other fields if needed and then click **Finish** to close the wizard.

  An SQL pattern editor opens on the design workspace.

• Delete the existing code and enter the code necessary to carry out the desired action, deleting the content of all tables which names start with "ex" in this example.

  ![SQL code example](image)

  **Note:**

  In the SQL template code, you must use the correct variable name attached to the table name parameter ("__TABLE_NAME__" in this example). To display the variable name used, put your pointer in the **Table Name** field in the basic settings of the **tELT** component.

• Press **Ctrl+S** to save the new user-defined SQL template.

The next step is to add the new user-defined SQL template to the SQL template list in the **tELT** component.

**To add the user-defined SQL template to the SQL template list:**
• In the **Component** view of **tELT**, click the **SQL Templates** tab to display the **SQLTemplate List**.

• Click the **Add** button and add two SQL template lines.

• Click in the first line to display a drop-down arrow and then click the arrow to display the SQL template list.

• Select in the list the user-defined SQL template you already created.

• Make sure that the SQL template in the second line is **Commit**.

• Save your job and press **F6** to execute it.

All tables in the MySQL examples database which names begin with "ex" are emptied from their content.

**Related scenario**

For **tMysqlTableList** related scenario, see **Iterating on a DB table and listing its column names** on page 2430.
tNamedPipeClose

Closes a named-pipe at the end of a process.
tNamedPipeClose closes a named-pipe opened with tNamedPipeOpen at the end of a process.

**tNamedPipeClose Standard properties**

These properties are used to configure tNamedPipeClose running in the Standard Job framework.
The Standard tNamedPipeClose component belongs to the File family.
The component in this framework is available in all Talend products.

**Basic settings**

| Pipe | Select an existing named-pipe from the list to close. |

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

**Global Variables**

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

**Usage**

| Usage rule | This component is usually used to close a named-pipe at the end of a Job. |

| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your pipe connection dynamically from multiple connections planned in your Job. When a dynamic parameter is defined, the Pipe box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic |
connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

**Limitation**

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

**Related scenario**

For a related scenario, see Writing and loading data through a named-pipe.
tNamedPipeOpen

Opens a named-pipe for writing data into it.
Used in inner-process communication, tNamedPipeOpen opens a named-pipe for writing data into it.

**tNamedPipeOpen Standard properties**

These properties are used to configure tNamedPipeOpen running in the Standard Job framework.
The Standard tNamedPipeOpen component belongs to the File family.
The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Name</th>
<th>Fill in the field with the name of the named-pipe.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Delete if already exist</td>
<td>Select this check box to avoid duplicate named-pipe.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>PIPE_NAME: the name of the named-pipe. This is a Flow variable and it returns a string.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>PIPE_NATIVE_NAME: the native name of the named-pipe. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td></td>
<td>PIPE_OUTPUTSTREAM: the output stream of the named-pipe. This is a Flow variable and it returns an object.</td>
</tr>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td></td>
<td>For further information about variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

**Usage**

| Usage rule | This component is usually used as the starting component in a inner-process communication Job. |
| Limitation                                                                 | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |

**Related scenario**

For a related scenario, see Writing and loading data through a named-pipe.
tNamedPipeOutput

Writes data into an existing open named-pipe.
tNamedPipeOutput writes data into a named-pipe opened with tNamedPipeOpen.

**tNamedPipeOutput Standard properties**

These properties are used to configure tNamedPipeOutput running in the Standard Job framework.
The Standard tNamedPipeOutput component belongs to the File family.
The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use existing pipe connection</td>
<td>Select this check box to use an existing named-pipe in the Pipe component list, or clear this check box to specify a named-pipe in Pipe name field.</td>
</tr>
<tr>
<td>Pipe component</td>
<td>Select an existing named-pipe component from the list.</td>
</tr>
<tr>
<td><strong>Note:</strong></td>
<td>This check box will display only when you select Use existing pipe connection.</td>
</tr>
<tr>
<td>Pipe name</td>
<td>Fill in the field with the name of an existing named-pipe.</td>
</tr>
<tr>
<td><strong>Note:</strong></td>
<td>This check box will display only when you clear Use existing pipe connection.</td>
</tr>
<tr>
<td>Row separator</td>
<td>String (ex: &quot;\n&quot; on Unix) to distinguish rows in the output file.</td>
</tr>
<tr>
<td>Field separator</td>
<td>Character, string or regular expression to separate fields of the output file.</td>
</tr>
<tr>
<td>CSV options</td>
<td>Select this check box to take into account all parameters specific to CSV files, in particular Escape char and Text enclosure parameters.</td>
</tr>
</tbody>
</table>
| Schema and Edit Schema   | A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either Built-in or stored remotely in the Repository. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
  • View schema: choose this option to view the schema only.  
  • Change to built-in property: choose this option to change the schema to Built-in for local changes. |
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

Click **Sync columns** to retrieve the schema from the previous component connected in the Job.

<table>
<thead>
<tr>
<th><strong>Built-in</strong>: The schema will be created and stored locally for this component only. Related topic: see <em>Talend Studio User Guide</em>.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Repository</strong>: The schema already exists and is stored in the Repository, hence can be reused in various projects and Job flowcharts. Related topic: see <em>Talend Studio User Guide</em>.</td>
</tr>
</tbody>
</table>

**Delete pipe if it exists**

Select this check box to avoid duplicate named-pipe.

**Advanced settings**

<table>
<thead>
<tr>
<th><strong>Boolean type</strong></th>
<th>Select a boolean type from the list.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to gather the Job processing metadata at a Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

**Global Variables**

| **Global Variables** | **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is a Flow variable and it returns an integer. **PIPE_NAME**: the name of the named-pipe. This is a Flow variable and it returns a string. **PIPE_NATIVE_NAME**: the native name of the named-pipe. This is a Flow variable and it returns a string. **PIPE_OUTPUTSTREAM**: the output stream of the named-pipe. This is a Flow variable and it returns an object. **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it. For further information about variables, see *Talend Studio User Guide*. |
## Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is usually connected to another component in a subjob that reads data from a source.</th>
</tr>
</thead>
</table>
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your pipe connection dynamically from multiple connections planned in your Job.  

The Dynamic settings table is available only when the Use existing pipe connection check box is selected in the Basic settings view. When a dynamic parameter is defined, the Pipe component list box in the Basic settings view becomes unusable.  

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |
| Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |
**tNeo4jBatchOutput**

Receives data from the preceding component and writes the data into a local Neo4j database. tNeo4jBatchOutput is used to write nodes in a Neo4j database based on the defined index.

**tNeo4jBatchOutput Standard properties**

These properties are used to configure tNeo4jBatchOutput running in the Standard Job framework. The Standard tNeo4jBatchOutput component belongs to the Big Data and the Databases NoSQL families. The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Use an existing connection</strong></td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined. Neo4j version V3.2.X only and does not support the remote mode. Do not reuse the connection to versions other than V3.2.X defined in a tNeo4jConnection component and do not select the <strong>Remote server</strong> check box in tNeo4jConnection. Do not use a 2.X.X version and a 3.X.X version in the same Job. Otherwise, class conflict issues occur.</td>
</tr>
<tr>
<td><strong>Database path</strong></td>
<td>Specify the directory to hold your data files. If the specified directory does not exist, it will be created. This field appears only if you do not select the <strong>Use an existing connection</strong> check box.</td>
</tr>
<tr>
<td><strong>Shutdown after job</strong></td>
<td>Select this check box to shutdown the Neo4j database connection when no more operations on Neo4j are going to be performed after the current component. Alternatively, you can use tNeo4jClose to shutdown the database. This avoids errors such as ‘Id file not properly shutdown’ at next execution of Jobs involving Neo4j. This check box is available only if the <strong>Use an existing connection</strong> check box is not selected.</td>
</tr>
<tr>
<td><strong>Field that contains the label list</strong></td>
<td>Select the column from the input schema you have defined in the preceding components to provide labels for the nodes to be created. When the input data provides multiple labels for a node, separate those labels by semi-colons (;) in the preceding components.</td>
</tr>
<tr>
<td><strong>Index name</strong></td>
<td>Enter, within double quotation marks, the name of the index to be created for the nodes. This index is used to store the identifiers of the nodes and help create relationships.</td>
</tr>
</tbody>
</table>
**Import identifier**

Select the column from the input schema you have defined in the preceding components to provide identifiers for the nodes to be created. These identifiers are stored in the index to be created and must be unique cross the index. Therefore, ensure that the column to be used contains only unique values.

**Save the identifier**

Select this check box to save the technical identifiers (native graph ids).

For further information about the different types of Neo4j entity identifiers, see Neo4j documentation: Entity identifier.

**Number of index elements in memory**

Enter, without double quotation marks, the cache size used to keep the index elements in memory. This value must be enough to keep all of the index elements in memory.

For further information, see Neo4j documentation: Memory tuning.

### Advanced settings

**Neo4j configuration**

Add parameters to the table to configure the database to be created.

For further information, see Neo4j documentation: Configuration settings.

When entering values, use the syntax demonstrated by the examples given alongside the column names of this Nodes files table.

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

**Global Variables**

**NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.
# Usage

| Usage rule | This component is used as an output component and it always needs an incoming link. |
tNeo4jBatchOutputRelationship

Receives data from the preceding component and writes relationships in bulk into a local Neo4j database.

**tNeo4jBatchOutputRelationship Standard properties**

These properties are used to configure tNeo4jBatchOutputRelationship running in the Standard Job framework.

The Standard tNeo4jBatchOutputRelationship component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| **Use existing connection** | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. This component supports Neo4j version V3.2.X only and does not support the remote mode. Therefore, do not reuse the connection to versions other than V3.2.X defined in a tNeo4jConnection component and do not select the Remote server check box in tNeo4jConnection. Do not use a 2.X.X version and a 3.X.X version in the same Job. Otherwise, class conflict issues occur. |
| **Database path** | Specify the directory to hold your data files. This field appears only if you do not select the Use an existing connection check box. |
| **Shutdown after job** | Select this check box to shutdown the Neo4j database connection when no more operations on Neo4j are going to be performed after the current component. Alternatively, you can use tNeo4jClose to shutdown the database. This avoids errors such as 'Id file not properly shutdown' at next execution of Jobs involving Neo4j. This check box is available only if the Use an existing connection check box is not selected. |
| **Field for relationship types** | Select the column from the input schema you have defined in the preceding components to provide types for the relationships to be created. |
| **Direction of the relationship** | Select the direction of the relationships to be created:  
  - **Outgoing**: The relationship starts from the start node to the end node.  
  - **Incoming**: The relationship starts from the end node to the start node. |
### Start node of the relationship

Defining the start node of each relationship using the node identifier:

- **Name of the batch index**: select the tNeo4jBatchOutput component used to create the start nodes. The name of the index for these nodes are retrieved from that component.
- **Field name for the batch index**: select the column from the input schema you have defined in the preceding components to provide the name of the start node of each relationship to be created.

### End node of the relationship

Defining the end node of each relationship using the node identifier:

- **Name of the batch index**: select the tNeo4jBatchOutput component used to create the end nodes. The name of the index for these nodes are retrieved from that component.
- **Field name for the batch index**: select the column from the input schema you have defined in the preceding components to provide the name of the end node of each relationship to be created.

### Die on error

Select the check box to stop the execution of the Job when an error occurs.

Clear the check box to skip any rows on error and complete the process for error-free rows.

### Advanced settings

**Neo4j configuration**

Add parameters to the table to configure the database to be created.

For further information, see Neo4j documentation: Configuration settings.

When entering values, use the syntax demonstrated by the examples given alongside the column names of this Nodes files table.

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

**Global Variables**

- **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

<table>
<thead>

<td>This component is used as an output component and it always needs an incoming link.</td>
</tr>
</tbody>
</table>

Writing information of actors and movies to Neo4j with hierarchical relationship using Neo4j Batch components

In this scenario, Neo4j Batch components are used to import data about actors and movies from two CSV files in a local Neo4j database and create relationship for the data based on another CSV file that describes the actors' roles in the movies.

This scenario applies only to Talend products with Big Data.

The Neo4j Batch components provided by Talend supports bulk writing to a local Neo4j database only. They can be used neither with Neo4j versions prior to V3.2.X nor alongside Neo4j components that are using one of those Neo4j versions.

The components to be used are:

- One tNeo4jConnection component: it opens the connection to Neo4j to be reused.
- Three tFileInputDelimited components: they read the input information of actors and movies.
- Two tNeo4jBatchOutput components: they write information of movies and actors to the connected Neo4j database.
- One tNeo4jBatchOutputRelationship component: it creates relationship between actors and movies.
- One tNeo4jBatchSchema component: it creates an uniqueness constraint on the nodes in the database.
Creating the Neo4j Batch Job

Procedure

1. Ensure that the status of your Neo4j service and Neo4j console is stop.
   If you are using command-line to manage Neo4j, you can use `neo4j status` to check the status; if you have installed the Neo4j desktop application, you can check it directly in this application.

2. From the Repository on the Integration perspective, create a Job and add the components to be used by typing their names in the design workspace or dropping them from the Palette.

3. Connect the first `tFileInputDelimited` component to the first `tNeo4jBatchOutput` component using a Row > Main link. This subJob imports the actors data in the Neo4j database.

4. Connect the second `tFileInputDelimited` component to the second `tNeo4jBatchOutput` component using a Row > Main link. This subJob imports the movies data in the Neo4j database.

5. Connect the third `tFileInputDelimited` component to the `tNeo4jBatchOutputRelationship` component using a Row > Main link. This subJob creates relationship between actors and movies.

6. Connect the subJobs using Trigger > On Subjob Ok links.

Configuring the Neo4j connection to be reused

Procedure

1. Double-click the `tNeo4jConnection` component to open its Basic settings view.
2. From the **DB Version** list, select **Neo4J 3.2.X**.

3. Ensure that the **Use a remote server** check box is clear because that the Neo4j Batch components work only on the local mode.

4. In the **Database path** field, enter the path or browse to the database file.

**Bulk-writing the actors data in Neo4j**

**Procedure**

1. Double-click the first **tFileInputDelimited** component to open its **Component** view.

2. In the **File name/Stream** field, enter the path or browse to the CSV file that describes the actors’ IDs, names and their labels to be used in Neo4j.

   The input CSV file used in this example reads as follows:

   ```
   keanu,"Keanu Reeves",Actor
   laurence,"Laurence Fishburne",Actor
   carrieanne,"Carrie-Anne Moss",Actor
   ```

   The double quotation marks on the actor names are not mandatory.

3. Click the [...] button next to **Edit schema** to open the schema editor, and define the input schema based on the structure of the input file.

   In this example, the columns are **id**, **name** and **label**, all of type **String**.
4. Click OK to close this editor and accept the propagation of the schema to the next component.

5. In the **Field separator** field, enter a comma (,) to replace the default semicolon (;).

6. Double-click the first **tNeo4jBatchOutput** component to open its **Component** view.

7. Select the **Use an existing connection** check box to reuse the Neo4j database connection opened by the tNeo4jConnection component.

8. Verify that the **Shutdown after Job** check box is clear.

9. From the **Field that contains the label list** drop-down list, select the column that provides labels.

10. In the **Index name** field, enter the name of the index to be created for the nodes.

11. From **Import identifier** drop-down list, select the column that provides IDs.

**Bulk-writing the movies data into Neo4j**

**Procedure**

1. Double-click the second **tFileInputDelimited** component to open its **Component** view.
2. In the **File name/Stream** field, enter the path or browse to the CSV file that describes the movies' IDs, names, release years and their labels to be used in Neo4j.

The input CSV file used in this example reads as follows:

```
tt0133093, "The Matrix", 1999, Movie
.tt0234215, "The Matrix Reloaded", 2003, Movie;Sequel
.tt0242653, "The Matrix Revolutions", 2003, Movie;Sequel
```

The double quotation marks on the movie names are not mandate.

3. Click the [...] button next to **Edit schema** to open the schema editor, and define the input schema based on the structure of the input file.

In this example, the columns are `id`, `title`, `released` and `label`.

4. Click **OK** to close this editor and accept the propagation of the schema to the next component.

5. In the **Field separator** field, enter a comma (,) to replace the default semicolon (;).

6. Double-click the second **tNeo4jBatchOutput** component to open its **Component** view.
7. Select the **Use an existing connection** check box to reuse the Neo4j database connection opened by the tNeo4jConnection component.

8. Verify that the **Shutdown after Job** check box is clear.

9. From the **Field that contains the label list** drop-down list, select the column that provides labels.

10. In the **Index name** field, enter the name of the index to be created for the nodes.

11. From **Import identifier** drop-down list, select the column that provides IDs.

---

**Creating relationships in bulk**

**Procedure**

1. Double-click the third **tFileInputDelimited** component to open its **Component** view.

2. In the **File name/Stream** field, enter the path or browse to the CSV file that describes the actor-movie relationships.
The input CSV file used in this example reads as follows:

<table>
<thead>
<tr>
<th>Name</th>
<th>Role</th>
<th>ID</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>keanu</td>
<td>&quot;Neo&quot;</td>
<td>tt0133093</td>
<td>ACTED_IN</td>
</tr>
<tr>
<td>keanu</td>
<td>&quot;Neo&quot;</td>
<td>tt0234215</td>
<td>ACTED_IN</td>
</tr>
<tr>
<td>keanu</td>
<td>&quot;Neo&quot;</td>
<td>tt0242653</td>
<td>ACTED_IN</td>
</tr>
<tr>
<td>laurence</td>
<td>&quot;Morpheus&quot;</td>
<td>tt0133093</td>
<td>ACTED_IN</td>
</tr>
<tr>
<td>laurence</td>
<td>&quot;Morpheus&quot;</td>
<td>tt0234215</td>
<td>ACTED_IN</td>
</tr>
<tr>
<td>laurence</td>
<td>&quot;Morpheus&quot;</td>
<td>tt0242653</td>
<td>ACTED_IN</td>
</tr>
<tr>
<td>carrieanne</td>
<td>&quot;Trinity&quot;</td>
<td>tt0133093</td>
<td>ACTED_IN</td>
</tr>
<tr>
<td>carrieanne</td>
<td>&quot;Trinity&quot;</td>
<td>tt0234215</td>
<td>ACTED_IN</td>
</tr>
<tr>
<td>carrieanne</td>
<td>&quot;Trinity&quot;</td>
<td>tt0242653</td>
<td>ACTED_IN</td>
</tr>
</tbody>
</table>

The double quotation marks on the role names are not mandatory. The value ACTED_IN is an user-defined relationship type that explains the relationship between the actors and the movies.

3. Click the [...] button next to Edit schema to open the schema editor, and define the input schema based on the structure of the input file.

In this example, the columns are from, role, to and type.

4. Click OK to close this editor and accept the propagation of the schema to the next component.

5. In the Field separator field, enter a comma (,) to replace the default semicolon (;).

6. Double-click the tNeo4jBatchOutputRelationship component to open its Component view.
7. Select the **Use an existing connection** check box to reuse the Neo4j database connection opened by the tNeo4jConnection component.

8. Verify that the **Shutdown after Job** check box is clear.

9. From the **Field for relationship type** drop-down list, select the column that provides the relationship types.

10. From the **Direction of the relationship** drop-down list, select **Outgoing**.

11. In the **Start node of the relationship** area, select the tNeo4jBatchOutput component that provides the index of the start nodes, which is the `asActors` index in this example from the first tNeo4jBatchOutput. Then from the **Field name for the batch index** drop-down list, select the column that provides the actor names as the start nodes.

12. Repeat this action in the **End node of the relationship** area to select the `asMovie` index from the second tNeo4jBatchOutput and then select the column that provides the movie names as the end nodes.

**Adding uniqueness constraints on the nodes**

**Procedure**

1. Double-click the tNeo4jBatchSchema component to open its **Component** view.
2. Select the **Use an existing connection** check box to reuse the Neo4j database connection opened by the tNeo4jConnection component.

3. Select the **Shutdown after Job** check box to properly close the connection after the execution.

4. In the **Schema definition** table, add two rows by clicking the [+ ] button twice:
   a) In the **Schema type** column, select **Node property is unique** for both of the rows to add uniqueness constraints to nodes in Neo4j.
   b) In the **For node with Label** column, enter, within double quotation marks, Actor and Movie respectively, which are the labels used by the actor nodes and the movie nodes. Therefore, what you enter here must be identical with the labels previously used when creating those nodes.
   c) In the **On property** column, enter, within double quotation marks, the node properties to which you need to add uniqueness constraints. For the actor nodes, enter name and for the movie nodes, enter title. The values you enter here must be identical with the column names previously defined to provide actor names and movie names for the nodes to be created by the tNeo4jBatchOutput components.

5. Press **Ctrl+S** to save the Job, and press **F6** or click **Run** on the Run tab to execute the Job.

**Results**

Once the Job runs successfully to the end, check the result in your Neo4j browser:
"Carrie...
"The Matrix

"Lauren
"Keanu Reeves"
"The Matrix

ACTED_IN <id>: 2 role: "Neo"
tNeo4jBatchSchema

Defines the schema of a local Neo4j database.

tNeo4jBatchSchema Standard properties

These properties are used to configure tNeo4jBatchSchema running in the Standard Job framework.

The Standard tNeo4jBatchSchema component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

Basic settings

| Use an existing connection | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. This component supports Neo4j version V3.2.X only and does not support the remote mode. Therefore, do not reuse the connection to versions other than V3.2.X defined in a tNeo4jConnection component and do not select the Remote server check box in tNeo4jConnection. Do not use a 2.X.X version and a 3.X.X version in the same Job. Otherwise, class conflict issues occur. |
| Database path | Specify the directory to hold your data files. If the specified directory does not exist, it will be created. This field appears only if you do not select the Use an existing connection check box. |
| Shutdown after job | Select this check box to shutdown the Neo4j database connection when no more operations on Neo4j are going to be performed after the current component. Alternatively, you can use tNeo4jClose to shutdown the database. This avoids errors such as 'Id file not properly shutdown’ at next execution of Jobs involving Neo4j. This check box is available only if the Use an existing connection check box is not selected. |
| Schema definition | Add indexes and unique property constraints to define the schema:  
  - **Schema type**: select whether it is an index (**Index on node property**) or a constraint (**Node property is unique**) to be defined.  
  - **For node with label**: enter, within double quotation marks, the label of a node.  
  - **On property**: enter, within double quotation marks, the property of a node. |
### Advanced settings

| Neo4j configuration | Add parameters to the table to configure the database to be created.  
|                     | For further information, see Neo4j documentation: Configuration settings.  
|                     | When entering values, use the syntax demonstrated by the examples given alongside the column names of this Nodes files table. |
| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

### Global Variables

| Global Variables | NB_LINE: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.  
|                 | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  
|                 | A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
|                 | To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.  
|                 | For further information about variables, see Talend Studio User Guide. |

### Usage

| Usage rule | This component is used standalone in a subJob to write a Neo4j graph schema. |
tNeo4jClose

Close an active connection to an Neo4j database in embedded mode.

**tNeo4jClose Standard properties**

These properties are used to configure tNeo4jClose running in the Standard Job framework.

The Standard tNeo4jClose component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| Connection | Select an active Neo4j database connection to be closed. |

**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

**Global Variables**

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

**Usage**

| Usage rule | This component is to be used along with other Neo4j components, especially with tNeo4jConnection. |

**Limitation**

| n/a |

**Related scenarios**

For scenario in which tNeo4jClose is used, see:

- Writing information of actors and movies to Neo4j with hierarchical relationship on page 2600,
• Creating nodes with a label using a Cypher query on page 2613, and
• Importing data from a CSV file to Neo4j using a Cypher query on page 2617.
tNeo4jConnection

Opens a connection to a Neo4j database to be reused by other Neo4j components.

*tNeo4jConnection* starts the database in embedded mode, and checks the server availability in REST mode.

### tNeo4jConnection Standard properties

These properties are used to configure *tNeo4jConnection* running in the Standard Job framework.

The Standard *tNeo4jConnection* component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

#### Basic settings

| DB version | Select the Neo4j version you are using. When you use V3.2.X:
| --- | --- |
|  | • If you work with a remote server, only *tNeo4jInput* and *tNeo4jRow* can reuse the connection defined in *tNeo4jConnection* because these components work with Neo4j remote servers only.
|  | • If you work with a local server, only *tNeo4jBatchOut put*, *tNeo4jBatchSchema* and *tNeo4jBatchOut putRelationship* can reuse the connection defined in *tNeo4jConnection* because these components work with Neo4j local servers only.
|  | Do not use a 2.X.X version and a 3.X.X version in the same Job. Otherwise, class conflict issues occur.
|  | Neo4j version 2.X.X is compatible only with Java 7 or higher but it offers support of advanced features such as node labels.
|  | Upon selecting a database version, you will be prompted to install the corresponding database driver JAR files if not yet installed. You can find more details about how to install external modules in Talend Help Center ([https://help.talend.com](https://help.talend.com)). |

<table>
<thead>
<tr>
<th>Remote server</th>
<th>Select this check box if you use a Neo4j remote server, and specify the root URL in the Server URL field.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• <strong>Set username</strong>: this check box is available when you have selected the <em>Use a remote server</em> check box and the Neo4j version you are using is earlier than 2.2. If the remote Neo4j server you want to connect to does not require user credentials, leave it clear.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Username</strong> and <strong>Password</strong>: enter the authentication information to connect to the remote Neo4j server to be used. Since Neo4j 2.2, user credentials are always required.</td>
</tr>
</tbody>
</table>

| Server URL | Specify the root URL. |
### tNeo4jConnection

This field is available only if the **Use a remote server** check box is selected.

| **Read only** | Select this check box if you want to use the embedded database in read only mode. It's useful if an application is already dedicated with the database.  
This check box is available only when you are using a 2.X.X version.  
**Warning:**  
Do not use this mode when you have any output Neo4j component in your Job such as **tNeo4jOutput**, **tNeo4jOutputRelationship** or **tNeo4jRow**. |
| **Database path** | If you use Neo4j in embedded mode, specify the path of data file.  
This field is available only if the **Use a remote server** check box is not selected. |

### Advanced settings

| **tStatCatcher Statistics** | Select this check box to collect the log data at a component level. |

### Global Variables

| **Global Variables** | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
For further information about variables, see **Talend Studio User Guide**. |

### Usage

| **Usage rule** | This component is generally used with other Neo4j components, particularly **tNeo4jClose**. |
| **Limitation** | n/a |

### Related scenarios

For scenario in which **tNeo4jConnection** is used, see:

- **Writing information of actors and movies to Neo4j with hierarchical relationship** on page 2600,
• Creating nodes with a label using a Cypher query on page 2613, and
• Importing data from a CSV file to Neo4j using a Cypher query on page 2617.
**tNeo4jImportTool**

Uses Neo4j Import Tool to create a Neo4j database and import large amounts of data in bulk from CSV files to this database.

**tNeo4jImportTool Standard properties**

These properties are used to configure tNeo4jImportTool running in the Standard Job framework.

The Standard tNeo4jImportTool component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

</table>

---

### Usage

| Usage rule | This component is to be used standalone in a subjob to load data in bulk from given CSV files that have been created with specific structure. For further information about the CSV structure required by Neo4j Import Tool, see Import. You can use tFileOutputDelimited to create the CSV files to be used. If so, bear the following configuration in mind:  
|            | • Line separator: " \n "  
|            | • Field separator: " , "  
|            | • Do not include headers.  
|            | • File encoding: UTF-8. |

---
**tNeo4jInput**

Reads data from Neo4j and sends data in the output **Talend** flow.

`tNeo4jInput` reads data from Neo4j based on Cypher query allowing any further transformation or processing of the data in the rest of the Job.

**tNeo4jInput Standard properties**

These properties are used to configure `tNeo4jInput` running in the Standard Job framework.

The Standard `tNeo4jInput` component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all **Talend products with Big Data** and in **Talend Data Fabric**.

**Basic settings**

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
</table>
| DB version                  | Select the Neo4j version you are using.  
When you are using Neo4j version 3.2.X, this component works in the remote mode only. Therefore, if you want to reuse a connection to Neo4j V3.2.X from `tNeo4jConnection`, ensure that you have selected the Remote server check box and properly configured the connection.  
Do not use a 2.X.X version and a 3.X.X version in the same Job. Otherwise, class conflict issues occur.  
Neo4j version 2.X.X is compatible only with Java 7 or higher but it offers support of advanced features such as node labels.  
This list is not shown if the Use an existing connection check box is selected.  
Upon selecting a database version, you will be prompted to install the corresponding database driver JAR files if not yet installed. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |
| Shutdown after job          | Select this check box to shutdown the Neo4j database connection when no more operations on Neo4j are going to be performed after the current component.  
Alternatively, you can use `tNeo4jClose` to shutdown the database.  
This avoids errors such as `id file not properly shutdown` at next execution of Jobs involving Neo4j.  
This check box is available only if the Use an existing connection check box is not selected. |
| Remote server               | Select this check box if you use a Neo4j remote server, and specify the root URL in the Server URL field. |
- **Set username**: this check box is available when you have selected the **Use a remote server** check box and the Neo4j version you are using is earlier than 2.2. If the remote Neo4j server you want to connect to does not require user credentials, leave it clear.

- **Username** and **Password**: enter the authentication information to connect to the remote Neo4j server to be used. Since Neo4j 2.2, user credentials are always required.

This check box appears only if you do not select the **Use an existing connection** check box and you are not using Neo4j V3.2.X. With V3.2.X, this component supports the remote mode only.

### Database path

If you use Neo4j in embedded mode, specify the path of data file.

This field appears only if you do not select the **Use an existing connection** check box or the **Remote server** check box.

### Schema and Edit Schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

### Query

Enter your Cypher query in double quotes, with return parameters matching the mapping table.

### Mapping

Complete this table to specify the column or columns to be extracted and the corresponding column family or families. The **Column** fields of this table are automatically filled once you have defined the schema; fill the **Return parameter** fields with return parameters to map the node properties in the Cypher query with the schema columns.

Be sure to enclose your return parameters in double quotes.

### Advanced settings

- **tStatCatcher Statistics**: Select this check box to gather the Job processing metadata at the Job level as well as at each component level.
Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_LINE: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td></td>
<td>For further information about variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component always needs an output link.</th>

</tbody>
</table>

Related scenarios

For a related scenario, see Writing data to a Neo4j database and reading specific data from it on page 2587.
tNeo4jOutput

Receives data from the preceding component and writes the data into Neo4j.

tNeo4jOutput is used to write data into a Neo4j database, and/or update or delete entries in the database based on the index defined.

**tNeo4jOutput Standard properties**

These properties are used to configure tNeo4jOutput running in the Standard Job framework.

The Standard tNeo4jOutput component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
</table>
| DB version                  | Select the Neo4j version you are using.  
|                             | This component does not support Neo4j version V3.2.X. Do not reuse the connection to V3.2.X defined in a tNeo4jConnection component.  
|                             | Do not use a 2.X.X version and a 3.X.X version in the same Job. Otherwise, class conflict issues occur.  
|                             | Neo4j version 2.X.X is compatible only with Java 7 or higher but it offers support of advanced features such as node labels.  
|                             | Upon selecting a database version, you will be prompted to install the corresponding database driver JAR files if not yet installed. You can find more details about how to install external modules in Talend Help Center ([https://help.talend.com](https://help.talend.com)). |
| Remote server               | Select this check box if you use a Neo4j remote server, and specify the root URL in the Server URL field.  
|                             | • **Set username**: this check box is available when you have selected the Use a remote server check box and the Neo4j version you are using is earlier than 2.2. If the remote Neo4j server you want to connect to does not require user credentials, leave it clear.  
|                             | • **Username** and **Password**: enter the authentication information to connect to the remote Neo4j server to be used. Since Neo4j 2.2, user credentials are always required.  
|                             | This check box appears only if you do not select the Use an existing connection check box. |
| **Database path** | If you use Neo4j in embedded mode, specify the directory to hold your data files. If the specified directory does not exist, it will be created.  
This field appears only if you do not select the Use an existing connection check box or the Remote server check box. |
| **Shutdown after job** | Select this check box to shutdown the Neo4j database connection when no more operations on Neo4j are going to be performed after the current component.  
Alternatively, you can use tNeo4jClose to shutdown the database.  
This avoids errors such as 'Id file not properly shutdown' at next execution of Jobs involving Neo4j.  
This check box is available only if the Use an existing connection check box is not selected. |
| **Mapping** | Click the [...] button or double-click the component on the design workspace to open the indexes and relationships mapping editor. Use it to index node or create relationships during the node insertion.  
- **Select the Auto indexed check box** for a column to automatically index nodes with this property.  
- **Index creation**: With a column selected, click the [+] button to create as many indexes as you want on nodes with the property corresponding to the selected column.  
  - **Name**: Specify an index name in double quotes.  
  - **Key**: Specify an index key in double quotes.  
  - **Value (empty for current row)**: Specify an index value in double quotes. If you leave this field empty, the default value of the index added on each node will be the value of this property of the current node.  
  - **Unique**: Select this check box if you want the defined index to be created only once within the graph, rather than on each node.  
- **Relationship creation**: With a column selected, click the [+] button to create as many relationships as you want for nodes with the property corresponding to the selected column.  
  - **Type**: Specify a relationship type in double quotes.  
  - **Direction**: Select a relationship direction, between Outgoing and Incoming.  
  - **Index name**: Specify an index name for the relationship, in double quotes.  
  - **Index key**: Specify an index key for the relationship, in double quotes.  
  - **Value (empty for current row)**: Specify an index value for the relationship, in double quotes. If you leave this field empty, the default value of the index added on the relationship will be the value of this property of the current node. |
| **Use label (Neo4j > 2.0)** | Select this check box to create nodes with a label. Enter your label name in the Label name field. |
This check box is not shown if Neo4j 1.X.X is selected from the **DB Version** list or **Delete** is selected from the **Data action** list.

Note that this option works only with Neo4j 2.0 onwards and Java 7.

### Data action

On the data of the node, you can perform:

- **Insert**: Add new node to the database.
- **Update**: Make changes to existing entries.
- **Update or insert**: Search the node with an index to update and make changes. If the node doesn’t exist, a new node will be inserted.
- **Delete**: Remove nodes fetched by the index according to the input flow.

### Index name

Specify the index name to query.

This field is available only if the action selected in **Data action** is other than **Insert**.

### Index key

Specify the index key to query.

This field is available only if the action selected in **Data action** is other than **Insert**.

### Index value

Select the index value to query.

This field is available only if the action selected in **Data action** is other than **Insert**.

### Schema and Edit schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

- **Built-In**: You create and store the schema locally for this component only.

- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.
You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

**Advanced settings**

**Commit every**

Enter the number of rows to be completed before committing batches of nodes to the DB. This option ensures transaction quality (but not rollback) and, above all, better performance at execution.

**Warning:** This option is only supported by the embedded mode of the database. You can't make transactions in REST mode.

**Batch import**

Select this check box to activate the batch mode.

**Warning:**
- This option is only supported by the embedded mode of the database.
- It is recommended that you perform a backup operation before executing the Job to prevent data corruption.

**Note:** If you have configured index creation on multiple columns in the *Mapping* table, it is recommended that you select the *Unique* check box in the index setting for the last column to avoid creating unwanted redundant indexes that may cause batch load issues.

If you want more explanations about memory mapping configuration of batch import, please refer to Neo4j documentation at: http://neo4j.com/docs/stable/batchinsert-examples.html.

**Node store mapped memory**

Type in the memory size in MB allocated to nodes.

**Relationship store mapped memory**

Type in the memory size in MB allocated to relationships.

**Property store mapped memory**

Type in the memory size in MB allocated to property.

**String store mapped memory**

Type in the memory size in MB allocated to strings.

**Array store mapped memory**

Type in the memory size in MB allocated to arrays.

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

**Global Variables**

**NB_LINE:** the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.

**ERROR_MESSAGE:** the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the
Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is used as an output component and it always needs an incoming link.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limitation</td>
<td>n/a</td>
</tr>
</tbody>
</table>

### Writing data to a Neo4j database and reading specific data from it

This scenario applies only to *Talend products with Big Data*.

This basic scenario describes a Job composed of two subJobs: the first subJob reads employees data from a CSV file and writes it to a Neo4j database, and then triggers the second subJob, which reads the employees data based on certain query conditions from the Neo4j database and displays the data on the Run console.

### Adding and linking components

**Procedure**

1. Create a Job and add the following components to the Job by typing theirs names in the design workspace or dropping them from the Palette:
   - a **tFileInputDelimited** component, to read the employees data from a CSV file,
   - a **tNeo4jOutput** component to write the employees data to a Neo4j database,
   - a **tNeo4jInput** component to read the employees data from the Neo4j database based on given conditions, and
   - a **tLogRow** component to display the data on the Run console.
2. Link the **tFileInputDelimited** component to the **tNeo4jOutput** component using a Row > Main connection.
3. Link the **tNeo4jInput** component to the **tLogRow** component using a Row > Main connection.
4. Link the **tFileInputDelimited** component to the **tNeo4jInput** component using a Trigger > On Subjob Ok connection.
5. Label the components to better identify their roles in the Job.
Configuring the components

Importing data to the Neo4j database

Procedure

1. Double-click the **tFileInputDelimited** component to open its **Basic settings** view on the Components tab.

2. In the **File name/Stream** field, specify the path to the CSV file that contains the employees data to read.

   The input CSV file used in this example is as follows:

```
employeeID;employeeName;age;hireDate;salary;managerID
1;Rutherford Roosevelt;38;06-10-2008;13336.58;m5
2;Warren Adams;43;05-22-2008;11626.68;m6
3;Andrew Roosevelt;55;04-01-2007;10052.95;m4
4;Herbert Quincy;54;06-14-2007;10694.71;m6
5;Woodrow Polk;33;04-01-2007;13751.50;m4
6;Theodore Johnson;47;01-26-2008;12426.87;m6
7;Benjamin Adams;32;02-25-2008;10438.65;m4
8;Woodrow Harrison;51;10-11-2008;11188.27;m5
9;George Truman;40;04-28-2008;14254.49;m5
10;Harry Jackson;38;04-01-2008;12798.78;m6
```
3. In the Header field, specify the number of rows to skip as header rows. In this example, the first row of the CSV file is the header row.

4. Click the [...] button next to Edit schema to open the Schema dialog box, and define the input schema based on the structure of the input file. In this example, the input schema is composed of six columns: employeeID (integer), employeeName (String), age (Integer), hireDate (Date), salary (Float), and managerID (String).

   When done, click OK to close the Schema dialog box and propagate the schema to the next component.

   ![Schema of Employees](image)

5. Click the tNeo4jOutput component and select the Component tab to open its Basic settings view.

   ![Write to Neo4j(tNeo4jOutput_1)](image)

6. Define a Neo4j database connection. In this example, the Neo4j database is accessible in REST mode, so select the Remote server check box and specify the URL of the Neo4j server in the Server URL field, “http://localhost:7474/db/data” in this example.

7. If needed, click the Sync columns button to ensure the component has the same schema as the preceding component.

   Keep the rest of the parameters as they are.
Reading data from the Neo4j database

Procedure

1. Double-click the **tNeo4jInput** component to open its **Basic settings** view.

   ![Neo4j Input Component](image)

   - **Connection**
     - Use an existing connection
     - DB Version: Neo4j 1.x.x
     - Remote server
   - **Server URL**: "http://localhost:7474/db/data"

   - **Schema**
     - Built-In
     - **Edit schema**
   - **Query**
     - "MATCH (n) WHERE n.age > 40 AND n.managerID = 'm0' RETURN n;"

   - **Mapping**
     - **Column**
       - id
       - name
       - age
       - hire_date
       - salary
       - manager_id
     - **Return parameter**
       - "n.employeeID"
       - "n.employeeName"
       - "n.age"
       - "n.hireDate"
       - "n.salary"
       - "n.managerID"

2. As in the **tNeo4jOutput** component, specify the URL of the Neo4j server to connect to, "http://localhost:7474/db/data" in this example.

3. Click the [...] button next to **Edit schema** and define the schema for employees information display. When done, click **OK** to close the **Schema** dialog box and propagate the schema to the next component.

   ![Schema Dialog Box](image)

   - **Schema of Read_from_Neo4j**
     - **Column**
       - id
       - name
       - age
       - hire_date
       - salary
       - manager_id
     - **Db Column**
       - id
       - name
       - age
       - hire_date
       - salary
       - manager_id
     - **Key**
       - Integer
       - String
       - Integer
       - Date
       - Float
       - String
     - **Date Pattern**
       - "MM-dd-yyyy"
     - **Le..."

   - The defined schema columns automatically appear in the **Mapping** table.
4. In the **Query** field, type in the Cypher query to match the data to read from the Neo4j database. In this example, use the following Cypher query to find employees who are more than 40 years old and are under the manager *m6*.

```
"MATCH (n) WHERE n.age > 40 AND n.managerID = 'm6' RETURN n;"
```

5. Fill the **Return parameter** field for each schema column with a return parameter in double quotes to map the node properties in the Neo4j database with the schema columns.

6. Double-click the **tLogRow** component to open its **Basic settings** view, and select the **Table (print values in cells of a table)** option to display the retrieved information in a table.

**Executing the Job**

**Procedure**

1. Press **Ctrl+S** to save the Job.
2. Press **F6** or click **Run** on the **Run** tab to run the Job.

![Execution](image)

The employees data of the CSV file is written to the Neo4j database and then the information of employees matching the set conditions is retrieved from the Neo4j database and displayed on the console.

**Writing family information to Neo4j and creating relationships**

This scenario applies only to **Talend products with Big Data**.

This scenario describes a Job that will write family information to labeled nodes in a remote Neo4j database and create relationships based on the family names.

**Adding and linking components**

**Procedure**

1. Create a Job and add the following components to the Job by typing theirs names in the design workspace or dropping them from the **Palette**:
   - a **tFileInputDelimited** component, to read the family data from a CSV file,
• a **tNeo4jOutput** component to write the family data to a Neo4j database and create relationships between husband and wife.

2. Link the **tFileInputDelimited** component to the **tNeo4jOutput** component using a **Row > Main** connection.

3. Label the components to better identify their roles in the Job.

![Diagram of connected components]

### Configuring the components

#### Configuring the data source

**Procedure**

1. Double-click the **tFileInputDelimited** component to open its **Basic settings** view on the **Components** tab.

   ![Basic settings view]

   - In the **File name/Stream** field, specify the path to the CSV file that contains the family data to read.
     - The input CSV file used in this example is as follows:

     ```
     Name;Gender;Age;Family
     Jenny;Female;24;the Johnsons
     Jack;Male;26;the Johnsons
     Richard;Male;35;the Blacks
     Anne;Female;36;the Whites
     Helen;Female;28;the Blacks
     Tom;Male;38;the Whites
     ```

   - In the **Header** field, specify the number of rows to skip as header rows. In this example, the first row of the CSV file is the header row.

   - Click the [...] button next to **Edit schema** to open the **Schema** dialog box, and define the input schema based on the structure of the input file. In this example, the input schema is composed of six columns: `name` (integer), `gender` (String), `age` (Integer), and `family` (String).
When done, click **OK** to close the **Schema** dialog box and propagate the schema to the next component.

**Writing data to Neo4j and creating indexes and relationships**

**Procedure**

1. Click the **tNeo4jOutput** component and select the **Component** tab to open its **Basic settings** view.

2. From the **DB Version** list, select **Neo4J 2.X.X** to enable node labeling.

3. Define a Neo4j database connection. In this example, the Neo4j database is accessible in REST mode, so select the **Remote server** check box and specify the URL of the Neo4j server in the **Server URL** field, "http://localhost:7474/db/data" in this example.
4. Double-click the **tNeo4jOutput** component or click the **Mapping** button on the component’s **Basic settings** view to open the index and relationship mapping editor.

5. With the **name** column selected from the schema panel, click the **Index creation** tab, click the [*] button to add a row in the table, and create an index named **first_name** on this column:
   - In the **Name** field, enter **first_name** between double quotation marks.
   - In the **Key** field, enter **first_name** between double quotation marks to give the index a key.

   Then click in the schema panel to validate your index creation.

6. With the **family** column selected from the schema panel, click the **Index creation** tab, click the [*] button to add a row in the table, and create an index named **family** on this column:
   - In the **Name** field, enter **family** between double quotation marks.
   - In the **Key** field, enter **family_name** between double quotation marks to give the index a key.

   Then click in the schema panel to validate your index creation.

7. With the **family** column selected from the schema panel, click the **Relationship creation** tab, click the [*] button to add a row in the table, and create a relationship named **Spouse** on this column based on the index named **family**:
   - In the **Type** field, enter **Spouse** between double quotation marks.
   - From the **Direction** list field, select either **Outgoing** or **Incoming**.
   - In the **Index Name** field, enter **family** between double quotation marks.
   - In the **Index Key** field, enter **family_name** between double quotation marks.

   Then click in the schema panel to validate your relationship creation, and click **OK** to close the mapping editor.
8. Select the Use label (Neo4j > 2.0) check box and enter Families between double quotation marks in the Label name field so that the nodes to be created will be labeled Families.

9. From the Data action list, select Insert or update, and set a reference key in the Index area that appears:
   - In Index name field, enter first_name between double quotation marks.
   - In Index key field, enter first_name between double quotation marks.
   - From Index value field, select name. As the Value field is left blank in index creation, the index value will be the value of the name column for each row.

   This way, when the Job is executed, nodes will be inserted or updated in the Neo4j database based on the first_name index: for each data row, if a node containing the same first name already exists in the database, the node will be updated; otherwise, a new node will be created.

**Executing the Job and checking the result**

**Procedure**

1. Press Ctrl+S to save the Job, and press F6 or click Run on the Run tab to run the Job.
2. In the address bar of your Web browser, enter the URL of the Neo4j database browser, http://localhost:7474/ in this example, and enter the following Cypher query in the command line to view the nodes.

   MATCH (:Families) RETURN ;

   As shown in the graphic view, three pairs of nodes labeled Families have been created and those with the same family name are linked together via the relationship Spouse.
tNeo4jOutputRelationship

Receives data from the preceding component and writes relationships into Neo4j.

tNeo4jOutputRelationship Standard properties

These properties are used to configure tNeo4jOutputRelationship running in the Standard Job framework.

The Standard tNeo4jOutputRelationship component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

Basic settings

<table>
<thead>
<tr>
<th>Use existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB version</td>
<td>Select the Neo4j version you are using. This component does not support Neo4j version V3.2.X. Do not reuse the connection to V3.2.X defined in a tNeo4jConnection component. Do not use a 2.X.X version and a 3.X.X version in the same Job. Otherwise, class conflict issues occur. Neo4j version 2.X.X is compatible only with Java 7 or higher but it offers support of advanced features such as node labels. This list is not shown if the Use an existing connection check box is selected. Upon selecting a database version, you will be prompted to install the corresponding database driver JAR files if not yet installed. You can find more details about how to install external modules in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>

</tbody>
</table>
| Remote server           | Select this check box if you use a Neo4j remote server, and specify the root URL in the Server URL field.  
  - **Set username**: this check box is available when you have selected the Use a remote server check box and the Neo4j version you are using is earlier than 2.2. If the remote Neo4j server you want to connect to does not require user credentials, leave it clear.  
  - **Username and Password**: enter the authentication information to connect to the remote Neo4j server to be used. Since Neo4j 2.2, user credentials are always required. This check box appears only if you do not select the Use an existing connection check box. |
| Database path           | If you use Neo4j in embedded mode, specify the path of data file. |
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `LINE` when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No upon completion** and choose this schema metadata again in the **Repository Content** window. |
| **Built-In**: You create and store the schema locally for this component only. |
| **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com). |
| **Server url** | If you use Neo4j in REST mode, specify the root URL. This field appears only if you select the **Remote server** check box. |
| **Shutdown after job** | Select this check box to shutdown the Neo4j database connection when no more operations on Neo4j are going to be performed after the current component.

Alternatively, you can use `tNeo4jClose` to shutdown the database.

This avoids errors such as ‘Id file not properly shutdown’ at next execution of Jobs involving Neo4j.

This check box is available only if the **Use an existing connection** check box is not selected. |
| **Relationship type** | Specify the relationship type to create for each row. |
| **Start node / Index name** | Specify the index name to query the starting node of the newest relationship. |
| **Start node / Index key** | Specify the index key to query the starting node. |
Start node / Index value | Select the index value to query the starting node.
---|---
Relationship direction | Select a relationship direction.
- **Outgoing**: The relationship starts from the start node to the end node.
- **Incoming**: The relationship starts from the end node to the start node.
End node / Index name | Specify the index name to query the ending node of the newest relationship.
End node / Index key | Specify the index key to query the ending node.
End node / Index value | Select the index value to query the ending node.
Mapping | Use this table to map relationship properties with the input schema columns.

**Advanced settings**

Commit every | Enter the number of rows to be completed before committing batches of nodes together the DB. This option ensures transaction quality (but not rollback) and, above all, better performance at execution.
This option is only supported by the embedded mode of the database. You can’t make transactions in REST mode.

Batch import | Select this check to activate the batch mode.
This option is only supported by the embedded mode of the database. **Be very careful with the batch import mode. Because this option is unsafe, perform a backup before Job execution.**
If you want more explanations about memory mapping configuration of batch import, please refer to Neo4j documentation at: [http://neo4j.com/docs/stable/batchinsert-examples.html](http://neo4j.com/docs/stable/batchinsert-examples.html)

Node store mapped memory | Type in the memory size in MB allocated to nodes.
Relationship store mapped memory | Type in the memory size in MB allocated to relationships.
Property store mapped memory | Type in the memory size in MB allocated to property.
String store mapped memory | Type in the memory size in MB in Mo allocated to strings.
Array store mapped memory | Type in the memory size in MB allocated to arrays.
tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

**Global Variables**

Global Variables | **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

---

**Usage**

<table>

**Writing information of actors and movies to Neo4j with hierarchical relationship**

This scenario applies only to [Talend products with Big Data](#).

This scenario describes a Job that will import information about actors and movies from two CSV files into a remote Neo4j database and then create relationship between the actors and the movies based on another CSV file that describes the actors’ roles in the movies.

**Adding and linking components**

**Procedure**

1. Create a Job and add the following components to the Job by typing theirs names in the design workspace or dropping them from the **Palette**:
   - a [tNeo4jConnection](#) component, to open a connection to a Neo4j database,
   - three [tFileInputDelimited](#) components, to read the input information of actors and movies,
   - two [tNeo4jOutput](#) components, to write information of movies and actors to the connected Neo4j database,
   - a [tNeo4jOutputRelationship](#) component, to create relationship between actors and movies, and
   - a [tNeo4jClose](#) component, to close the previous opened Neo4j connection at the end of Job execution.

2. Link the first [tFileInputDelimited](#) to the first [tNeo4jOutput](#) component using a **Row > Main** connection. This subJob will import the actors data into the Neo4j database.

3. Link the second [tFileInputDelimited](#) component to the second [tNeo4jOutput](#) component using a **Row > Main** connection. This subJob will import the movies data into the Neo4j database.

4. Link the third [tFileInputDelimited](#) component to the [tNeo4jOutputRelationship](#) component using a **Row > Main** connection. This subJob will create relationship between actors and movies.
5. Link the subjobs using Trigger > On Subjob Ok connections.
6. Label the components to better identify their roles in the Job.

**Configuring the components**

**Opening a Neo4j database connection**

**Procedure**

1. Double-click the `tNeo4jConnection` component to open its *Basic settings* view on the *Component* tab.
2. From the **DB Version** list, select **Neo4J 2.X.X** to enable node labeling.

3. Select the **Use a remote server** check box and specify the URL of the Neo4j server in the **Server URL** field, "http://localhost:7474/db/data" in this example.

### Importing the actors data into Neo4j

#### Procedure

1. Double-click the first **tFileInputDelimited** component to open its **Basic settings** view on the **Component** tab.

2. In the **File name/Stream** field, specify the path to the CSV file that describes the actors’ names, the years they were born in, and their roles in the movies.

   The input CSV file used in this example is as follows:

<table>
<thead>
<tr>
<th>Name</th>
<th>Born</th>
</tr>
</thead>
<tbody>
<tr>
<td>Keanu Reeves</td>
<td>1964</td>
</tr>
<tr>
<td>Laurence Fishburne</td>
<td>1961</td>
</tr>
<tr>
<td>Carrie-Anne Moss</td>
<td>1967</td>
</tr>
</tbody>
</table>

3. In the **Header** field, specify the number of rows to skip as header rows. In this example, the first row of the CSV file is the header row.

4. Click the [...] button next to **Edit schema** to open the **Schema** dialog box, and define the input schema based on the structure of the input file. In this example, the input schema is composed of two columns, **name** and **born**, both of type String.

   When done, click **OK** to close the **Schema** dialog box and propagate the schema to the next component.
5. Click the first `tNeo4jOutput` component and select the **Component** tab to open its **Basic settings** view.

6. Select the **Use an existing connection** check box to reuse the Neo4j database connection opened by the `tNeo4jConnection` component, which is the only connection component used in this example.

7. Double-click the `tNeo4jOutput` component or click the **Mapping** button on the component’s **Basic settings** view to open the index and relationship mapping editor.

8. With the `name` column selected from the schema panel, click the **Index creation** tab, click the `[+]` button to add a row in the table, and create an index named `name` on this column:
   - In the **Name** field, enter `name` between double quotation marks.
   - In the **Key** field, enter `name` between double quotation marks to give the index a key `name`.

Then click in the schema panel to validate your index creation, and click **OK** to close the mapping editor.
9. Select the **Use label (Neo4j > 2.0)** check box and enter *Actors* between double quotation marks in the **Label name** field so that the nodes to be created will be labeled *Actors*.

**Importing the movies data into Neo4j**

**Procedure**

1. Double-click the second **tFileInputDelimited** component to open its **Basic settings** view on the **Component** tab.

2. In the **File name/Stream** field, specify the path to the CSV file that contains the information of the movies.
The input CSV file used in this example is as follows:

```
Title;Released;Tagline
The Matrix;03-31-1999;Welcome to the Real World
The Matrix Reloaded;05-07-2003;Free Your Mind
The Matrix Revolutions;10-27-2003;Everything that has a Beginning has an End
```

3. In the **Header** field, specify the number of rows to skip as header rows. In this example, the first row of the CSV file is the header row.

4. Click the [...] button next to **Edit schema** to open the **Schema** dialog box, and define the input schema based on the structure of the input file. In this example, the input schema is composed of three columns, **title** (type String), **released** (type Date), and **tagline** (type String).

When done, click **OK** to close the **Schema** dialog box and propagating the schema to the next component.

5. Click the second **tNeo4jOutput** component and select the **Component** tab to open its **Basic settings** view.

6. Select the **Use an existing connection** check box to reuse the Neo4j database connection opened by the **tNeo4jConnection** component, which is the only connection component used in this example.

7. Double-click the **tNeo4jOutput** component or click the **Mapping** button on the component’s **Basic settings** view to open the index and relationship mapping editor.

8. With the **title** column selected from the schema panel, click the **Index creation** tab, click the [+ ] button to add a row in the table, and create an index named **title** on this column:

   • In the **Name** field, enter **title** between double quotation marks.
   • In the **Key** field, enter **title** between double quotation marks to give the index a key.

Then click in the schema panel to validate your index creation, and click **OK** to close the mapping editor.
9. Select the **Use label (Neo4j > 2.0)** check box and enter *Movies* between double quotation marks in the **Label name** field so that the nodes to be created will be labeled *Movies*.

**Creating actor-movie relationship in Neo4j**

**Procedure**

1. Double-click the third **tFileInputDelimited** component to open its **Basic settings** view on the **Component** tab.

2. In the **File name/Stream** field, specify the path to the CSV file that describes the actors’ roles in the movies.
The input CSV file used in this example is as follows:

<table>
<thead>
<tr>
<th>Actor</th>
<th>Movie</th>
<th>Role</th>
</tr>
</thead>
<tbody>
<tr>
<td>Keanu Reeves</td>
<td>The Matrix; Neo</td>
<td>Neo</td>
</tr>
<tr>
<td>Keanu Reeves</td>
<td>The Matrix Reloaded; Neo</td>
<td>Neo</td>
</tr>
<tr>
<td>Keanu Reeves</td>
<td>The Matrix Revolutions; Neo</td>
<td>Neo</td>
</tr>
<tr>
<td>Laurence Fishburne</td>
<td>The Matrix; Morpheus</td>
<td>Morpheus</td>
</tr>
<tr>
<td>Laurence Fishburne</td>
<td>The Matrix Reloaded; Morpheus</td>
<td>Morpheus</td>
</tr>
<tr>
<td>Laurence Fishburne</td>
<td>The Matrix Revolutions; Morpheus</td>
<td>Morpheus</td>
</tr>
<tr>
<td>Carrie-Anne Moss</td>
<td>The Matrix; Trinity</td>
<td>Trinity</td>
</tr>
<tr>
<td>Carrie-Anne Moss</td>
<td>The Matrix Reloaded; Trinity</td>
<td>Trinity</td>
</tr>
<tr>
<td>Carrie-Anne Moss</td>
<td>The Matrix Revolutions; Trinity</td>
<td>Trinity</td>
</tr>
</tbody>
</table>

3. In the **Header** field, specify the number of rows to skip as header rows. In this example, the first row of the CSV file is the header row.

4. Click the [...] button next to **Edit schema** to open the **Schema** dialog box, and define the input schema based on the structure of the input file. In this example, the input schema is composed of three columns, *actor*, *movie*, and *role*, all of type String.
   
   When done, click **OK** to close the **Schema** dialog box and propagate the schema to the next component.

5. Double-click the **tNeo4jOutputRelationship** component to open its **Basic settings** view.

6. Select the **Use an existing connection** check box to reuse the Neo4j database connection opened by the **tNeo4jConnection** component, which is the only connection component used in this example.

7. In the **Relationship type** field, enter the type of relationship to be created, between double quotation marks. In this example, the relationship type is *ACTED_IN*, which will appear as the label of the relationship between nodes.

8. Define the start and end nodes and the direction of the relationship to be created. In this example, the relationship will be created from *Actors* nodes, on which an index called *name* has been defined, to *Movies* nodes, on which an index called *title* has been defined.
- **Start node:** enter *name* between double quotation marks in the **Index name** and **Index key** fields, and select the schema column *name* from the **Index value** list. As the **Value** field is left blank in index creation, the index value will be the value of column *name* for each row.
- From the **Relationship direction** list, select **Outgoing**.
- **End node:** enter *title* between double quotation marks in the **Index name** and **Index key** fields, and select the schema column *title* from the **Index value** list. As the **Value** field is left blank in index creation, the index value will be the value of column *title* for each row.

9. Click the [+ ] button three times to add three rows in the **Mapping** table to define three properties of the relationship:

<table>
<thead>
<tr>
<th>Property</th>
<th>Value taken from...</th>
</tr>
</thead>
<tbody>
<tr>
<td><em>Actor</em></td>
<td><em>actor</em> column of the schema</td>
</tr>
<tr>
<td><em>Movie</em></td>
<td><em>movie</em> column of the schema</td>
</tr>
<tr>
<td><em>Role</em></td>
<td><em>role</em> column of the schema</td>
</tr>
</tbody>
</table>

**Executing the Job and checking the result**

**Procedure**

1. Press Ctrl+S to save the Job, and press F6 or click Run on the Run tab to run the Job.
2. In the address bar of your Web browser, enter the URL of the Neo4j database browser, http://localhost:7474/ in this example, and enter the following Cypher query in the command line to view the nodes with the specified relationship between them.

   ```cypher
   MATCH (a)-[:`ACTED_IN`]->(b) RETURN a,b;
   ```

As shown in the graphic view, *Actors* nodes are linked with *Movies* nodes via the relationship *ACTED_IN*, with properties as defined in the Job.
MATCH (a:`ACTED_IN`)-->(b) RETURN a,b;
tNeo4jRow

Executes the stated Cypher query onto the specified Neo4j database.

Depending on the nature of the query, tNeo4jRow acts on the data (although without handling data).

tNeo4jRow is the specific component for Neo4j database query. It implements a flow in the Job design although it doesn’t provide output.

**tNeo4jRow Standard properties**

These properties are used to configure tNeo4jRow running in the Standard Job framework.

The Standard tNeo4jRow component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| Use an existing connection | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. |
| DB version | Select the Neo4j version you are using.  
When you are using Neo4j version 3.2.X, this component works in the remote mode only. Therefore, if you want to reuse a connection to Neo4j V3.2.X from tNeo4jConnection, ensure that you have selected the Remote server check box and properly configured the connection.  
Do not use a 2.X.X version and a 3.X.X version in the same Job. Otherwise, class conflict issues occur.  
Neo4j version 2.X.X is compatible only with Java 7 or higher but it offers support of advanced features such as node labels.  
This list is not shown if the Use an existing connection check box is selected.  
Upon selecting a database version, you will be prompted to install the corresponding database driver JAR files if not yet installed. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |
| Remote server | Select this check box if you use a Neo4j remote server, and specify the root URL in the Server URL field.  
- Set username: this check box is available when you have selected the Use a remote server check box and the Neo4j version you are using is earlier than 2.2. If the remote Neo4j server you want to connect to does not require user credentials, leave it clear.  
- Username and Password: enter the authentication information to connect to the remote Neo4j server to be used. Since Neo4j 2.2, user credentials are always required. |
<table>
<thead>
<tr>
<th><strong>Check Box</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>This check box appears only if you do not select the Use an existing connection check box and you are not using Neo4j V3.2.X. With V3.2.X, this component supports the remote mode only.</strong></td>
<td></td>
</tr>
</tbody>
</table>
| **Database path** | If you use Neo4j in embedded mode, specify the directory to hold your data files. If the specified directory does not exist, it will be created.  
This field appears only if you do not select the Use an existing connection check box or the Remote server check box. |
| **Shutdown after job** | Select this check box to shutdown the Neo4j database connection when no more operations on Neo4j are going to be performed after the current component.  
Alternatively, you can use tNeo4jClose to shutdown the database.  
This avoids errors such as 'Id file not properly shutdown' at next execution of Jobs involving Neo4j.  
This check box is available only if the Use an existing connection check box is not selected. |
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.  
Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
• **View schema**: choose this option to view the schema only.  
• **Change to built-in property**: choose this option to change the schema to Built-in for local changes.  
• **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |
| **Built-In**: | You create and store the schema locally for this component only. |
| **Repository**: | You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.  
When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.  
You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com). |
| **Query** | Enter your Cypher query in double quotes. If you have some parameters corresponding to the input schema columns, |
declare them with curly brackets ({}) and map them in the Parameters table.

| Parameters | Click the [+] button to add parameters corresponding to your Cypher query and map them with the input schema columns.  
|------------|--------------------------------------------------|
|            | • **Parameter name**: Type in the name of your parameter, in double quotes.  
|            | • **Parameter value**: Select the schema column you want to map your parameter with.  

| Die on error | This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows.  

### Advanced settings

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level.  
|-------------------------|--------------------------------------------------|

| Commit every | Enter the number of rows to be completed before committing batches of nodes together the database. This option ensures transaction quality (but not rollback) and, above all, better performance at execution.  
|--------------|--------------------------------------------------|

This option is only supported by the embedded mode of the database. You cannot make transactions in REST mode, that is to say, not on a remote server in the deprecated 2.X.X versions.

### Global Variables

| Global Variables | **NB_NODE_INSERTED**: the number of nodes inserted. This is an After variable and it returns a long.  
|------------------|--------------------------------------------------|
|                  | **NB_RELATIONSHIP_INSERTED**: the number of relationships inserted. This is an After variable and it returns a long.  
|                  | **NB_PROPERTY_UPDATED**: the number of properties updated. This is an After variable and it returns a long.  
|                  | **NB_NODE_DELETED**: the number of nodes deleted. This is an After variable and it returns a long.  
|                  | **NB_RELATIONSHIP_DELETED**: the number of relationships deleted. This is an After variable and it returns a long.  
|                  | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
|                  | A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
|                  | To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
|                  | For further information about variables, see Talend Studio User Guide.  

Usage

<table>
<thead>

Creating nodes with a label using a Cypher query

This scenario applies only to Talend products with Big Data.

This scenario describes a Job that creates nodes with a label in an embedded Neo4j database using a Cypher query, and then displays some properties of the specified node on the console.

Adding and linking components

Procedure

1. Create a Job and add the following components to the Job by typing theirs names in the design workspace or dropping them from the Palette:
   - a `tNeo4jConnection` component, to open a connection to a Neo4j database,
   - a `tNeo4jRow` component, to create nodes in the Neo4j database with a Cypher query,
   - a `tNeo4jInput` component, to read the specified properties of the created nodes,
   - a `tLogRow` component, to display the data on the Run console, and
   - a `tNeo4jClose` component, to close the Neo4j database connection established by the `tNeo4jConnection` component.

2. Link the `tNeo4jConnection` component to the `tNeo4jRow` component using a Trigger > On Subjob Ok connection.

3. Link the `tNeo4jRow` component to the `tNeo4jInput` component using a Trigger > On Subjob Ok connection.

4. Link the `tNeo4jInput` component to the `tLogRow` component using a Row > Main connection.

5. Link the `tNeo4jInput` component to the `tNeo4jClose` component using a Trigger > On Subjob Ok connection.
Configuring the components

Configuring a Neo4j database connection and nodes creation

Procedure

1. Double-click the tNeo4jConnection component to open its Basic settings view on the Component tab.

2. From the DB Version list, select Neo4j 2.X.X to enable node labeling support.

3. In the Database path field, specify the directory for your data files, "E:/Talend/DB/Neo4j/data" in this example.

   In this example, you will use Neo4j in embedded mode; to connect to a remote Neo4j server via REST, click the Use a remote server check box and specify the URL of the Neo4j server.
4. Double-click the **tNeo4jRow** component to open its **Basic settings** view on the **Component** tab.

![tNeo4jRow Component](image)

5. Select the **Use an existing connection** check box to reuse the Neo4j database connection opened by the **tNeo4jConnection** component, which is the only connection component used in this example.

6. In the **Query** field, type in the Cypher query to be executed by the component.

   In this example, type in the following query to create two nodes with the label **Managers** and three properties - **id**, **name**, and **position**:

   ```cypher
   CREATE (a:Managers { id: 1, name: 'Gerald White', position: 'HR directory'})
   CREATE (b:Managers { id: 2, name: 'Jimmy Black', position: 'Sales manager'})
   ```

   As this component does not have an input flow, leave the schema and the parameter settings blank.

**Configuring data retrieving and display**

**Procedure**

1. Double-click the **tNeo4jInput** component to open its **Basic settings** view.

![tNeo4jInput Component](image)

2. Select the **Use an existing connection** check box to reuse the connection opened by the **tNeo4jConnection** component.
3. Click the [...] button next to Edit schema and define the schema corresponding to the node properties you want to retrieve and display. In this example, the schema is composed of two columns, name and position, both of type String. When done, click OK to close the Schema dialog box and propagate the schema to the next component.

4. In the Query field, type in the Cypher query to match the data to read from the Neo4j database. In this example, use the following Cypher query to find the name and position of the manager whose ID is 2.

"MATCH (ee:Managers{id:2}) RETURN ee.name, ee.position;"

or

"MATCH (ee:Managers) WHERE ee.id = 2 RETURN ee.name, ee.position;"

5. Fill the Return parameter field for each schema column with a return parameter in double quotes to map the node properties in the Neo4j database with the schema columns.

6. Double-click the tLogRow component to open its Basic settings view, and select the Table (print values in cells of a table) option to display the retrieved information in a table.

**Executing the Job**

**Procedure**

1. Press Ctrl+S to save the Job.
2. Press F6 or click Run on the Run tab to run the Job.
Two nodes are created in the Neo4j database based on the Cypher query, with the data files written in the specified directory, and the defined information is retrieved and displayed on the console.

**Importing data from a CSV file to Neo4j using a Cypher query**

This scenario applies only to Talend products with Big Data.

This scenario describes a Job that first imports employees data from a CSV file into a Neo4j database using a Cypher query, and then displays the information on the console.

**Adding and linking components**

**Procedure**

1. Create a Job and add the following components to the Job by typing theirs names in the design workspace or dropping them from the Palette:
   - a `tNeo4jConnection` component, to open a connection to a Neo4j database,
   - a `tFileInputDelimited` component, to read the source data from a CSV file,
   - a `tNeo4jRow` component, to write the employees data to the Neo4j database with a Cypher query,
   - a `tNeo4jInput` component, to read the employees data from the Neo4j database,
   - a `tLogRow` component, to display the data on the Run console, and
   - a `tNeo4jClose` component, to close the Neo4j database connection opened by the `tNeo4jConnection` component.

2. Link the `tNeo4jConnection` component to the `tFileInputDelimited` component using a Trigger > On Subjob Ok connection.

3. Link the `tFileInputDelimited` component to the `tNeo4jRow` component using a Row > Main connection.

4. Link the `tFileInputDelimited` component to the `tNeo4jInput` component using a Trigger > On Subjob Ok connection.

5. Link the `tNeo4jInput` component to the `tLogRow` component using a Row > Main connection.

6. Link the `tNeo4jInput` component to the `tNeo4jClose` component using a Trigger > On Subjob Ok connection.

7. Label the components to better identify their roles in the Job.
Configuring the components

Configuring a Neo4j database connection

Procedure

1. Double-click the **tNeo4jConnection** component to open its **Basic settings** view on the **Component** tab.

2. From the DB Version list, select **Neo4J 2.X.X**.

3. Select the **Use a remote server** check box and specify the URL of the Neo4j server in the **Server URL** field, "http://localhost:7474/db/data" in this example.
In this example, you will use Neo4j in REST mode; to connect to a remote Neo4j server in embedded mode, clear the Use a remote server check box and specify the Neo4j data file directory in the Database path field.

Configuring data import

Procedure

1. Double-click the tFileInputDelimited component to open its Basic settings view on the Component tab.

   ![Basic settings view](image)

2. In the File name/Stream field, specify the path to the CSV file that contains the employees data to read.

   The input CSV file used in this example is as follows:

   ```
   employeeID;employeeName;age;hireDate;salary;managerID
   1;Rutherford Roosevelt;38;06-10-2008;13336.58;m5
   2;Warren Adams;43;05-22-2008;11626.68;m6
   3;Andrew Roosevelt;55;04-01-2007;10052.95;m4
   4;Herbert Quincy;54;06-14-2007;10694.71;m6
   5;Woodrow Polk;33;08-14-2007;13751.50;m4
   6;Theodore Johnson;47;01-26-2008;12426.87;m6
   7;Benjamin Adams;32;02-25-2008;10438.65;m4
   8;Woodrow Harrison;51;10-11-2008;11188.27;m5
   9;George Truman;40;04-28-2008;14254.49;m5
   10;Harry Jackson;38;04-01-2008;12798.78;m6
   ```

3. In the Header field, specify the number of rows to skip as header rows. In this example, the first row of the CSV file is the header row.

4. Click the [...] button next to Edit schema to open the Schema dialog box, and define the input schema based on the structure of the input file. In this example, the input schema is composed of six columns: employeeID (integer), employeeName (String), age (Integer), hireDate (Date), salary (Double), and managerID (String).

   When done, click OK to close the Schema dialog box and propagate the schema to the next component.
5. Double-click the **tNeo4jRow** component to open its **Basic settings** view on the **Component** tab.

6. Select the **Use an existing connection** check box to reuse the Neo4j database connection opened by the **tNeo4jConnection** component, which is the only connection component used in this example.

7. In the **Query** field, type in the Cypher query to be executed by the component.

   In this example, type in the following query to create nodes with the label `Employees` and six properties, to hold the data from the input flow:

   - **ID**, which will take the value of the variable parameter `id`,
   - **Name**, which will take the value of the variable parameter `name`,
   - **Age**, which will take the value of the variable parameter `age`,
- **HireDate**, which will the value of the variable parameter `hire_date`.
- **Salary**, which will take the value of the variable parameter `salary`, and
- **ManagerID**, which will the value of the variable parameter `manager_id`.

```
"CREATE (n:Employees{ID:{id}, Name:{name}, Age:{age}, HireDate:{hire_date}, Salary: {salary}, ManagerID:{manager_id}})"
```

8. In the **Parameters** table, type in the variable parameters in the **Parameter** field in accordance with your Cypher query, and map each of them with an input schema column by selecting it from the **Parameter value** list field.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Parameter value</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;id&quot;</td>
<td>employeeID</td>
</tr>
<tr>
<td>&quot;name&quot;</td>
<td>employeeName</td>
</tr>
<tr>
<td>&quot;age&quot;</td>
<td>age</td>
</tr>
<tr>
<td>&quot;hire_date&quot;</td>
<td>hireDate</td>
</tr>
<tr>
<td>&quot;salary&quot;</td>
<td>salary</td>
</tr>
<tr>
<td>&quot;manager_id&quot;</td>
<td>managerID</td>
</tr>
</tbody>
</table>

**Configuring data retrieving and display**

**Procedure**

1. Double-click the **tNeo4jInput** component to open its **Basic settings** view.

2. Select the **Use an existing connection** check box to reuse the connection opened the **tNeo4jConnection** component.

3. Click the [...] button next to **Edit schema** and define the schema corresponding to the node properties you want to retrieve and display.

   When done, click **OK** to close the **Schema** dialog box and propagate the schema to the next component.
The defined schema columns automatically appear in the Mapping table.

4. In the Query field, type in the Cypher query to match the data to read from the Neo4j database. In this example, use the following Cypher query to retrieve all the properties of all the nodes with the label Employees.

```
"MATCH (n:Employees) RETURN *;"
```

5. Fill the Return parameter field for each schema column with a return parameter in double quotes to map the node properties in the Neo4j database with the schema columns.

6. Double-click the tLogRow component to open its Basic settings view, and select the Table (print values in cells of a table) option to display the retrieved information in a table.

**Executing the Job**

**Procedure**

1. Press Ctrl+S to save the Job.
2. Press F6 or click Run on the Run tab to run the Job.
The employees data in the CSV file is written to the Neo4j database and displayed on the console.

Importing data from a CSV file to Neo4j and creating relationships using a single Cypher query

This scenario applies only to Talend products with Big Data.

This scenario describes a Job that imports family information from a CSV file into a remote Neo4j database and create relationships between persons and families using a single Cypher query through a **tNeo4jRow** component.

Below is content of the CSV file to import data from in this example:

<table>
<thead>
<tr>
<th>Name</th>
<th>Gender</th>
<th>Age</th>
<th>Family</th>
</tr>
</thead>
<tbody>
<tr>
<td>Jenny</td>
<td>Female</td>
<td>24</td>
<td>the Johnsons</td>
</tr>
<tr>
<td>Jack</td>
<td>Male</td>
<td>26</td>
<td>the Johnsons</td>
</tr>
<tr>
<td>Richard</td>
<td>Male</td>
<td>35</td>
<td>the Blacks</td>
</tr>
<tr>
<td>Anne</td>
<td>Female</td>
<td>36</td>
<td>the Whites</td>
</tr>
<tr>
<td>Helen</td>
<td>Female</td>
<td>28</td>
<td>the Blacks</td>
</tr>
<tr>
<td>Tom</td>
<td>Male</td>
<td>38</td>
<td>the Whites</td>
</tr>
</tbody>
</table>

As **MERGE** is used with **LOAD CSV** in this example, to ensure the Cypher query is executed in an efficient way, another **tNeo4jRow** component is used to create an index on the property to merge.

Adding and linking components

**Procedure**

1. Create a Job and add two **tNeo4jRow** components to the Job by typing the component name in the design workspace or dropping them from the Palette.
2. Link the components using a **Trigger > On Sub Job Ok** connection.
3. Label the components to better identify their roles in the Job.
Configuring the components

Creating an index

Procedure

1. Double-click the first tNeo4jRow component to open its Basic settings view on the Component tab.

```
CREATE INDEX ON :Family(name)
```

2. From the DB Version list, select Neo4J 2.X.X.
3. Select the Remote server check box and specify the URL of the Neo4j server in the Server URL field, "http://localhost:7474/db/data" in this example.
4. In the Query field, type in the following query to create an index on the property you are going to merge, which is the name property of the Family nodes in this example:

```
"CREATE INDEX ON :Family(name)"
```

Importing data and creating relationships

Procedure

1. Double-click the second tNeo4jRow component to open its Basic settings view on the Component tab.
2. From the DB Version list, select Neo4j 2.X.X.

3. Select the Remote server check box and specify the URL of the Neo4j server in the Server URL field, "http://localhost:7474/db/data" in this example.

4. In the Query field, type in the following Cypher query to import family data from the CSV file, create relevant Person and Family nodes, and create relationships between persons and families:

   ```
   "LOAD CSV WITH HEADERS FROM 'file:E:/Talend/Data/Input/families.csv' AS csvLine
   FIELDTERMINATOR ';'
   MERGE (family:Family { name: csvLine.Family })
   CREATE (person:Person { name: csvLine.Name, gender: csvLine.Gender, age: toInt(csvLine.Age)})
   CREATE (person)-[:From]->(family)
   ```

**Executing the Job and checking the result**

**Procedure**

1. Press Ctrl+S to save the Job, and press F6 or click Run on the Run tab to run the Job.

2. In the address bar of your Web browser, enter the URL of the Neo4j database browser, http://localhost:7474/ in this example, and enter the following Cypher query in the command line to view the Person and Family nodes linked via the relationship From:

   ```
   MATCH (a:Person)-[:`From`]->(b:Family) RETURN a,b;
   ```

As shown in the graphic view, nodes labeled Family and Person have been created and the nodes of persons from the same families are linked with the relevant Family nodes via the relationship From.
MATCH (a:Person)-[:From]-(b:Family) RETURN a, b;
tNetezzaBulkExec

Offers gains in performance while carrying out the Insert operations to a Netezza database.

**tNetezzaBulkExec Standard properties**

These properties are used to configure tNetezzaBulkExec running in the Standard Job framework.

The Standard tNetezzaBulkExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in:</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository:</strong></td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:</td>
</tr>
<tr>
<td></td>
<td>1. In the parent level, register the database connection to be shared in the <strong>Basic settings</strong> view of the connection component which creates that very database connection.</td>
</tr>
<tr>
<td></td>
<td>2. In the child level, use a dedicated connection component to read that registered database connection.</td>
</tr>
<tr>
<td></td>
<td>For an example about how to share a database connection across Job levels, see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Host</td>
<td>Database server IP address.</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data.</td>
</tr>
</tbody>
</table>
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

<table>
<thead>
<tr>
<th>Table</th>
<th>Name of the table to be written. Note that only one table can be written at a time and that the table must exist for the insert operation to succeed.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Schema and Edit Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <code>line</code> when naming the fields.</td>
</tr>
<tr>
<td><strong>Built-In</strong></td>
<td>You create and store the schema locally for this component only.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
</tr>
</tbody>
</table>

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

| File Name | Name of the file to be loaded. This file should be located on the same machine where the Studio is installed or where the Job using **tNetezzaBulkExec** is deployed. |

### Advanced settings

<p>| <strong>Field Separator</strong> | Character, string or regular expression to separate fields. |
| <strong>Escape character</strong> | Character of the row to be escaped. |
| <strong>Date format / Date delimiter</strong> | Use Date format to distinguish the way years, months and days are represented in a string. Use Date delimiter to specify the separator between date values. |
| <strong>Time format/ Time delimiter</strong> | Use Time format to distinguish the time is represented in a string. Use Time delimiter to specify the separator between time values. |
| <strong>Encoding</strong> | Select the encoding from the list or select <strong>Custom</strong> and define it manually. This field is compulsory for DB data handling. |</p>
<table>
<thead>
<tr>
<th><strong>Max Errors</strong></th>
<th>Enter the maximum error limit that will not stop the process.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Skip Rows</strong></td>
<td>Enter the number of rows to be skipped.</td>
</tr>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

### Global Variables

**Global Variables**

- **NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see **Talend Studio User Guide**.

### Usage

**Usage rule**

This component is mainly used when non particular transformation is required on the data to be loaded on to the database.

**Dynamic settings**

Click the **[+]** button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

**Limitation**

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the
Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

**Related scenarios**

For use cases in relation with tNetezzaBulkExec, see the following scenarios:

- Inserting transformed data in MySQL database on page 2493.
- Inserting data in bulk in MySQL database on page 2500.
- Truncating and inserting file data into an Oracle database on page 2700.
tNetezzaClose

Closes the transaction committed in the connected Netezza database.

tNetezzaClose Standard properties

These properties are used to configure tNetezzaClose running in the Standard Job framework.

The Standard tNetezzaClose component belongs to the Databases family.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tNetezzaConnection component in the list if more than one connection are planned for the current Job.</td>
</tr>
</tbody>
</table>

Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

Usage

| Usage rule | This component is to be used along with Netezza components, especially with tNetezzaConnection and tNetezzaCommit. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |
Related scenarios

No scenario is available for the Standard version of this component yet.
tNetezzaCommit

Validates the data processed through the Job into the connected Netezza database.

Using a unique connection, tNetezzaCommit commits in one go a global transaction instead of doing that on every row or every batch and thus provides gain in performance.

**tNetezzaCommit Standard properties**

These properties are used to configure tNetezzaCommit running in the Standard Job framework.

The Standard tNetezzaCommit component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tNetezzaConnection component in the list if more than one connection are planned for the current Job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Warning:**

*If you want to use a Row > Main connection to link tNetezzaCommit to your Job, your data will be committed row by row. In this case, do not select the Close connection check box or your connection will be closed before the end of your first row commit.*

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is more commonly used with other tNetezza* components, especially with the tNetezzaConnection and tNetezzaRollback components. |
| Dynamic settings | Click the [+ ] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to acces |
s database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenario

For tNetezzaCommit related scenario, see Inserting data in mother/daughter tables on page 2437.
**tNetezzaConnection**

Opens a connection to a Netezza database to be reused in the subsequent subJob or subJobs.

**tNetezzaConnection Standard properties**

These properties are used to configure tNetezzaConnection running in the Standard Job framework.

The Standard tNetezzaConnection component belongs to the Databases and the ELT families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
<tr>
<td><strong>Property type</strong></td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td><strong>Built-in</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><strong>Host</strong></td>

</tr>
<tr>
<td><strong>Use or register a shared DB Connection</strong></td>
<td>Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the <strong>Shared DB Connection Name</strong> field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child. This option is incompatible with the <strong>Use dynamic job</strong> and <strong>Use an independent process to run subjob</strong> options of the tRunJob component. Using a shared connection together...</td>
</tr>
</tbody>
</table>
### tNetezzaConnection

with a **tRunJob** component with either of these two options enabled will cause your Job to fail.

#### Advanced settings

| Auto Commit | Select this check box to commit any changes to the database automatically upon the transaction. With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component. Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component. |
| tStatCatcher Statistics | Select this check box to gather the job processing metadata at a Job level as well as at each component level. |

#### Usage

| Usage rule | This component is more commonly used with other tNetezza* components, especially with the **tNetezzaCommit** and **tNetezzaRollback** components. |
| Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |

#### Related scenarios

For a **tNetezzaConnection** related scenario, see Inserting data in mother/daughter tables on page 2437.
tNetezzaInput

Reads a database and extracts fields from a Netezza database based on a query.
tNetezzaInput executes a DB query with a strictly defined order which must correspond to the schema definition. Then it passes on the field list to the next component via a Main row link.

**tNetezzaInput Standard properties**

These properties are used to configure tNetezzaInput running in the Standard Job framework.
The Standard tNetezzaInput component belongs to the Databases family.
The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
<tr>
<td><strong>Property type</strong></td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td><strong>Built-in</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><strong>Use an existing connection</strong></td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

This icon opens a database connection wizard and stores the database connection parameters you set in the component Basic settings view.

For more information about setting up and storing database connection parameters, see Talend Studio User Guide.
**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th>Host</th>
<th>Database server IP address</th>

<td><strong>This component covers all possible SQL queries for Netezza databases.</strong></td>
<td></td>
</tr>
</tbody>
</table>

**Dynamic settings**

Click the [*] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the...
Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

| Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |

**Related scenarios**

Related scenarios for **tNetezzainput** are:

- Reading data from different MySQL databases using dynamically loaded connection parameters on page 491.
tNetezzaNzLoad

Inserts data into a Netezza database table using Netezza’s nzload utility.

tNetezzaNzLoad bulk loads data into a Netezza table either from an existing data file, an input flow, or directly from a data flow in streaming mode through a named-pipe.

**tNetezzaNzLoad Standard properties**

These properties are used to configure tNetezzaNzLoad running in the Standard Job framework.
The Standard tNetezzaNzLoad component belongs to the Databases family.
The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either <strong>Built-in</strong> or <strong>Repository</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Built-in</strong>: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Host</th>
<th>Database server IP address.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>Listening port number of the DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the Netezza database.</td>
</tr>
</tbody>
</table>

**Username and Password**

DB user authentication data.
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

<table>
<thead>
<tr>
<th>Table</th>
<th>Name of the table into which the data is to be inserted.</th>
</tr>
</thead>
</table>

**Action on table**

On the table defined, you can perform one of the following operations before loading the data:

- **None**: No operation is carried out.
- **Drop and create a table**: The table is removed and created again.
- **Create a table**: The table does not exist and gets created.
- **Create table if not exists**: The table is created if it does not exist.
- **Drop table if exists and create**: The table is removed if it already exists and created again.
- **Clear table**: The table content is deleted before the data is loaded.
- **Truncate table**: executes a truncate statement prior to loading the data to clear the entire content of the table.
### Schema and Edit Schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

**Built-In:** You create and store the schema locally for this component only.

**Repository:** You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema:** choose this option to view the schema only.
- **Change to built-in property:** choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection:** choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

### Data file

Full path to the data file to be used. If this component is used on its own (not connected to another component with input flow) then this is the name of an existing data file to be loaded into the database. If it is connected, with an input flow to another component; this is the name of the file to be generated and written with the incoming data to later be used with nzload to load into the database.

### Use named-pipe

Select this check box to use a named-pipe instead of a data file. This option can only be used when the component is connected with an input flow to another component. When the check box is selected, no data file is generated and the data is transferred to nzload through a named-pipe. This option greatly improves performance in both Linux and Windows.

**Note:**

This component on named-pipe mode uses a JNI interface to create and write to a named-pipe on any Windows platform. Therefore the path to the associated JNI DLL must be configured inside the java library path. The component comes with two DLLs for both 32 and 64 bit operating systems that are automatically provided in the Studio with the component.

### Named-pipe name

Specify a name for the named-pipe to be used. Ensure that the name entered is valid.
### Advanced settings

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use existing control file</td>
<td>Select this check box to provide a control file to be used with the nzload utility instead of specifying all the options explicitly in the component. When this check box is selected, Data file and the other nzload related options no longer apply. Please refer to Netezza’s nzload manual for details on creating a control file.</td>
</tr>
<tr>
<td>Note:</td>
<td>The global variable NB_LINE is not supported when any control file is being used.</td>
</tr>
<tr>
<td>Control file</td>
<td>Enter the path to the control file to be used, between double quotation marks, or click [...] and browse to the control file. This option is passed on to the nzload utility via the -cf argument.</td>
</tr>
<tr>
<td>Field separator</td>
<td>Character, string or regular expression used to separate fields.</td>
</tr>
<tr>
<td>Warning:</td>
<td>This is nzload’s delim argument. If you do not use the Wrap quotes around fields option, you must make sure that the delimiter is not included in the data that's inserted to the database. The default value is \t or TAB. To improve performance, use the default value.</td>
</tr>
<tr>
<td>Wrap quotes around fields</td>
<td>This option is only applied to columns of String, Byte, Byte[], Char, and Object types. Select either:</td>
</tr>
<tr>
<td>None:</td>
<td>do not wrap column values in quotation marks.</td>
</tr>
<tr>
<td>Single quote:</td>
<td>wrap column values in single quotation marks.</td>
</tr>
<tr>
<td>Double quote:</td>
<td>wrap column values in double quotation marks.</td>
</tr>
<tr>
<td>Warning:</td>
<td>If using the Single quote or Double quote option, it is necessary to use \ as the Escape char.</td>
</tr>
<tr>
<td>Advanced options</td>
<td>Set the nzload arguments in the corresponding table. Click [*] as many times as required to add arguments to the table. Click the Parameter field and choose among the arguments from the list. Then click the corresponding Value field and enter a value between quotation marks. For details about the available parameters, see Parameters on page 2644.</td>
</tr>
<tr>
<td>Encoding</td>
<td>Select the encoding type from the list.</td>
</tr>
<tr>
<td>Specify nzload path</td>
<td>Select this check box to specify the full path to the nzload executable. You must check this option if the nzload path is not specified in the PATH environment variable.</td>
</tr>
</tbody>
</table>
tNetezzaNzLoad

Full path to nzload executable

Full path to the nzload executable on the machine in use. It is advisable to specify the nzload path in the PATH environment variable instead of selecting this option.

Global Variables

Global Variables

NB_LINE: the number of rows processed. This is an After variable and it returns an integer.

ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule

This component is mainly used when non particular transformation is required on the data to be loaded onto the database.

This component can be used as a standalone or an output component.

Parameters

The following table lists the parameters you can use in the Advanced options table in the Advanced settings tab.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-if</td>
<td>Name of the log file to generate. The logs will be appended if the log file already exists. If the parameter is not specified, the default name for the log file is '&lt;table_name&gt;.&lt;db_name&gt;.nzlog'. And it's generated under the current working directory where the job is running.</td>
</tr>
<tr>
<td>-bf</td>
<td>Name of the bad file to generate. The bad file contains all the records that could not be loaded due to an internal Netezza error. The records will be appended if the bad file already exists. If the parameter is not specified, the default name for the bad file is '&lt;table_name&gt;.&lt;db_name&gt;.nzbad'. And it's generated under the current working directory where the job is running.</td>
</tr>
<tr>
<td>-outputDir</td>
<td>Directory path to where the log and the bad file are generated. If the parameter is not specified the files are generated under the current working directory.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>-logFileSize</td>
<td>Maximum size for the log file. The value is in MB. The default value is 2000 or 2GB. To save hard disk space, specify a smaller amount if your job runs often.</td>
</tr>
<tr>
<td>-compress</td>
<td>Specify this option if the data file is compressed. Valid values are &quot;TRUE&quot; or &quot;FALSE&quot;. Default value if &quot;FALSE&quot;. This option is only valid if this component is used by itself and not connected to another component via an input flow.</td>
</tr>
<tr>
<td>-skipRows &lt;n&gt;</td>
<td>Number of rows to skip from the beginning of the data file. Set the value to '1' if you like to skip the header row from the data file. The default value is '0'. This option should only be used if this component is used by itself and not connected to another component via an input flow.</td>
</tr>
<tr>
<td>-maxRows &lt;n&gt;</td>
<td>Maximum number of rows to load from the data file. This option should only be used if this component is used by itself and not connected to another component via an input flow.</td>
</tr>
<tr>
<td>-maxErrors</td>
<td>Maximum number of error records to allow before terminating the load process. The default value is '1'.</td>
</tr>
<tr>
<td>-ignoreZero</td>
<td>Binary zero bytes in the input data will generate errors. Set this option to 'NO' to generate error or to 'YES' to ignore zero bytes. The default value is 'NO'.</td>
</tr>
<tr>
<td>-requireQuotes</td>
<td>This option requires all the values to be wrapped in quotes. The default value is &quot;FALSE&quot;. This option currently does not work with input flow. Use this option only in standalone mode with an existing file.</td>
</tr>
<tr>
<td>-nullValue &lt;token&gt;</td>
<td>Specify the token to indicate a null value in the data file. The default value is 'NULL'. To improve slightly performance you can set this value to an empty field by specifying the value as single quotes: &quot;&quot;&quot;.</td>
</tr>
<tr>
<td>-fillRecord</td>
<td>Treat missing trailing input fields as null. You do not need to specify a value for this option in the value field of the table. This option is not turned on by default, therefore input fields must match exactly all the columns of the table by default. Trailing input fields must be nullable in the database.</td>
</tr>
<tr>
<td>-ctrlChar</td>
<td>Accept control chars in char/varchar fields (must escape NUL, CR and LF). You do not need to specify a value for this option in the value field of the table. This option is turned off by default.</td>
</tr>
<tr>
<td>-ctnInString</td>
<td>Accept un-escaped CR in char/varchar fields (LF becomes only end of row). You do not need to specify a value for this option in the value field of the table. This option is turned off by default.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>-truncString</td>
<td>Truncate any string value that exceeds its declared char/varchar storage. You do not need to specify a value for this option in the value field of the table. This option is turned off by default.</td>
</tr>
<tr>
<td>-dateStyle</td>
<td>Specify the date format in which the input data is written in. Valid values are: &quot;YMD&quot;, &quot;Y2MD&quot;, &quot;DMY&quot;, &quot;DNY2&quot;, &quot;MDY&quot;, &quot;MMDY&quot;, &quot;MONDY&quot;, &quot;MONDY2&quot;. The default value is &quot;YMD&quot;. The date format of the column in the component's schema must match the value specified here. For example if you want to load a DATE column, specify the date format in the component schema as 'yyyy-MM-dd' and the -dateStyle option as 'YMD'. For more description on loading date and time fields, see Loading DATE, TIME and TIMESTAMP columns on page 2647.</td>
</tr>
<tr>
<td>-dateDelim</td>
<td>Delimiter character between date parts. The default value is &quot;.&quot; for all date styles except for &quot;MONDY[2]&quot; which is &quot; &quot; (empty space). The date format of the column in the component's schema must match the value specified here.</td>
</tr>
<tr>
<td>-y2Base</td>
<td>First year expressible using two digit year (Y2) dateStyle.</td>
</tr>
<tr>
<td>-timeStyle</td>
<td>Specify the time format in which the input data is written in. Valid values are: &quot;24HOUR&quot; and &quot;12HOUR&quot;. The default value is &quot;24HOUR&quot;. For slightly better performance you should keep the default value. The time format of the column in the component's schema must match the value specified here. For example if you want to load a TIME column, specify the date format in the component schema as 'HH:mm:ss' and the -timeStyle option as '24HOUR'. For more description on loading date and time fields, see Loading DATE, TIME and TIMESTAMP columns on page 2647.</td>
</tr>
<tr>
<td>-timeDelim</td>
<td>Delimiter character between time parts. The default value is &quot;&quot;.</td>
</tr>
<tr>
<td>-timeRoundNanos</td>
<td>Allow but round non-zero digits with smaller than microsecond resolution.</td>
</tr>
<tr>
<td>-boolStyle</td>
<td>Specify the format in which Boolean data is written in the data. The valid values are: &quot;1_0&quot;, &quot;T_F&quot;, &quot;Y_N&quot;, &quot;TRUE_FALSE&quot;, &quot;YES&quot;. The default value is &quot;1_0&quot;. For slightly better performance keep the default value.</td>
</tr>
<tr>
<td>-allowRelay</td>
<td>Allow load to continue after one or more SPU reset or failed over. The default behaviour is not allowed.</td>
</tr>
</tbody>
</table>
Loading DATE, TIME and TIMESTAMP columns

When this component is used with an input flow, the date format specified inside the component’s schema must match the value specified for -dateStyle, -dateDelim, -timeStyle, and -timeDelim options.

<table>
<thead>
<tr>
<th>DB Type</th>
<th>Schema date format</th>
<th>-dateStyle</th>
<th>-dateDelim</th>
<th>-timeStyle</th>
<th>-timeDelim</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATE</td>
<td>&quot;yyyy-MM-dd&quot;</td>
<td>&quot;YMD&quot;</td>
<td>&quot;:&quot;</td>
<td>n/a</td>
<td>n/a</td>
</tr>
<tr>
<td>TIME</td>
<td>&quot;HH:mm:ss&quot;</td>
<td>n/a</td>
<td>n/a</td>
<td>&quot;24HOUR&quot;</td>
<td>&quot;:&quot;</td>
</tr>
<tr>
<td>TIMESTAMP</td>
<td>&quot;yyyy-MM-dd HH:mm:ss&quot;</td>
<td>&quot;YMD&quot;</td>
<td>&quot;:&quot;</td>
<td>&quot;24HOUR&quot;</td>
<td>&quot;:&quot;</td>
</tr>
</tbody>
</table>

Related scenario

For a related use case, see Inserting data in bulk in MySQL database on page 2500.
**tNetezzaOutput**

Writes, updates, makes changes or suppresses entries in a Netezza database.
tNetezzaOutput executes the action defined on the table and/or on the data contained in the table, based on the flow incoming from the preceding component in the designed Job.

**tNetezzaOutput Standard properties**

These properties are used to configure tNetezzaOutput running in the Standard Job framework. The Standard tNetezzaOutput component belongs to the Databases family.
The component in this framework is available in all Talend products.

*Note:* This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-in:</strong> No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository:</strong> Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>![icon]</td>
<td>Click this icon to open a database connection wizard and store the database connection parameters you set in the component <strong>Basic settings</strong> view.</td>
</tr>
<tr>
<td></td>
<td>For more information about setting up and storing database connection parameters, see <strong>Talend Studio User Guide</strong>.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see [Talend Studio User Guide](#).

<table>
<thead>
<tr>
<th>Host</th>
<th>Database server IP address</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Table</td>
<td>Name of the table to be written. Note that only one table can be written at a time</td>
</tr>
<tr>
<td>Action on table</td>
<td>On the table defined, you can perform one of the following operations:</td>
</tr>
<tr>
<td>Default</td>
<td>No operation is carried out.</td>
</tr>
<tr>
<td>Drop and create a table</td>
<td>The table is removed and created again.</td>
</tr>
<tr>
<td>Create a table</td>
<td>The table does not exist and gets created.</td>
</tr>
<tr>
<td>Create a table if not exists</td>
<td>The table is created if it does not exist.</td>
</tr>
<tr>
<td>Drop a table if exists and create</td>
<td>The table is removed if it already exists and created again.</td>
</tr>
<tr>
<td>Clear a table</td>
<td>The table content is deleted.</td>
</tr>
<tr>
<td>Action on data</td>
<td>On the data of the table defined, you can perform:</td>
</tr>
<tr>
<td>Insert</td>
<td>Add new entries to the table. If duplicates are found, job stops.</td>
</tr>
<tr>
<td>Update</td>
<td>Make changes to existing entries</td>
</tr>
<tr>
<td>Insert or update</td>
<td>Insert a new record. If the record with the given reference already exists, an update would be made.</td>
</tr>
<tr>
<td>Update or insert</td>
<td>Update the record with the given reference. If the record does not exist, a new record would be inserted.</td>
</tr>
<tr>
<td>Delete</td>
<td>Remove entries corresponding to the input flow.</td>
</tr>
</tbody>
</table>
**Warning:**

It is necessary to specify at least one column as a primary key on which the Update and Delete operations are based. You can do that by clicking Edit Schema and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the Advanced settings view where you can simultaneously define primary keys for the Update and Delete operations. To do that: Select the Use field options check box and then in the Key in update column, select the check boxes next to the column names you want to use as a base for the Update operation. Do the same in the Key in delete column for the Delete operation.

<table>
<thead>
<tr>
<th><strong>Schema and Edit schema</strong></th>
<th>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-In</strong></td>
<td>You create and store the schema locally for this component only.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually. You can find more details about how to verify default values in retrieved schema in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
<tr>
<td><strong>Click Edit schema</strong></td>
<td>Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:</td>
</tr>
<tr>
<td></td>
<td>• <strong>View schema</strong>: choose this option to view the schema only.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Change to built-in property</strong>: choose this option to change the schema to Built-in for local changes.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Update repository connection</strong>: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select <strong>No</strong> upon completion and choose this schema metadata again in the Repository Content window.</td>
</tr>
</tbody>
</table>

| **Die on error**           | This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a Row > Rejects link. |
## Advanced settings

| **Additional JDBC parameters** | Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the **Use an existing connection** check box in the **Basic settings**.

**Note:**
You can press Ctrl+Space to access a list of predefined global variables.

| **Use Batch** | Select this check box to activate the batch mode for data processing.

**Note:**
This check box is available only when you have selected the **Insert**, **Update** or the **Delete** option in the **Action on data** list.

| **Batch Size** | Specify the number of records to be processed in each batch.

This field appears only when the **Use batch mode** check box is selected.

| **Commit every** | Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and, above all, better performance at executions.

| **Additional Columns** | This option is not offered if you create (with or without drop) the DB table. This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing.

**Name:** Type in the name of the schema column to be altered or inserted as new column

**SQL expression:** Type in the SQL statement to be executed in order to alter or insert the relevant column data.

**Position:** Select **Before**, **Replace** or **After** following the action to be performed on the reference column.

**Reference column:** Type in a column of reference that the tDBOutput can use to place or replace the new or altered column.

| **Use field options** | Select this check box to customize a request, especially when there is double action on data.

| **tStatCatcher Statistics** | Select this check box to collect log data at the component level. |
### Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE</strong></td>
<td>the number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_UPDATED</strong></td>
<td>the number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_INSERTED</strong></td>
<td>the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_DELETED</strong></td>
<td>the number of rows deleted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_REJECTED</strong></td>
<td>the number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>ERROR_MESSAGE</strong></td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

### Usage

| Usage rule | This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible. This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in a Netezza database. It also allows you to create a reject flow using a **Row > Rejects** link to filter data in error. For an example of **tMySqlOutput** in use, see Retrieving data in error with a Reject link on page 2485. |

### Dynamic settings

Click the [+ ] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic...
settings and context variables, see Talend Studio User Guide.

| Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |

**Related scenarios**

For **tNetezzaOutput** related topics, see:

- Inserting a column and altering data using **tMysqlOutput** on page 2477.
tNetezzaRollback

Cancels the transaction committed in the connected Netezza database to avoid committing part of a transaction involuntarily.

**tNetezzaRollback Standard properties**

These properties are used to configure tNetezzaRollback running in the Standard Job framework.

The Standard tNetezzaRollback component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tNetezzaConnection component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

### Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

### Usage

| Usage rule | This component is more commonly used with other tNetezza* components, especially with the tNetezzaConnection and tNetezzaCommit components. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection. |
Related scenarios

For tNetezzaRollback related scenario, see Rollback from inserting data in mother/daughter tables on page 2440.
tNetezzaRow

Executes the SQL query stated onto the specified Netezza database.

Depending on the nature of the query and the database, tNetezzaRow acts on the actual DB structure or on the data (although without handling data). The SQLBuilder tool helps you write easily your SQL statements.

tNetezzaRow is the specific component for this database query. It implements a flow in the job design although it does not provide output.

**tNetezzaRow Standard properties**

These properties are used to configure tNetezzaRow running in the Standard Job framework.

The Standard tNetezzaRow component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td><strong>Built-in:</strong> No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td><strong>Repository:</strong> Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
<td></td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
<table>
<thead>
<tr>
<th><strong>Host</strong></th>
<th>Database server IP address</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Schema and Edit Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word Line when naming the fields.</td>
</tr>
<tr>
<td><strong>Built-In</strong>:</td>
<td>You create and store the schema locally for this component only.</td>
</tr>
<tr>
<td><strong>Repository</strong>:</td>
<td>You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
</tr>
<tr>
<td><strong>Table Name</strong></td>
<td>Enter the name of the table to be processed.</td>
</tr>
<tr>
<td><strong>Query type</strong></td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td><strong>Built-in</strong>:</td>
<td>Fill in manually the query statement or build it graphically using SQLBuilder</td>
</tr>
<tr>
<td><strong>Repository</strong>:</td>
<td>Select the relevant query stored in the Repository. The Query field gets accordingly filled in.</td>
</tr>
<tr>
<td><strong>Query</strong></td>
<td>Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.</td>
</tr>
<tr>
<td><strong>Die on error</strong></td>
<td>This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a Row &gt; Rejects link.</td>
</tr>
</tbody>
</table>
## Advanced settings

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Additional JDBC parameters</strong></td>
<td>Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the Use an existing connection check box in the Basic settings.</td>
</tr>
<tr>
<td><strong>Propagate QUERY’s recordset</strong></td>
<td>Select this check box to insert the result of the query into a COLUMN of the current flow. Select this column from the use column list. <strong>Note:</strong> This option allows the component to have a different schema from that of the preceding component. Moreover, the column that holds the QUERY’s recordset should be set to the type of Object and this component is usually followed by tParseRecordSet.</td>
</tr>
<tr>
<td><strong>Use PreparedStatement</strong></td>
<td>Select this check box if you want to query the database using a PreparedStatement. In the Set PreparedStatement Parameter table, define the parameters represented by &quot;?&quot; in the SQL instruction of the Query field in the Basic Settings tab. <strong>Parameter Index:</strong> Enter the parameter position in the SQL instruction. <strong>Parameter Type:</strong> Enter the parameter type. <strong>Parameter Value:</strong> Enter the parameter value. <strong>Note:</strong> This option is very useful if you need to execute the same query several times. Performance levels are increased.</td>
</tr>
<tr>
<td><strong>Commit every</strong></td>
<td>Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions.</td>
</tr>
<tr>
<td><strong>tStat Catcher Statistics</strong></td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

## Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>QUERY</strong></td>
<td>the query statement being processed. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td><strong>NB_EFFECTED</strong></td>
<td>the number of effected rows. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>ERROR_MESSAGE</strong></td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
</tbody>
</table>

2658
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component offers the flexibility of the DB query and covers all possible SQL queries.</th>
</tr>
</thead>
</table>

Dynamic settings

Click the \[+\] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

Related scenarios

For related scenarios, see:

- Combining two flows for selective output on page 2514
- Removing and regenerating a MySQL table index on page 2508
tNetezzaSCD

Reflects and tracks changes in a dedicated Netezza SCD table.

tNetezzaSCD addresses Slowly Changing Dimension needs, reading regularly a source of data and logging the changes into a dedicated SCD table.

**tNetezzaSCD Standard properties**

These properties are used to configure tNetezzaSCD running in the Standard Job framework.

The Standard tNetezzaSCD component belongs to the Business Intelligence and the Databases families.

The component in this framework is available in all Talend products.

*Note:* This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Host</td>
<td>Database server IP address.</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
</tbody>
</table>

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.
<table>
<thead>
<tr>
<th>Database</th>
<th>Name of the database.</th>
</tr>
</thead>
</table>
| Username and Password | DB user authentication data.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| Table | Name of the table to be written. Note that only one table can be written at a time. |
| Action on table | Select to perform one of the following operations on the table defined:  
None: No action is carried out on the table.  
Create table: A new table is created.  
Create table if not exists: A table is created if it does not exist. |
| Schema and Edit schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.  
Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
• View schema: choose this option to view the schema only.  
• Change to built-in property: choose this option to change the schema to Built-in for local changes.  
• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |
| Built-in: | The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide. |
| Repository: | The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide. |
| SCD Editor | The SCD editor helps to build and configure the data flow for slowly changing dimension outputs.  
For more information, see SCD management methodology on page 2522. |
| Use memory saving Mode | Select this check box to maximize system performance. |
| Source keys include Null | Select this check box to allow the source key columns to have Null values. |
**Warning:**
Special attention should be paid to the uniqueness of the source key(s) values when this option is selected.

<table>
<thead>
<tr>
<th>Die on error</th>
<th>This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.</th>
</tr>
</thead>
</table>

## Advanced settings

<table>
<thead>
<tr>
<th>Additional JDBC parameters</th>
<th>Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the <strong>Use an existing connection</strong> check box in the <strong>Basic settings</strong>.</th>
</tr>

</thead>
</table>

### Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

| Limitation | This component does not support using SCD type 0 together with other SCD types. |

## Related scenario

For related scenarios, see tMysqlSCD on page 2519.
tNetsuiteConnection

Creates a connection to the NetSuite SOAP server so that other NetSuite components in the Job can reuse the connection.

tNetsuiteConnection Standard properties

These properties are used to configure tNetsuiteConnection running in the Standard Job framework.
The Standard tNetsuiteConnection component belongs to the Business family.
The component in this framework is available in all Talend products.

Basic settings

<table>
<thead>
<tr>
<th>Endpoint</th>
<th>Enter the WebService URL required to connect to the NetSuite server.</th>
</tr>
</thead>
<tbody>
<tr>
<td>API version</td>
<td>Select the version of the NetSuite API you are connecting to.</td>
</tr>
<tr>
<td></td>
<td>As of version 7.1, API versions 2014.2 and 2016.2 have been deprecated.</td>
</tr>
<tr>
<td>E-mail and Password</td>
<td>Enter your user credentials to access the NetSuite SOAP service.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Role</td>
<td>Enter your NetSuite role ID.</td>
</tr>
<tr>
<td>Account</td>
<td>Enter your NetSuite web services account number (also called account ID).</td>
</tr>
<tr>
<td>Application ID</td>
<td>Enter the NetSuite application ID generated for your account.</td>
</tr>
<tr>
<td></td>
<td>An application ID is required starting from NetSuite version 2015 and above. You can find your application ID or create a new one on NetSuite’s Manage Integration page.</td>
</tr>
</tbody>
</table>

Advanced settings

| Enable customizations | Select this check box to instruct the component to retrieve customizations - custom record types and custom fields. |
|                       | With this option enabled, custom record types will be retrieved and can be selected in the Record Type dialog box, and custom fields will be retrieved and included into the schema. |
|                       | This option is enabled by default. You can disable it if you don’t need custom record types or custom fields. |
|                       | With this option enabled in the tNetsuiteConnection component, all the other components using this connection will have this option enabled. |
tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | This component is more commonly used with other NetSuite components. |

Related scenario

No scenario is available for this component yet.
tNetsuiteInput

Invokes the NetSuite SOAP service and retrieves data according to the conditions you specify.

**tNetsuiteInput Standard properties**

These properties are used to configure tNetsuiteInput running in the Standard Job framework.

The Standard tNetsuiteInput component belongs to the Business and the Cloud families.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Connection Component</strong></td>
<td>Select a tNetsuiteConnection component to reuse its connection details to set up the connection to the NetSuite server. With a tNetsuiteConnection selected, the settings related to connection setup will not be displayed.</td>
</tr>
<tr>
<td><strong>Endpoint</strong></td>
<td>Enter the WebService URL required to connect to the NetSuite server.</td>
</tr>
<tr>
<td><strong>API version</strong></td>
<td>Select the version of the NetSuite API you are connecting to. As of version 7.1, API versions 2014.2 and 2016.2 have been deprecated.</td>
</tr>
<tr>
<td><strong>E-mail and Password</strong></td>
<td>Enter your user credentials to access the NetSuite SOAP service. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Role</strong></td>
<td>Enter your NetSuite role ID.</td>
</tr>
<tr>
<td><strong>Account</strong></td>
<td>Enter your NetSuite web services account number (also called account ID).</td>
</tr>
<tr>
<td><strong>Application ID</strong></td>
<td>Enter the NetSuite application ID generated for your account. An application ID is required starting from NetSuite version 2015 and above. You can find your application ID or create a new one on NetSuite’s Manage Integration page.</td>
</tr>
<tr>
<td><strong>Record Type</strong></td>
<td>Click the [...] button next to the field to open a dialog box, and then select a record type you want to retrieve or select the Use custom object check box and specify a custom record type in the Object Name field.</td>
</tr>
<tr>
<td><strong>Schema and Edit schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
</tbody>
</table>
**Built-In:** You create and store the schema locally for this component only.

**Repository:** You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema:** choose this option to view the schema only.
- **Change to built-in property:** choose this option to change the schema to **Built-In** for local changes.
- **Update repository connection:** choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Warning:**
The schema of this component is dynamically filled with columns corresponding to the NetSuite service fields, which vary depending on the **Record Type** selected. You can delete columns that are not relevant to your operation, but do not rename any schema columns or this may cause execution errors.

### Search conditions

Define search conditions to match fields for data retrieval. Click the 
[+] button to add as many rows as you need, each row for a condition, and define each of your conditions:

- **Field:** select a field to search based on the condition.
- **Operator:** select an operator for the field search condition.
- **Value:** enter the value for the field search condition.
- **Value 2:** enter the second value for the field search condition, if relevant depending on the operator you select.

### Advanced settings

**Body fields only**
Select this check box to retrieve only body fields. Clear this check box to retrieve body fields and sublist values.

**Enable customizations**
Select this check box to instruct the component to retrieve customizations - custom record types and custom fields. With this option enabled, custom record types will be retrieved and can be selected in the **Record Type** dialog box, and custom fields will be retrieved and included into the schema.

This option is enabled by default. You can disable it if you don’t need custom record types or custom fields.
tNetsuitInput

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

Global Variables

| Global Variables | NB_LINE: the number of rows processed. This is an After variable and it returns an integer. |
| N | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. |
| N | A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. |
| N | To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. |
| N | For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | This component is usually used as a start component in a Talend flow and it requires an output component. |

Handling data with NetSuite

This scenario describes a Job that reads data from NetSuite, transforms the data and writes the transformed data to NetSuite, finally displays the transformed data on the console.

Adding the components

Create a new Job and add the following five components by typing their names in the design workspace or dropping them from the Palette:
• two `tNetsuiteInput` components: to read data that matches the specified search criteria from the NetSuite server.
• a `tMap` component: to transform the input data to the output structure.
• a `tNetsuiteOutput` component: to write the transformed data into the NetSuite server.
• a `tLogRow` component: to display the data received from the NetSuite server.

Configuring and linking the components

Reading, transforming, and writing data in NetSuite

Procedure

1. Double-click the first `tNetsuiteInput` to open its **Basic settings** view.

   ![tNetsuiteInput Configuration](image)

   2. In the **Endpoint**, **API version**, **E-mail**, **Password**, **Role**, **Account**, and **Application ID** fields, enter the information required to access NetSuite.

   3. Click the `[...]` button next to the **Record Type** field, and from the dialog box that opens select **Location** to read the location type information from NetSuite.

      The schema corresponding to the location record type is automatically retrieved.

   4. Define a search condition.

      a) Click the `[+]` button below the **Search conditions** table to add one row.

      b) Click the cell of the **Field** column and select `internalId` from the drop-down list.

      c) Click the cell of the **Operator** column and select **List - Any Of** from the drop-down list.

      d) In the cell of the **Value** column, enter `java.util.Arrays.asList("1")` to retrieve only the record whose `internalId` is set to 1.

      5. Connect the first `tNetsuiteInput` to `tMap` using a **Row > Main** connection.

      6. Double-click `tNetsuiteOutput` to open its **Basic settings** view.
7. In the **Endpoint**, **API version**, **E-mail**, **Password**, **Role**, **Account**, and **Application ID** fields, enter the information required to access NetSuite.

8. In the **Action** list, select **insert** to insert the transformed data into NetSuite.

9. Click the [...] button next to the **Record Type** field, and in the dialog box that opens select **Location** to write the location type information into NetSuite.

10. Click the [...] button next to **Edit schema** to open the schema editor. You can see the schema has already been prefilled. Keep only the columns that are relevant to your operation and delete others. In this example, keep the column **Name**, **Parent**, **IncludeChildren**, **IsInactive**, **TranPrefix**, **Logo**, **MakeInventoryAvailable**, **MakeInventoryAvailableStore**, **CustomFieldList**, and **ExternalId**.

11. Connect **tMap** to **tNetSuiteOutput** using a **Row > “New Output” (Main)** connection. In the pop-up dialog box, enter the name of the output connection, **out** in this example. Then click **Yes** to let **tMap** get the schema of the target component **tNetSuiteOutput**.

12. Double-click **tMap** to open its **Map Editor** and configure data flow mappings.
a) In the **out** output table, set the value of the **Name** column by entering "Paris" in the corresponding **Expression** column field.

b) Drag and drop the **Parent** column in the **row1** input table onto the **Expression** column of the corresponding row in the **out** output table.

c) Do the same to drag and drop other columns **IncludeChildren**, **IsInactive**, **TranPrefix**, **Logo**, **MakeInventoryAvailable**, **MakeInventoryAvailableStore**, **CustomFieldList**, and **ExternalId** in the **row1** input table onto the **Expression** column of the corresponding row in the **out** output table.

**Retrieving the transformed data from NetSuite**

**Procedure**

1. Double-click the second **tNetsuitInput** to open its **Basic settings** view.
2. In the **Endpoint**, **API version**, **E-mail**, **Password**, **Role**, **Account**, and **Application ID** fields, enter the information required to access NetSuite.

3. Click the [...] button next to the **Record Type** field, and from the dialog box that opens select **Location** to read the location type information from NetSuite.

   The schema corresponding to the location record type is automatically retrieved.

4. Define a search condition.
   a) Click the [+ ] button below the **Search condition** table to add one row.
   b) Click the cell of the **Field** column and select **name** from the drop-down list.
   c) Click the cell of the **Operator** column and select **String - Contains** from the drop-down list.
   d) In the cell of the **Value** column, enter **Paris** to retrieve only the record whose **name** contains **Paris**.

5. Double-click **tLogRow** to open its **Basic settings** view.

6. In the **Mode** area, select **Vertical (each row is a key/value list)** for better readability of the result.

7. Connect the second **tNetsuitelInput** to **tLogRow** using a **Row > Main** connection.

8. Connect the first **tNetsuitelInput** to the second **tNetsuitelInput** using a **Trigger > OnSubjobOk** connection.
Saving and executing the Job

Procedure

1. Press **Ctrl + S** to save the Job.
2. Press **F6** or click **Run** on the **Run** tab to run the Job.

As shown above, the data has been transformed and written into NetSuite, then the transformed data is retrieved from NetSuite and displayed on the console.
tNetsuiteOutput

Invokes the NetSuite SOAP service and inserts, updates, or removes data on the NetSuite SOAP server.

**tNetsuiteOutput Standard properties**

These properties are used to configure tNetsuiteOutput running in the Standard Job framework.

The Standard tNetsuiteOutput component belongs to the Business and the Cloud families.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Connection Component</th>
<th>Select a tNetsuiteConnection component to reuse its connection details to set up the connection to the NetSuite server. With a tNetsuiteConnection selected, the settings related to connection setup will not be displayed.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Endpoint</td>
<td>Enter the WebService URL required to connect to the NetSuite server.</td>
</tr>
<tr>
<td>API version</td>
<td>Select the version of the NetSuite API you are connecting to. As of version 7.1, API versions 2014.2 and 2016.2 have been deprecated.</td>
</tr>
<tr>
<td>E-mail and Password</td>
<td>Enter your user credentials to access the NetSuite SOAP service. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Role</td>
<td>Enter your NetSuite role ID.</td>
</tr>
<tr>
<td>Account</td>
<td>Enter your NetSuite web services account number (also called account ID).</td>
</tr>
<tr>
<td>Application ID</td>
<td>Enter the NetSuite application ID generated for your account. An application ID is required starting from NetSuite version 2015 and above. You can find your application ID or create a new one on NetSuite’s Manage Integration page.</td>
</tr>
<tr>
<td>Record Type</td>
<td>Click the [...] button next to the field to open a dialog box, and then select a record type you want to retrieve or select the Use custom object check box and specify a custom record type in the Object Name field.</td>
</tr>
<tr>
<td>Schema and Edit schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td><strong>Built-In</strong></td>
<td>You create and store the schema locally for this component only.</td>
</tr>
<tr>
<td>-------------</td>
<td>---------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| **Repository** | You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.  
When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.  
You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com). |
| **Click Edit schema** | to make changes to the schema. If the current schema is of the Repository type, three options are available:  
- **View schema**: choose this option to view the schema only.  
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.  
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.  
Click **Sync columns** to retrieve the schema from the previous component connected in the Job. |
| **Warning:** | The schema of this component is prefilled with columns corresponding to the NetSuite service fields, which vary depending on the **Record Type** selected. You can delete columns that are not relevant to your operation, but do not rename any schema columns or this may cause execution errors. |
| **Action** | Select an action to perform from the list.  
- **Add**: Adds a new record to your data. If a duplicate is found and the **Die on error** check box is selected, the Job stops; if the **Die on error** check box is cleared, the duplicate is ignored and the Job continues.  
- **Update**: Makes changes to an existing record.  
If the record corresponding to the specified **Internal ID** does not exist, and the **Die on error** check box is selected, the Job stops.  
To use this option, the **InternalId** column must exist in the schema and set as Key.  
- **Upsert**: Updates the **record** corresponding to the specified **ID**, or inserts a new record if it does not exist.  
To use this option, a column for record **ID** must exist in the schema and set as Key.  
- **Delete**: Removes an existing record. |
If the record corresponding to the specified Internal ID does not exist and the **Die on error** check box is selected, the Job stops.

To use this option, the *InternalId* column must exist in the schema and set as Key.

<table>
<thead>
<tr>
<th>Sync outgoing schema</th>
</tr>
</thead>
<tbody>
<tr>
<td>After the component schema is updated, click this button propagate the schema to the outgoing flow(s), which can be a normal flow, a reject flow, or both, if the component has any.</td>
</tr>
</tbody>
</table>

### Advanced settings

<table>
<thead>
<tr>
<th>Enable customizations</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select this check box to instruct the component to retrieve customizations - custom record types and custom fields. With this option enabled, custom record types will be retrieved and can be selected in the <strong>Record Type</strong> dialog box, and custom fields will be retrieved and included into the schema. This option is enabled by default. You can disable it if you don't need custom record types or custom fields.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Use native Upsert operation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select this check box to use the Upsert operation provided by NetSuite. To use NetSuite's Upsert operation, the ExternalId column must exist in the schema and set as Key. This option is available when <strong>Upsert</strong> is selected from the <strong>Action</strong> list in <strong>Basic settings</strong>. By default, for compatibility reasons, this option is disabled and the component performs the Add or Update action for an upsert depending on whether the record ID is specified.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Batch size</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specify the number of records to be processed in each batch. Note that batching will be disabled if the output component has an outgoing flow.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select this check box to gather the Job processing metadata at the Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE</strong>: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer. <strong>CURRENT_INTERNALID</strong>: The internal ID of the record currently inserted or processed. This is a Flow variable and it returns an integer. <strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

| Usage rule | This component is usually used as an end component in a Talend flow and it requires an input component. |

Related scenario

For a related scenario, see Handling data with NetSuite on page 2668.
tNormalize

Normalizes the input flow following SQL standard to help improve data quality and thus eases the data update.

**tNormalize Standard properties**

These properties are used to configure tNormalize running in the Standard Job framework.

The Standard tNormalize component belongs to the Processing family.

The component in this framework is available in all Talend products.

**Basic settings**

| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
  • View schema: choose this option to view the schema only.  
  • Change to built-in property: choose this option to change the schema to Built-in for local changes.  
  • Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Built-In:</td>
<td>You create and store the schema locally for this component only.</td>
</tr>
<tr>
<td>Repository:</td>
<td>You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
</tr>
<tr>
<td>Column to normalize</td>
<td>Select the column from the input flow which the normalization is based on.</td>
</tr>
<tr>
<td>Item separator</td>
<td>Enter the separator which will delimit data in the input flow.</td>
</tr>
</tbody>
</table>

**Note:**
The item separator is based on regular expressions, so the character `.` (a special character for regular expression) should be avoided or used carefully here.
Advanced settings

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Get rid of duplicated rows from output</td>
<td>Select this check box to deduplicate rows in the data of the output flow.</td>
</tr>
<tr>
<td>Use CSV parameters</td>
<td>Select this check box to include CSV specific parameters such as escape mode and enclosure character.</td>
</tr>
<tr>
<td>Discard the trailing empty strings</td>
<td>Select this check box to discard the trailing empty strings.</td>
</tr>
<tr>
<td>Trim resulting values</td>
<td>Select this check box to trim leading and trailing whitespace from the resulting data.</td>
</tr>
<tr>
<td><strong>Note:</strong></td>
<td>When both Discard the trailing empty string and Trim resulting values check boxes are selected, the former works first.</td>
</tr>
<tr>
<td>tStatCatcher Statistics</td>
<td>Select this check box to gather the Job processing metadata at the Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERROR_MESSAGE</td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td>NB_LINE</td>
<td>the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.</td>

</tr>
</tbody>
</table>

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>This component can be used as intermediate step in a data flow.</td>
</tr>
<tr>
<td>Limitation</td>
<td>Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
</tbody>
</table>
Normalizing data

This simple scenario illustrates a Job that normalizes a list of tags for Web forum topics, and displays the result in a table on the Run console.

This list is not well organized and it contains trailing empty strings, leading and trailing whitespace, and repeated tags, as shown below.

ldap, db2, jdbc driver, grid computing, talend architecture, content, environment,, tmap,, eclipse, database, java, postgresql, tmap, database, java, sybase, deployment,, repository, database, informix, java

Setting up the Job

Procedure

1. Drop the following components from the Palette to the design workspace: tFileInputDelimited, tNormalize, tLogRow.

2. Connect the components using Row > Main connections.

Configuring the components

Procedure

1. Double-click the tFileInputDelimited component to open its Basic settings view.

   ![tFileInputDelimited component configuration]

2. In the File name field, specify the path to the input file to be normalized.
3. Click the [...] button next to Edit schema to open the Schema dialog box, and set up the input schema by adding one column named Tags. When done, click OK to validate your schema setup and close the dialog box, leaving the rest of the settings as they are.

4. Double-click the tNormalize component to open Basic settings view.

5. Check the schema, and if necessary, click Sync columns to get the schema synchronized with the input component.

6. Define the column the normalization operation is based on.
   In this use case, the input schema has only one column, Tags, so just accept the default setting.

7. In the Advanced settings view, select the Get rid of duplicate rows from output, Discard the trailing empty strings, and Trim resulting values check boxes.

8. In the tLogRow component, select the Print values in the cells of table radio button.
Saving and executing the Job

Procedure

1. Press Ctrl+S to save your Job.
2. Click Run on the Run tab or press F6 to execute the Job.

The list is tidied up, with duplicate tags, leading and trailing whitespace and trailing empty strings removed, and the result is displayed in a table cell on the console.
tOleDbInput

Executes a DB query with a strictly defined order which must correspond to the schema definition and passes on the field list to the next component via a Main row link.

This component reads a database and extracts fields based on a query. It offers the flexibility benefit of the DB query and covers all possible SQL queries.

**tOleDbInput Standard properties**

These properties are used to configure tOleDbInput running in the Standard Job framework.

The Standard tOleDbInput component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <strong>line</strong> when naming the fields.</td>
</tr>
<tr>
<td><strong>Table Name</strong></td>
<td>Enter the name of the table to be processed.</td>
</tr>
<tr>
<td><strong>Query Type</strong></td>
<td>Select either <strong>Built-in</strong> or <strong>Repository</strong> query type from the drop-down list.</td>
</tr>
</tbody>
</table>

**Built-In**: You create and store the schema locally for this component only.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.
<table>
<thead>
<tr>
<th>Repository: Select the relevant query stored in the Repository. The <strong>Query</strong> field gets accordingly filled in.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Guess Query</td>
</tr>
<tr>
<td>Guess schema</td>
</tr>
<tr>
<td>Query</td>
</tr>
</tbody>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th>Trim all the String/Char columns</th>
<th>Select this check box to remove leading and trailing whitespace from all the String/Char columns.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Trim column</td>
<td>Select the check box in Trim column to remove leading and trailing whitespace from the corresponding column.</td>
</tr>
<tr>
<td>This field appears only when the Trim all the String/Char columns check box is cleared.</td>
<td></td>
</tr>
<tr>
<td>tStatCatcher Statistics</td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_LINE: the number of rows processed. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td>QUERY: the query statement being processed. This is a Flow variable and it returns a string.</td>
<td></td>
</tr>
<tr>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
<td></td>
</tr>
<tr>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
<td></td>
</tr>
<tr>
<td>To fill up a field or expression with a variable, press <strong>Ctrl + Space</strong> to access the variable list and choose the variable to use from it.</td>
<td></td>
</tr>
<tr>
<td>For further information about variables, see <strong>Talend Studio User Guide</strong>.</td>
<td></td>
</tr>
</tbody>
</table>

**Usage**

| Usage rule | This component is used as a start component in a Job and it always needs an output link. |

**Related scenario**

For similar scenarios, see **tMysqlInput** on page 2448.
tOleDbOutput

Executes the action defined on the table and/or on the data contained in the table, based on the flow incoming from the preceding component in the Job.

This component writes, updates, makes changes or suppresses entries in a database.

tOleDbOutput Standard properties

These properties are used to configure tOleDbOutput running in the Standard Job framework.

The Standard tOleDbOutput component belongs to the Databases family.

The component in this framework is available in all Talend products.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Enter the connection string used to open the database. For details, please see <a href="http://msdn.microsoft.com/en-us/library/system.data.oledb.oledbconnection.connectionstring.aspx">http://msdn.microsoft.com/en-us/library/system.data.oledb.oledbconnection.connectionstring.aspx</a>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>Specify the name of the table to be written. Note that only one table can be written at a time.</td>
</tr>
<tr>
<td>Action on data</td>
<td>Select one of the following actions that you want to perform on the data from the drop-down list.</td>
</tr>
<tr>
<td></td>
<td>• Insert: insert data.</td>
</tr>
<tr>
<td></td>
<td>• Update: update data.</td>
</tr>
<tr>
<td></td>
<td>• Insert or update: insert a new record. If the record with the given reference already exists, an update would be made.</td>
</tr>
<tr>
<td></td>
<td>• Update or insert: update the record with the given reference. If the record does not exist, a new record would be inserted.</td>
</tr>
<tr>
<td></td>
<td>• Delete: delete data.</td>
</tr>
</tbody>
</table>

Warning:
It is necessary to specify at least one column as a primary key on which the Update or Delete operation is based. You can do that by clicking Edit schema and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the Advanced settings view where you can simultaneously define primary keys for the Update or Delete operation. To do that, select the Use field options check box and then in the Key in update or Key in delete column, select the check box(es) next to the column name(s) you want to use as a base for the Update or Delete operation.

| Clear data in table | Select this check box to delete data in the defined table before any operation. |
| Schema and Edit schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next |
When you create a Spark Job, avoid the reserved word `line` when naming the fields.

| **Built-In** | You create and store the schema locally for this component only. |
| **Repository** | You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. |

Click [Edit schema](#) to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-In** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select *No upon completion* and choose this schema metadata again in the [Repository Content](#) window.

### Advanced settings

<table>
<thead>
<tr>
<th><strong>Additional columns</strong></th>
<th>This option allows you to call SQL functions to perform actions on columns, provided that these are not insert, update or delete actions, or actions that require pre-processing.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Name</strong></td>
<td>Type in the name of the schema column to be altered or inserted.</td>
</tr>
<tr>
<td><strong>SQL expression</strong></td>
<td>Type in the SQL statement to be executed in order to alter or insert the data in the corresponding column.</td>
</tr>
<tr>
<td><strong>Position</strong></td>
<td>Select <em>Before</em>, <em>After</em> or <em>Replace</em>, depending on the action to be performed on the reference column.</td>
</tr>
<tr>
<td><strong>Reference column</strong></td>
<td>Type in a reference column used to locate or replace the new column, or the column to be modified.</td>
</tr>
</tbody>
</table>

This option is not available if you have just created the DB table (even if you delete it beforehand).

| **Use field options** | Select this check box to customize a request, especially if multiple actions are being carried out on the data. |

<table>
<thead>
<tr>
<th><strong>Field options</strong></th>
<th>Select the check box(es) in the table if you want to use the corresponding schema column(s) as a base for your operation.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Key in update</strong></td>
<td>define the primary key to use in an update operation.</td>
</tr>
<tr>
<td><strong>Key in delete</strong></td>
<td>define the primary key to use in a delete operation.</td>
</tr>
<tr>
<td><strong>Updatable</strong></td>
<td>define the column(s) to update.</td>
</tr>
<tr>
<td><strong>Insertable</strong></td>
<td>define the column(s) to insert.</td>
</tr>
</tbody>
</table>
**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE</strong></td>
<td>The number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_UPDATED</strong></td>
<td>The number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_INSERTED</strong></td>
<td>The number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_DELETED</strong></td>
<td>The number of rows deleted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_REJECTED</strong></td>
<td>The number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>QUERY</strong></td>
<td>The query statement processed. This is an After variable and it returns a string.</td>
</tr>
<tr>
<td><strong>ERROR_MESSAGE</strong></td>
<td>The error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press `Ctrl + Space` to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>This component is normally an end component of a Job and always needs an input link.</td>
</tr>
</tbody>
</table>

**Related scenario**

For similar scenarios, see [tMysqlOutput](#) on page 2471.
tOleDbRow

Acts on the actual database structure or on the data depending on the nature of the query and the database.

tOleDbRow is the specific component for this database query. It executes the SQL query stated in the specified database.

**tOleDbRow Standard properties**

These properties are used to configure tOleDbRow running in the Standard Job framework.

The Standard tOleDbRow component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Enter the connection string that contains the database. For details, see <a href="http://msdn.microsoft.com/en-us/library/system.data.oledb.oledbconnection.connectionstring.aspx">http://msdn.microsoft.com/en-us/library/system.data.oledb.oledbconnection.connectionstring.aspx</a>.</td>
</tr>
<tr>
<td><strong>Schema and Edit Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td><strong>Built-In</strong></td>
<td>You create and store the schema locally for this component only.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
</tr>
<tr>
<td><strong>Table Name</strong></td>
<td>Name of the table to be processed.</td>
</tr>
<tr>
<td><strong>Query type</strong></td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td><strong>Built-in</strong></td>
<td>Fill in manually the query statement or build it graphically using SQLBuilder</td>
</tr>
</tbody>
</table>
**Repository:** Select the relevant query stored in the Repository. The Query field gets accordingly filled in.

**Guess Query**
Click the **Guess Query** button to generate the query which corresponds to your table schema in the **Query** field.

**Query**
Enter your database query paying particularly attention to properly sequence the fields in order to match the schema definition.

**Die on error**
This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a **Row > Rejects** link.

### Advanced settings

**Propagate QUERY’s recordset**
Select this check box to insert the result of the query in a **COLUMN** of the current flow. Select this column from the **use column** list.

*Note:*
This option allows the component to have a different schema from that of the preceding component. Moreover, the column that holds the QUERY’s recordset should be set to the type of **Object** and this component is usually followed by **tParseRecordSet**.

**Use PreparedStatement**
Select this check box if you want to query the database using a PreparedStatement. In the **Set PreparedStatement Parameter** table, define the parameters.

- **Parameter Index:** Enter the parameter position in the SQL instruction.
- **Parameter Type:** Enter the parameter type.
- **Parameter Value:** Enter the parameter value.

*Note:*
This option is very useful if you need to execute the same query several times. Performance levels are increased

**tStatCatcher Statistics**
Select this check box to collect log data at the component level.

### Global Variables

**Global Variables**

- **QUERY:** the query statement being processed. This is a Flow variable and it returns a string.
- **ERROR_MESSAGE:** the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component offers the flexibility of the database query and covers all possible SQL queries.</th>
</tr>
</thead>
</table>

| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |

### Related scenario

For similar scenarios, see tMysqlRow on page 2504.
tOpenbravoERPIInput

Extracts data from OpenBravoERP database according to the conditions defined in specific columns. tOpenbravoERPIInput connects to an OpenBravoERP database entity via the appropriate Web service.

**tOpenbravoERPIInput Standard properties**

These properties are used to configure tOpenbravoERPIInput running in the Standard Job framework. The Standard tOpenbravoERPIInput component belongs to the Business family. The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Openbravo REST WebService URL</td>
<td>Enter the URL of the Web service that allows you to connect to the OpenbravoERP database.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>User authentication information. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Entity</td>
<td>Select the appropriate entity from the drop-down list.</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td></td>
<td>Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:</td>
</tr>
<tr>
<td></td>
<td>• View schema: choose this option to view the schema only.</td>
</tr>
<tr>
<td></td>
<td>• Change to built-in property: choose this option to change the schema to Built-in for local changes.</td>
</tr>
<tr>
<td></td>
<td>• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.</td>
</tr>
<tr>
<td></td>
<td>Click Sync columns to retrieve the schema from the previous component connected in the Job.</td>
</tr>
<tr>
<td>WHERE Clause</td>
<td>Enter your WHERE clause.</td>
</tr>
</tbody>
</table>

**Note:**
For this component, the schema corresponds to a selected entity.
### Order by
Select this check box to define how to order the results (the elements in the drop-down list depend on the entity selected).

**Sort:** Choose whether to organise the results in either **Ascending** or **Descending** order.

### First result
Enter the row number you want to retrieve first.

### Max result
Enter the maximum number of results you want to retrieve.

### Advanced settings

<table>
<thead>
<tr>
<th>Advanced separator (for numbers)</th>
<th>Select this check box to modify the separators to be used for the numbers. Either:Thousands separator or Decimal separator</th>
</tr>
</thead>
</table>

| tStatCatcher Statistics | Select this check box to collect the log data at a component level. |

### Global Variables

| Global Variables | **NB_LINE:** the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer. **ERROR_MESSAGE:** the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it. For further information about variables, see [Talend Studio User Guide](#). |

### Usage

| Usage rule | This component is generally used as an input component. An output component is required. |

### Related Scenario

For a scenario in which *tOpenbravoERPImput* might be used, see [Writing data in a Microsoft CRM database and putting conditions on columns to extract specified rows](#) on page 2218.
tOpenbravoERPOutput

Writes data in an OpenbravoERP database.

tOpenbravoERPOutput writes an object in an OpenbravoERP database via the appropriate Web service.

**tOpenbravoERPOutput Standard properties**

These properties are used to configure tOpenbravoERPOutput running in the Standard Job framework. The Standard tOpenbravoERPOutput component belongs to the Business family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Openbravo REST Webservice URL</td>
<td>Enter the URL of the Web service that allows you to connect to the OpenbravoERP database.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>User authentication information. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Action on data</td>
<td>From the list, select the one of the following actions: Update/Create or Remove</td>
</tr>
<tr>
<td>Use existing data file</td>
<td>Select this check box if desired and then select the file by browsing your directory.</td>
</tr>
<tr>
<td>Entity</td>
<td>Select the appropriate entity from the drop-down list.</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available: View schema: choose this option to view the schema only. Change to built-in property: choose this option to change the schema to Built-in for local changes. Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.</td>
</tr>
</tbody>
</table>
Click **Sync columns** to retrieve the schema from the previous component connected in the Job.

### Advanced settings

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
<th>Select this check box to collect the log data at a component level.</th>
</tr>
</thead>
</table>

### Global Variables

**Global Variables**

- **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.
- **NB_LINE_UPDATED**: the number of rows updated. This is an After variable and it returns an integer.
- **NB_LINE_CREATED**: the number of rows created. This is an After variable and it returns an integer.
- **NB_LINE_REMOVED**: the number of rows removed. This is an After variable and it returns an integer.
- **NB_LINE_UNAUTHORIZED**: the number of rows unauthorized. This is an After variable and it returns an integer.
- **NB_LINE_FAILED**: the number of rows failed. This is an After variable and it returns an integer.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is used as an output component. It requires an input component.</th>
</tr>
</thead>
</table>

### Related scenario

For a scenario in which **tOpenbravoERPOutput** may be used, see *Writing data in a Microsoft CRM database and putting conditions on columns to extract specified rows* on page 2218.
tOracleBulkExec

Offers gains in performance during operations performed on data of an Oracle database. tOracleBulkExec inserts, appends, replaces or truncate data in an Oracle database.

The tOracleOutputBulk and tOracleBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tOracleOutputBulkExec component, detailed in a separate section. The advantage of using two separate steps is that the data can be transformed before it is loaded in the database.

tOracleBulkExec Standard properties

These properties are used to configure tOracleBulkExec running in the Standard Job framework. The Standard tOracleBulkExec component belongs to the Databases family. The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in: No property data stored centrally.</td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

Use an existing connection

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
### Connection type

- **Oracle OCI**: Select this connection type to use Oracle Call Interface with a set of C-language software APIs that provide an interface to the Oracle database.
- **Oracle Service Name**: Select this connection type to use the TNS alias that you give when you connect to the remote database.
- **Oracle SID**: Select this connection type to uniquely identify a particular database on a system.
- **Oracle Custom**: Select this connection type to access a clustered database.

### DB Version

Select the Oracle version in use.

### Host

IP address of the database server.

### Port

Port number listening the database server.

### Database

Database name.

### Schema

Schema name.

### Username and Password

DB user authentication data.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

### Table

Name of the table to be written. Note that only one table can be written at a time.

### Action on table

On the table defined, you can perform one of the following operations:

- **None**: No operation is carried out.
- **Drop and create table**: The table is removed and created again.
- **Create table**: The table does not exist and gets created.
- **Create table if not exists**: The table is created if it does not exist.
- **Drop table if exists and create**: The table is removed if it already exists and created again.
- **Clear table**: The table content is deleted.
- **Truncate table**: The table content is deleted. You do not have the possibility to rollback the operation.

### Data file name

Name of the file to be loaded.

**Warning:**
This file should be located on the same machine as the Jobserver.

### Action on data

On the data of the table defined, you can perform:
### Insert
Insert data to an empty table. If the table already contains data, the Job stops and the existing data remains in the table.

### Update
Update the existing data. You have to set the key on the schema if this option is selected.

### Append
Append data to the table, whether the table is empty or not.

### Replace
If the table already contains data, delete all the existing data and insert the new data. If the table is empty, insert the new data.

### Truncate
If the table already contains data, truncate all the existing data and insert the new data. If the table is empty, insert the new data.

### Schema and Edit Schema
A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either **Built-in** or stored remotely in the **Repository**.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

### Built-In
You create and store the schema locally for this component only.

### Repository
You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

---

### Advanced settings

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Advanced separator (for number)</td>
<td>Select this check box to change the separator used for the numbers.</td>
</tr>
<tr>
<td>Use existing control file</td>
<td>Select this check box if you use a control file (.ctl) and specify its path in the .ctl file name field.</td>
</tr>
</tbody>
</table>
| Record format               | Define the record format.  
**Default**: format parameters are set by default. |
<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
</table>
| Stream: set Record terminator. | **Fixed**: set the Record length.  
**Variable**: set the Field size of the record length. |
| Specify .ctl file's INTO TABLE clause manually | Select this check box to manually fill in the INTO TABLE clause of the control file. |
| Fields terminated by | Character, string or regular expression to separate fields:  
- **None**: no separator is used.  
- **Whitespace**: the separator used is a space.  
- **EOF (used for loading LOBs from lobfile)**: the separator used is an EOF character (End Of File).  
- **Other terminator**: set another terminator in the Field terminator field. |
| Use fields enclosure | Select this check box if you want to use enclosing characters for the text:  
- **Fields enclosure (left part)**: character delimiting the left of the field.  
- **Field enclosure (right part)**: character delimiting the right of the field. |
| Use schema’s Date Pattern to load Date field | Select this check box to use the date pattern of the schema in the date field. |
| Specify field condition | Select this check box to define data loading condition. |
| Preserve blanks | Select this check box to preserve the blanks. |
| Trailing null columns | Select this check box to load null columns. |
| Load options | Click + to add data loading options:  
- **Parameter**: select a loading parameter from the list.  
- **Value**: enter a value for the parameter selected. |
| NLS Language | In the list, select the language used for the data that are not used in Unicode. |
| Set Parameter NLS_TERRITORY | Select this check box to modify the territory conventions used for day and weeks numbering. Your OS value is the default value used. |
| Encoding | Select the encoding from the list, or enter the encoding between double quotes if it does not exist in the list. This field is compulsory for database data handling. |
| Output | Select the type of output for the standard output of the Oracle database:  
- **to console**.  
- **to global variable**. |
| Convert columns and table names to uppercase | Select this check box to uppercase the names of the columns and the name of the table. |
### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_LINE_DATA: the number of rows read. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>NB_LINE_BAD: the number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>NB_LINE_INSERTED: the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>RETURN_CODE: the return code indicating the result of processing. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This dedicated component offers performance and flexibility of Oracle DB query handling.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic settings</td>
<td>Click the ![button] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.</td>
</tr>
</tbody>
</table>

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |
The database server/client must be installed on the same machine where the Studio is installed or where the Job using **tOracleBulkExec** is deployed, so that the component functions properly.

### Truncating and inserting file data into an Oracle database

This scenario describes how to truncate the content of an Oracle database and load the content of an input file. The related Job is composed of three components that respectively creates the content, output this content into a file to be loaded into the Oracle database after the database table has been truncated.

### Building the Job

**Procedure**

1. Drop the following components: **tOracleInput**, **tFileOutputDelimited** and **tOracleBulkExec** from the Palette to the design workspace.
2. Connect the **tOracleInput** to the **tFileOutputDelimited** using a **Row > Main** link.
3. Connect the **tOracleInput** to the **tOracleBulkExec** using a **OnSubjobOk** trigger link.

### Results

![Diagram of the Job](image)

### Configuring the components

**Procedure**

1. Double-click the **tOracleInput** to open its **Basic settings** view.
2. Define the Oracle connection details. It is recommended to store the database connection details in the **Metadata** folder of the **Repository** tree view in order to retrieve them easily at any time in any Job.
3. Define the schema, if it is not stored in the Repository. In this example, the schema contains four columns as follows: ID_Contract, ID_Client, Contract_type and Contract_Value.

4. Define the tFileOutputDelimited component parameters, including output File Name, Row separator and Fields delimiter.

5. Double-click on the tOracleBulkExec to define the database populating properties.

6. In the Property Type list, select Repository if you stored the database connection details under the Metadata node of the Repository or select Built-in to define them manually. In this scenario, use the Built-in mode.

7. Set the connection parameters in the following fields: Host, Port, Database, Schema, Username, and Password.

8. Fill in the name of the Table to be populated and the Action on data to be carried out. In this use case, select insert.

9. In the Schema list, select Built-in, and click the [...] button next to the Edit schema field to define the structure of the data to be passed to the next component.

10. Click the Advanced settings view to configure the advanced settings of the component.
11. Select the **Use an existing control file** check box if you want to use a control file (.ctl) storing the status of the physical structure of the database. Or, fill in the following fields manually: **Record format**, **Specify .ctl file’s INTO TABLE clause manually**, **Field terminated by**, **Use field enclosure**, **Use schema’s Date Pattern to load Date field**, **Specify field condition**, **Preserve blanks**, **Trailing null columns**, **Load options**, **NLS Language** and **Set Parameter NLS_TERRITORY** according to your database.

12. In the **Encoding** list, select the encoding, or enter the encoding between double quotes if it does not exist in the list.

13. In the **Output** list, select **to console** to output the standard output of the database in the console.

**Executing the Job**

**Procedure**

1. Press **Ctrl+S** to save your Job.
2. Press **F6** to run the Job. The log is shown in the console of the **Run** view and the table is populated with the parameter file data.

**Results**

Related topic: see [Inserting data in bulk in MySQL database](#) on page 2500.
tOracleClose

Closes the transaction committed in the connected Oracle database.

**tOracleClose Standard properties**

These properties are used to configure tOracleClose running in the Standard Job framework.

The Standard tOracleClose component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

Related scenarios

No scenario is available for the Standard version of this component yet.
tOracleCommit

Validates the data processed through the Job into the connected Oracle database

Using a unique connection, this component commits in one go a global transaction instead of doing that on every row or every batch and thus provides gain in performance.

**tOracleCommit Standard properties**

These properties are used to configure tOracleCommit running in the Standard Job framework.

The Standard tOracleCommit component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td>Component list</td>
<td>Select the <strong>tOracleConnection</strong> component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Warning:**

*If you want to use a Row > Main connection to link tOracleCommit to your Job, your data will be committed row by row. In this case, do not select the Close connection check box or your connection will be closed before the end of your first row commit.*

### Advanced settings

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.  
This property is available only when the **Need Client authentication** check box is selected. |
| **Disable CBC protection** | Select this check box to disable the use of CBC (Cipher Block Chaining) in SSL authentication. |
This property is available only when the **Use SSL** check box is selected.

### Additional JDBC parameters

Specify additional connection properties for the DB connection you are creating.

**Note:**
You can set the encoding parameters through this field.

### Use or register a shared DB Connection

Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the **Shared DB Connection Name** field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child.

This option is incompatible with the **Use dynamic job** and **Use an independent process to run subjob** options of the **tRunJob** component. Using a shared connection together with a **tRunJob** component with either of these two options enabled will cause your Job to fail.

This check box is not available when the **Specify a data source alias** check box is selected.

### Specify a data source alias

Select this check box and specify the alias of a data source created on the **Talend Runtime** side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in **Talend Runtime**.

### Advanced settings

#### Auto Commit

Select this check box to commit any changes to the database automatically upon the transaction.

With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component.

Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component.

#### tStatCatcher Statistics

Select this check box to gather the job processing metadata at a Job level as well as at each component level.
Usage

| Usage rule | This component is more commonly used with other tOracle* components, especially with the tOracleCommit and tOracleRollback components. |

Related scenario

For tOracleConnection related scenario, see tMysqlConnection on page 2436
tOracleInput

Reads an Oracle database and extracts fields based on a query.

tOracleInput executes a database query with a strictly defined order which must correspond to the schema definition. Then it passes on the field list to the next component via a Main row link.

tOracleInput Standard properties

These properties are used to configure tOracleInput running in the Standard Job framework.
The Standard tOracleInput component belongs to the Databases family.
The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
</table>
| Property type | Either Built-In or Repository.  
| | Built-In: No property data stored centrally.  
| | Repository: Select the repository file where the properties are stored. |
| Click icon | Click this icon to open a database connection wizard and store the database connection parameters you set in the component Basic settings view.  
| | For more information about setting up and storing database connection parameters, see Talend Studio User Guide. |
| Use an existing connection | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. |

Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:  
1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.  
2. In the child level, use a dedicated connection component to read that registered database connection.  
For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
<table>
<thead>
<tr>
<th><strong>Connection type</strong></th>
<th>Drop-down list of available drivers:</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Oracle OCI</strong></td>
<td>Select this connection type to use Oracle Call Interface with a set of C-language software APIs that provide an interface to the Oracle database.</td>
</tr>
<tr>
<td><strong>Oracle Custom</strong></td>
<td>Select this connection type to access a clustered database.</td>
</tr>
<tr>
<td><strong>Oracle Service Name</strong></td>
<td>Select this connection type to use the TNS alias that you give when you connect to the remote database.</td>
</tr>
<tr>
<td><strong>WALLET</strong></td>
<td>Select this connection type to store credentials in an Oracle wallet.</td>
</tr>
<tr>
<td><strong>Oracle SID</strong></td>
<td>Select this connection type to uniquely identify a particular database on a system.</td>
</tr>
</tbody>
</table>

| **DB Version** | Select the Oracle version in use. |
| **Host** | Database server IP address. |
| **Port** | Listening port number of DB server. |
| **Database** | Name of the database. |

| **Oracle schema** | Oracle schema name. |

| **Username and Password** | DB user authentication data. |
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings. |

| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields. |

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window. |

| **Built-In** | You create and store the schema locally for this component only. |
| **Repository** | You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. |

| **Table name** | Database table name. |
### Query type and Query

Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.

### Specify a data source alias

Select this check box and specify the alias of a data source created on the Talend Runtime side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in Talend Runtime.

If you use the component's own DB configuration, your data source connection will be closed at the end of the component. To prevent this from happening, use a shared DB connection with the data source alias specified.

This check box is not available when the Use an existing connection check box is selected.

### Advanced settings

#### Additional JDBC parameters

Specify additional connection properties for the database connection you are creating. The properties are separated by semicolon and each property is a key-value pair, for example, `encryption=1;clientname=Talend`.

This field is not available if the Use an existing connection check box is selected.

#### tStatCatcher Statistics

Select this check box to collect log data at the component level.

#### Use cursor

Select this check box and in the Cursor size field displayed, specify the number of rows to fetch in one go from the database. The performance can be improved by tuning this fetch size to an appropriate value.

#### Trim all the String/Char columns

Select this check box to remove leading and trailing whitespace from all the String/Char columns.

#### Trim column

Remove leading and trailing whitespace from defined columns.

#### No null values

Check this box to improve the performance if there are no null values.

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_LINE: the number of rows processed. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>QUERY: the query statement being processed. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
</tbody>
</table>
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component covers all possible SQL queries for Oracle databases.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic settings</td>
<td>Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Limitation</td>
<td>Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
</tbody>
</table>

Using context parameters when reading a table from an Oracle database

In this scenario, we will read a table from an Oracle database using a context parameter to refer to the table name.

Dropping and linking the components

Procedure

1. Create a new Job and add the following components by typing their names in the design workspace or dropping them from the Palette: a tOracleInput component and a tLogRow component.
2. Connect tOracleInput to tLogRow using a Row > Main link.

<Diagram>

Configuring the components

Procedure

1. Double-click tOracleInput to open its Basic Settings view in the Component tab.

   ![Basic Settings]

   - Connection Type: Oracle SID
   - Database: TALEND
   - Username: talend
   - Password: ********

2. Select a connection type from the Connection Type drop-down list. In this example, it is Oracle SID.
   Select the version of the Oracle database to be used from the DB Version drop-down list. In this example, it is Oracle 12-7.
   In the Host field, enter the Oracle database server’s IP address. In this example, it is 192.168.31.32.
   In the Database field, enter the database name. In this example, it is TALEND.
   In the Oracle schema field, enter the Oracle schema name. In this example, it is TALEND.
   In the Username and Password fields, enter the authentication details.

3. Click the [...] button next to Edit schema to open the schema editor.
4. Click the [+] button to add four columns: ID and AGE of the integer type, NAME and SEX of the string type.

Click OK to close the schema editor and accept the propagation prompted by the pop-up dialog box.

5. Put the cursor in the Table Name field and press F5 for context parameter setting. The dialog box New Context Parameter pops up.

   ![New Context Parameter dialog box]

For more information about context settings, see Talend Studio User Guide.

6. In the Name field, enter the context parameter name. In this example, it is TABLE.

   In the Default value field, enter the name of the Oracle database table to be queried. In this example, it is PERSON.
7. Click Finish to validate the setting.
   The context parameter context.TABLE automatically appears in the Table Name field.

8. In the Query Type list, select Built-In. Then, click Guess Query to get the query statement.

   ```
   "SELECT "+context.TABLE+"."ID",
   +context.TABLE+"."NAME,
   +context.TABLE+"."SEX,
   +context.TABLE+"."AGE
   FROM *"+context.TABLE
   ```

9. Double-click tLogRow to open its Basic settings view in the Component tab.

10. In the Mode area, select **Table (print values in cells of a table)** for a better display of the results.

### Saving and executing the Job

**Procedure**

1. Press Ctrl + S to save the Job.
2. Press F6 to run the Job.

   ```
   [statistics] connecting to socket on port 3750
   [statistics] connected
   +---------------------+
   | tLogRow_1           |
   +---------------------+
   | ID | NAME  | SEX | AGE |
   +-----+------+-+-----|
   | 1   | Ford  | Male| 25  |
   | 2   | Rose  | Female| 30  |
   | 3   | Sabrina | Female| 28  |
   | 4   | Teddy | Male| 32  |
   | 5   | Kate  | Male| 35  |
   +-----+------+-+-----|
   [statistics] disconnected
   ```

   As shown above, the data in the Oracle database table PERSON is displayed on the console.

**Related scenarios**

For related scenarios, see:
- Reading data from different MySQL databases using dynamically loaded connection parameters on page 491.
tOracleOutput

 Writes, updates, makes changes or suppresses entries in an Oracle database.

 tOracleOutput executes the action defined on the table and/or on the data contained in the table, based on the flow incoming from the preceding component in the Job.

 tOracleOutput Standard properties

 These properties are used to configure tOracleOutput running in the Standard Job framework.

 The Standard tOracleOutput component belongs to the Databases family.

 The component in this framework is available in all Talend products.

 Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

 Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

 Click this icon to open a database connection wizard and store the database connection parameters you set in the component Basic settings view.

 For more information about setting up and storing database connection parameters, see Talend Studio User Guide.

When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th>Connection type</th>
<th>Drop-down list of available drivers:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oracle OCI:</td>
<td>Select this connection type to use Oracle Call Interface with a set of C-language software APIs that provide an interface to the Oracle database.</td>
</tr>
<tr>
<td>Oracle Custom:</td>
<td>Select this connection type to access a clustered database.</td>
</tr>
<tr>
<td>Oracle Service Name:</td>
<td>Select this connection type to use the TNS alias that you give when you connect to the remote database.</td>
</tr>
<tr>
<td>WALLET:</td>
<td>Select this connection type to store credentials in an Oracle wallet.</td>
</tr>
<tr>
<td>Oracle SID:</td>
<td>Select this connection type to uniquely identify a particular database on a system.</td>
</tr>
</tbody>
</table>

| DB Version | Select the Oracle version in use. |
| Host       | Database server IP address. |
| Port       | Listening port number of DB server. |
| Database   | Name of the database. |

| Username and Password | DB user authentication data. |
|                       | To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings. |

| Table | Name of the table to be written. Note that only one table can be written at a time. |

| Action on table | **Note:** The **Action on table** list will not be available if you select the **Enable parallel execution** check box in the **Advanced settings** view. |
|                | On the table defined, you can perform one of the following operations: |
|                | **Default:** No operation is carried out. |
| **Drop and create table**: The table is removed and created again. |
| **Create table**: The table does not exist and gets created. |
| **Create table if not exists**: The table is created if it does not exist. |
| **Drop table if exists and create**: The table is removed if it already exists and created again. |
| **Clear table**: The table content is deleted. |
| **Truncate table**: The table content is deleted. You do not have the possibility to rollback the operation. |
| **Truncate table with reuse storage**: The table content is deleted. You do not have the possibility to rollback the operation. However, it is allowed to reuse the existing storage allocated to the table though the storage is considered empty. |

**Warning:**
If you select the **Use an existing connection** check box and select an option other than **Default** from the **Action on table list**, a commit statement will be generated automatically before the data insert/update/delete operation.

**Action on data**

| **Insert**: Add new entries to the table. If duplicates are found, job stops. |
| **Update**: Make changes to existing entries |
| **Insert or update**: Insert a new record. If the record with the given reference already exists, an update would be made. |
| **Update or insert**: Update the record with the given reference. If the record does not exist, a new record would be inserted. |
| **Delete**: Remove entries corresponding to the input flow. |

**Warning:**
It is necessary to specify at least one column as a primary key on which the Update and Delete operations are based. You can do that by clicking **Edit Schema** and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the **Advanced settings** view where you can simultaneously define primary keys for the Update and Delete operations. To do that: Select the **Use field options** check box and then in the **Key in update column**, select the check boxes next to the column names you want to use as a base for the Update operation. Do the same in the **Key in delete column** for the Delete operation.

**Schema and Edit schema**

| A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either **Built-in** or stored remotely in the **Repository**. |
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Built-In**: You create and store the schema locally for this component only.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

**Die on error**

This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a **Row > Rejects** link.

**Specify a data source alias**

Select this check box and specify the alias of a data source created on the **Talend Runtime** side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in **Talend Runtime**.

If you use the component's own DB configuration, your data source connection will be closed at the end of the component. To prevent this from happening, use a shared DB connection with the data source alias specified.

This check box is not available when the **Use an existing connection** check box is selected.

### Advanced settings

**Additional JDBC parameters**

Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the **Use an existing connection** check box in the **Basic settings**.

**Note:**

You can press **Ctrl+Space** to access a list of predefined global variables.
<table>
<thead>
<tr>
<th><strong>Commit every</strong></th>
<th>Enter the number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and, above all, better performance at execution.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>tStat Catcher Statistics</strong></td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
<tr>
<td><strong>Additional Columns</strong></td>
<td>This option is not offered if you create (with or without drop) the DB table. This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing.</td>
</tr>
<tr>
<td><strong>Name:</strong></td>
<td>Type in the name of the schema column to be altered or inserted as new column.</td>
</tr>
<tr>
<td><strong>SQL expression:</strong></td>
<td>Type in the SQL statement to be executed in order to alter or insert the relevant column data.</td>
</tr>
<tr>
<td><strong>Position:</strong></td>

</tr>
</tbody>
</table>
### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE</strong></td>
</tr>
<tr>
<td><strong>NB_LINE_UPDATED</strong></td>
</tr>
<tr>
<td><strong>NB_LINE_INSERTED</strong></td>
</tr>
<tr>
<td><strong>NB_LINE_DELETED</strong></td>
</tr>
<tr>
<td><strong>NB_LINE_REJECTED</strong></td>
</tr>
<tr>
<td><strong>QUERY</strong></td>
</tr>
</tbody>
</table>

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
</tr>
</thead>
<tbody>
<tr>
<td>This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible. This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in a Oracle database. It also allows you to create a reject flow using a Row &gt; Rejects link to filter data in error. For an example of <strong>tMysqlOutput</strong> in use, see <em>Retrieving data in error with a Reject link</em> on page 2485.</td>
</tr>
</tbody>
</table>

### Dynamic settings

<table>
<thead>
<tr>
<th>Dynamic settings</th>
</tr>
</thead>
<tbody>
<tr>
<td>Click the <strong>[+]</strong> button to add a row in the table and fill the <strong>Code</strong> field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.</td>
</tr>
</tbody>
</table>

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see *Reading data from databases through context-based dynamic connections* on page 2457 and *Reading data from different MySQL databases using dynamically loaded connection parameters* on page 491. For more information on Dynamic
**tOracleOutput**

<table>
<thead>
<tr>
<th><strong>settings</strong> and context variables, see Talend Studio User Guide.</th>
</tr>
</thead>
</table>

**Limitation**

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

## Related scenarios

For **tOracleOutput** related topics, see:

- Inserting a column and altering data using **tMysqlOutput** on page 2477.
tOracleOutputBulk

Writes a file with columns based on the defined delimiter and the Oracle standards.

The tOracleOutputBulk and tOracleBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tOracleOutputBulkExec component, detailed in a separate section. The advantage of using two separate steps is that the data can be transformed before it is loaded in the database.

tOracleOutputBulk Standard properties

These properties are used to configure tOracleOutputBulk running in the Standard Job framework.

The Standard tOracleOutputBulk component belongs to the Databases family.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>

<tr>
<th>tStatCatcher Statistics</th>
<th>Select this check box to gather the job processing metadata at a job level as well as at each component level.</th>
</tr>
</thead>
</table>

---

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th><strong>NB_LINE</strong>: the number of rows processed. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is to be used along with tOracleBulkExec component. Used together they offer gains in performance while feeding a Oracle database.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component family</td>
<td>Databases/Oracle</td>
</tr>
</tbody>
</table>

### Related scenarios

For use cases in relation with tOracleOutputBulk, see the following scenarios:

- Inserting transformed data in MySQL database on page 2493.
- Inserting data in bulk in MySQL database on page 2500.
- Truncating and inserting file data into an Oracle database on page 2700.
**tOracleOutputBulkExec**

Executes the Insert action in the specified Oracle database.

As a dedicated component, it allows gains in performance during Insert operations to an Oracle database.

The tOracleOutputBulk and tOracleBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tOracleOutputBulkExec component.

**tOracleOutputBulkExec Standard properties**

These properties are used to configure tOracleOutputBulkExec running in the Standard Job framework.

The Standard tOracleOutputBulkExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td><strong>Built-in</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

**Connection type**

Drop-down list of available drivers:

- **Oracle OCI**: Select this connection type to use Oracle Call Interface with a set of C-language software APIs that provide an interface to the Oracle database.
- **Oracle Service Name**: Select this connection type to use the TNS alias that you give when you connect to the remote database.
- **Oracle SID**: Select this connection type to uniquely identify a particular database on a system.
- **Oracle Custom**: Select this connection type to access a clustered database.

**DB Version**

Select the Oracle version in use.

**Host**

Database server IP address.

Currently, only *localhost*, 127.0.0.1 or the exact IP address of the local machine is allowed for proper functioning. In other words, the database server must be installed on the same machine where the Studio is installed or where the Job using `tOracleOutputBulkExec` is deployed.

**Port**

Listening port number of DB server.

**Database**

Name of the database.

**Schema**

Name of the schema.

**Username and Password**

DB user authentication data.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

**Table**

Name of the table to be written. Note that only one table can be written at a time and that the table must exist for the insert operation to succeed.

**Action on table**

On the table defined, you can perform one of the following operations:

- **None**: No operations is carried out.
<table>
<thead>
<tr>
<th><strong>Action on data</strong></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Insert</strong></td>
<td>Insert data to an empty table. If the table already contains data, the Job stops and the existing data remains in the table.</td>
</tr>
<tr>
<td><strong>Update</strong></td>
<td>Update the existing data. You have to set the key on the schema if this option is selected.</td>
</tr>
<tr>
<td><strong>Append</strong></td>
<td>Append data to the table, whether the table is empty or not.</td>
</tr>
<tr>
<td><strong>Replace</strong></td>
<td>If the table already contains data, delete all the existing data and insert the new data. If the table is empty, insert the new data.</td>
</tr>
<tr>
<td><strong>Truncate</strong></td>
<td>If the table already contains data, truncate all the existing data and insert the new data. If the table is empty, insert the new data.</td>
</tr>
</tbody>
</table>

### File Name
Name of the file to be generated and loaded.

**Warning:**
This file is generated on the machine specified by the URI in the Host field so it should be on the same machine as the database server.

### Create directory if not exists
This check box is selected by default. It creates a directory to hold the output table if required.

### Append
Select this check box to add the new rows at the end of the file.

### Action on data
On the data of the table defined, you can perform:

- **Insert**: Insert data to an empty table. If the table already contains data, the Job stops and the existing data remains in the table.
- **Update**: Update the existing data. You have to set the key on the schema if this option is selected.
- **Append**: Append data to the table, whether the table is empty or not.
- **Replace**: If the table already contains data, delete all the existing data and insert the new data. If the table is empty, insert the new data.
- **Truncate**: If the table already contains data, truncate all the existing data and insert the new data. If the table is empty, insert the new data.

### Schema and Edit Schema
A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either Built-in or stored remotely in the Repository.

Click **Edit schema** to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon
completion and choose this schema metadata again in the Repository Content window.

**Built-In**: You create and store the schema locally for this component only.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

**Field separator**
Character, string or regular expression to separate fields.

**Advanced settings**

| Advanced separator (for number) | Select this check box to change data separators for numbers:  
**Thousands separator**: define separators you want to use for thousands.  
**Decimal separator**: define separators you want to use for decimals. |
| Field separator | Character, string or regular expression to separate fields. |
| Row separator | String (ex: \n on Unix) to separate rows. |
| Specify .ctl file's INTO TABLE clause manually | Select this check box to enter manually the INTO TABLE clause of the control file directly into the code. |
| Use schema's Date Pattern to load Date field | Select this check box to use the date model indicated in the schema for dates. |
| Specify field condition | Select this check box to define a condition for loading data. |
| Preserve blanks | Select this check box to preserve blank spaces. |
| Trailing null columns | Select this check box to load data with all empty columns. |
| Load options | Click + to add data loading options:  
**Parameter**: select a loading parameter from the list.  
**Value**: enter a value for the parameter selected. |
| NLS Language | From the drop-down list, select the language for your data if the data is not in Unicode. |
| Set Parameter NLS_TERRITORY | Select this check box to modify the conventions used for date and time formats. The default value is that of the operating system. |
### Encoding
Select the encoding from the list or select Custom and define it manually. This field is compulsory for DB data handling.

### Oracle encoding type
Select the Oracle-specific encoding type for the data to be processed. This encoding type allows `tOracleOutputBulkExec` to properly generate the Sybase Bulk command.

### Output
Select the type of output for the standard output of the Oracle database:
- to console,
- to global variable.

### Convert columns and table names to uppercase
Select this check box to put columns and table names in uppercase.

### Bulk file parameters
Set the parameters Buffer Size and StringBuilder Size for a performance gain according to the memory size.

### tStatCatcher Statistics
Select this check box to gather the job processing metadata at a job level as well as at each component level.

## Usage

### Usage rule
This component is mainly used when no particular transformation is required on the data to be loaded onto the database.

### Dynamic settings
Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

### Limitation
The database server/client must be installed on the same machine where the Studio is installed or where the Job using `tOracleOutputBulkExec` is deployed, so that the component functions properly.
Related scenarios

For use cases in relation with tOracleOutputBulkExec, see the following scenarios:

- Inserting transformed data in MySQL database on page 2493.
- Inserting data in bulk in MySQL database on page 2500.
- Truncating and inserting file data into an Oracle database on page 2700.
tOracleRollback

Cancels the transaction commit in the connected Oracle database to avoid committing part of a transaction involuntarily.

**tOracleRollback Standard properties**

These properties are used to configure tOracleRollback running in the Standard Job framework.

The Standard tOracleRollback component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tOracleConnection component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics                        | Select this check box to collect log data at the component level. |

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is more commonly used with other tOracle* components, especially with the tOracleConnection and tOracleCommit components.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic settings</td>
<td>Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection</td>
</tr>
</tbody>
</table>
Related scenario

For tOracleRollback related scenario, see tMysqlRollback on page 2502
**tOracleRow**

Executes the stated SQL query on the specified Oracle database.

Depending on the nature of the query and the database, tOracleRow acts on the actual DB structure or on the data (although without handling data). The SQLBuilder tool helps you write easily your SQL statements.

tOracleRow is the specific component for this database query. It executes the SQL query stated onto the specified database. The row suffix means the component implements a flow in the job design although it doesn’t provide output.

**tOracleRow Standard properties**

These properties are used to configure tOracleRow running in the Standard Job framework.

The Standard tOracleRow component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
### Connection type

Drop-down list of available drivers:

- **Oracle OCI**: Select this connection type to use Oracle Call Interface with a set of C-language software APIs that provide an interface to the Oracle database.
- **Oracle Service Name**: Select this connection type to use the TNS alias that you give when you connect to the remote database.
- **Oracle SID**: Select this connection type to uniquely identify a particular database on a system.
- **Oracle Custom**: Select this connection type to access a clustered database.

### DB Version

Select the Oracle version in use.

### Host

Database server IP address.

### Port

Listening port number of DB server.

### Database

Name of the database.

### Username and Password

DB user authentication data.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

### Schema and Edit Schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

### Query type

Either **Built-in** or **Repository**.

- **Built-in**: Fill in manually the query statement or build it graphically using SQLBuilder
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.
**Repository**: Select the relevant query stored in the Repository. The Query field gets accordingly filled in.

**Query**

Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.

**Use NB_LINE_**

This option allows you to feed the variable with the number of rows inserted/updated/deleted to the next component or sub-job. This field only applies if the query entered in **Query** field is an INSERT, UPDATE or DELETE query.

- **NONE**: does not feed the variable.
- **INSERTED**: feeds the variable with the number of rows inserted.
- **UPDATED**: feeds the variable with the number of rows updated.
- **DELETED**: feeds the variable with the number of rows deleted.

**Specify a data source alias**

Select this check box and specify the alias of a data source created on the Talend Runtime side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in Talend Runtime. If you use the component’s own DB configuration, your data source connection will be closed at the end of the component. To prevent this from happening, use a shared DB connection with the data source alias specified.

This check box is not available when the **Use an existing connection** check box is selected.

**Die on error**

This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a **Row > Rejects** link.

**Advanced settings**

**Propagate QUERY’s recordset**

Select this check box to insert the result of the query into a COLUMN of the current flow. Select this column from the **use column** list.

**Note:**

This option allows the component to have a different schema from that of the preceding component. Moreover, the column that holds the QUERY’s recordset should be set to the type of Object and this component is usually followed by **tParseRecordSet**.

**Use PreparedStatement**

Select this check box if you want to query the database using a PreparedStatement. In the **Set PreparedStatement Parameter** table, define the parameters represented by “?” in the SQL instruction of the **Query** field in the **Basic Settings** tab.

**Parameter Index**: Enter the parameter position in the SQL instruction.
**Parameter Type**: Enter the parameter type.

**Parameter Value**: Enter the parameter value.

**Note**: This option is very useful if you need to execute the same query several times. Performance levels are increased. You can also use PreparedStatement to avoid SQL injection. For a detailed scenario of utilizing this feature, see Using PreparedStatement objects to query data on page 2509.

**Commit every**

Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions.

**tStatCatcher Statistics**

Select this check box to collect log data at the component level.

### Global Variables

**QUERY**: the query statement being processed. This is a Flow variable and it returns a string.

**NB LINE UPDATED**: the number of rows updated. This is an After variable and it returns an integer.

**NB LINE INSERTED**: the number of rows inserted. This is an After variable and it returns an integer.

**NB LINE DELETED**: the number of rows deleted. This is an After variable and it returns an integer.

**ERROR MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

### Usage

**Usage rule**

This component offers the flexibility of the DB query and covers all possible SQL queries.

**Dynamic settings**

Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an
environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

**Related scenarios**

For related topics, see:

- Combining two flows for selective output on page 2514
- Procedure on page 625.
- Removing and regenerating a MySQL table index on page 2508.
- Using PreparedStatement objects to query data on page 2509.
tOracleSCD

Reflects and tracks changes in a dedicated Oracle SCD table.
tOracleSCD addresses Slowly Changing Dimension needs, reading regularly a source of data and logging the changes into a dedicated SCD table.

**tOracleSCD Standard properties**

These properties are used to configure tOracleSCD running in the Standard Job framework.
The Standard tOracleSCD component belongs to the Business Intelligence and the Databases families.
The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-in:</strong> No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository:</strong> Select the Repository file where properties are stored. The following fields are pre-filled in using fetched data.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
|                           | **Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:  
1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.  
2. In the child level, use a dedicated connection component to read that registered database connection.  
For an example about how to share a database connection across Job levels, see **Talend Studio User Guide**. |

| Connection type           | Drop-down list of available drivers:

<td>Select this connection type to uniquely identify a particular database on a system.</td>
</tr>
<tr>
<td><strong>Oracle Custom</strong></td>
<td>Select this connection type to access a clustered database.</td>
</tr>
</tbody>
</table>

**DB Version**
Select the Oracle version you are using.

**Host**
Database server IP address.

**Port**
Listening port number of DB server.

**Database**
Name of the database.

**Schema**
Name of the DB schema.

**Username and Password**
DB user authentication data.
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

**Table**
Name of the table to be written. Note that only one table can be written at a time.

**Action on table**
Select to perform one of the following operations on the table defined:
- None: No action is carried out on the table.
- Create table: A new table is created.
- Create table if not exists: A table is created if it does not exist.

**Schema and Edit schema**
A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:
- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Built-in**: The schema is created and stored locally for this component only. Related topic: see **Talend Studio User Guide**.
Repository: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide.

**SCD Editor**
The SCD editor helps to build and configure the data flow for slowly changing dimension outputs. For more information, see SCD management methodology on page 2522.

**Use memory saving Mode**
Select this check box to maximize system performance.

**Source keys include Null**
Select this check box to allow the source key columns to have Null values.

**Warning:**
Special attention should be paid to the uniqueness of the source key(s) values when this option is selected.

**Die on error**
This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

### Advanced settings

**Additional JDBC parameters**
Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the Use an existing connection check box in the Basic settings.

**End date time details**
Specify the time value of the SCD end date time setting in the format of `HH:mm:ss`. The default value for this field is `12:00:00`.

This field appears only when SCD Type 2 is used and Fixed year value is selected for creating the SCD end date.

**tStatCatcher Statistics**
Select this check box to collect log data at the component level.

**Debug mode**
Select this check box to display each step during processing entries in a database.

### Global Variables

**Global Variables**

- **NB_LINE_UPDATED**: the number of rows updated. This is an After variable and it returns an integer.
- **NB_LINE_INSERTED**: the number of rows inserted. This is an After variable and it returns an integer.
- **NB_LINE_REJECTED**: the number of rows rejected. This is an After variable and it returns an integer.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is used as Output component. It requires an Input component and Row main link as input.</th>
</tr>
</thead>
</table>

| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |
|---|---|

| Limitation | This component does not support using SCD type 0 together with other SCD types. |

### Related scenario

For related scenarios, see tMysqlSCD on page 2519.
tOracleSCDELT

Reflects and tracks changes in a dedicated Oracle SCD table through SQL queries.

tOracleSCDELT addresses Slowly Changing Dimension needs through SQL queries (server-side processing mode), and logs the changes into a dedicated Oracle SCD table.

**tOracleSCDELT Standard properties**

These properties are used to configure tOracleSCDELT running in the Standard Job framework.

The Standard tOracleSCDELT component belongs to the Business Intelligence and the Databases families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<tr>
<td><strong>Repository:</strong></td>
<td>Select the repository file where Properties are stored. The fields that come after are pre-filled in using the fetched data.</td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined.

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

**Connection type**

Drop-down list of available drivers:
**Oracle OCI**: Select this connection type to use Oracle Call Interface with a set of C-language software APIs that provide an interface to the Oracle database.

**Oracle Service Name**: Select this connection type to use the TNS alias that you give when you connect to the remote database.

**Oracle SID**: Select this connection type to uniquely identify a particular database on a system.

**Oracle Custom**: Select this connection type to access a clustered database.

**DB Version**
Select the Oracle version you are using.

**Host**
The IP address of the database server.

**Port**
Listening port number of database server.

**Database**
Name of the database

**Username and Password**
User authentication data for a dedicated database.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

**Source table**
Name of the input DB2 SCD table.

**Table**
Name of the table to be written. Note that only one table can be written at a time

**Action on table**
Select to perform one of the following operations on the table defined:

- **None**: No action carried out on the table.
- **Drop and create table**: The table is removed and created again
- **Create table**: A new table gets created.
- **Create table if not exists**: A table gets created if it does not exist.
- **Clear table**: The table content is deleted. You have the possibility to rollback the operation.
- **Truncate table**: The table content is deleted. You do not have the possibility to rollback the operation.

**Schema and Edit schema**
A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `LINE` when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and
| **Surrogate Key** | Select the surrogate key column from the list. |
| **Creation** | Select the method to be used for the surrogate key generation.  
For more information regarding the creation methods, see [SCD management methodology](#) on page 2522. |
| **Source Keys** | Select one or more columns to be used as keys, to ensure the unicity of incoming data. |
| **Source fields value include Null** | Select this check box to allow the source columns to have Null values.  
**Note:**  
The source columns here refer to the fields defined in the [SCD type 1 fields](#) and [SCD type 2 fields](#) tables. |
| **Use SCD Type 1 fields** | Use type 1 if tracking changes is not necessary. SCD Type 1 should be used for typos corrections for example. Select the columns of the schema that will be checked for changes. |
| **Use SCD Type 2 fields** | Use type 2 if changes need to be tracked down. SCD Type 2 should be used to trace updates for example. Select the columns of the schema that will be checked for changes.  
**Start date:** Adds a column to your SCD schema to hold the start date value. You can select one of the input schema columns as Start Date in the SCD table.  
**End Date:** Adds a column to your SCD schema to hold the end date value for the record. When the record is currently active, the End Date column shows a null value, or you can select [Fixed Year value](#) and fill it in with a fictive year to avoid having a null value in the End Date field.  
**Note:** To avoid duplicated change records, it is recommended to select a column that can identify each change for this field.  
**Log Active Status:** Adds a column to your SCD schema to hold the [true](#) or [false](#) status value. This column helps to easily spot the active record.  
**Log versions:** Adds a column to your SCD schema to hold the version number of the record. |

Related scenario

For related scenarios, see:

- Tracking data changes in a Snowflake table using the tJDBCSCDELT component on page 1859.
- Tracking data changes in a PostgreSQL table using the tPostgreSQLSCDELT component on page 3039.
tOracleSP

Calls an Oracle database stored procedure.

tOracleSP offers a convenient way to centralize multiple or complex queries in a database and call them easily.

**tOracleSP Standard properties**

These properties are used to configure tOracleSP running in the Standard Job framework.

The Standard tOracleSP component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<table>
<thead>

<tr>
<td>Username and Password</td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either Built-in or stored remotely in the Repository. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:</td>
</tr>
<tr>
<td></td>
<td>• View schema: choose this option to view the schema only.</td>
</tr>
<tr>
<td></td>
<td>• Change to built-in property: choose this option to change the schema to Built-in for local changes.</td>
</tr>
<tr>
<td></td>
<td>• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.</td>
</tr>
<tr>
<td>Built-In</td>
<td>You create and store the schema locally for this component only.</td>
</tr>
<tr>
<td>Repository</td>
<td>You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
</tr>
<tr>
<td>SP Name</td>
<td>Type in the exact name of the Stored Procedure (or Function)</td>
</tr>
<tr>
<td>Is Function / Return result in</td>
<td>Select this check box, if the stored procedure is a function and one value only is to be returned. Select on the list the schema column, the value to be returned is based on.</td>
</tr>
</tbody>
</table>
Click the Plus button and select the various Schema Columns that will be required by the procedures. Note that the SP schema can hold more columns than there are parameters used in the procedure.

Select the **Type** of parameter:
- **IN**: Input parameter.
- **OUT**: Output parameter/return value.
- **IN OUT**: Input parameter is to be returned as value, likely after modification through the procedure (function).
- **RECORDSET**: Input parameters is to be returned as a set of values, rather than single value.

**Note:**
Check Inserting data in mother/daughter tables on page 2437 if you want to analyze a set of records from a database table or DB query and return single records.

The **Custom Type** is used when a Schema Column you want to use is user-defined. Two Custom Type columns are available in the Parameters table. In the first Custom Type column:
- Select the check box in the Custom Type column when the corresponding Schema Column you want to use is of user-defined type.
- If all listed Schema Columns in the Parameters table are of custom type, you can select the check box before Custom Type once for them all.

Select a database type from the **DB Type** list to map the source database type to the target database type:
- **Auto-Mapping**: Map the source database type to the target database type automatically (default).
- **CLOB**: Character large object.
- **BLOB**: Binary large object.
- **DECIMAL**: Decimal numeric object.
- **NUMERIC**: Character 0 to 9.
- **XMLTYPE**: XML schema type.

**Warning:**
When mapping a column selected from the Return result in list box or set to the IN or OUT type of parameter to XMLTYPE, make sure that the column is of type String in the schema.

In the second Custom Type column, you can precise what the custom type is. The type may be:
- **STRUCT**: used for one element.
- **ARRAY**: used for a collection of elements.

In the Custom name column, specify the name of the custom type that you have given to this type.
Warning:
*When an OUT parameter uses the custom type, make sure that its corresponding Schema Column has chosen the Object type in the schema table.*

### Specify a data source alias
Select this check box and specify the alias of a data source created on the *Talend Runtime* side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in *Talend Runtime*.

### Advanced settings

<table>
<thead>
<tr>
<th><strong>Additional JDBC parameters</strong></th>
<th>Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the <em>Use an existing connection</em> check box in the Basic settings.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NLS Language</strong></td>
<td>In the list, select the language used for the data that are not used in Unicode.</td>
</tr>
<tr>
<td><strong>NLS Territory</strong></td>
<td>Select the conventions used for date and time formats. The default value is that of the operating system.</td>
</tr>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to gather the job processing metadata at a Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

### Usage

<table>
<thead>
<tr>
<th><strong>Usage rule</strong></th>
<th>This component is used as intermediary component. It can be used as start component but only input parameters are thus allowed.</th>
</tr>
</thead>
</table>
| **Dynamic settings** | Click the [*] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.  

The **Dynamic settings** table is available only when the *Use an existing connection* check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.  

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |

<table>
<thead>
<tr>
<th><strong>Limitation</strong></th>
<th>The Stored Procedures syntax should match the Database syntax.</th>
</tr>
</thead>
</table>
When the parameters set in this component are of Custom Type, the tJava family components should be placed before the component in order for users to define values for the custom-type parameters, or after the component so as to read and output the Out-type custom parameters.

Checking number format using a stored procedure

The following job aims at connecting to an Oracle Database containing Social Security Numbers and their holders’ name, calling a stored procedure that checks the SSN format against a standard ###-##-#### format. Then the verification output results, 1 for valid format and 0 for wrong format get displayed onto the execution console.

1. Drag and drop the following components from the Palette: tOracleConnection, tOracleInput, tOracleSP, and tLogRow.
2. Link the tOracleConnection to the tOracleInput using a Then Run connection as no data is handled here.
3. And connect the other components using a Row Main link as rows are to be passed on as parameter to the SP component and to the console.
4. In the tOracleConnection, define the details of connection to the relevant Database. You will then be able to reuse this information in all other DB-related components.
5. Then select the tOracleInput and define its properties.
   - Select the Use an existing connection check box and select the tOracleConnection component in the list in order to reuse the connection details that you already set.
   - Select Repository as Property type as the Oracle schema is defined in the DB Oracle connection entry of the Repository. If you haven’t recorded the Oracle DB details in the Repository, then fill in the Schema name manually.
• Then select **Repository** as **Schema**, and retrieve the relevant schema corresponding to your Oracle DB table.

<table>
<thead>
<tr>
<th></th>
<th>ID</th>
<th>NAME</th>
<th>CITY</th>
<th>SSNUMBER</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>Jack</td>
<td>LA</td>
<td>123-45-6789</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>Tom</td>
<td>NYC</td>
<td>123-45-6789</td>
</tr>
<tr>
<td>3</td>
<td>3</td>
<td>Bill</td>
<td>SF</td>
<td>123-45-6789</td>
</tr>
<tr>
<td>4</td>
<td>4</td>
<td>Jana</td>
<td>NYC</td>
<td>236-52-2955</td>
</tr>
<tr>
<td>5</td>
<td>5</td>
<td>Brandon</td>
<td>SLC</td>
<td>561-52-2267</td>
</tr>
</tbody>
</table>

• In this example, the SSN table has a four-column schema that includes **ID**, **NAME**, **CITY** and **SSNUMBER**.

• In the **Query** field, type in the following Select query or select it in the list, if you stored it in the Repository.

```
select ID, NAME, CITY, SSNUMBER from SSN
```

• Then select the **tOracleSP** and define its **Basic settings**.

• Like for the **tOracleInput** component, select **Repository** in the **Property type** field and select the **Use an existing connection** check box, then select the relevant entries in the respective list.

• The schema used for the **tOracleSP** slightly differs from the input schema. Indeed, an extra column (**SSN_Valid**) is added to the Input schema. This column will hold the format validity status (1 or 0) produced by the procedure.

• In the **SP Name** field, type in the exact name of the stored procedure (or function) as called in the Database. In this use case, the stored procedure name is **is_ssn**.
The basic function used in this particular example is as follows:

```sql
CREATE OR REPLACE FUNCTION is_ssn(string_in VARCHAR2)
RETURN PLS_INTEGER
IS
  -- validating ###-##-#### format
BEGIN
  IF TRANSLATE(string_in, '0123456789A', 'AAAAAAAAAAB') = 'AAA-AA-AAAA' THEN
    RETURN 1;
  END IF;
  RETURN 0;
END is_ssn;
/
```

As a return value is expected in this use case, the procedure acts as a function, so select the **Is function** check box.

The only return value expected is based on the `ssn_valid` column, hence select the relevant list entry.

In the **Parameters** area, define the input and output parameters used in the procedure. In this use case, only the `SSNumber` column from the schema is used in the procedure.

Click the plus sign to add a line to the table and select the relevant column (`SSNumber`) and type (`IN`).

Then select the **tLogRow** component and click Sync Column to make sure the schema is passed on from the preceding **tOracleSP** component.

Select the **Print values in cells of a table** check box to facilitate the output reading.

Then save your job and press **F6** to run it.

On the console, you can read the output results. All input schema columns are displayed even though they are not used as parameters in the stored procedure.

The final column shows the expected return value, whether the SS Number checked is valid or not.

**Note:**

Check Inserting data in mother/daughter tables on page 2437 if you want to analyze a set of records from a database table or DB query and return single records.
Related scenarios

For related scenarios, see:

- Retrieving personal information using a stored procedure on page 2415.
- Using tMysqlSP to find a State Label using a stored procedure on page 2539.
- Executing a stored procedure using tMDMSP on page 2159.
tOracleTableList

Lists the names of specified Oracle tables using a SELECT statement based on a WHERE clause. tOracleTableList iterates on a set of tables through a defined Oracle connection.

tOracleTableList Standard properties

These properties are used to configure tOracleTableList running in the Standard Job framework.
The Standard tOracleTableList component belongs to the Databases family.
The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is to be used along with other Oracle components, especially with \texttt{tOracleConnection}.</th>
</tr>
</thead>
</table>

#### Dynamic settings

Click the \([\ast]\) button to add a row in the table and fill the \texttt{Code} field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

### Related scenarios

For a \texttt{tOracleTableList} related scenario, see Iterating on DB tables and deleting their content using a user-defined SQL template on page 2544.
tPaloCheckElements

Checks whether elements are present in an incoming data flow existing in a given cube. This component can be used along with tPaloOutputMulti. It checks if the elements from the input stream exist in the given cube, before writing them. It can also define a default value to be used for nonexistent elements.

**tPaloCheckElements Standard properties**

These properties are used to configure tPaloCheckElements running in the Standard Job framework. The Standard tPaloCheckElements component belongs to the Business Intelligence family. The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Use an existing connection</strong></td>

</tr>
<tr>
<td></td>
<td>- Stop: the entire process is interrupted.</td>
</tr>
<tr>
<td><strong>Schema and Edit Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:</td>
</tr>
</tbody>
</table>
- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Built-in**: The schema is created and stored locally for this component only. Related topic: see *Talend Studio User Guide*.

**Repository**: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see *Talend Studio User Guide*.

Define the elements to be checked in the table provided.
- **Column**: shows the column(s) from the input schema. It is completed automatically once a schema is retrieved or created.
- **Element type**: select the element type for the input column. Only one column can be defined as **Measure**.
- **Default**: type in the default value to be used if you have selected the **Use default** option in the **On element error** field.

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data on the component level. |

**Global Variables**

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. |

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

**Usage**

| Usage rule | This component requires an input component. |
| Connections | Outgoing links (from this component to another):

**Row**: Main; Rejects  
**Trigger**: Run if; On Component Ok; On Component Error.  

Incoming links (from one component to this one):

**Row**: Main; Rejects  

For further information regarding connections, see *Talend Studio User Guide*. |
| --- | --- |
| Limitation | This component only works on Normal Palo cubes.  
Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center ([https://help.talend.com](https://help.talend.com)). |

**Related scenario**

For a related scenario, see *Rejecting inflow data when the elements to be written do not exist in a given cube* on page 2809.
tPaloClose

Closes an active connection to a Palo Server.

This component is used to disconnect a connection to a Palo server to release occupied resources.

**tPaloClose Standard properties**

These properties are used to configure tPaloClose running in the Standard Job framework.
The Standard tPaloClose component belongs to the Business Intelligence family.
The component in this framework is available in all Talend products.

**Basic settings**

| Component List | Select a tPaloConnection component from the drop-down list if more than one connection is planned for the current Job. |

**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

**Global Variables**

| ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. |
| A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. |
| To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. |
| For further information about variables, see Talend Studio User Guide. |

**Usage**

| Usage rule | This component is more commonly used with other Palo components, especially tPaloConnection. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for |
example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see *Reading data from databases through context-based dynamic connections* on page 2457 and *Reading data from different MySQL databases using dynamically loaded connection parameters* on page 491. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

**Related scenarios**

No scenario is available for the Standard version of this component yet.
tPaloConnection

Opens a connection to a Palo Server and allows other components involved in a process to share the connection for the duration of the process.

**tPaloConnection Standard properties**

These properties are used to configure tPaloConnection running in the Standard Job framework. The Standard tPaloConnection component belongs to the Business Intelligence family.

The component in this framework is available in all Talend products.

### Basic settings

<table>
<thead>
<tr>
<th>Host Name</th>
<th>Enter the host name or the IP address of the host server.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server Port</td>
<td>Type in the listening port number of the Palo server.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>Enter the Palo user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
</tbody>
</table>

### Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

### Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

### Usage

| Usage rule | This component is used along with Palo components to offer a shared connection to a Palo server. |
| Connections | Outgoing links (from this component to another): |
**Trigger**: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error.

Incoming links (from one component to this one):

**Row**: Iterate

For further information regarding connections, see *Talend Studio User Guide*.

**Limitation**

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

**Related scenario**

For related scenarios, see *Creating a dimension with elements* on page 2785.
tPaloCube

Performs operations on a given Palo cube.
This component creates, deletes or clears Palo cubes from existing dimensions in a Palo database.

**tPaloCube Standard properties**

These properties are used to configure tPaloCube running in the Standard Job framework.
The Standard tPaloCube component belongs to the Business Intelligence family.
The component in this framework is available in all Talend products.

**Basic settings**

| Use an existing connection | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.
Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Host Name</td>
<td>Enter the host name or the IP address of the host server.</td>
</tr>
<tr>
<td>Server Port</td>
<td>Type in the listening port number of the Palo server.</td>
</tr>
</tbody>
</table>
| Username and Password      | Enter the Palo user authentication data.
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| Database                   | Type in the name of the database in which the operation is to take place. |
| Cube                       | Type in the name of the cube where the operation is to take place. |
| Cube type                  | From the drop-down list, select the type of cube on which the operation is to be carried out:
- Normal: this is the normal and default type of cube.
- Attribute: an Attribute cube is created with a normal cube.
- User Info: User Info cubes can be created/modified with this component. |
| Action on cube             | Select the operation you want to carry out on the cube defined:
- Create cube: the cube does not exist and will be created.
- Create cube if not exists: the cube is created if it does not exist.
- Delete cube if exists and create: the cube is deleted if it already exists and a new one will be created.
- Delete cube: the cube is deleted from the database. |
- **Clear cube**: the data is cleared from the cube.

### Dimension list

Add rows and enter the name of existing database dimension’s to be used in the cube. The order of the dimensions in the list determines the order of the dimensions created.

### Advanced settings

- **tStat Catcher Statistics**
  Select this check box to collect log data at the component level.

### Global Variables

**Global Variables**

- **CUBENAME**: the name of the cube. This is an After variable and it returns a string.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.
- A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.
- To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.
- For further information about variables, see *Talend Studio User Guide*.

### Usage

**Usage rule**

Can be used as a standalone component for dynamic cube creation with a defined dimension list.

**Connections**

- **Outgoing links** (from this component to another):
  - **Trigger**: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error.

- **Incoming links** (from one component to this one):
  - **Row**: Iterate
    - **Trigger**: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error.

- For further information regarding connections, see *Talend Studio User Guide*.

### Limitation

- The cube creation process does not create dimensions from scratch, so the dimensions to be used in the cube must be created beforehand.
- Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can
Creating a cube in an existing database

The Job in this scenario creates a new two dimensional cube in the Palo demo database *Biker*.

To replicate this scenario, proceed as follows:

**Configuring the tPaloCube component**

**Procedure**

1. Drop **tPaloCube** from the **Palette** onto the design workspace.
2. Double-click **tPaloCube** to open its **Component** view.

3. In the **Host name** field, type in the host name or the IP address of the host server, *localhost* for this example.
4. In the Server Port field, type in the listening port number of the Palo server. In this scenario, it is 7777.

5. In the Username field and the Password field, type in the authentication information. In this example, both of them are admin.

6. In the Database field, type in the database name in which you want to create the cube, Biker in this example.

7. In the Cube field, type in the name you want to use for the cube to be created, for example, bikerTalend.

8. In the Cube type field, select the Normal type from the drop-down list for the cube to be created, meaning this cube will be normal and default.

9. In the Action on cube field, select the action to be performed. In this scenario, select Create cube.

10. Under the Dimension list table, click the plus button twice to add two rows into the table.

11. In the Dimension list table, type in the name for each newly added row to replace the default row name. In this scenario, type in Months for the first row and Products for the second. These two dimensions exist already in the Biker database where the new cube will be created.

**Job execution**

Press F6 to run the Job.

A new cube has been created in the Biker database and the two dimensions are added into this cube.
**tPaloCubeList**

Retrieves a list of cube details from the given Palo database.

This component lists cube names, cube types, number of assigned dimensions, the number of filled cells from the given database.

**Discovering the read-only output schema of tPaloCubeList**

The below table presents information related to the read-only schema of the tPaloCubeList component.

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cube_id</td>
<td>int</td>
<td>Internal id of the cube.</td>
</tr>
<tr>

**Row**: Main, Iterate;  
**Trigger**: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error. |
The Job in this scenario retrieves detailed information of the cubes pertaining to the demo Palo database, Biker.

To replicate this scenario, proceed as follows:

**Setting up the Job**

**Procedure**

1. Drop **tPaloCubeList** and **tLogRow** from the component **Palette** onto the design workspace.
2. Right-click **tPaloCubeList** to open the contextual menu.
3. From this menu, select **Row > Main** to link the two components.

**Configuring the tPaloCube component**

**Procedure**

1. Double-click the **tPaloCube** component to open its **Component** view.
2. In the **Host name** field, type in the host name or the IP address of the host server, *localhost* for this example.

3. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is **7777**.

4. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are *admin*.

5. In the **Database** field, type in the database name in which you want to create the cube, *Biker* in this example.

**Job execution**

Press **F6** to run the Job.

The cube details are retrieved from the *Biker* database and are listed in the console of the **Run** view.

```

Incoming links (from one component to this one):

**Row**: Iterate

**Trigger**: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error

For further information regarding connections, see [Talend Studio User Guide](https://help.talend.com).

**Limitation**

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

### Creating a database

The Job in this scenario creates a new database on a given Palo server.
To replicate this scenario, proceed as follows:

**Procedure**

1. Drop **tPaloDatabase** from the component **Palette** onto the design workspace.
2. Double-click the **tPaloDatabase** component to open its **Component** view.

![Image of tPaloDatabase component settings](image)

3. In the **Host name** field, type in the host name or the IP address of the host server, *localhost* for this example.
4. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is **7777**.
5. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are *admin*.
6. In the **Database** field, type in the database name in which you want to create the cube, *talenddatabase* in this example.
7. In the **Action on database** field, select the action to be performed. In this scenario, select **Create database** as the database to be created does not exist.
8. Press **F6** to run the Job.

**Results**

A new database is created on the given Palo server.
**tPaloDatabaseList**

Lists database names, database types, number of cubes, number of dimensions, database status and database id from a given Palo server.

The tPaloDatabaseList retrieves a list of database details from the given Palo server.

**Discovering the read-only output schema of tPaloDatabaseList**

The below table presents information related to the read-only output schema of the tPaloDatabaseList component.

Retrieving detailed database information from a given Palo server

The Job in this scenario retrieves details of all of the databases from a given Palo server.

To replicate this scenario, proceed as follows:

Setting up the Job

Procedure

1. Drop tPaloDatabaseList and tLogRow from the component Palette onto the design workspace.
2. Right-click tPaloDatabaseList to open the contextual menu.
3. From this menu, select Row > Main to link the two components.

Configuring the tPaloDatabaseList component

Procedure

1. Double-click the tPaloDatabaseList component to open its Component view.

   ![tPaloDatabaseList_1](image)

   - **Basic settings**:
     - Use an existing connection
     - Connection configuration
       - Host name: localhost
       - Server Port: 7777
       - Username: admin
       - Password: ********

   2. In the Host name field, type in the host name or the IP address of the host server, localhost for this example.
3. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is **7777**.

4. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are *admin*.

**Job execution**

Press **F6** to run the Job.

Details of all of the databases in the Palo server are retrieved and listed in the console of the **Run** view.

<table>
<thead>
<tr>

For further information about the output schema, see **Discovering the read-only output schema of tPaloDatabaseList** on page 2778.
tPaloDimension

Manages Palo dimensions, even elements inside a database.

The tPaloDimension creates, drops or recreates dimensions with or without dimension elements inside a Palo database.

**tPaloDimension Standard properties**

These properties are used to configure tPaloDimension running in the Standard Job framework.

The Standard tPaloDimension component belongs to the Business Intelligence family.

The component in this framework is available in all Talend products.

**Basic settings**

| Use an existing connection | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level. |
| Host Name | Enter the host name or the IP address of the host server. |
| Server Port | Type in the listening port number of the Palo server. |
| Username and Password | Enter the Palo user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| Database | Type in the name of the database in which the dimensions are managed. |
| Dimension | Type in the name of the dimension on which the given operation should take place. |
| Action on dimension | Select the operation you want to perform on the dimension of interest:  
- **None**: no action is taken on this dimension.  
- **Create dimension**: the dimension does not exist and will be created.  
- **Create dimension if not exists**: this dimension is created only when it does not exist.  
- **Delete dimension if exists and create**: this dimension is deleted if exist and then a new one will be created.  
- **Delete dimension**: this dimension is removed from the database. |
### Create dimension elements

Select this check box to activate the dimension management fields and create dimension elements along with the creation of this dimension.

### Advanced settings

<table>
<thead>
<tr>
<th>tStat Catcher Statistics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

### Global Variables

| DIMENSIONNAME: the name of the dimension. This is an After variable and it returns a string. |
| ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. |

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

<table>

<td>With this option, you activate the corresponding parameter fields to be completed.</td>
<td></td>
</tr>
</tbody>
</table>

**Element’s type**

**Creation mode**

### Connections

<table>
<thead>
<tr>
<th></th>
<th>Outgoing links (from this component to another):</th>
</tr>
</thead>
<tbody>
<tr>
<td>Trigger:</td>
<td>Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th></th>
<th>Incoming links (from one component to this one):</th>
</tr>
</thead>
<tbody>
<tr>
<td>Row:</td>
<td>Main; Iterate</td>
</tr>
<tr>
<td>Trigger:</td>
<td>Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error.</td>
</tr>
</tbody>
</table>

For further information regarding connections, see *Talend Studio User Guide.*

### Limitation

Deletion of dimension elements is only possible with the consolidation type *None.* Only consolidation type *Self-Referenced* allows the placing of an factor on this consolidation.

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).
Creating a dimension with elements

The Job in this scenario creates a date dimension with simple element hierarchy composed of three levels: \textit{Year}, \textit{Month}, \textit{Date}.

To replicate this scenario, proceed as follows:

\begin{itemize}
  \item \textbf{Setting up the Job}

  \begin{enumerate}
    \item Drop \texttt{tPaloConnection}, \texttt{tRowGenerator}, \texttt{tMap}, \texttt{tPaloDimension} from the component \texttt{Palette} onto the design workspace.
    \item Right-click \texttt{tPaloConnection} to open the contextual menu and select \texttt{Trigger > On Subjob Ok} to link it to \texttt{tRowGenerator}.
    \item Right-click \texttt{tRowGenerator} to open the contextual menu and select \texttt{Row > Main} to link it to \texttt{tMap}.
  \end{enumerate}

  \begin{itemize}
    \item \texttt{tRowGenerator} is used to generate rows at random in order to simplify this process. In the real case, you can use one of the other input components to load your actual data.
  \end{itemize}

  \item Right-click \texttt{tMap} to open the contextual menu and select \texttt{Row > New output} to link to \texttt{tPaloDimension}, then name it as \texttt{out1} in the dialog box that pops up.

\end{itemize}

\begin{itemize}
  \item \textbf{Setting up the DB connection}

  \begin{enumerate}
    \item Double-click the \texttt{tPaloConnection} component to open its \texttt{Component} view.
  \end{enumerate}
\end{itemize}
2. In the **Host name** field, type in the host name or the IP address of the host server, *localhost* for this example.

3. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is 7777.

4. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are *admin*.

**Configuring the input component**

**Procedure**

1. Double-click **tRowGenerator** to open its editor.

```
<table>
<thead>
<tr>
<th>Schema</th>
<th>Functions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Column</td>
<td>Key</td>
</tr>
<tr>
<td>random_date</td>
<td>Date</td>
</tr>
</tbody>
</table>
```

```
Function parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>min</td>
<td>&quot;2010-01-01&quot;</td>
<td>minimum date</td>
</tr>
<tr>
<td>max</td>
<td>&quot;2010-12-31&quot;</td>
<td>maximum date (superior to ...)</td>
</tr>
</tbody>
</table>
```

2. On the upper part of the editor, click the plus button to add one column and rename it as **random_date** in the **Column** column.

3. In the newly added row, select **Date** in the **Type** column and **getRandomDate** in the **Functions** column.

4. In the **Function parameters** view on the lower part of this editor, type in the new minimum date and maximum date values in the **Value** column. In this example, the minimum is *2010-01-01*, the maximum is *2010-12-31*.

5. Click **OK** to validate your modifications and close the editor.

6. On the dialog box that pops up, click **OK** to propagate your changes.

**Configuration in the tMap editor**

**Procedure**

1. Double-click **tMap** to open its editor.
2. On the **Schema editor** view on the lower part of the **tMap** editor, under the **out1** table, click the plus button to add three rows.

3. In the **Column** column of the **out1** table, type in the new names for the three newly added rows. They are **Year**, **Month**, and **Date**. These rows are then added automatically into the **out1** table on the upper part of the **tMap** editor.

4. In the **out1** table on the upper part of the **tMap** editor, click the **Expression** column in the **Year** row to locate the cursor.

5. Press **Ctrl+space** to open the drop-down variable list.

6. Double-click **TalendDate.formatDate** to select it from the list. The expression to get the date displays in the **Year** row under the **Expression** column. The expression is `TalendDate.formatDate("yyyy-MM-dd HH:mm:ss",myDate)`.

7. Replace the default expression with `TalendDate.formatDate("yyyy",row1.random_date)`.

8. Do the same for the **Month** row and the **Date** row to add this default expression and to replace it with `TalendDate.formatDate("MM",row1.random_date)` for the **Month** row and with `TalendDate.formatDate("dd-MM-yyyy", row1.random_date)` for the **Date** row.

9. Click OK to validate this modification and accept the propagation by clicking **OK** in the dialog box that pops up.

**Configuring the tPaloDimension component**

**Procedure**

1. On the workspace, double-click **tPaloDimension** to open its **Component** view.
2. Select the **Use an existing connection** check box. Then **tPaloConnection_1** displays automatically in the **Connection configuration** field.

3. In the **Database** field, type in the database in which the new dimension is created, *talendDatabase* for this scenario.

4. In the **Dimension** field, type in the name you want to use for the dimension to be created, for example, *Date*.

5. In the **Action on dimension** field, select the action to be performed. In this scenario, select **Create dimension if not exist**.

6. Select the **Create dimension elements** check box.

7. In the **Consolidation Type** area, select the **Normal** check box.

8. Under the element hierarchy table in the **Consolidation Type** area, click the plus button to add three rows into the table.

9. In the **Input column** column of the element hierarchy table, select *Year* from the drop-down list for the first row, *Month* for the second and *Date* for the third. This determinates levels of elements from different columns of the input schema.

**Job execution**

Press **F6** to run the Job.

A new dimension is then created in your Palo database *talendDatabase*. 
tPaloDimensionList

Retrieves a list of dimension details from the given Palo database.

tPaloDimensionList lists dimension names, dimension types, number of dimension elements, maximum dimension indent, maximum dimension depth, maximum dimension level, dimension id from a given Palo server.

Discovering the read-only output schema of tPaloDimensionList

The below table presents information related to the read-only output schema of the tPaloDimensionList component.

<table>
<thead>
<tr>
<th>Database</th>

</tr>
</tbody>
</table>

tPaloDimensionList Standard properties

These properties are used to configure tPaloDimensionList running in the Standard Job framework.
The Standard tPaloDimensionList component belongs to the Business Intelligence family.
The component in this framework is available in all Talend products.

Basic settings

| Use an existing connection | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. |
Note that when a Job contains the parent Job and the child Job, **Component List** presents only the connection components in the same Job level.

<table>
<thead>
<tr>
<th><strong>Host Name</strong></th>
<th>Enter the host name or the IP address of the host server.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Server Port</strong></td>
<td>Type in the listening port number of the Palo server.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>Enter the Palo user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>The name of the database where the dimensions of interest reside.</td>
</tr>
<tr>
<td><strong>Retrieve cube dimensions</strong></td>
<td>Select this check box to retrieve dimension information from an existing cube.</td>
</tr>
<tr>
<td><strong>Cube</strong></td>
<td>Type in the name of the cube from which dimension information is retrieved. <strong>Note:</strong> Available when you select the Retrieve cube dimensions check box.</td>
</tr>
</tbody>
</table>
| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
  - **View schema**: choose this option to view the schema only.  
  - **Change to built-in property**: choose this option to change the schema to Built-in for local changes.  
  - **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the **Repository Content** window.  
  - **Built-in**: The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide.  
  - **Repository**: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide. |

**Advanced settings**

| **tStat Catcher Statistics** | Select this check box to collect log data at the component level. |
Global Variables

| DIMENSIONNAME: the name of the dimension. This is a Flow variable and it returns a string. |
| ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. |
| A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. |
| To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. |
| For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule |
| This component can be used in standalone or as start component of a process. |

Connections

| Outgoing links (from this component to another): |
| Row: Main; Iterate. |
| Trigger: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error. |

| Incoming links (from one component to this one): |
| Row: Iterate |
| Trigger: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error. |

Limitation

| The output schema is fixed and read-only. |
| Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |

Retrieving detailed dimension information from a given database

The Job in this scenario retrieves details of all of the dimensions from a given database.
To replicate this scenario, proceed as follows:

**Setting up the Job**

**Procedure**
1. Drop `tPaloDimensionList` and `tLogRow` from the component Palette onto the design workspace.
2. Right-click `tPaloDimensionList` to open the contextual menu.
3. From this menu, select `Row > Main` to link the two components.

**Configuring the tPaloDimensionList component**

**Procedure**
1. Double-click the `tPaloDimensionList` component to open its Component view.
2. In the Host name field, type in the host name or the IP address of the host server, `localhost` for this example.
3. In the Server Port field, type in the listening port number of the Palo server. In this scenario, it is `7777`.
4. In the Username field and the Password field, type in the authentication information. In this example, both of them are `admin`.
5. In the Database field, type in the database name where the dimensions of interest reside, `Biker` in this example.

**Job execution**

Press F6 to run the Job.

Details of all the dimensions in the `Biker` database are retrieved and listed in the console of the Run view.
For further information about the output schema, see Discovering the read-only output schema of tPaloDimensionList on page 2790.

</tr>
</tbody>
</table>
- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

| **Build-in** | The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide. |
| **Repository** | The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide. |

**Cube Query**

| Column | The schema columns are added automatically to this column once defined in the schema editor. The schema columns are used to stored the retrieved dimension elements. |
| **Dimensions** | Type in each of the dimension names of the cube from which you want to retrieve dimension elements. |
| **Elements** | Type in the dimension elements from which data is retrieved. If several elements are needed from one single dimension, separate them with a comma. |

**Advanced settings**

- **tStat Catcher Statistics**: Select this check box to collect log data at the component level.

**Global Variables**

- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

  A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component requires an output component.</th>
</tr>
</thead>
</table>

### Connections

Outgoing links (from this component to another):
- **Row**: Main
- **Trigger**: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error.

Incoming links (from one component to this one):
- **Row**: Iterate
- **Trigger**: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error.

For further information regarding connections, see *Talend Studio User Guide*.

### Limitation

According to the architecture of OLAP-Systems only one single value (text or numeric) could be retrieved from the cube. The **MEASURE** column and the **TEXT** column are fixed and read-only.

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

### Retrieving dimension elements from a given cube

The Job in this scenario retrieves several dimension elements from a demo Palo cube *Sales*.

To replicate this scenario, proceed as follows:

#### Setting up the Job

**Procedure**

1. Drop **tPalInputMulti** and **tLogRow** from the component **Palette** onto the design workspace.
2. Right-click **tPalInputMulti** to open its contextual menu.
3. In the menu, select Row > Main to connect tPaloInputMulti to tLogRow with a row link.

Setting up the DB connection

Procedure

1. Double-click the tPaloInputMulti component to open its Component view.

[Image of the tPaloInputMulti component]

2. In the Host name field, type in the host name or the IP address of the host server, localhost for this example.

3. In the Server Port field, type in the listening port number of the Palo server. In this scenario, it is 7777.

4. In the Username field and the Password field, type in the authentication information. In this example, both of them are admin.

Configuring the Cube Query

Procedure

1. In the Database field, type in the database name in which the cube to be used is stored.

2. In the Cube field, type in the cube name in which the dimensions of interests are stored. In this scenario, it is one of the demo cubes Sales.

3. In the Cube type field, select the Normal type from the drop-down list for the cube to be created, meaning this cube will be normal and default.

4. Next to the Edit schema field, click the three-dot button to open the schema editor.
5. In the schema editor, click the plus button to add the rows of the schema to be edited. In this example, add rows corresponding to all of the dimensions stored in the Sales cube: Products, Regions, Months, Years, Datatypes, Measures. Type in them in the order given in this cube.

6. Click **OK** to validate this editing and accept the propagation of this change to the next component. Then these columns are added automatically into the **Column** column of the **Cube query** table in the **Component** view. If the order is not consistent with the one in the Sales cube, adapt it using the up and down arrows under the schema table.

7. In the **Dimensions** column of the **Cube query** table, type in each of the dimension names stored in the Sales cube regarding to each row in the **Column** column. In the Sales cube, the dimension names are: Products, Regions, Months, Years, Datatypes, Measures.

8. In the **Elements** columns of the **Cube query** table, type in the dimension elements you want to retrieve regarding to the dimensions they belong to. In this example, the elements to be retrieved are All Products, Germany and Austria (Belonging to the same dimension Regions, these two elements are entered in the same row and separated with a comma), Jan, 2009, Actual, Turnover.

**Job execution**

**Procedure**

1. Click **tLogRow** to open its **Component** view.

2. In the **Mode** area, select the **Table (print values in cells of a table)** check box to display the execution result in a table.
3. Press F6 to run the Job.

Results

The dimension elements and the corresponding Measure values display in the Run console.

```

**Related scenario**

For related topic, see *Writing data into a given cube* on page 2806.
tPaloOutputMulti

Takes the input stream and writes it to a given Palo cube. The tPaloOutputMulti writes data (elements as well as values) into a Palo cube.

### tPaloOutputMulti Standard properties

These properties are used to configure tPaloOutputMulti running in the Standard Job framework. The Standard tPaloOutputMulti component belongs to the Business Intelligence family. The component in this framework is available in all Talend products.

#### Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level.</td>
</tr>
<tr>
<td>Host Name</td>
<td>Enter the host name or the IP address of the host server.</td>
</tr>
<tr>
<td>Server Port</td>
<td>Type in the listening port number of the Palo server.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>Enter the Palo user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Database</td>
<td>Type in the name of the database where the cube of interest resides.</td>
</tr>
<tr>
<td>Cube</td>
<td>Type in the name of the cube in which the incoming data is written.</td>
</tr>
<tr>
<td>Cube type</td>
<td>Select the cube type from the drop-down list for the cube of concern. This type may be:</td>
</tr>
<tr>
<td></td>
<td>- Normal</td>
</tr>
<tr>
<td></td>
<td>- Attribut</td>
</tr>
<tr>
<td></td>
<td>- System</td>
</tr>
<tr>
<td></td>
<td>- User Info</td>
</tr>
<tr>
<td>Commit size</td>
<td>Type in the row count of each batch to be written into the cube.</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
</tbody>
</table>
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

<table>
<thead>
<tr>
<th><strong>Built-in</strong></th>
<th>The schema is created and stored locally for this component only. Related topic: see <em>Talend Studio User Guide</em>.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Repository</strong></td>
<td>The schema already exists and is stored in the Repository, hence can be reused. Related topic: see <em>Talend Studio User Guide</em>.</td>
</tr>
</tbody>
</table>

**Measure value**

Select the column from the input stream which holds the Measure or Text values.

**Splash mode**

Select the splash mode used to write data into a consolidated element. The mode may be:

- **Add**: it writes values to the underlying elements.
- **Default**: it uses the default splash mode.
- **Set**: it simply sets or replaces the current value and make the distribution based on the other values.
- **Disable**: it applies no splashing.

For further information about the Palo splash modes, see Palo’s user guide.

**Add values**

Select this check box to add new values to the current values for a sum. Otherwise these new values will overwrite the current ones.

**Use eventprocessor**

Select this check box to call the supervision server.

**Die on error**

This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

### Advanced settings

| **tStat Catcher Statistics** | Select this check box to collect log data at the component level. |

### Global Variables

| **Global Variables** | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the |

2805
Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component requires an input component.</th>
</tr>
</thead>
</table>

Connections

Outgoing links (from this component to another):

- **Row**: Main
- **Trigger**: Run if; On Component Ok; On Component Error.

Incoming links (from one component to this one):

- **Row**: Main; Reject

For further information regarding connections, see Talend Studio User Guide.

Limitation

Numeric measures are only be accepted as Double or String type. When the string type is used, write the value to be processed between quotation marks.

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

Writing data into a given cube

The Job in this scenario writes new values in the Sales cube given as demo in the Demo database installed with Palo.

![Diagram](image)

To replicate this scenario, proceed as follows:
Setting up the Job

Procedure
1. Drop tFixedFlowInput and tPaloOutputMulti from the component Palette onto the design workspace.
2. Right-click tFixedFlowInput to open its contextual menu.
3. In this menu, select Row > Main to connect this component to tPaloOutputMulti.

Configuring the input component

Procedure
1. Double-click the tFixedFlowInput component to open its Component view.

![Component view](image)

2. Click the three-dot button to open the schema editor.

```plaintext
<table>
<thead>
<tr>
<th>Column</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Products</td>
<td>&quot;Desktop L&quot;</td>
</tr>
<tr>
<td>Regions</td>
<td>&quot;Germany&quot;</td>
</tr>
<tr>
<td>Months</td>
<td>&quot;Jan&quot;</td>
</tr>
<tr>
<td>Years</td>
<td>&quot;2009&quot;</td>
</tr>
<tr>
<td>Datatypes</td>
<td>&quot;Actual&quot;</td>
</tr>
<tr>
<td>Measures</td>
<td>&quot;Turnover&quot;</td>
</tr>
<tr>
<td>Value</td>
<td>1234.56</td>
</tr>
</tbody>
</table>
```

2. Click the three-dot button to open the schema editor.
3. In the schema editor, click the plus button to add 7 rows and rename them respectively as Products, Regions, Months, Years, Datatypes, Measures and Values. The order of these rows must be consistent with that of the corresponding dimensions in the Sales cube and the type of the Value column where the measure value resides is set to double/Double.

4. Click OK to validate the editing and accept the propagation prompted by the dialog box that pops up. Then the schema column labels display automatically in the Value table under the Use single table check box, in the Mode area.

5. In the Value table, type in values for each row in the Value column. In this example, these values are: Desktop L, Germany, Jan, 2009, Actual, Turnover, 1234.56.

Configuring the output component

Procedure

1. Double-click tPaloOutputMulti to open its Component view.
2. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is 7777.

3. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are *admin*.

4. In the **Database** field, type in the database name in which you want to create the cube, *Demo* in this example.

5. In the **Cube** field, type in the name of the cube you want to write data in, for example, *Sales*.

6. In the **Cube type** field, select the **Normal** type from the drop-down list for the cube to be created, meaning this cube will be normal and default.

7. In the **Measure Value** field, select the Measure element. In this scenario, select *Value*.

**Job execution**

Press **F6** to run the Job.

The inflow data has been written into the *Sales* cube.

![Database Table Example]

**Rejecting inflow data when the elements to be written do not exist in a given cube**

The Job in this scenario tries to write data into the *Sales* cube but as the elements of interest do not exist in this cube, the inflow data is rejected.

![Job Execution Diagram]

To replicate this scenario, proceed as follows:
Setting up the Job

Procedure
1. Drop \texttt{tFixedFlowInput}, \texttt{tPaloCheckElements}, \texttt{tPaloOutputMulti} and \texttt{tLogRow} from the component Palette onto the design workspace.
2. Right-click \texttt{tFixedFlowInput} to open its contextual menu.
3. In this menu, select \texttt{Row} \textgreater \texttt{Main} to connect this component to \texttt{tPaloCheckElements}.
4. Do the same to connect \texttt{tPaloOutputMulti} using \texttt{row} link.
5. Right-click \texttt{tPaloCheckElements} to open its contextual menu.
6. In this menu, select \texttt{Row} \textgreater \texttt{Reject} to connect this component to \texttt{tLogRow}.

Configuring the input component

Procedure
1. Double-click the \texttt{tFixedFlowInput} component to open its Component view.

2. Click the three-dot button to open the schema editor.
3. In the schema editor, click the plus button to add 7 rows and rename them respectively as *Products, Regions, Months, Years, Datatypes, Measures* and *Values*. The order of these rows must be consistent with that of the corresponding dimensions in the *Sales* cube and the type of the *Value* column where the measure value resides is set to double/Double.

4. Click **OK** to validate the editing and accept the propagation prompted by the dialog box that pops up. Then the schema column labels display automatically in the *Value* table under the **Use single table** check box, in the **Mode** area.

5. In the *Value* table, type in values for each row in the *Value* column. In this example, these values are: *Smart Products, Germany, Jan, 2009, Actual, Turnover, 1234.56*. The *Smart Products* element does not exist in the *Sales* cube.

**Configuring the tPaloCheckElements component**

**Procedure**

1. Double-click **tPaloCheckElements** to open its **Component** view.
2. In the **Host name** field, type in *localhost*.

3. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is 7777.

4. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are *admin*.

5. In the **Database** field, type in the database name in which you want to create the cube, *Demo* in this example.

6. In the **Cube** field, type in the name of the cube you want to write data in, for example, *Sales*.

7. In the **On Element error** field, select *Reject row* from the drop-down list.

8. In the element table at the bottom of the **Basic settings** view, click the **Element type** column in the **Value** row and select *Measure* from the drop-down list.

### Configuring the output component

**Procedure**

1. Double-click **tPaloOutputMulti** to open its **Component** view.
2. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is **7777**.

3. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are **admin**.

4. In the **Database** field, type in the database name in which you want to create the cube, **Demo** in this example.

5. In the **Cube** field, type in the name of the cube you want to write data in, for example, **Sales**.

6. In the **Cube type** field, select the **Normal** type from the drop-down list for the cube to be created, meaning this cube will be normal and default.

7. In the **Measure Value** field, select the Measure element. In this scenario, select **Value**.

**Job execution**

Press **F6** to run the Job.

The data to be written is rejected and displayed in the console of the **Run** view. You can read that the error message is **Smart Products**.

```

Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | This component can be used in standalone for rule creation, deletion or update. |

Connections

| Connections | Outgoing links (from this component to another): Trigger: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error. Incoming links (from one component to this one): Row: Iterate Trigger: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error. For further information regarding connections, see Talend Studio User Guide. |

Limitation

| Limitation | Update or deletion of a rule is available only when this rule has been created with external ID. Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |

Creating a rule in a given cube

The Job in this scenario creates a rule applied on dimensions of a given cube.
To replicate this scenario, proceed as follows:

**Setting up the DB connection**

**Procedure**

1. Drop **tPaloRule** from the component **Palette** onto the design workspace.
2. Double-click the **tPaloRule** component to open its **Component** view.

3. In the **Host name** field, type in the host name or the IP address of the host server, **localhost** for this example.
4. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is **7777**.
5. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are **admin**.
6. In the **Database** field, type in the database name in which the dimensions applying the created rules reside, **Biker** in this example.
7. In the **Cube** field, type in the name of the cube which the dimensions applying the created rules belong to, for example, **Orders**.
Setting the Cube rules

Procedure

1. Under the Cube rules table, click the plus button to add a new row.
2. In the Cube rules table, type in ['2009'] = 123 in the Definition column, OrderRule1 in the External Id column and Palo Demo Rules in the Comment column.
3. In the Activated column, select the check box.
4. In the Action column, select Create from the drop-down list.

Job execution

Press F6 to run the Job.

The new rule has been created and the value of every 2009 element is 123.
tPaloRuleList

Lists all rules, formulas, comments, activation status, external IDs from a given cube. The tPaloRuleList retrieves a list of rule details from the given Palo database.

Discovering the read-only output schema of tPaloRuleList

The following table presents information related to the read-only output schema of the tPaloRuleList component.

<table>
<thead>
<tr>
<th>Database</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rule_identifier</td>
<td>long</td>
<td>The internal identifier/id for this rule.</td>
</tr>
<tr>
<td>rule_definition</td>
<td>string</td>
<td>The formula of this rule. For further information about this formula, see the Palo user guide.</td>
</tr>
<tr>
<td>ruleExtern_id</td>
<td>string</td>
<td>The user-defined external id.</td>
</tr>
<tr>
<td>ruleComment</td>
<td>string</td>
<td>The user-edited comment on this rule.</td>
</tr>
<tr>
<td>ruleActivated</td>
<td>boolean</td>
<td>Indicates if this rule had been activated or not.</td>
</tr>
</tbody>
</table>

tPaloRuleList Standard properties

These properties are used to configure tPaloRuleList running in the Standard Job framework. The Standard tPaloRuleList component belongs to the Business Intelligence family. The component in this framework is available in all Talend products.

Basic settings

- **Use an existing connection**: Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level.

- **Host Name**: Enter the host name or the IP address of the host server.

- **Server Port**: Type in the listening port number of the Palo server.

- **Username and Password**: Enter the Palo user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

- **Database**: The name of the database where the cube of interest resides.
<table>
<thead>
<tr>
<th>Cube</th>
<th>Type in the name of the cube in which you want to retrieve the rule information.</th>
</tr>
</thead>
</table>
| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.  
Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
- **View schema**: choose this option to view the schema only.  
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.  
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |
| **Built-in**: The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide. | |
| **Repository**: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide. | |
| Advanced settings | |
| tStat Catcher Statistics | Select this check box to collect log data at the component level. |
| Global Variables | |
| Global Variables | | **NB_RULES**: the number of rules. This is an After variable and it returns an integer.  
**EXTERNAL_RULEID**: the external ID of the rule. This is a Flow variable and it returns a string.  
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
For further information about variables, see Talend Studio User Guide. |
**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component can be used in standalone or as start component of a process.</th>

</table>

**Retrieving detailed rule information from a given cube**

The Job in this scenario retrieves rule details applied on the dimensions of a given cube.

To replicate this scenario, proceed as follows:

**Setting up the Job**

**Procedure**

1. Drop **tPaloRuleList** and **tLogRow** from the component **Palette** onto the design workspace.
2. Right-click **tPaloRuleList** to open the contextual menu.
3. From this menu, select **Row > Main** to link the two components.

**Configuring the tPaloRuleList component**

**Procedure**

1. Double-click the **tPaloRuleList** component to open its **Component** view.
2. In the **Host name** field, type in the host name or the IP address of the host server, *localhost* for this example.

3. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is **7777**.

4. In the **Username** and **Password** fields, type in the authentication information. In this example, both of them are *admin*.

5. In the **Database** field, type in the database name where the dimensions applying the rules of interest reside, *Biker* in this example.

6. In the **Cube** field, type in the name of the cube which the rules of interest belong to.

**Job execution**

Press **F6** to run the Job.

Details of all of the rules in the *Orders* cube are retrieved and listed in the console of the **Run** view.

```
[statistics] connecting to socket on port 3743

```

[statistics] disconnected

Job tpalo ended at 16:35 12/11/2010. [exit code=0]

For further information about the output schema, see Discovering the read-only output schema of *tPaloRuleList* on page 2818.
tParAccelBulkExec

Improves performance when loading data in ParAccel database.

The tParAccelOutputBulk and tParAccelBulkExec are generally used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tParAccelOutputBulkExec component, detailed in a different section. The advantage of using two separate steps is that the data can be transformed before it is loaded in the database.

The tParAccelBulkExec performs an Insert action on the data.

**tParAccelBulkExec Standard properties**

These properties are used to configure tParAccelBulkExec running in the Standard Job framework.

The Standard tParAccelBulkExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
<table>
<thead>
<tr>
<th><strong>Host</strong></th>
<th>Database server IP address.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of the DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Database name.</td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>Exact name of the schema.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Table</strong></td>
<td>Name of the table to be written. Note that only one table can be written at a time</td>
</tr>
</tbody>
</table>
| **Action on table** | On the table defined, you can perform one of the following operations:  
  - **None**: No operation is carried out.  
  - **Drop and create table**: The table is removed and created again.  
  - **Create table**: The table does not exist and gets created.  
  - **Create table if not exists**: The table is created if it does not exist.  
  - **Drop table if exists and create**: The table is removed if already exists and created again.  
  - **Clear table**: The table content is deleted. |
| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.  
  - **Built-In**: You create and store the schema locally for this component only.  
  - **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.  
    - When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.  
    - You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).  
  - Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
    - **View schema**: choose this option to view the schema only.  
    - **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes. |
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

### Advanced settings

| **Copy mode** | Select the copy mode you want to use from either:  
**Basic**: Standard mode, without optimisation.  
**Parallel**: Allows you to use several internal ParAccel APIs in order to optimise loading speed. |
|---------------|--------------------------------------------------------------------------------------------------|
| **Filename**  | Name of the file to be loaded.  
**Warning:** This file is located on the machine specified by the URI in the **Host** field so it should be on the same machine as the database server. |
| **File Type** | Select the file type from the list. |
| **Field Layout** | Select the field layout from the list. |
| **Field separator** | Character, string or regular expression to separate fields. |
| **Explicit IDs** | The ID is already present in the file to be loaded or will be set by the database. |
| **Remove Quotes** | Select this check box to remove quotation marks from the file to be loaded. |
| **Max. Errors** | Type in the maximum number of errors before your Job stops. |
| **Date Format** | Type in the date format to be used. |
| **Time/Timestamp Format** | Enter the date and hour format to be used. |
| **Additional COPY Options** | Enter the specific, customized ParAccel option that you want to use. |
| **Log file** | Browse to or enter the access path to the log file in your directory. |
| **Logging level** | Select the information type you want to record in your log file. |
| **tStat Catcher Statistics** | Select this check box to collect log data at the component level. |
## Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component covers all possible SQL database queries. It allows you to carry out actions on a table or on the data of a table in a ParAccel database. It enables you to create a reject flow, with a Row &gt; Reject link filtering the data in error. For a usage example, see Retrieving data in error with a Reject link on page 2485.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic settings</td>
<td>Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Limitation</td>

For more information on Dynamic... |
Related scenarios

No scenario is available for the Standard version of this component yet.
tParAccelCommit

Commits in one go a global transaction, using a unique connection, instead of doing that on every row or every batch and thus provides gain in performance.

The tParAccelCommit validates the data processed through the job into the connected DB.

**tParAccelCommit Standard properties**

These properties are used to configure tParAccelCommit running in the Standard Job framework.

The Standard tParAccelCommit component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

</tr>
</tbody>
</table>
Related scenario

For tParAccelCommit related scenario, see Inserting data in mother/daughter tables on page 2437
tParAccelConnection

Opens a connection to the specified database that can then be reused in the subsequent subjob or subjobs.

The tParAccelConnection opens a connection to the database for a current transaction.

### tParAccelConnection Standard properties

These properties are used to configure tParAccelConnection running in the Standard Job framework.

The Standard tParAccelConnection component belongs to the Databases and the ELT families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

#### Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Host</td>
<td>Database server IP address</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database</td>
</tr>
<tr>
<td>Schema</td>
<td>Name of the schema</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Use or register a shared DB Connection</td>
<td>Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the Shared DB Connection Name field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child. This option is incompatible with the Use dynamic job and Use an independent process to run subjob options of the</td>
</tr>
</tbody>
</table>
tParAccelConnection

**tRunJob** component. Using a shared connection together with a **tRunJob** component with either of these two options enabled will cause your Job to fail.

### Advanced settings

<table>
<thead>
<tr>
<th>Auto Commit</th>
<th>Select this check box to commit any changes to the database automatically upon the transaction. With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component. Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component.</th>
</tr>
</thead>
</table>

| tStatCatcher Statistics | Select this check box to gather the job processing metadata at a Job level as well as at each component level. |

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is more commonly used with other tParAccel* components, especially with the <strong>tParAccelCommit</strong> and <strong>tParAccelRollback</strong> components.</th>
</tr>
</thead>
</table>

| Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center ([https://help.talend.com](https://help.talend.com)). |

### Related scenario

For **tParAccelConnection** related scenario, see **tMysqlConnection** on page 2436
### tParAccelInput

Reads a database and extracts fields based on a query.

`tParAccelInput` executes a DB query with a strictly defined order which must correspond to the schema definition. Then it passes on the field list to the next component via a Main row link.

### tParAccelInput Standard properties

These properties are used to configure `tParAccelInput` running in the Standard Job framework.

The Standard `tParAccelInput` component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

#### Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>

<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

[Icon] Click this icon to open a database connection wizard and store the database connection parameters you set in the component **Basic settings** view.

For more information about setting up and storing database connection parameters, see *Talend Studio User Guide*.

| Use an existing connection | Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined. |
Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Host</strong></td>
<td>Database server IP address.</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of the DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database</td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>Exact name of the schema</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Schema and Edit Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-In</strong>: You create and store the schema locally for this component only.</td>

<tr>
<td><strong>Table name</strong></td>
<td>Name of the table to be read.</td>
</tr>
</tbody>
</table>
Enter your DB query paying particularly attention to sequence the fields properly in order to match the schema definition.

Click the **Guess Query** button to generate the query which corresponds to your table schema in the Query field.

Click the **Guess schema** button to retrieve the table schema.

When selected, helps to decide the row set to work with at a time and thus optimize performance.

Select this check box to remove leading and trailing whitespace from all the String/Char columns.

Remove leading and trailing whitespace from defined columns.

Select this check box to collect log data at the component level.

NB_LINE: the number of rows processed. This is an After variable and it returns an integer.

QUERY: the query statement being processed. This is a Flow variable and it returns a string.

ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see **Talend Studio User Guide**.

This component covers all possible SQL queries for ParAccel databases.

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the Modules tab in the **Integration** perspective of your studio. You can
find more details about how to install external modules in Talend Help Center (https://help.talend.com).

| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |

## Related scenarios

For related scenarios, see:
tParAccelOutput

Executes the action defined on the table and/or on the data of a table, according to the input flow form the previous component.

The tParAccelOutput writes, updates, modifies or deletes the data in a database.

**tParAccelOutput Standard properties**

These properties are used to configure tParAccelOutput running in the Standard Job framework.

The Standard tParAccelOutput component belongs to the Databases family.

The component in this framework is available in all Talend products.

*Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.*

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>

</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><img src="image" alt="Icon" /></td>
<td>Click this icon to open a database connection wizard and store the database connection parameters you set in the component <strong>Basic settings</strong> view. For more information about setting up and storing database connection parameters, see <em>Talend Studio User Guide</em>.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th>Host</th>
<th>Database server IP address.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>Listening port number of the DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Database name.</td>
</tr>
<tr>
<td>Schema</td>
<td>Exact name of the schema.</td>
</tr>
</tbody>
</table>
| Username and Password | DB user authentication data.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| Table        | Name of the table to be written. Note that only one table can be written at a time |
| **Action on table** | On the table defined, you can perform one of the following operations:  
**None:** No operation is carried out.  
**Drop and create table:** The table is removed and created again.  
**Create table:** The table does not exist and gets created.  
**Create table if not exists:** The table is created if it does not exist.  
**Drop table if exists and create:** The table is removed if already exists and created again.  
**Clear table:** The table content is deleted. |
| **Action on data** | On the data of the table defined, you can perform:  
**Insert:** Add new entries to the table. If duplicates are found, job stops.  
**Update:** Make changes to existing entries  
**Insert or update:** Insert a new record. If the record with the given reference already exists, an update would be made.  
**Update or insert:** Update the record with the given reference. If the record does not exist, a new record would be inserted.  
**Delete:** Remove entries corresponding to the input flow. |
Warning:

It is necessary to specify at least one column as a primary key on which the Update and Delete operations are based. You can do that by clicking Edit Schema and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the Advanced settings view where you can simultaneously define primary keys for the Update and Delete operations. To do that: Select the Use field options check box and then in the Key in update column, select the check boxes next to the column names you want to use as a base for the Update operation. Do the same in the Key in delete column for the Delete operation.

<table>
<thead>
<tr>
<th>Schema and Edit Schema</th>
<th>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</th>

</tr>
<tr>
<td></td>
<td><strong>NB_LINE_DELETED</strong>: the number of rows deleted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_REJECTED</strong>: the number of rows rejected. This is an After variable and it returns an integer.</td>
<td></td>
</tr>
<tr>
<td><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
<td></td>
</tr>
</tbody>
</table>

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

## Usage

### Usage rule

This component covers all possible SQL database queries. It allows you to carry out actions on a table or on the data of a table in a ParAccel database. It enables you to create a reject flow, with a Row > Rejects link filtering the data in error. For a usage example, see Retrieving data in error with a Reject link on page 2485.

### Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

### Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).
Related scenarios

For a related scenario, see:

- Inserting a column and altering data using tMysqlOutput on page 2477.
**tParAccelOutputBulk**

Prepares the file to be used as parameter in the INSERT query to feed the ParAccel database.

The tParAccelOutputBulk and tParAccelBulkExec are generally used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tParAccelOutputBulkExec component, detailed in a different section. The advantage of using two separate steps is that the data can be transformed before it is loaded in the database.

The tParAccelOutputBulk writes a file with columns based on the defined delimiter and the ParAccel standards.

**tParAccelOutputBulk Standard properties**

These properties are used to configure tParAccelOutputBulk running in the Standard Job framework. The Standard tParAccelOutputBulk component belongs to the Databases family.

The component in this framework is available in all **Talend products**.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td><strong>Property type</strong></td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><strong>File Name</strong></td>
<td>Name of the file to be generated.</td>
</tr>
<tr>
<td><strong>Warning:</strong></td>
<td>This file is generated on the local machine or a shared folder on the LAN.</td>
</tr>
<tr>
<td><strong>Append</strong></td>
<td>Select this check box to add the new rows at the end of the file</td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <code>line</code> when naming the fields.</td>
</tr>
<tr>
<td><strong>Built-In</strong></td>
<td>You create and store the schema locally for this component only.</td>
</tr>
</tbody>
</table>
Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

### Advanced settings

<table>
<thead>
<tr>
<th>Row separator</th>
<th>String (ex: &quot;\n&quot; on Unix) to distinguish rows.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Field separator</td>
<td>Character, string or regular expression to separate fields.</td>

<tr>
<td>Include header</td>
<td>Select this check box to include the column header.</td>
</tr>
<tr>
<td>Encoding</td>
<td>Select the encoding type from the list or select Custom and define it manually. This field is compulsory for DB data handling.</td>
</tr>
<tr>
<td>tStat Catcher Statistics</td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>Global Variables</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE</strong>: the number of rows processed. This is an After variable and it returns an integer.</td>
<td></td>
</tr>
<tr>
<td><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</td>
<td></td>
</tr>
<tr>
<td><strong>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</strong></td>
<td></td>
</tr>
<tr>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
<td></td>
</tr>
<tr>
<td>To fill up a field or expression with a variable, press <strong>Ctrl + Space</strong> to access the variable list and choose the variable to use from it.</td>
<td></td>
</tr>
</tbody>
</table>
For further information about variables, see *Talend Studio User Guide*.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is to be used along with tParAccelBulkExec component. Used together they offer gains in performance while feeding a ParAccel database.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component family</td>
<td>Databases/ParAccel</td>
</tr>
</tbody>

### Related scenarios

For use cases in relation with **tParAccelOutputBulk**, see the following scenarios:

- Inserting transformed data in MySQL database on page 2493.
- Inserting data in bulk in MySQL database on page 2500.
- Truncating and inserting file data into an Oracle database on page 2700.
tParAccelOutputBulkExec

Improves performance when loading data in ParAccel database.

The tParAccelOutputBulk and tParAccelBulkExec are generally used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in tParAccelOutputBulkExec.

The tParAccelOutputBulkExec performs an Insert action on the data.

tParAccelOutputBulkExec Standard properties

These properties are used to configure tParAccelOutputBulkExec running in the Standard Job framework.

The Standard tParAccelOutputBulkExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

Usage

<table>
<thead>
<tr>
<th>Rule</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Usage rule</strong></td>
<td>This component covers all possible SQL database queries. It allows you to carry out actions on a table or on the data of a table in a ParAccel database. It enables you to create a reject flow, with a Row &gt; Reject link filtering the data in error. For a usage example, see Retrieving data in error with a Reject link on page 2485.</td>
</tr>
<tr>
<td><strong>Limitation</strong></td>
<td>The database server must be installed on the same machine where the Studio is installed or where the Job using tParAccelOutputBulkExec is deployed, so that the component functions properly.</td>
</tr>
</tbody>
</table>
Related scenarios

For related scenarios, see:

- Inserting transformed data in MySQL database on page 2493 of tMysqlOutputBulk.
- Inserting data in bulk in MySQL database on page 2500 of tMysqlOutputBulkExec.
- Truncating and inserting file data into an Oracle database on page 2700 of tOracleBulkExec.
tParAccelRollback

Avoids to commit part of a transaction involuntarily.
The tParAccelRollback cancels the transaction commit in the connected DB.

**tParAccelRollback Standard properties**

These properties are used to configure tParAccelRollback running in the Standard Job framework.
The Standard tParAccelRollback component belongs to the Databases family.
The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tParAccelConnection component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

### Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

### Usage

| Usage rule | This component is more commonly used with other tParAccel* components, especially with the tParAccelConnection and tParAccelCommit components. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connections. |
Related scenario

For `tParAccelRollback` related scenario, see `tMysqlRollback` on page 2502.
tParAccelRow

Acts on the actual DB structure or on the data (although without handling data), depending on the nature of the query and the database. The SQLBuilder tool helps you write easily your SQL statements.

The tParAccelRow is the specific component for this database query. It executes the SQL query stated onto the specified database. The row suffix means the component implements a flow in the job design although it doesn’t provide output.

tParAccelRow Standard properties

These properties are used to configure tParAccelRow running in the Standard Job framework.

The Standard tParAccelRow component belongs to the Databases family.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in:</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository:</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

Use an existing connection

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
| **Host** | Database server IP address |
| **Port** | Listening port number of DB server. |
| **Database** | Name of the database |
| **Schema** | Exact name of the schema. |
| **Username and Password** | DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. | **Built-In**: You create and store the schema locally for this component only. **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. |
| **Table Name** | Name of the table to be read. |
| **Query type** | Either Built-in or Repository. |
| **Built-in**: | Fill in manually the query statement or build it graphically using SQLBuilder. **Repository**: Select the relevant query stored in the Repository. The Query field gets accordingly filled in. |
| **Guess Query** | Click the Guess Query button to generate the query which corresponds to your table schema in the Query field. |
| **Query** | Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition. |
Die on error

This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a Row > Rejects link.

Advanced settings

Propagate QUERY’s recordset

Select this check box to insert the result of the query into a COLUMN of the current flow. Select this column from the use column list.

Note:
This option allows the component to have a different schema from that of the preceding component. Moreover, the column that holds the QUERY’s recordset should be set to the type of Object and this component is usually followed by tParseRecordSet.

Use PreparedStatement

Select this check box if you want to query the database using a PreparedStatement. In the Set PreparedStatement Parameter table, define the parameters represented by ‘?’ in the SQL instruction of the Query field in the Basic Settings tab.

Parameter Index: Enter the parameter position in the SQL instruction.
Parameter Type: Enter the parameter type.
Parameter Value: Enter the parameter value.

Note:
This option is very useful if you need to execute the same query several times. Performance levels are increased.

Commit every

Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions.

tStat Catcher Statistics

Select this check box to collect log data at the component level.

Global Variables

Global Variables

QUERY: the query statement being processed. This is a Flow variable and it returns a string.

ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component offers the flexibility benefit of the DB query and covers all possible SQL queries.</th>
</tr>
</thead>
</table>

Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

Related scenarios

For a related scenario, see:

- Combining two flows for selective output on page 2514
- Procedure on page 625.
- Removing and regenerating a MySQL table index on page 2508.
tParAccelSCD

Addresses Slowly Changing Dimension needs, reading regularly a source of data and logging the changes into a dedicated SCD table

The tParAccelSCD reflects and tracks changes in a dedicated ParAccel SCD table.

**tParAccelSCD Standard properties**

These properties are used to configure tParAccelSCD running in the Standard Job framework.

The Standard tParAccelSCD component belongs to the Business Intelligence and the Databases families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the Repository file where properties are stored. The following fields are pre-filled in using fetched data.</td>
</tr>
</tbody>
</table>

Use an existing connection

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<p>| Connection type | Select the relevant driver on the list. |
| Host | Database server IP address. |</p>
<table>
<thead>
<tr>
<th><strong>Port</strong></th>
<th>Listening port number of DB server.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database.</td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>Name of the DB schema.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Table</strong></td>
<td>Name of the table to be written. Note that only one table can be written at a time.</td>
</tr>
</tbody>
</table>
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
  • **View schema**: choose this option to view the schema only.  
  • **Change to built-in property**: choose this option to change the schema to Built-in for local changes.  
  • **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |
| **SCD Editor** | The SCD editor helps to build and configure the data flow for slowly changing dimension outputs. For more information, see SCD management methodology on page 2522. |
| **Use memory saving Mode** | Select this check box to maximize system performance. |
| **Source keys include Null** | Select this check box to allow the source key columns to have Null values. **Warning:** Special attention should be paid to the uniqueness of the source key(s) values when this option is selected. |
| **Built-in** | The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide. |
| **Repository** | The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide. |
### Advanced settings

<table>
<thead>
<tr>
<th><strong>Die on error</strong></th>
<th>This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.</th>
</tr>
</thead>
</table>

**End date time details**

Specify the time value of the SCD end date time setting in the format of \texttt{HH:mm:ss}. The default value for this field is \texttt{12:00:00}.

This field appears only when SCD Type 2 is used and Fixed year value is selected for creating the SCD end date.

<table>
<thead>
<tr>
<th><strong>Debug mode</strong></th>
<th>Select this check box to display each step during processing entries in a database.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th><strong>tStatCatcher Statistics</strong></th>
<th>Select this check box to collect log data at the component level.</th>
</tr>
</thead>
</table>

### Global Variables

**Global Variables**

<table>
<thead>
<tr>
<th><strong>Global Variables</strong></th>
<th><strong>NB_LINE_UPDATED</strong>: the number of rows updated. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>NB_LINE_INSERTED</strong>: the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td><strong>NB_LINE_REJECTED</strong>: the number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

### Usage

**Usage rule**

This component is used as Output component. It requires an Input component and Row main link as input.

**Dynamic settings**

Click the [*] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.
The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see [Reading data from databases through context-based dynamic connections on page 2457](#) and [Reading data from different MySQL databases using dynamically loaded connection parameters on page 491](#). For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

| Limitation | This component does not support using SCD type 0 together with other SCD types. |

**Related scenario**

For related scenarios, see [tMysqlSCD on page 2519](#).
tParseRecordSet

Parses a recordset rather than individual records from a table.

The tParseRecordSet parses a set of records from a database table or DB query and possibly returns single records.

tParseRecordSet Standard properties

These properties are used to configure tParseRecordSet running in the Standard Job framework. The Standard tParseRecordSet component belongs to the Databases family. The component in this framework is available in all Talend products.

Basic settings

<table>
<thead>
<tr>
<th>Prev. Comp. Column list</th>
<th>Set the column from the database that holds the recordset.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td>Built-in</td>
<td>The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Repository</td>
<td>The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

| Attribute table | Set the position value of each column for single records from the recordset. |

Advanced settings

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |
Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_LINE: the number of rows processed. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>

</table>

Related Scenario

For an example of tParseRecordSet in use, see Using PreparedStatement objects to query data on page 2509.
tPigAggregate

Adds one or more additional columns to the output of the grouped data to create data to be used by Pig.

The tPigAggregate groups the original data by column and adds one or more additional columns to the output of preceding grouped data.

**tPigAggregate Standard properties**

These properties are used to configure tPigAggregate running in the Standard Job framework.

The Standard tPigAggregate component belongs to the Big Data and the Processing families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.
  |
  | Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:
  | • **View schema**: choose this option to view the schema only.
  | • **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
  | • **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.
  |
  | **Built-in**: The schema will be created and stored locally for this component only. Related topic: *Talend Studio User Guide*.
  |
  | **Repository**: The schema already exists and is stored in the Repository, hence can be reused in various projects and Job designs. Related topic: see *Talend Studio User Guide*.
  |
  | **Group by** | Click the plus button to add one or more columns to set tuples in the source data as group condition.
  |
  | **Operations** | Click the plus button to add one or more columns to generate one or more additional output columns based on conditions:
  | **Additional Output Column**: Select a column in the original data as output column.
  | **Function**: Functions for operation on input data.
## Input Column

Select a column in the original data as input column.

### Advanced settings

<td>ERROR_MESSAGE</td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

### Usage

| Usage rule | This component is commonly used as intermediate step together with input component and output component. |

### Prerequisites

The Hadoop distribution must be properly installed, so as to guarantee the interaction with Talend Studio. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native. For example, the library for Windows is \lib\native\MapRClient.dll in the MapR client jar file. For further information, see the following link from MapR: http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr.

  Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path.

- Set the -Djava.library.path argument, for example, in the Job Run VM arguments area of the Run/Debug view in the Preferences dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of...
The **Data viewer** to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

**Limitation**

Knowledge of Pig scripts is required.

### Related scenario

For a **tPigAggregate** related scenario, *Aggregating values and sorting data* on page 137 of **tAggregateRow**.
**tPigCode**

Extends the functionalities of a Talend Job through using Pig scripts.

The tPigCode enters personalized Pig code to integrate it in Talend program. You can execute this code only once.

**tPigCode Standard properties**

These properties are used to configure tPigCode running in the Standard Job framework.

The Standard tPigCode component belongs to the Big Data and the Processing families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
• View schema: choose this option to view the schema only.  
• Change to built-in property: choose this option to change the schema to Built-in for local changes.  
• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |
<table>

</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-In</strong></td>
<td>You create and store the schema locally for this component only.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
</tr>
</tbody>
</table>
| **Scripts** | Type in Pig scripts you want to execute depending on the task you need to perform. For further information about Pig functions syntax, see Apache’s documentation about Pig UDF: [http://pig.apache.org](http://pig.apache.org)  
Pig components output tuples and automatically set up an alias for each tuple. When you use a tuple in your Pig script, you have to enter the right alias.  
The alias syntax is Component_ID_rowID_Result, for example, tPigCode_1_row2_Result. |
Advanced settings

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
<th>Select this check box to gather the Job processing metadata at the Job level as well as at each component level.</th>
</tr>
</thead>
</table>

| Enable escape | Select this check box so that you can simply write plain Pig code in the Scripts field without need to bear in mind the escape characters, otherwise required for proper Java code generation. |

Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | This component is commonly used as intermediate step together with input component and output component. A tPigCode component can execute only one Pig Latin statement, therefore, if you need to execute multiple statements, you have to use a corresponding number of tPigCode components to run them, one after another. If a particular .jar file is required to execute a statement, you need to register that library file via the tPigLoad component that starts the Pig process in question. |

Prerequisites

| Prerequisites | The Hadoop distribution must be properly installed, so as to guarantee the interaction with Talend Studio. The following list presents MapR related information for example. • Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native. For example, the library for Windows is \lib\native\MapRClient.dll in the MapR client jar file. For further information, see the following link from MapR: http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr. Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path. |
• Set the -Djava.library.path argument, for example, in the Job Run VM arguments area of the Run/Debug view in the Preferences dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

Limitation

Knowledge of Pig scripts is required.

Selecting a column of data from an input file and store it into a local file

This scenario applies only to Talend products with Big Data.

This scenario describes a three-component Job that selects a column of data that matches filter condition defined in tPigCode and stores the result into a local file.

Setting up the Job

Procedure

1. Drop the following components from the Palette to the design workspace: tPigCode, tPigLoad, tPigStoreResult.
2. Right-click tPigLoad to connect it to tPigCode using a Row > Pig Combine connection.
3. Right-click tPigCode to connect it to tPigStoreResult using a Row > Pig Combine connection.

Loading the data

Procedure

1. Double-click tPigLoad to open its Basic settings view.
2. Click the three-dot button next to Edit schema to add columns for tPigLoad.

3. Click the plus button to add Name, Country and Age and click OK to save the setting.

4. Select Local from the Mode area.

5. Fill in the Input filename field with the full path to the input file.
   In this scenario, the input file is CustomerList which contains rows of names, country names and age.

6. Select PigStorage from the Load function list.

7. Leave rest of the settings as they are.

**Configuring the tPigCode component**

**Procedure**

1. Double-click tPigCode component to open its Basic settings view.
2. Click **Sync columns** to retrieve the schema structure from the preceding component.

3. Fill in the **Script Code** field with following expression:

   ```pig
   tPigCode_1_row2_RESULT = foreach tPigLoad_1_row1_RESULT generate $0 as name;
   ```

   This filter expression selects column *Name* from *CustomerList*.

**Saving the result data to a local file**

**Procedure**

1. Double-click **tPigStoreResult** to open its **Basic settings** view.

   ![tPigStoreResult Basic settings](image)

   - **Result file**: `/home/source_n_output/Result`
   - **Store function**: PigStorage
   - **Field separator**: `;`

2. Click **Sync columns** to retrieve the schema structure from the preceding component.

3. Fill in the **Result file** field with the full path to the result file.

   In this scenario, the result is saved in *Result* file.

4. Select **Remove result directory if exists**.

5. Select PigStorage from the **Store function** list.

6. Leave rest of the settings as they are.

**Executing the Job**

Save your Job and press **F6** to run it.
<table>
<thead>
<tr>
<th>Name</th>

</tr>
</tbody>
</table>

The `Result` file is generated containing the selected column of data.
**tPigCoGroup**

Performs the Pig COGROUP operation to group and aggregate data incoming from multiple Pig flows. The tPigCoGroup groups data from as many inputs as needed incoming from its preceding Pig components and aggregates the grouped data using some given function before sending the data to the next Pig component.

**tPigCoGroup Standard properties**

These properties are used to configure tPigCoGroup running in the Standard Job framework. The Standard tPigCoGroup component belongs to the Big Data and the Processing families. The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields. Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
• **View schema**: choose this option to view the schema only.  
• **Change to built-in property**: choose this option to change the schema to Built-in for local changes.  
• **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window. |
| **Built-In**: You create and store the schema locally for this component only. |
| **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. |
| **Group by** | Click the `[+]` button to add one or more columns of the input flows to this **Group by** table so as to set these columns as group condition. |
| **Output mapping** | This table is automatically filled with the output schema you have defined using the **Schema** field. Then complete this table to configure how the grouped data is aggregated in the output flow:  
• **Function**: select the function you need to use to aggregate a given column. |
**Source schema**: select the input flow from which you aggregate the data.

**Expression**: select the column to be aggregated and if needed, edit expressions

---

Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path.

- Set the -Djava.library.path argument, for example, in the Job Run VM arguments area of the Run/Debug view in the Preferences dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

| Limitation | Knowledge of Pig scripts is required. |

### Aggregating data from two relations using COGROUP

This scenario applies only to Talend products with Big Data.

In this scenario, a four-component Job is designed to aggregate two relations on top of a given Hadoop cluster.

The two relations used in this scenario consist of the following sample data:

1. Alice, turtle, 17
   Alice, goldfish, 17
   Alice, cat, 17
   Bob, dog, 18
   Bob, cat, 18
   John, dog, 19
   Mary, goldfish, 16
   Bill, dog, 20
This relation is composed of three columns that read *owner*, *pet* and *age* (of the owners).

<table>
<thead>
<tr>
<th>Name</th>
<th>Pets</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cindy, Alice</td>
<td>Alice</td>
</tr>
<tr>
<td>Mark, Alice</td>
<td></td>
</tr>
<tr>
<td>Paul, Bob</td>
<td></td>
</tr>
<tr>
<td>Paul, Jane</td>
<td></td>
</tr>
<tr>
<td>John, Mary</td>
<td></td>
</tr>
<tr>
<td>William, Bill</td>
<td></td>
</tr>
</tbody>
</table>

This relation provides a list of students’ names alongside their friends, of which some are pet owners displayed in the first relation. Therefore, the schema of this relation contains two columns: *student* and *friend*.

Before replicating this scenario, you need to write the sample data into the HDFS system of the Hadoop cluster to be used. To do this, you can use `tHDFSOutput`. For further information about this component, see `tHDFSOutput` on page 1518.

The data used in this scenario is inspired by the examples that Pig’s documentation uses to explain the GROUP and the GOGROUP operators. For related information, please see Apache’s documentation for Pig.

**Linking the components**

**Procedure**

1. In the Integration perspective of the Studio, create an empty Job from the Job Designs node in the Repository tree view.
   For further information about how to create a Job, see *Talend Studio User Guide*.

2. In the workspace, enter the name of the component to be used and select this component from the list that appears. In this scenario, the components are two `tPigLoad` components, a `tPigCoGroup` component and a `tPigStoreResult` component. One of the two `tPigLoad` components is used as the main loading component to connect to the Hadoop cluster to be used.

3. Connect the main `tPigLoad` component to `tPigCoGroup` using the Row > Main link.

4. Do the same to connect the second `tPigLoad` component to `tPigCoGroup`. The Lookup label appears over this link.

5. Repeat the operation to connect `tPigCoGroup` to `tPigStoreResult`.

**Reading data into the Pig flow**

**Reading the owner-pet sample data**

**Procedure**

1. Double-click the main `tPigLoad` component to open its Component view.
2. Click the [...] button next to Edit schema to open the schema editor and click the [+ ] button three times to add three rows.

3. In the Column column, rename the new rows to owner, pet and age, respectively, and in the Type column of the age row, select Integer.

4. Click OK to validate these changes and accept the propagation prompted by the pop-up dialog box.

5. In the Mode area, select Map/Reduce to use the remote Hadoop cluster to be used.

6. In the Distribution and the Version lists, select the Hadoop distribution you are using. In this example, HortonWorks Data Platform V2.1.0 (Baikal) is selected.

7. In the Load function list, select PigStorage. Then, the corresponding parameters to be set appear.

8. In the NameNode URI and the Resource manager fields, enter the locations of those services, respectively. If you are using WebHDFS, the location should be webhdfs://masternode:portnumber; WebHDFS with SSL is not supported yet.

9. Select the Set Resource manager scheduler address check box and enter the URI of this service in the field that is displayed. This allows you to use the Scheduler service defined in the Hadoop cluster to be used. If this service is not defined in your cluster, you can ignore this step.

10. In the User name field, enter the name of the user having the appropriate right to write data in the cluster. In this example, it is hdfs.

11. In the Input file URI field, enter the path pointing to the relation you need to read data from. As explained previously, the relation to be read here is the one containing the owner and pet sample data.
12. In the **Field separator** field, enter the separator of the data to be read. In this example, it is semicolon (;).

**Loading the student-friend sample data**

**Procedure**

1. Double-click the second **tPigLoad** component to open its **Component** view.

   ![Component view of tPigLoad]

2. Click the [...] button next to **Edit schema** to open the schema editor.

3. Click the [+] button twice to add two rows and in the **Column** column, rename them to **student** and **friend**, respectively.

4. Click **OK** to validate these changes and accept the propagation prompted by the pop-up dialog box.

5. In the **Mode** area, select **Map/Reduce**.
   
   This component reuses the Hadoop connection you have configured in that main **tPigLoad** component. Therefore, the **Distribution** and the **Version** fields have been automatically filled with the values from that main loading component.

6. In the **Load function** field, select the **PigStorage** function to read the source data.
7. In the **Input file URI** field, enter the directory where the source data is stored. As explained previously, this data is from the second relation containing the student and friend sample data.

**Aggregating the relations**

**Procedure**

1. Double-click **tPigCoGroup** to open its **Component** view.

![Component view](image)

2. Click the [...] button next to **Edit schema** to open the schema editor.

3. Click the [+ ] button five times to add five rows and in the **Column** column, rename them to **owner_friend**, **age**, **pet_number**, **pet** and **student**, respectively.

4. In the **Type** column of the **age** row, select **Integer**.

5. Click **OK** to validate these changes and accept the propagation prompted by the pop-up dialog box.

6. In the **Group by** table, click the [+ ] button once to add one row.

7. Then you need to set the grouping condition in this **Group by** table to aggregate the two input relations. In each column representing the input relation, click the newly added row and select the column you need to use to compose the grouping condition. In this scenario, the **owner** column from the owner-pet relation and the **friend** column from the student-friend relation are selected because they have common records. Based on these columns, the two relations are aggregated into bags.

The bags regarding the record **Alice** might read as follow:

```
Alice,{{Alice,turtle,17},{Alice,goldfish,17},{Alice,cat,17}},{{Cindy,Alice},{Mark,Alice}}
```

8. In the **Output mapping** table, the output schema you defined previously has been automatically fed into the **Column** column. You need to complete this table to define how the grouped bags are aggregated into the schema of the output relation. The following list provides more details about how this aggregation is configured for this scenario:
<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>owner_friend</td>
<td>Receive the literal records incoming from the columns that are used as the grouping condition. For this reason, select the <strong>EMPTY</strong> function from the <strong>Function</strong> drop-down list so that the incoming records stay as is. Then select <code>row1</code> from the <strong>Source schema</strong> list and <code>owner</code> from the <strong>Expression</strong> list to read the records from the corresponding input column; you can as well select <code>row2</code> and <code>friend</code>, the records to be received are the same because the <code>owner</code> column and the <code>friend</code> column are joined when they are used as grouping condition. Note that the label <code>row1</code> is the ID of the input link and thus may be different in your scenario.</td>
</tr>
<tr>
<td>age</td>
<td>Receive the age data. As shown in the example bags in the previous step, the age of an owner repetitively appears in one of the bags after the grouping. You can select the <strong>AVG</strong> function from the <strong>Function</strong> list to make the average of the repetitive values such that this age appears only once in the final result. Then select <code>row1</code> from the <strong>Source schema</strong> list and <code>age</code> from the <strong>Expression</strong> list.</td>
</tr>
<tr>
<td>pet_number</td>
<td>Receive how many pets an owner has. Select the <strong>COUNT</strong> function from the <strong>Function</strong> list to perform this calculation. Then select <code>row1</code> from the <strong>Source schema</strong> list and <code>pet</code> from the <strong>Expression</strong> list.</td>
</tr>
<tr>
<td>pet and student</td>
<td>Receive the grouped records from the input <code>pet</code> and <code>student</code> columns, respectively. Select <strong>EMPTY</strong> for both of them and from the <strong>Source schema</strong> list of each, select the corresponding input schema and from the <strong>Expression</strong> list, the corresponding column.</td>
</tr>
</tbody>
</table>

**Writing the aggregated data**

**Procedure**

1. Double-click `tPigStoreResult` to open its **Component** view.
2. If this component does not have the same schema of the preceding component, a warning icon appears. In this case, click the **Sync columns** button to retrieve the schema from the preceding one and once done, the warning icon disappears.

3. In the **Result folder URI** field, enter the path in HDFS pointing to the location you want to write the result in.

4. Select the **Remove result directory if exists** check box.

5. From the **Store function** list, select **PigStorage**.

6. In the **Field separator** field, enter the separator you want to use. In this scenario, enter a comma (,).

**Executing the Job**

Then you can press **F6** to run this Job.

Once done, check the result from the HDFS system you are using.

You can read, for example, that the pet owner *Alice* is 17 years old, has 3 pets, a cat, a goldfish and a turtle and two of her friends are Mark and Cindy.
# tPigCross

Uses CROSS operator to compute the Cartesian product.

The tPigCross computes the cross data of two or more relations.

## tPigCross Standard properties

These properties are used to configure tPigCross running in the Standard Job framework.

The Standard tPigCross component belongs to the Big Data and the Processing families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

### Basic settings

| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
- View schema: choose this option to view the schema only.  
- Change to built-in property: choose this option to change the schema to Built-in for local changes.  
- Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |
<table>

### Advanced settings

<table>
<thead>
<tr>
<th>Use partitioner</th>
<th>Select this check box to specify the Hadoop Partitioner that controls the partitioning of the keys of the intermediate map-outputs. For further information about the usage of Hadoop Partitioner, see:</th>
</tr>
</thead>
</table>
Increase parallelism
Select this check box to set the number of reduce tasks for the MapReduce Jobs.

StatCatcher Statistics
Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

Global Variables

Global Variables
ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule
This component is commonly used as intermediate step together with input component and output component.

Prerequisites
The Hadoop distribution must be properly installed, so as to guarantee the interaction with Talend Studio. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR's documentation, the library or libraries of a MapR client corresponding to each OS version can be found under MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native. For example, the library for Windows is \lib\native\MapRClient.dll in the MapR client jar file. For further information, see the following link from MapR: http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr.

Without adding the specified library or libraries, you may encounter the following error: java.library.path.

- Set the -Djava.library.path argument, for example, in the Job Run VM arguments area of the Run/Debug view in the Preferences dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.
<table>

</thead>
</table>

**Related scenarios**

No scenario is available for the Standard version of this component yet.
tPigDistinct

Removes duplicate tuples in a relation.

**tPigDistinct Standard properties**

These properties are used to configure tPigDistinct running in the Standard Job framework.

The Standard tPigDistinct component belongs to the Big Data and the Processing families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
• **View schema**: choose this option to view the schema only.  
• **Change to built-in property**: choose this option to change the schema to Built-in for local changes.  
• **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global Variables**

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable |
and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

---

**Usage**

**Usage rule**

This component is commonly used as intermediate step together with input component and output component.

**Warning:**

*This component will not maintain the original order in the input file.*

---

**Prerequisites**

The Hadoop distribution must be properly installed, so as to guarantee the interaction with *Talend Studio*. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under `MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native`. For example, the library for Windows is `\lib\native\MapRClient.dll` in the MapR client jar file. For further information, see the following link from MapR: [http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr](http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr).

Without adding the specified library or libraries, you may encounter the following error: *no MapRClient in java.library.path.*

- Set the `-Djava.library.path` argument, for example, in the **Job Run VM arguments** area of the **Run/Debug** view in the **Preferences** dialog box in the **Window** menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the **Data viewer** to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

**Limitation**

Knowledge of Pig scripts is required.
Related scenario

For more information regarding the `tPigDistinct` component in use, see Filtering rows of data based on a condition and saving the result to a local file on page 2889 of `tPigFilterRow`.
tPigFilterColumns

Selects data or filters out data from a relation based on defined filter conditions.
The tPigFilterColumns selects one or more columns from a relation based on defined condition.

**tPigFilterColumns Standard properties**

These properties are used to configure tPigFilterColumns running in the Standard Job framework.
The Standard tPigFilterColumns component belongs to the Big Data and the Processing families.
The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

</table>

**Limitation**

| Knowledge of Pig script is required. |

**Related Scenario**

For a PigFilterColumns related scenario, see Joining two files based on an exact match and saving the result to a local file on page 2896 of PigJoin.
tPigFilterRow

Applies filtering conditions on one or more specified columns, in a Pig process, in order to split or filter data from a relation.

The tPigFilterRow filters or splits the input flow in a Pig process based on conditions set on given column(s).

**tPigFilterRow Standard properties**

These properties are used to configure tPigFilterRow running in the Standard Job framework.

The Standard tPigFilterRow component belongs to the Big Data and the Processing families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word 'line' when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:
| • View schema: choose this option to view the schema only.
| • Change to built-in property: choose this option to change the schema to Built-in for local changes.
| • Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.
| Built-In: You create and store the schema locally for this component only.
| Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.
| Filter configuration | Click the Add button beneath the Filter configuration table to set one or more filter conditions.
| Note that when the column to be used by a condition is of the string type, the text to be entered in the Value column must be surrounded by both single and double quotation marks (for example, "California"), because the double quotation marks are required by Talend's code generator and the single quotation marks required by Pig's grammar. |
Use advanced filter

Select this check box to define advanced filter condition by entering customized filter expression in the Filter field.

**Advanced settings**

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

**Global Variables**

**Global Variables**

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see **Talend Studio User Guide**.

**Usage**

**Usage rule**

This component is commonly used as an intermediate step in a Pig process.

**Prerequisites**

The Hadoop distribution must be properly installed, so as to guarantee the interaction with **Talend Studio**. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under `MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native`. For example, the library for Windows is `\lib\native\MapRClient.dll` in the MapR client jar file. For further information, see the following link from MapR: http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr.

Without adding the specified library or libraries, you may encounter the following error: `no MapRClient in java.library.path`.

- Set the `-Djava.library.path` argument, for example, in the **Job Run VM arguments** area of the **Run/Debug** view in the **Preferences** dialog box in the **Window** menu. This argument provides to the Studio...
Filtering rows of data based on a condition and saving the result to a local file

This scenario applies only to Talend products with Big Data.

This scenario describes a four-component Job that filters a list of customers to find out customers from a particular country, and saves the result list to a local file. Before the input data is filtered, duplicate entries are first removed from the list.

The input file contains three columns: Name, Country, and Age, and it has some duplicate entries, as shown below:

<table>
<thead>
<tr>
<th>Name</th>
<th>Country</th>
<th>Age</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mario</td>
<td>PuertoRico</td>
<td>49</td>
</tr>
<tr>
<td>Mike</td>
<td>USA</td>
<td>22</td>
</tr>
<tr>
<td>Ricky</td>
<td>PuertoRico</td>
<td>37</td>
</tr>
<tr>
<td>Silvia</td>
<td>Spain</td>
<td>20</td>
</tr>
<tr>
<td>Billy</td>
<td>Canada</td>
<td>21</td>
</tr>
<tr>
<td>Ricky</td>
<td>PuertoRico</td>
<td>37</td>
</tr>
<tr>
<td>Romeo</td>
<td>UK</td>
<td>19</td>
</tr>
<tr>
<td>Natasha</td>
<td>Russia</td>
<td>25</td>
</tr>
<tr>
<td>Juan</td>
<td>Cuba</td>

</tr>
<tr>
<td>Bob</td>
<td>Jamaica</td>
<td>55</td>
</tr>
<tr>
<td>Mario</td>
<td>PuertoRico</td>
<td>49</td>
</tr>
</tbody>
</table>

Dropping and linking components

Procedure

1. Drop the following components from the Palette to the design workspace: tPigLoad, tPigDistinct, tPigFilterRow, and tPigStoreResult.
2. Right-click tPigLoad, select Row > Pig Combine from the contextual menu, and click tPigDistinct to link these two components.
3. Repeat this operation to link tPigDistinct to tPigFilterRow, and tPigFilterRow to tPigStoreResult using Row > Pig Combine connections to form a Pig process.
Configuring the components

Loading the input data and removing duplicates

Procedure

1. Double-click tPigLoad to open its Basic settings view.

2. Click the [...] button next to Edit schema to open the Schema dialog box.
3. Click the [+] button to add three columns according to the data structure of the input file: Name (string), Country (string) and Age (integer), and then click OK to save the setting and close the dialog box.

4. Click Local in the Mode area.

5. Fill in the Input file URI field with the full path to the input file.

6. Select PigStorage from the Load function list, and leave rest of the settings as they are.

7. Double-click tPigDistinct to open its Basic settings view, and click Sync columns to make sure that the input schema structure is correctly propagated from the preceding component. This component will remove any duplicates from the data flow.

**Configuring the filter**

**Procedure**

1. Double-click tPigFilterRow to open its Basic settings view.

2. Click Sync columns to make sure that the input schema structure is correctly propagated from the preceding component.

3. Select Use advanced filter and fill in the Filter field with filter expression:

   "Country matches 'PuertoRico'"

This filter expression selects rows of data that contains "PuertoRico" in the Country column.
Configuring the file output

Procedure

1. Double-click tPigStoreResult to open its Basic settings view.

![Basic settings view](image)

2. Click Sync columns to make sure that the input schema structure is correctly propagated from the preceding component.

3. Fill in the Result file field with the full path to the result file.

4. If the target file already exists, select the Remove result directory if exists check box.

5. Select PigStorage from the Store function list, and leave rest of the settings as they are.

Saving and executing the Job

Procedure

1. Press Ctrl+S to save your Job.

2. Press F6 or click the Run button on the Run tab to run the Job.

The result file contains the information of customers from the specified country.
**tPigJoin**

Performs inner joins and outer joins of two files based on join keys to create data that will be used by Pig.

The **tPigJoin** performs join of two files based on join keys.

**tPigJoin Standard properties**

These properties are used to configure **tPigJoin** running in the Standard Job framework.

The Standard **tPigJoin** component belongs to the Big Data and the Processing families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| Schema and Edit schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields. Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
  - **View schema**: choose this option to view the schema only.  
  - **Change to built-in property**: choose this option to change the schema to *Built-in* for local changes.  
  - **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select *No* upon completion and choose this schema metadata again in the **Repository Content** window.  

**Note:**

To make this component work, two schemas must be set: the schema of the main flow and the schema of the lookup flow. In the output part of the main schema, the columns of the main input file must be manually concatenated with those of the lookup file. |
<table>

**Prerequisites**

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under `MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native`. For example, the library for Windows is `\lib\native\MapClient.dll` in the MapR client jar file. For further information, see the following link from MapR: [http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr](http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr).
Joins two files based on an exact match and saving the result to a local file

This scenario applies only to Talend products with Big Data.

This scenario describes a four-component Job that combines data of an input file and a reference file that matches a given join key, removes unwanted columns, and then saves the final result to a local file.

The main input file contains the information about people's IDs, first names, last names, group IDs, and salaries, as shown below:

```
1;Woodrow;Johnson;3;1013.39
2;Millard;Monroe;2;8077.59
3;Calvin;Eisenhower;3;6866.88
4;Lyndon;Wilson;3;5726.28
5;Ronald;Garfield;2;4158.58
6;Rutherford;Buchanan;3;2897.00
7;Calvin;Coolidge;1;6560.66
8;Ulysses;Roosevelt;2;7854.78
9;Grover;Tyler;1;5226.88
10;Bill;Tyler;2;8964.66
```

The reference file contains only the information of group IDs and group names:

```
1;group_A
2;group_B
```

Dropping and linking the components

**Procedure**

1. Drop the following components from the Palette to the design workspace: `tPigLoad`, `tPigJoin`, `tPigFilterColumns`, and `tPigStoreResult`.
2. Connect these components in a series using `Row > Pig Combine` connections.
Configuring the components

Loading the main input file

Procedure

1. Double-click tPigLoad to open its Basic settings view.

2. Click the [...] button next to Edit schema to open the Schema dialog box.
3. Click the [+] button to add columns, name them and define the column types according to the structure of the input file. In this example, the input schema has five columns: id (integer), firstName (string), lastName (string), groupId (integer), and salary (double).

Then click OK to validate the setting and close the dialog box.

4. Click Local in the Mode area.

5. Select PigStorage from the Load function list.

6. Fill in the Input file URI field with the full path to the input file, and leave the rest of the setting as they are.

**Loading the reference file and setting up an inner join**

**Procedure**

1. Double-click tPigJoin to open its Basic settings view.
2. Click the [...] for the main schema to open the Schema dialog box.

3. Check that input schema is correctly retrieved from the preceding component. If needed, click the ->>> button to copy all the columns of the input schema to the output schema.

4. Click the [+] button under the output panel to add new columns according to the data structure of the reference file, groupId_ref (integer) and groupName (string) in this example. Then click OK to close the dialog box.

5. Click the [...] for the schema lookup flow to open the Schema dialog box.
6. Click the [+] button under the output panel to add two columns: `groupId_ref` (integer) and `groupName` (string), and then click **OK** to close the dialog box.

7. In the **Filename** field, specify the full path to the reference file.

8. Click the [+] button under the **Join key** table to add a new line, and select `groupId` and `groupId_ref` respectively from the **Input** and **Lookup** lists to match data from the main input flow with data from the lookup flow based on the group ID.

9. From the **Join Mode** list, select **inner-join**.

**Defining the final output schema and the output file**

**Procedure**

1. Double-click **tPigFilterColumns** to open its **Basic settings** view.

2. Click the [...] button next to **Edit schema** to open the **Schema** dialog box.
3. From the input schema, select the columns you want to include in your result file by clicking them one after another while pressing the Shift key, and click the -> button to copy them to the output schema. Then, click OK to validate the schema setting and close the dialog box.
   In this example, we want the result file to include all the information except the group IDs.

4. Double-click tPigStoreResult to open its Basic settings view.

5. Click Sync columns to retrieve the schema structure from the preceding component.

6. Fill in the Result file field with the full path to the result file, and select the Remove result file directory if exists check box.

7. Select PigStorage from the Store function list, and leave rest of the settings as they are.

**Saving and executing the Job**

**Procedure**

1. Press Ctrl+S to save your Job.

2. Press F6 or click Run on the Run tab to run the Job.
   The result file includes all the information related to people of group A and group B, except their group IDs.

</tbody>
</table>
tPigLoad

Loads original input data to an output stream in just one single transaction, once the data has been validated.

The tPigLoad sets up a connection to the data source for a current transaction.

**tPigLoad Standard properties**

These properties are used to configure tPigLoad running in the Standard Job framework.

The Standard tPigLoad component belongs to the Big Data and the Processing families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-In or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Built-In</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file where the properties are stored. The properties are stored centrally under the Hadoop Cluster node of the Repository tree. The fields that come after are pre-filled in using the fetched data. For further information about the Hadoop Cluster node, see the Getting Started Guide.</td>
</tr>
</tbody>
</table>

**Schema and Edit Schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

Built-In: You create and store the schema locally for this component only.
**Repository:** You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

<table>
<thead>
<tr>
<th>Local</th>
<th>Click this radio button to run Pig scripts in <strong>Local</strong> mode. In this mode, all files are installed and run from your local host and file system.</th>
</tr>
</thead>
</table>

**Execution engine**

Select the framework you need to use to perform your Pig Job.

This Tez mode is available only when you are using one of the following distributions:
- Hortonworks: V2.2 +.
- Custom: this option allows you to connect to a distribution supporting Tez but not officially supported by Talend.

Before using Tez, ensure that the Hadoop cluster you are using supports Tez. You will need to configure the access to the relevant Tez libraries via the Advanced settings view of this component.

For further information about Pig on Tez, see Apache's related documentation in [https://cwiki.apache.org/confluence/display/PIG/Pig+on+Tez](https://cwiki.apache.org/confluence/display/PIG/Pig+on+Tez).

**Distribution and Version**

Select the cluster you are using from the drop-down list. The options in the list vary depending on the component you are using. Among these options, the following ones require specific configuration:

- If available in this Distribution drop-down list, the Microsoft HD Insight option allows you to use a Microsoft HD Insight cluster. For this purpose, you need to configure the connections to the HD Insight cluster and the Windows Azure Storage service of that cluster in the areas that are displayed. For detailed explanation about these parameters, search for configuring the connection manually on Talend Help Center ([https://help.talend.com](https://help.talend.com)).
- If you select Amazon EMR, you can find more details about how to configure an Amazon EMR cluster in Talend Help Center ([https://help.talend.com](https://help.talend.com)).
- The Custom option allows you to connect to a cluster different from any of the distributions given in this list, that is to say, to connect to a cluster not officially supported by Talend.

1. Select **Import from existing version** to import an officially supported distribution as base and then add other required jar files which the base distribution does not provide.
2. Select **Import from zip** to import the configuration zip for the custom distribution to be used. This zip file should contain the libraries of the different Hadoop elements and the index file of these libraries.

In Talend Exchange, members of Talend community have shared some ready-for-use configuration zip files which you can download from this Hadoop configuration list and directly use them in your connection accordingly. However, because of the ongoing evolution of the different Hadoop-
related projects, you might not be able to find the configuration zip corresponding to your distribution from this list; then it is recommended to use the **Import from existing version** option to take an existing distribution as base to add the jars required by your distribution.

Note that custom versions are not officially supported by **Talend**. **Talend** and its community provide you with the opportunity to connect to custom versions from the Studio but cannot guarantee that the configuration of whichever version you choose will be easy, due to the wide range of different Hadoop distributions and versions that are available. As such, you should only attempt to set up such a connection if you have sufficient Hadoop experience to handle any issues on your own.

**Note:**

In this dialog box, the active check box must be kept selected so as to import the jar files pertinent to the connection to be created between the custom distribution and this component.

For a step-by-step example about how to connect to a custom distribution and share this connection, see **Connecting to a custom Hadoop distribution** on page 1569.

The other parameters related to the connection to your cluster could be:

- **Use Kerberos authentication**:

  If you are accessing the Hadoop cluster running with Kerberos security, select this check box, then, enter the Kerberos principal name for the NameNode in the field displayed. This enables you to use your user name to authenticate against the credentials stored in Kerberos.

  - If this cluster is a MapR cluster of the version 5.0.0 or later, you can set the MapR ticket authentication configuration in addition or as an alternative by following the explanation in **Connecting to a security-enabled MapR** on page 1629.

    Keep in mind that this configuration generates a new MapR security ticket for the username defined in the Job in each execution. If you need to reuse an existing ticket issued for the same username, leave both the **Force MapR ticket authentication** check box and the **Use Kerberos authentication** check box clear, and then MapR should be able to automatically find that ticket on the fly.

In addition, since this component performs Map/Reduce computations, you also need to authenticate the related services such as the Job history server and the Resource manager or Jobtracker depending on your distribution in the corresponding field. These principals can be found in the configuration files of your distribution. For example, in a CDH4 distribution, the Resource manager principal is set in the `yarn-`
This check box is available depending on the Hadoop distribution you are connecting to.

The HBase related principals are required by the HBaseStorage function only.

- **Use a keytab to authenticate:**

  Select the **Use a keytab to authenticate** check box to log into a Kerberos-enabled system using a given keytab file. A keytab file contains pairs of Kerberos principals and encrypted keys. You need to enter the principal to be used in the **Principal** field and the access path to the keytab file itself in the **Keytab** field. This keytab file must be stored in the machine in which your Job actually runs, for example, on a Talend Jobserver.

  Note that the user that executes a keytab-enabled Job is not necessarily the one a principal designates but must have the right to read the keytab file being used. For example, the user name you are using to execute a Job is **user1** and the principal to be used is **guest**; in this situation, ensure that **user1** has the right to read the keytab file to be used.

- **NameNode URI:**

  Type in the location of the NameNode corresponding to the Map/Reduce version to be used. If you are using WebHDFS, the location should be `webhdfs://masternode:portnumber`; WebHDFS with SSL is not supported yet.

- **Resource Manager:**

  Type in the location of the ResourceManager service of your cluster.

  In JobHistory, you can easily find the execution status of your Pig Job because the name of the Job is automatically created by concatenating the name of the project that contains the Job, the name and version of the Job itself and the label of the first PigLoad component used in it. The naming convention of a Pig Job in JobHistory is `ProjectName_JobNameVersion_FirstComponentName`.

  Then you can continue to set the following parameters depending on the configuration of the Hadoop cluster to be used (if you leave the check box of a parameter clear, then at runtime, the configuration about this parameter in the Hadoop cluster to be used will be ignored):

  1. Select the **Set resourcemanager scheduler address** check box and enter the Scheduler address in the field that appears.

  2. Select the **Set jobhistory address** check box and enter the location of the JobHistory server of the Hadoop cluster to be used. This allows the metrics information of the current Job to be stored in that JobHistory server.

  3. Select the **Set staging directory** check box and enter this directory defined in your Hadoop cluster for temporary files created by running programs. Typically, this directory can be found under the **site.xml** file and the Job history principal in the **mapred-site.xml** file.
yarn.app.mapreduce.am.staging-dir property in the configuration files such as yarn-site.xml or mapred-site.xml of your distribution.

4. Allocate proper memory volumes to the Map and the Reduce computations and the ApplicationMaster of YARN by selecting the Set memory check box in the Advanced settings view.

5. Select the Set Hadoop user check box and enter the user name under which you want to execute the Job. Since a file or a directory in Hadoop has its specific owner with appropriate read or write rights, this field allows you to execute the Job directly under the user name that has the appropriate rights to access the file or directory to be processed.

6. Select the Use datanode hostname check box to allow the Job to access datanodes via their hostnames. This actually sets the dfs.client.use.datanode.hostname property to true. When connecting to a S3N filesystem, you must select this check box.

For further information about these parameters, see the documentation or contact the administrator of the Hadoop cluster to be used.

- **User name:**

  Enter the user name under which you want to execute the Job. Since a file or a directory in Hadoop has its specific owner with appropriate read or write rights, this field allows you to execute the Job directly under the user name that has the appropriate rights to access the file or directory to be processed. Note that this field is available depending on the distribution you are using.

- **Parameters related to Qubole:**

  1. Click the ... button next to the API Token field to enter the authentication token generated for the Qubole user account to be used. For further information about how to obtain this token, see Manage Qubole account from the Qubole documentation.

     This token allows you to specify the user account you want to use to access Qubole. Your Job automatically uses the rights and permissions granted to this user account in Qubole.

  2. Select the Cluster label check box and enter the name of the Qubole cluster to be used. If leaving this check box clear, the default cluster is used.

     If you need details about your default cluster, ask the administrator of your Qubole service. You can also read this article from the Qubole documentation to find more information about configuring a default Qubole cluster.

  3. Select the Change API endpoint check box and select the region to be used. If leaving this check box clear, the default region is used.

     For further information about the Qubole Endpoints supported on QDS-on-AWS, see Supported Qubole Endpoints on Different Cloud Providers.
4. Configure the connection to the S3 file system to be used to temporarily store the dependencies of your Job so that your Qubole cluster has access to these dependencies.

- **Access key and Secret key**: enter the authentication information required to connect to the Amazon S3 bucket to be used.
  
  To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

- **Bucket name**: enter the name of the bucket in which you want to store the dependencies of your Job. This bucket must already exist on S3.

- **Temporary resource folder**: enter the directory in which you want to store the dependencies of your Job. For example, enter `temp_resources` to write the dependencies in the `/temp_resources` folder in the bucket.
  
  If this folder already exists at runtime, its contents are overwritten by the upcoming dependencies; otherwise, this folder is automatically created.

- **Region**: specify the AWS region by selecting a region name from the list. For more information about the AWS Region, see [Regions and Endpoints](#).

| WebHCat configuration | Enter the address and the authentication information of the Microsoft HD Insight cluster to be used. For example, the address could be your hdinsight_cluster_name.azurehdinsight.net and the authentication information is your Azure account name: ychen. The Studio uses this service to submit the Job to the HD Insight cluster.  
  
  In the **Job result folder** field, enter the location in which you want to store the execution result of a Job in the Azure Storage to be used. |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| HDInsight configuration | • The **Username** is the one defined when creating your cluster. You can find it in the **SSH + Cluster login** blade of your cluster.  
  
  • The **Password** is defined when creating your HDInsight cluster for authentication to this cluster. |
| Windows Azure Storage configuration | Enter the address and the authentication information of the Azure Storage account to be used. In this configuration, you do not define where to read or write your business data but define where to deploy your Job only. Therefore always use the Azure Storage system for this configuration.  
  
  In the **Container** field, enter the name of the container to be used. You can find the available containers in the **Blob** blade of the Azure Storage account to be used.  
  
  In the **Deployment Blob** field, enter the location in which you want to store the current Job and its dependent libraries in this Azure Storage account. |
Inspect the classpath for configurations

Select this check box to allow the component to check the configuration files in the directory you have set with the $HADOOP_CONF_DIR variable and directly read parameters from these files in this directory. This feature allows you to easily change the Hadoop configuration for the component to switch between different environments, for example, from a test environment to a production environment.

In this situation, the fields or options used to configure Hadoop connection and/or Kerberos security are hidden.

If you want to use certain parameters such as the Kerberos parameters but these parameters are not included in these Hadoop configuration files, you need to create a file called talend-site.xml and put this file into the same directory defined with $HADOOP_CONF_DIR. This talend-site.xml file should read as follows:

```xml
<!-- Put site-specific property overrides in this file. -->
<configuration>
    <property>
        <name>talend.kerberos.authentication</name>
        <value>kinit</value>
        <description>Set the Kerberos authentication method to use. Valid values are: kinit or keytab.</description>
    </property>
    <property>
        <name>talend.kerberos.keytab.principal</name>
        <value>user@BIGDATA.COM</value>
        <description>Set the keytab's principal name.</description>
    </property>
    <property>
        <name>talend.kerberos.keytab.path</name>
        <value>/kdc/user.keytab</value>
        <description>Set the keytab's path.</description>
    </property>
    <property>
        <name>talend.encryption</name>
        <value>none</value>
        <description>Set the encryption method to use. Valid values are: none or ssl.</description>
    </property>
    <property>
        <name>talend.ssl.trustStore.path</name>
        <value>ssl</value>
        <description>Set SSL trust store path.</description>
    </property>
</configuration>
```
The parameters read from these configuration files override the default ones used by the Studio. When a parameter does not exist in these configuration files, the default one is used.

Load function

Select a load function for data to be loaded:

- **PigStorage**: Loads data in UTF-8 format.
- **BinStorage**: Loads data in machine-readable format.
- **TextLoader**: Loads unstructured data in UTF-8 format.
- **HCatLoader**: Loads data from HCatalog managed tables using Pig scripts. This function is available only when you have selected HortonWorks as the Hadoop distribution to be used from the **Distribution** and the **Version** fields displayed in the **Map/Reduce** mode. For further information about HCatLoader, see [https://hive.apache.org/javadocs/r2.1.1/api/org/apache/hive/hcatalog/pig/HCatLoader.html](https://hive.apache.org/javadocs/r2.1.1/api/org/apache/hive/hcatalog/pig/HCatLoader.html).
- **HBaseStorage**: Loads data from HBase. Then you need to complete the HBase configuration in the **HBase configuration** area displayed.
- **SequenceFileLoader**: Loads data of the SequenceFile formats. Then you need to complete the configuration of the file to be loaded in the **Sequence Loader Configuration** area that appears. This function is for the **Map/Reduce** mode only.
- **RCFilePigStorage**: Loads data of the RCFile format. This function is for the **Map/Reduce** mode only.
- **AvroStorage**: Loads Avro files. For further information about AvroStorage, see Apache's documentation on [https://cwiki.apache.org/confluence/display/PIG/AvroStorage](https://cwiki.apache.org/confluence/display/PIG/AvroStorage). This function is for the **Map/Reduce** mode only.
- **ParquetLoader**: Loads Parquet file. This function is for the **Map/Reduce** mode only.
- **Custom**: Loads data using any user-defined load function. To do this, you need to register, in the **Advanced settings** tab view, the jar file containing the function to be used, and then, in the field displayed next to this **Load function** field, specify that function.

For example, after registering a jar file called `piggybank.jar`, you can enter `org.apache.pig.piggybank.storage.XMLLoader('attr') as (xml:chararray)` to use the custom function, `XMLLoader` contained in that jar file. For further information about this `piggybank.jar` file, see [https://cwiki.apache.org/confluence/display/PIG/PiggyBank](https://cwiki.apache.org/confluence/display/PIG/PiggyBank).
Note that when the file format to be used is **PARQUET**, you might be prompted to find the specific PARQUET jar file and install it into the Studio.

- When the connection mode to Hive is **Embedded**, the Job is run in your local machine and calls this jar installed in the Studio.
- When the connection mode to Hive is **Standalone**, the Job is run in the server hosting Hive and this jar file is sent to the HDFS system of the cluster you are connecting to. Therefore, ensure that you have properly defined the NameNode URI in the corresponding field of the **Basic settings** view.

This jar file can be downloaded from Apache's site. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

### Input file URI

Fill in this field with the full local path to the input file.

**Note:**
This field is not available when you select **HCatLoader** from the **Load function** list or when you are using an **S3** endpoint.

### Use S3 endpoint

Select this check box to read data from a given Amazon S3 bucket folder.

Once this **Use S3 endpoint** check box is selected, you need to enter the following parameters in the fields that appear:

- **S3 bucket name and folder**: enter the bucket name and its folder from which you need to read data. You need to separate the bucket name and the folder name using a slash (/).

- **Access key** and **Secret key**: enter the authentication information required to connect to the Amazon S3 bucket to be used.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

Note that the format of the S3 file is **S3N** (S3 Native Filesystem).

### HCatLog Configuration

Fill the following fields to configure HCatLog managed tables on HDFS (Hadoop distributed file system):

**Distribution** and **Version**:

Select the cluster you are using from the drop-down list. The options in the list vary depending on the component you are using. Among these options, the following ones requires specific configuration:

- If available in this **Distribution** drop-down list, the **Microsoft HD Insight** option allows you to use a Microsoft HD Insight cluster. For this purpose, you need to configure the connections to the HD Insight cluster and the Windows Azure Storage service of that cluster in the areas that are displayed. For detailed explanation about these parameters, search for configuring the connection manually on Talend Help Center (https://help.talend.com).
- If you select **Amazon EMR**, you can find more details about how to configure an Amazon EMR cluster in Talend Help Center (https://help.talend.com).
- The **Custom** option allows you to connect to a cluster different from any of the distributions given in this list, that is to say, to connect to a cluster not officially supported by Talend.

**HCat metastore**: Enter the location of the HCatalog’s metastore, which is actually Hive’s metastore, a system catalog. For further information about Hive and HCatalog, see http://hive.apache.org/.

**Database**: The database in which tables are placed.

**Table**: The table in which data is stored.

**Partition filter**: Fill this field with the partition keys to list partitions by filter.

### Note:
**HCatLoader Configuration area** is enabled only when you select HCatLoader from the Load function list. For further information about the usage of HCatLoader, see https://cwiki.apache.org/confluence/display/Hive/HCatalog. For further information about the usage of **Partition filter**, see https://cwiki.apache.org/confluence/display/HCATALOG/Design+Document+-+Java+APIs+for+HCatalog+DDL+Commands.

<table>
<thead>
<tr>
<th>Field separator</th>
<th>Enter character, string or regular expression to separate fields for the transferred data.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Note:</strong></td>
<td>This field is enabled only when you select PigStorage from the Load function list.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Compression</th>
<th>Select the <strong>Force to compress the output data</strong> check box to compress the data when the data is outputted by tPigStoreResult at the end of a Pig process.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Hadoop provides different compression formats that help reduce the space needed for storing files and speed up data transfer. When you need to write and compress data using the Pig program, by default you have to add a compression format as a suffix to the path pointing to the folder in which you want to write data, for example, <code>/user/ychen/out.bz2</code>. However, if you select this check box, the output data will be compressed even if you do not add any compression format to that path, such as <code>/user/ychen/out</code>.</td>
</tr>
<tr>
<td><strong>Note:</strong></td>
<td>The output path is set in the Basic settings view of tPigStoreResult.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>HBase configuration</th>
<th>This area is available to the HBaseStorage function. The parameters to be set are:</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Zookeeper quorum:</strong></td>
<td>Type in the name or the URL of the Zookeeper service you use to coordinate the transaction between your Studio and your database. Note that when you configure the Zookeeper, you might need to explicitly set the zookeeper.znode.parent.</td>
</tr>
</tbody>
</table>
property to define the path to the root znode that contains all the znodes created and used by your database; then select the **Set Zookeeper znode parent** check box to define this property.

**Zookeeper client port:**
Type in the number of the client listening port of the Zookeeper service you are using.

**Table name:**
Enter the name of the HBase table you need to load data from.

**Load key:**
Select this check box to load the row key as the first column of the result schema. In this situation, you must have created this column in the schema.

**Mapping:**
Complete this table to map the columns of the table to be used with the schema columns you have defined for the data flow to be processed.

### Sequence Loader configuration

This area is available only to the **SequenceFileLoader** function. Since a SequenceFile record consists of binary key/value pairs, the parameters to be set are:

**Key column:**
Select the Key column of a key/value record.

**Value column**
Select the Value column of a key/value record.

**Die on subJob error**
This check box is cleared by default, meaning to skip the row on subjob error and to complete the process for error-free rows.

### Advanced settings

**Tez lib**
Select how the Tez libraries are accessed:

- **Auto install:** at runtime, the Job uploads and deploys the Tez libraries provided by the Studio into the directory you specified in the **Install folder in HDFS** field, for example, `/tmp/usr/tez`. If you have set the `tez.lib.uris` property in the properties table, this directory overrides the value of that property at runtime. But the other properties set in the properties table are still effective.

- **Use exist:** the Job accesses the Tez libraries already deployed in the Hadoop cluster to be used. You need to enter the path pointing to those libraries in the **Lib path (folder or file)** field.

- **Lib jar:** this table appears when you have selected **Auto install** from the **Tez lib** list and the distribution you are using is **Custom**. In this table, you need to add the Tez libraries to be uploaded.

**Hadoop Properties**
*Talend Studio* uses a default configuration for its engine to perform operations in a Hadoop distribution. If you need to use a custom configuration in a specific situation, complete this table with the property or properties to be customized.
Then at runtime, the customized property or properties will override those default ones.

- Note that if you are using the centrally stored metadata from the Repository, this table automatically inherits the properties defined in that metadata and becomes uneditable unless you change the Property type from Repository to Built-in.

For further information about the properties required by Hadoop and its related systems such as HDFS and Hive, see the documentation of the Hadoop distribution you are using or see Apache’s Hadoop documentation on http://hadoop.apache.org/docs and then select the version of the documentation you want. For demonstration purposes, the links to some properties are listed below:

- Typically, the HDFS-related properties can be found in the hdfs-default.xml file of your distribution, such as http://hadoop.apache.org/docs/r2.6.0/hadoop-project-dist/hadoop-hdfs/hdfs-default.xml.
- Apache also provides a page to list the Hive-related properties: https://cwiki.apache.org/confluence/display/Hive/Configuration+Properties.

| Register jar | Click the [+] button to add rows to the table and from these rows, browse to the jar files to be added. For example, in order to register a jar file called piggybank.jar, click the [+] button once to add one row, then click this row to display the [...] browse button, and click this button to browse to the piggybank.jar file following the Select Module wizard. |
| Define functions | Use this table to define UDFs (User-Defined Functions), especially those requiring alias such as Apache DataFu Pig functions, to be executed when loading data. Click the button to add as many rows as you need and specify an alias and a UDF in the relevant fields for each row. If your Job includes a tPigMap component, once you have defined UDFs for this component in the tPigMap, this table is automatically filled. Likewise, once you have defined UDFs in this table, the Define functions table in the tPigMap component’s Map Editor is automatically filled. For information on how to define UDFs when mapping Pig flows, see the section on mapping Big Data flows of the Talend Open Studio for Big Data Getting Started Guide. For more information on Apache DataFu Pig, see http://datafu.incubator.apache.org/. |
| Pig properties | Talend Studio uses a default configuration for its Pig engine to perform operations. If you need to use a custom configuration in a specific situation, complete this table with the property or properties to be customized. Then at runtime, the customized property or properties will override those default ones. For example, the default_parallel key used in Pig could be set as 20. |
| HBaseStorage configuration | Add and set more HBaseStorage loader options in this table. The options are: ```
gt: the minimum key value;``` |
**lt**: the maximum key value;  
**gte**: the minimum key value (included);  
**lte**: the maximum key value (included);  
**limit**: maximum number of rows to retrieve per region;  
**caching**: number of rows to cache;  
**caster**: the converter to use for reading values out of HBase. For example, HBaseBinaryConverter.

### Define the jars to register for HCatalog
This check box appears when you are using **tHCatLoader**, while you can leave it clear as the Studio registers the required jar files automatically. In case any jar file is missing, you can select this check box to display the **Register jar for HCatalog** table and set the correct path to that missing jar.

### Path separator in server
Leave the default value of the **Path separator in server** as it is, unless you have changed the separator used by your Hadoop distribution's host machine for its PATH variable or in other words, that separator is not a colon (:). In that situation, you must change this value to the one you are using in that host.

### Mapred job map memory mb and Mapred job reduce memory mb
You can tune the map and reduce computations by selecting the **Set memory** check box to set proper memory allocations for the computations to be performed by the Hadoop system.

In that situation, you need to enter the values you need in the **Mapred job map memory mb** and the **Mapred job reduce memory mb** fields, respectively. By default, the values are both 1000 which are normally appropriate for running the computations.

The memory parameters to be set are **Map (in Mb)**, **Reduce (in Mb)** and **ApplicationMaster (in Mb)**. These fields allow you to dynamically allocate memory to the map and the reduce computations and the ApplicationMaster of YARN.

### tStatCatcher Statistics
Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).
### Usage

#### Usage rule

This component is always used to start a Pig process and needs **tPigStoreResult** at the end to output its data.

In the **Map/Reduce** mode, you need only configure the Hadoop connection for the first **tPigLoad** component of a Pig process (a subjob), and any other **tPigLoad** component used in this process reuses automatically that connection created by that first **tPigLoad** component.

#### Prerequisites

The Hadoop distribution must be properly installed, so as to guarantee the interaction with Talend Studio. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under `MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native`. For example, the library for Windows is `\lib\native\MapRClient.dll` in the MapR client jar file. For further information, see the following link from MapR: [http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr](http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr).

Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path.

- Set the `-Djava.library.path` argument, for example, in the Job Run VM arguments area of the Run/Debug view in the Preferences dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

#### Limitation

Knowledge of Pig scripts is required. If you select HCatLoader as the load function, knowledge of HCatalog DDL (HCatalog Data Definition Language, a subset of Hive Data Definition Language) is required. For further information about HCatalog DDL, see [https://cwiki.apache.org/confluence/display/Hive/HCatalog](https://cwiki.apache.org/confluence/display/Hive/HCatalog).

### Loading an HBase table

This scenario applies only to Talend products with Big Data.

This scenario uses **tPigLoad** and **tPigStoreResult** to read data from HBase and to write them to HDFS.
The HBase table to be used has three columns: \textit{id}, \textit{name} and \textit{age}, among which \textit{id} and \textit{age} belong to the column family, \textit{family1} and \textit{name} to the column family, \textit{family2}.

The data stored in that HBase table are as follows:

1;Albert;23
2;Alexandre;24
3;Alfred-Hubert;22
4;Andre;40
5;Didier;28
6;Anthony;35
7;Artus;32
8;Catherine;34
9;Charles;21
10;Christophe;36
11;Christian;67
12;Danniel;54
13;Elisabeth;58
14;Emile;32
15;Gregory;30

To replicate this scenario, perform the following operations:

\textbf{Linking the components}

\textbf{Procedure}

1. In the \textbf{Integration} perspective of \textit{Talend Studio}, create an empty Job, named \textit{hbase\_storage} for example, from the \textbf{Job Designs} node in the \textbf{Repository} tree view.

   For further information about how to create a Job, see the \textit{Talend Studio User Guide}.

2. Drop \texttt{tPigLoad} and \texttt{tPigStoreResult} onto the workspace.

3. Connect them using the \textit{Row > Pig combine} link.

\textbf{Configuring \texttt{tPigLoad}}

\textbf{Procedure}

1. Double-click \texttt{tPigLoad} to open its \textbf{Component} view.
2. Click the button next to Edit schema to open the schema editor.

3. Click the button four times to add four rows and rename them: rowkey, id, name and age. The rowkey column put at the top of the schema to store the HBase row key column, but in practice, if you do not need to load the row key column, you can create only the other three columns in your schema.
4. Click **OK** to validate these changes and accept the propagation prompted by the pop-up dialog box.

5. In the **Mode** area, select **Map/Reduce**, as we are using a remote Hadoop distribution.

6. In the **Distribution** and the **Version** fields, select the Hadoop distribution you are using. In this example, we are using **HortonWorks Data Platform V1**.

7. In the **Load function** field, select **HBaseStorage**. Then, the corresponding parameters to set appear.

8. In the **NameNode URI** and the **Resource Manager** fields, enter the locations of those services, respectively. If you are using WebHDFS, the location should be webhdfs://masternode:portnumber; WebHDFS with SSL is not supported yet.

9. In the **Zookeeper quorum** and the **Zookeeper client port** fields, enter the location information of the Zookeeper service to be used.

10. If the Zookeeper znode parent location has been defined in the Hadoop cluster you are connecting to, you need to select the **Set zookeeper znode parent** check box and enter the value of this property in the field that is displayed.

11. In the **Table name** field, enter the name of the table from which tPigLoad reads the data.

12. Select the **Load key** check box if you need to load the HBase row key column. In this example, we select it.

13. In the **Mapping** table, four rows have been added automatically. In the **Column family:qualifier** column, enter the HBase columns you need to map with the schema columns you defined. In this scenario, we put **family1:id** for the **id** column, **family2:name** for the **name** column and **family1:age** for the **age** column.

### Configuring tPigStoreResult

**Procedure**

1. Double-click **tPigStoreResult** to open its **Component** view.
2. In the Result file field, enter the directory where you need to store the result. As tPigStoreResult reuses automatically the connection created by tPigLoad, the path in this scenario is the directory in the machine hosting the Hadoop distribution to be used.

3. Select Remove result directory if exists.

4. In the Store function field, select PigStorage to store the result in the UTF-8 format.

**Executing the Job**

Then you can press F6 run this Job.

Once done, you can verify the result in the HDFS system used.

If you need to obtain more details about the Job, it is recommended to use the web console of the Jobtracker provided by the Hadoop distribution you are using.

In JobHistory, you can easily find the execution status of your Pig Job because the name of the Job is automatically created by concatenating the name of the project that contains the Job, the name and version of the Job itself and the label of the first tPigLoad component used in it. The naming convention of a Pig Job in JobHistory is `ProjectName_JobNameVersion_FirstComponentName`.
**tPigMap**

Transforms and routes data from single or multiple sources to single or multiple destinations.

The tPigMap transforms and routes the data in a Pig process. It provides a graphic interface that enables sophisticated configuration of multiple data flows.

### Optional map settings

On the input side:

<table>
<thead>
<tr>
<th>Lookup properties</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Join Model</strong></td>
<td><strong>Inner Join;</strong>&lt;br&gt;<strong>Left Outer Join;</strong>&lt;br&gt;<strong>Right Outer Join;</strong>&lt;br&gt;<strong>Full Outer Join.</strong>&lt;br&gt;The default join option is <strong>Left Outer Join</strong> when you do not activate this option settings panel by displaying it. These options perform the join of two or more flows based on common field values.&lt;br&gt;When more than one lookup tables need joining, the main input flow starts the joining from the first lookup flow, then uses the result to join the second and so on in the same manner until the last lookup flow is joined.</td>
</tr>
<tr>
<td><strong>Join Optimization</strong></td>
<td><strong>None;</strong>&lt;br&gt;<strong>Replicated;</strong>&lt;br&gt;<strong>Skewed;</strong>&lt;br&gt;<strong>Merge.</strong>&lt;br&gt;The default join option is <strong>None</strong> when you do not activate this option settings panel by displaying it. These options are used to perform more efficient join operations. For example, if you are using the parallelism of multiple reduce tasks, the <strong>Skewed</strong> join can be used to counteract the load imbalance problem if the data to be processed is sufficiently skewed.&lt;br&gt;Each of these options is subject to the constraints explained in Apache’s documentation about Pig Latin.</td>
</tr>
<tr>
<td><strong>Custom Partitioner</strong></td>
<td>Enter the Hadoop partitioner you need to use to control the partitioning of the keys of the intermediate map-outputs. For example, enter, in double quotation marks,&lt;br&gt;<code>org.apache.pig.test.utils.SimpleCustomPartitioner</code>&lt;br&gt;to use the partitioner <strong>SimpleCustomPartitioner</strong>.&lt;br&gt;For further information about the code of this <strong>SimpleCustomPartitioner</strong>, see Apache's documentation about Pig Latin. The jar file of this partitioner must have been registered in the <strong>Register jar</strong> table in the <strong>Advanced settings</strong> view of the tPigLoad component linked with the tPigMap component to be used.</td>
</tr>
<tr>
<td><strong>Increase Parallelism</strong></td>
<td>Enter the number of reduce tasks. For further information about the parallel features, see Apache’s documentation about Pig Latin.</td>
</tr>
</tbody>
</table>
On the output side:

<table>
<thead>
<tr>
<th>Output properties</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Catch Output Reject</td>
<td>True; False. This option, once activated, allows you to catch the records rejected by a filter you can define in the appropriate area.</td>
</tr>
<tr>
<td>Catch Lookup Inner Join Reject</td>
<td>True; False. This option, once activated, allows you to catch the records rejected by the inner join operation performed on the input flows.</td>
</tr>
</tbody>
</table>

**tPigMap Standard properties**

These properties are used to configure tPigMap running in the Standard Job framework.

The Standard tPigMap component belongs to the Big Data and the Processing families.

The component in this framework is available in all [Talend products with Big Data](https://www.talend.com/products/big-data) and in [Talend Data Fabric](https://www.talend.com/products/data-fabric).

**Basic settings**

<table>
<thead>
<tr>
<th>Mapping links display as</th>
<th>Auto: the default setting is curves links, Curves: the mapping display as curves, Lines: the mapping displays as straight lines. This last option allows to slightly enhance performance.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Map editor</td>
<td>It allows you to define the tPigMap routing and transformation properties.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

**Global Variables**

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. |
|-------------------|------------------------------------------------------------------------------------------------------------------|
Usage

Usage rule | Possible uses are from a simple reorganization of fields to the most complex Jobs of data multiplexing or demultiplexing transformation, concatenation, inversion, filtering/splitting and more, in a Pig process.

Limitation | The use of tPigMap supposes minimum Java and Pig Latin knowledge in order to fully exploit its functionalities. This component is a junction step, and for this reason cannot be a start nor end component in the Job.

Joining data about road conditions in a Pig process

This scenario applies only to Talend products with Big Data.

The Job in this scenario uses two tPigLoad components to read data about the traffic conditions and the related events on given roads from a given Hadoop distribution, joins and filters the data using tPigMap, and writes the results into that Hadoop distribution using two tPigStoreResult.

The Hadoop distribution to be used is keeping the data about traffic situation such as normal or jam and the data about the traffic-related events such as road work, rain and even no event. In this example, the data to be used reads as follows:
1. The traffic situation data stored in the directory `/user/ychen/tpigmap/date&traffic`:

   - 2013-01-11 00:27:53; Bayshore Freeway; jam
   - 2013-02-28 07:01:18; Carpinteria Avenue; jam
   - 2013-01-26 11:27:59; Bayshore Freeway; normal
   - 2013-03-07 20:48:51; South Highway; jam
   - 2013-02-07 07:40:10; Lindbergh Blvd; normal
   - 2013-01-22 17:13:55; Pacific Hwy S; normal
   - 2013-03-17 23:12:26; Carpinteria Avenue; normal
   - 2013-01-15 08:06:53; San Diego Freeway; jam
   - 2013-03-19 15:18:28; Monroe Street; jam
   - 2013-01-20 05:53:12; Newbury Road; normal

2. The event data stored in the directory `/user/ychen/tpigmap/date&event`:

   - 2013-01-11 00:27:53; Bayshore Freeway; road work
   - 2013-02-28 07:01:18; Carpinteria Avenue; rain
   - 2013-01-26 11:27:59; Bayshore Freeway; road work
   - 2013-03-07 20:48:51; South Highway; no event
   - 2013-02-07 07:40:10; Lindbergh Blvd; second-hand market
   - 2013-01-22 17:13:55; Pacific Hwy S; no event
   - 2013-03-17 23:12:26; Carpinteria Avenue; no event
   - 2013-01-15 08:06:53; San Diego Freeway; second-hand market
   - 2013-03-19 15:18:28; Monroe Street; road work
   - 2013-01-20 05:53:12; Newbury Road; no event

For any given moment shown in the timestamps in the data, one row is logged to reflect the traffic situation and another row to reflect the traffic-related event. You need to join the data into one table in order to easily detect how the events on a given road are impacting the traffic.

**Note:**

The data used in this example is a sample with limited size.

To replicate this scenario, ensure that the Studio to be used has the appropriate right to read and write data in that Hadoop distribution and then proceed as follows:

**Linking the components**

**Procedure**

1. In the **Integration** perspective of **Talend Studio**, create an empty Job, named `pigweather` for example, from the **Job Designs** node in the **Repository** tree view. For further information about how to create a Job, see the **Talend Studio User Guide**.

2. Drop two **tPigLoad** components, **tPigMap** and two **tPigStoreResult** onto the workspace. The components can be labelled if needs be. In this scenario, we label the two **tPigLoad** components as `traffic` and `event`, respectively, which load accordingly the traffic data and the related event data. Then we label the two **tPigStoreResult** components as `normal` and `jam`, respectively, which write accordingly the results to the Hadoop distribution to be used. For further information about how to label a component, see the **Talend Studio User Guide**.

3. Right-click the **tPigLoad** component labeled `traffic` to connect it to **tPigMap** using the **Row > Pig combine** link from the contextual menu.

4. Repeat this operation to link the **tPigLoad** component labeled `event` to **tPigMap**, too. As this is the second link created, it becomes automatically the lookup link.

5. Use the **Row > Pig combine** link again to connect **tPigMap** to each of the two **tPigStoreResult** components.
You need to name these links in the dialog box popped up once you select the link type from the contextual menu. In this scenario, we name the link to `tPigStoreResult` labeled `normal as out` and the link to `tPigStoreResult` labeled `jam as reject`.

### Configuring tPigLoad

#### Loading the traffic data

**Procedure**

1. Double-click the `tPigLoad` labeled `traffic` to open its *Component* view.

2. Click the button next to *Edit schema* to open the schema editor.

3. Click the button three times to add three rows and in the *Column* column, rename them as `date, street` and `traffic`, respectively.
4. Click OK to validate these changes.

5. In the Mode area, select the Map/Reduce option, as we need the Studio to connect to a remote Hadoop distribution.

6. In the Distribution list and the Version field, select the Hadoop distribution to be used. In this example, it is Hortonworks Data Platform V1.0.0.

7. In the Load function list, select the PigStorage function to read the source data, as the data is a structured file in human-readable UTF-8 format.

8. In the NameNode URI and the Resource Manager fields, enter the locations of the master node and the Resource Manager of the Hadoop distribution to be used, respectively. If you are using WebHDFS, the location should be webhdfs://masternode:portnumber; WebHDFS with SSL is not supported yet.

9. In the Input file URI field, enter the directory where the data about the traffic situation is stored. As explained earlier, the directory in this example is /user/ychen/tpigmap/date&traffic.

10. In the Field separator field, enter ; depending on the separator used by the source data.

**Loading the event data**

**Procedure**

1. Double-click the tPigLoad labeled event to open its Component view.
2. Click the button next to **Edit schema** to open the schema editor.

3. Click the button three times to add three rows and in the Column column, rename them as **date**, **street** and **event**, respectively.

4. Click **OK** to validate these changes.

5. In the Mode area, select **Map/Reduce**.

   As you have configured the connection to the given Hadoop distribution in that first **tPigLoad** component, **traffic**, this event component reuses that connection and therefore, the corresponding options in the Distribution and the Version lists have been automatically selected.

6. In the Load function field, select the **PigStorage** function to read the source data.

7. In the Input file URI field, enter the directory where the event data is stored. As explained earlier, the directory in this example is "/user/ychen/tpigmap/date&event".

### Configuring **tPigMap**

1. Double-click **tPigMap** to open its Map Editor view.
Creating the output schema

Procedure

1. On the input side (left side) of the Map Editor, each of the two tables represents one of the input flow, the upper one for the main flow and the lower one for the lookup flow.
   On the output side (right side), the two tables represent the output flows that you named as `out1` and `reject` earlier.
   From the main flow table, drop its three columns onto each of the output flow table.
2. From the lookup flow, drop the `event` column onto each of the output flow table.
   Then from the Schema editor view, you can see the schemas of the both sides have been completed and as well, click each table to display its schema in this view.

Setting the mapping conditions

Procedure

1. On the lookup flow table, click the button to open the setting panel in this table.
2. In the Join Model row, select Left Outer Join to ensure that every record of the main flow is included in this join.
3. On the `out1` output flow table, click the button to display the editing field for the filter expression.
4. Enter `'normal'== row1.traffic`
   This allows tPigMap to output only the traffic records reading `normal` in the `out1` flow.
5. On the `reject` output flow table, click the button to open the setting panel.
6. In the Catch Output Reject row, select true to output the traffic records reading `jam` in the `reject` flow.
7. Click Apply, then click OK to validate these changes and accept the propagation prompted by the pop-up dialog box.

Configuring tPigStoreResult

Procedure

1. Double-click the tPigStoreResult labeled `normal` to open its Component view.
2. In the **Result file** field, enter the directory you need to write the result in. In this scenario, it is `/user/ychen/tpigmap/traffic_normal`, which receives the records reading `normal`.

3. Select **Remove result directory if exists** check box.

4. In the **Store function** list, select **PigStorage** to write the records in human-readable UTF-8 format.

5. In the **Field separator** field, enter `;`.

6. Repeat the same operations to configure the **tPigStoreResult** labeled `jam`, but set the directory, in the **Result file** field, as `/user/ychen/tpigmap/traffic_jam`.

### Results

**Note:**

If either of the components does not retrieve its schema from **tPigMap**, a warning icon appears. In this case, click the **Sync columns** button to retrieve the schema from the preceding one and once done, the warning icon disappears.

### Executing the Job

Then you can press **F6** to run this Job.

Once done, verify the results in the Hadoop distribution used.

File: `/user/ychen/tpigmap/traffic_jam/part-r-00000`

From the `traffic_jam` records, you can analyze what event is often going on in the meantime of a traffic jam and from the `traffic_normal` records, how the smooth traffic situation is maintained.
If you need to obtain more details about the Job, it is recommended to use the web console of the Jobtracker provided by the Hadoop distribution you are using.

In JobHistory, you can easily find the execution status of your Pig Job because the name of the Job is automatically created by concatenating the name of the project that contains the Job, the name and version of the Job itself and the label of the first tPigLoad component used in it. The naming convention of a Pig Job in JobHistory is ProjectName_JobNameVersion_FirstComponentName.
tPigReplicate

Performs different operations on the same schema.

The tPigReplicate, used after an input Pig component, duplicates the incoming schema into as many identical output flows as needed.

**tPigReplicate Standard properties**

These properties are used to configure tPigReplicate running in the Standard Job framework.

The Standard tPigReplicate component belongs to the Big Data and the Processing families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available: 
- View schema: choose this option to view the schema only.
- Change to built-in property: choose this option to change the schema to Built-in for local changes.
- Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.
Click Sync columns to retrieve the schema from the previous component connected in the Job. |

| Built-In | You create and store the schema locally for this component only. |
| Repository | You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. |

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |
### Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

### Usage

| Usage rule | This component is not startable (green background); it requires tPigLoad as the input component and expects other Pig components to handle its output flow(s). |

### Prerequisites

| Prerequisites | The Hadoop distribution must be properly installed, so as to guarantee the interaction with Talend Studio. The following list presents MapR related information for example.  
• Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native. For example, the library for Windows is \lib\native\MapRClient.dll in the MapR client jar file. For further information, see the following link from MapR: http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr.  
Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path.  
• Set the -Djava.library.path argument, for example, in the Job Run VM arguments area of the Run/Debug view in the Preferences dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.  
For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using. |

### Connections

| Connections | Outgoing links (from this component to another):  
Row: Pig combine. This link joins all data processes designed in the Job and executes them simultaneously.  
Incoming links (from one component to this one): |
Replicating a flow and sorting two identical flows respectively

This scenario applies only to Talend products with Big Data.

The Job in this scenario uses Pig components to handle names and states loaded from a given HDFS system. It reads and replicates the input flow, then sorts the two identical flows based on name and state respectively, and writes the results back into that HDFS.

Before starting to replicate this Job, ensure that you have the appropriate right to read and write data in the Hadoop distribution to be used and that Pig is properly installed in that distribution.

Linking the components

Procedure

1. In the Integration perspective of Talend Studio, create an empty Job, named Replicate for example, from the Job Designs node in the Repository tree view.
   For further information about how to create a Job, see the Talend Studio User Guide.

2. Drop tPigLoad, tPigReplicate, two tPigSort and two tPigStoreResult onto the workspace.
   The tPigLoad component reads data from the given HDFS system. The sample data used in this scenario reads as follows:

   Andrew Kennedy;Mississippi
   Benjamin Carter;Louisiana
   Benjamin Monroe;West Virginia
   Bill Harrison;Tennessee
   Calvin Grant;Virginia
   Chester Harrison;Rhode Island
   Chester Hoover;Kansas
   Chester Kennedy;Maryland
   Chester Polk;Indiana
   Dwight Nixon;Nevada
The location of the data in this scenario is /user/ychen/raw/Name&State.csv.

3. Connect them using the Row > Pig combine links.

**Configuring tPigLoad**

**Procedure**

1. Double-click tPigLoad to open its Component view.

2. Click the button next to Edit schema to open the schema editor.
3. Click the button twice to add two rows and name them Name and State, respectively.
4. Click OK to validate these changes and accept the propagation prompted by the pop-up dialog box.
5. In the Mode area, select Map/Reduce because the Hadoop to be used in this scenario is installed in a remote machine. Once selecting it, the parameters to be set appear.
6. In the Distribution and the Version lists, select the Hadoop distribution to be used.
7. In the Load function list, select PigStorage
8. In the NameNode URI field and the Resource Manager field, enter the locations of the NameNode and the ResourceManager to be used for Map/Reduce, respectively. If you are using WebHDFS, the location should be webhdfs://masternode:portnumber; WebHDFS with SSL is not supported yet.
9. In the Input file URI field, enter the location of the data to be read from HDFS. In this example, the location is /user/ychen/raw/NameState.csv.
10. In the Field separator field, enter the semicolon ;

Configuring tPigReplicate

Procedure

1. Double-click tPigReplicate to open its Component view.

2. Click the button next to Edit schema to open the schema editor to verify whether its schema is identical with that of its preceding component.
Note:
If this component does not have the same schema of the preceding component, a warning icon appears. In this case, click the Sync columns button to retrieve the schema from the preceding one and once done, the warning icon disappears.

Configuring tPigSort

About this task
Two tPigSort components are used to sort the two identical output flows: one based on the Name column and the other on the State column.

Procedure
1. Double-click the first tPigSort component to open its Component view to define the sorting by name.

2. In the Sort key table, add one row by clicking the button under this table.
3. In the Column column, select Name from the drop-down list and select ASC in the Order column.
4. Double-click the other tPigSort to open its Component view to define the sorting by state.
5. In the **Sort key** table, add one row, then select **Name** from the drop-down list in the **Column** column and select **ASC** in the **Order** column.

### Configuring `tPigStoreResult`

**About this task**

Two `tPigStoreResult` components are used to write each of the sorted data into HDFS.

**Procedure**

1. Double-click either the first `tPigStoreResult` component to open its **Component** view to write the data sorted by name.

   ![Component view](image)

2. In the **Result file** field, enter the directory where the data will be written. This directory will be created if it does not exist. In this scenario, we put `/user/ychen/sort/tPigreplicate/byName.csv`.

3. Select **Remove result directory if exists**.

4. In the **Store function** list, select **PigStorage**.

5. In the **Field separator** field, enter the semicolon `;`

6. Do the same for the other `tPigStoreResult` component but set another directory for the data sorted by state. In this scenario, it is `/user/ychen/sort/tPigreplicate/byState.csv`.

---

---
Executing the Job

About this task
Then you can run this Job.

Procedure
Press F6 to run this Job.

Results
Once done, browse to the locations where the results were written in HDFS.
The following image presents the results sorted by name:

File: /user/ychen/sort/tPigreplicate/byName.csv/part-r-00000

The following image presents the results sorted by state:
If you need to obtain more details about the Job, it is recommended to use the web console of the Jobtracker provided by the Hadoop distribution you are using.

In JobHistory, you can easily find the execution status of your Pig Job because the name of the Job is automatically created by concatenating the name of the project that contains the Job, the name and version of the Job itself and the label of the first PigLoad component used in it. The naming convention of a Pig Job in JobHistory is ProjectName_JobNameVersion_FirstComponentName.
**tPigSort**

Sorts relation based on one or more defined sort keys.

**tPigSort Standard properties**

These properties are used to configure tPigSort running in the Standard Job framework.

The Standard tPigSort component belongs to the Big Data and the Processing families.

The component in this framework is available in all [Talend products with Big Data](https://www.talend.com/products/big-data) and in [Talend Data Fabric](https://www.talend.com/products/data-fabric).

**Basic settings**

| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
- **View schema**: choose this option to view the schema only.  
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.  
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-in</strong>: The schema will be created and stored locally for this component only. Related topic: see <a href="https://www.talend.com/products/big-data">Talend Studio User Guide</a>.</td>
<td></td>
</tr>
<tr>
<td><strong>Repository</strong>: The schema already exists and is stored in the Repository, hence can be reused in various projects and Job designs. Related topic: see <a href="https://www.talend.com/products/big-data">Talend Studio User Guide</a>.</td>
<td></td>
</tr>
<tr>
<td><strong>Sort key</strong></td>
<td>Click the Add button beneath the Sort key table to add one or more lines to specify column and sorting order for each sort key.</td>
</tr>
</tbody>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th>Increase parallelism</th>
<th>Select this check box to set the number of reduce tasks for the MapReduce Jobs</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to gather the Job processing metadata at the Job level as well as at each component level.</td>
</tr>
</tbody>
</table>
### Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

### Usage

| Usage rule | This component is commonly used as intermediate step together with input component and output component. |

### Prerequisites

| Prerequisites | The Hadoop distribution must be properly installed, so as to guarantee the interaction with Talend Studio. The following list presents MapR related information for example.  
- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native. For example, the library for Windows is \lib\native\MapRClient.dll in the MapR client jar file. For further information, see the following link from MapR: http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr. Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path. 
- Set the -Djava.library.path argument, for example, in the Job Run VM arguments area of the Run/Debug view in the Preferences dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR. For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using. |

### Limitation

| Limitation | Knowledge of Pig scripts is required. |

---

**Sorting data in ascending order**

This scenario applies only to Talend products with Big Data.
This scenario describes a three-component Job that sorts rows of data based on one or more sorting conditions and stores the result into a local file.

Setting up the Job

Procedure

1. Drop the following components from the Palette to the design workspace: tPigSort, tPigLoad, tPigStoreResult.
2. Connect tPigLoad to tPigFilterRow using a Row > Pig Combine connection.
3. Connect tPigFilterRow to tPigStoreResult using a Row > Pig Combine connection.

Loading the data

Procedure

1. Double-click tPigLoad to open its Basic settings view.
2. Click the [...] button next to Edit schema to add columns for tPigLoad.
3. Click the [+ button to add Name, Country and Age and click OK to save the setting.
4. Select Local from the Mode area.
5. Fill in the Input filename field with the full path to the input file.
   In this scenario, the input file is CustomerList that contains rows of names, country names and age.
6. Select PigStorage from the Load function list.
7. Leave rest of the settings as they are.

**Setting the sorting condition**

**Procedure**

1. Double-click tPigSort to open its Basic settings view.

2. Click Sync columns to retrieve the schema structure from the preceding component.
3. Click the [+ button beneath the Sort key table to add a new sort key. Select Age from the Column list and select ASC from the Order list.
   This sort key will sort the data in CustomerList in ascending order based on Age.

**Saving the data to a local file**

**Procedure**

1. Double-click tPigStoreResult to open its Basic settings view.
2. Click **Sync columns** to retrieve the schema structure from the preceding component.

3. Select **Remove result directory if exists**.

4. Fill in the **Result file** field with the full path to the result file.
   In this scenario, the result of filter is saved in *Lucky_Customer* file.

5. Select **PigStorage** from the **Store function** list.

6. Leave rest of the settings as they are.

**Executing the Job**

Save your Job and press **F6** to run it.

The *Lucky_Customer* file is generated containing the data in ascending order based on *Age*. 
tPigStoreResult

Stores the result of your Pig Job into a defined data storage space.

**tPigStoreResult Standard properties**

These properties are used to configure tPigStoreResult running in the Standard Job framework.

The Standard tPigStoreResult component belongs to the Big Data and the Processing families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Repository or Built-in.</td>
</tr>
<tr>
<td></td>
<td>The Repository option allows you to reuse the connection properties centrally stored under the Hadoop cluster node of the Repository tree. Once selecting it, the button appears, then you can click it to display the list of the stored properties and from that list, select the properties you need to use. Once done, the appropriate parameters are automatically set. Otherwise, if you select Built-in, you need to manually set each of the parameters.</td>
</tr>
</tbody>
</table>

**Schema and Edit Schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

- **Built-In**: You create and store the schema locally for this component only.

- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

**Use S3 endpoint**

Select this check box to write data into a given Amazon S3 bucket folder.
Once this **Use S3 endpoint** check box is selected, you need to enter the following parameters in the fields that appear:

- **S3 bucket name and folder**: enter the bucket name and its folder in which you need to write data. You need to separate the bucket name and the folder name using a slash (/).
- **Access key** and **Secret key**: enter the authentication information required to connect to the Amazon S3 bucket to be used.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

Note that the format of the S3 file is S3N (S3 Native Filesystem).

### Result folder URI

Select the path to the result file in which data is stored.

### Remove result directory if exists

Select this check box to remove an existing result directory.

**Note:**
This check box is disabled when you select **HCatStorer** from the **Store function** list.

### Store function

Select a store function for data to be stored:

- **PigStorage**: Stores data in UTF-8 format.
- **BinStorage**: Stores data in machine-readable format.
- **PigDump**: Stores data as tuples in human-readable UTF-8 format.
- **HCatStorer**: Stores data in HCatalog managed tables using Pig scripts.
- **HBaseStorage**: Stores data in HBase. Then you need to complete the HBase configuration in the `HBase configuration` area displayed.
- **SequenceFileStorage**: Stores data of the SequenceFile formats. Then you need to complete the configuration of the file to be stored in the **Sequence Storage Configuration** area that appears.
- **RCFilePigStorage**: Stores data of the RCFile format.
- **AvroStorage**: Stores Avro files. For further information about AvroStorage, see Apache’s documentation on [https://cwiki.apache.org/confluence/display/PIG/AvroStorage](https://cwiki.apache.org/confluence/display/PIG/AvroStorage).
- **ParquetStorer**: Stores Parquet files. Then from the **Associate tPigLoad component** list, you need to select the **tPigLoad** component in which the connection to the MapReduce cluster to be used is defined. Then from the **Compression** list that appears, select the compression mode you need to use to handle the PARQUET file. The default mode is **Uncompressed**.
- **Custom**: Stores data using any user-defined store function. To do this, you need to register, in the **Advanced settings** tab view, the jar file containing the function to be used, and then, in the field displayed next to this **Store function** field, specify that function.
Note that when the file format to be used is PARQUET, you might be prompted to find the specific PARQUET jar file and install it into the Studio.

- When the connection mode to Hive is **Embedded**, the Job is run in your local machine and calls this jar installed in the Studio.
- When the connection mode to Hive is **Standalone**, the Job is run in the server hosting Hive and this jar file is sent to the HDFS system of the cluster you are connecting to. Therefore, ensure that you have properly defined the NameNode URI in the corresponding field of the **Basic settings** view.

This jar file can be downloaded from Apache’s site. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

| HCatalog Configuration | Fill the following fields to configure HCatalog managed tables on HDFS (Hadoop distributed file system):

- **Distribution** and **Version**: Select the Hadoop distribution to which you have defined the connection in the tPigLoad component, used in the same Pig process of the active tPigStoreResult.

  If that tPigLoad component connects to a custom Hadoop distribution, you must select **Custom** for this tPigStoreResult component, too. Then the Custom jar table appears, in which, you need to add only the jar files required by the selected **Store function**.

- **HCat metastore**: Enter the location of the HCatalog’s metastore, which is actually Hive’s metastore.

- **Database**: The database in which tables are placed.

- **Table**: The table in which data is stored.

- **Partition filter**: Fill this field with the partition keys to list partitions by filter.

  **Note**: HCatalog Configuration area is enabled only when you select HCatStorer from the **Store function** list. For further information about the usage of HCatalog, see https://cwiki.apache.org/confluence/display/Hive/HCatalog. For further information about the usage of Partition filter, see https://cwiki.apache.org/confluence/display/HCATALOG/Design+Document++Java+APIs+for+HCatalog+DDL+Commands.

| HBase configuration | This area is available to the HBaseStorage function. The parameters to be set are:

- **Distribution** and **Version**: Select the Hadoop distribution to which you have defined the connection in the tPigLoad component, used in the same Pig process of the active tPigStoreResult.

  If that tPigLoad component connects to a custom Hadoop distribution, you must select **Custom** for this tPigStoreResult component, too. Then the Custom jar table appears, in which, you need to add only the jar files required by the selected **Store function**.
Zookeeper quorum:
Type in the name or the URL of the Zookeeper service you use to coordinate the transaction between your Studio and your database. Note that when you configure the Zookeeper, you might need to explicitly set the `zookeeper.znode.parent` property to define the path to the root znode that contains all the znodes created and used by your database; then select the Set Zookeeper znode parent check box to define this property.

Zookeeper client port:
Type in the number of the client listening port of the Zookeeper service you are using.

Table name:
Enter the name of the HBase table you need to store data in. The table must exist in the target HBase.

Row key column:
Select the column used as the row key column of the HBase table.

Store row key column to Hbase column:
Select this check box to make the row key column an HBase column belonging to a specific column family.

Mapping:
Complete this table to map the columns of the table to be used with the schema columns you have defined for the data flow to be processed.

The Column column of this table is automatically filled once you have defined the schema; in the Family name column, enter the column families you want to create or use to group the columns in the Column column. For further information about a column family, see Apache documentation at Column families.

Field separator
Enter character, string or regular expression to separate fields for the transferred data.

**Note:**
This field is enabled only when you select PigStorage from the Store function list.

Sequence Storage configuration
This area is available only to the SequenceFileStorage function. Since a SequenceFile record consists of binary key/value pairs, the parameters to be set are:

Key column:
Select the Key column of a key/value record.

Value column
Select the Value column of a key/value record.

Advanced settings

Register jar
Click the [+] button to add rows to the table and from these rows, browse to the jar files to be added. For example, in order to register a jar file called piggybank.jar, click the [+] button once to add one row, then click this row to display
the [...] browse button, and click this button to browse to the piggybank.jar file following the Select Module wizard.

| HBaseStorage configuration | Add and set more HBaseStorage storer options in this table. The options are:
|                           | loadKey: enter true to store the row key as the first column of the result schema, otherwise, enter false;
|                           | gt: the minimum key value;
|                           | lt: the maximum key value;
|                           | gte: the minimum key value (included);
|                           | lte: the maximum key value (included);
|                           | limit: maxum number of rows to retrieve per region;
|                           | caching: number of rows to cache;
|                           | caster: the converter to use for writing values to HBase. For example, Utf8StorageConverter. |

| Define the jars to register | This check box appears when you are using thHCatStorer, while by default, you can leave it clear as the Studio registers the required jar files automatically. In case any jar file is missing, you can select this check box to display the Register jar for HCatalog table and set the correct path to that missing jar. |

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

### Global Variables

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it. For further information about variables, see **Talend Studio User Guide**. |

### Usage

| Usage rule | This component is always used to end a Pig process and needs tPigLoad at the beginning of that chain to provide data. This component reuses automatically the connection created by the tPigLoad component in that Pig process. Note that if you use Hortonworks Data Platform V2.0.0, the type of the operating system for running the distribution and a Talend Job must be the same, such as Windows or Linux. Otherwise, you have to use Talend Jobserver to execute the Job in the same type of operating system in |

2949
which the Hortonworks Data Platform V2.0.0 distribution you are using is run.

| Prerequisites | The Hadoop distribution must be properly installed, so as to guarantee the interaction with Talend Studio. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native. For example, the library for Windows is \lib\native\MapRClient.dll in the MapR client jar file. For further information, see the following link from MapR: http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr.

Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path.
- Set the -Djava.library.path argument, for example, in the Job Run VM arguments area of the Run/Debug view in the Preferences dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

| Limitation | Knowledge of Pig scripts is required. If you select HCatStorer as the store function, knowledge of HCatLog DDL (HCatLog Data Definition Language, a subset of Hive Data Definition Language) is required. For further information about HCatLog DDL, see https://cwiki.apache.org/confluence/display/Hive/HCatalog.

| Related Scenario |

- Related scenario in which tPigStoreResult uses the Local mode, see Sorting data in ascending order on page 2941 of tPigSort.
- Related scenario in which tPigStoreResult uses the Map/Reduce mode, see Loading an HBase table on page 2916.
**tPivotToColumnsDelimited**

Fine-tunes the selection of data to output.

The tPivotToColumnsDelimited outputs data based on an aggregation operation carried out on a pivot column.

**tPivotToColumnsDelimited Standard properties**

These properties are used to configure tPivotToColumnsDelimited running in the Standard Job framework.

The Standard tPivotToColumnsDelimited component belongs to the File family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pivot column</td>
<td>Select the column from the incoming flow that will be used as pivot for the aggregation operation.</td>
</tr>
<tr>
<td>Aggregation column</td>
<td>Select the column from the incoming flow that contains the data to be aggregated.</td>
</tr>
<tr>
<td>Aggregation function</td>
<td>Select the function to be used in case several values are available for the pivot column.</td>
</tr>
<tr>
<td>Group by</td>
<td>Define the aggregation sets, the values of which will be used for calculations.</td>
</tr>
<tr>
<td>Input Column</td>
<td><strong>Input Column</strong>: Match the input column label with your output columns, in case the output label of the aggregation set needs to be different.</td>
</tr>
<tr>
<td>File Name</td>
<td>Name or path to the file to be processed and/or the variable to be used.</td>
</tr>
<tr>
<td></td>
<td>For further information about how to define and use a variable in a Job, see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Field separator</td>
<td>Character, string or regular expression to separate fields of the output file.</td>
</tr>
<tr>
<td>Row separator</td>
<td>String (ex: <code>\n</code> on Unix) to distinguish rows in the output file.</td>
</tr>
</tbody>
</table>

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE</strong></td>
<td>the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_OUT</strong></td>
<td>the number of rows written to the file by the component. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>ERROR_MESSAGE</strong></td>
<td>the error message generated by the component when an error occurs. This is an After variable</td>
</tr>
</tbody>
</table>
and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press `Ctrl + Space` to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component requires an input flow.</th>
</tr>
</thead>
</table>

| Limitation          | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center ([https://help.talend.com](https://help.talend.com)). |

### Using a pivot column to aggregate data

The following scenario describes a Job that aggregates data from a delimited input file, using a defined pivot column.

### Dropping and linking components

**Procedure**

1. Drop the following component from the **Palette** to the design workspace: **tFileInputDelimited**, **tPivotToColumnsDelimited**.
2. Link the two components using a **Row > Main** connection.

### Configuring the components

**Set the input component**

**Procedure**

1. Double-click the **tFileInputDelimited** component to open its **Basic settings** view.
2. Browse to the input file to fill out the **File Name** field.
   The file to use as input file is made of 3 columns, including: **ID, Question** and the corresponding **Answer**
   
<table>
<thead>
<tr>
<th>Id</th>
<th>Question</th>
<th>Answer</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Name</td>
<td>Juan</td>
</tr>
<tr>
<td>2</td>
<td>Name</td>
<td>Jean</td>
</tr>
<tr>
<td>3</td>
<td>Name</td>
<td>John</td>
</tr>
<tr>
<td>1</td>
<td>Gender</td>
<td>M</td>
</tr>
<tr>
<td>2</td>
<td>Gender</td>
<td>F</td>
</tr>
<tr>
<td>3</td>
<td>Gender</td>
<td>M</td>
</tr>
<tr>
<td>1</td>
<td>Surgery</td>
<td>Yes</td>
</tr>
<tr>
<td>2</td>
<td>Surgery</td>
<td>No</td>
</tr>
<tr>
<td>3</td>
<td>Surgery</td>
<td>Yes</td>
</tr>
<tr>
<td>1</td>
<td>Age</td>
<td>45</td>
</tr>
<tr>
<td>2</td>
<td>Age</td>
<td>23</td>
</tr>
<tr>
<td>3</td>
<td>Age</td>
<td>42</td>
</tr>
</tbody>
</table>

3. Define the **Row** and **Field** separators, in this example, respectively: carriage return and semi-colon
4. As the file contains a header line, define it also.
5. Set the schema describing the three columns: **ID, Questions, Answers**.

**Set the output component**

**Procedure**

1. Double-click the `tPivotToColumnsDelimited` component to open its **Basic settings** view.
2. In the **Pivot column** field, select the pivot column from the input schema. This is often the column presenting most duplicates (pivot aggregation values).

3. In the **Aggregation column** field, select the column from the input schema that should get aggregated.

4. In the **Aggregation function** field, select the function to be used in case duplicates are found out.

5. In the **Group by** table, add an Input column, that will be used to group by the aggregation column.

6. In the **File Name** field, browse to the output file path. And on the **Row** and **Field separator** fields, set the separators for the aggregated output rows and data.

**Saving and executing the Job**

**Procedure**

1. Press Ctrl+S to save your Job.

2. Press F6 or click Run on the Run tab to execute the Job.

<table>
<thead>
<tr>
<th>id</th>
<th>Name</th>
<th>Gender</th>
<th>Surgery</th>
<th>Age</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Mary</td>
<td>M</td>
<td>Yes</td>
<td>45</td>
</tr>
<tr>
<td>2</td>
<td>Jean</td>
<td>M</td>
<td>No</td>
<td>23</td>
</tr>
<tr>
<td>3</td>
<td>John</td>
<td>F</td>
<td>Yes</td>
<td>42</td>
</tr>
</tbody>
</table>

The output file shows the newly aggregated data.
tPOP

Fetches one or more email messages from a server using the POP3 or IMAP protocol.

tPOP uses the POP or IMAP protocol to connect to a specific email server. Then it fetches one or more email messages and writes the recovered information in specified files. Parameters in the Advanced settings view allows you to use filters on your selection.

**tPOP Standard properties**

These properties are used to configure tPOP running in the Standard Job framework.

The Standard tPOP component belongs to the Internet family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Host</strong></td>
<td>IP address of the email server you want to connect to.</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Port number of the email server.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>User authentication data for the email server.</td>
</tr>
<tr>
<td></td>
<td><strong>Username</strong>: enter the username you use to access your email box.</td>
</tr>
<tr>
<td></td>
<td><strong>Password</strong>: enter the password you use to access your email box.</td>
</tr>
<tr>
<td><strong>Output directory</strong></td>
<td>Enter the path to the file in which you want to store the email messages you retrieve from the email server, or click the three-dot button next to the field to browse to the file.</td>
</tr>
<tr>
<td><strong>Filename pattern</strong></td>
<td>Define the syntax of the names of the files that will hold each of the email messages retrieved from the email server, or press Ctrl+Space to display the list of predefined patterns.</td>
</tr>
<tr>
<td><strong>Retrieve all emails?</strong></td>
<td>Select this check box to retrieve all email messages present on the specified server.</td>
</tr>
<tr>
<td><strong>Number of emails to retrieve</strong></td>
<td>Enter the number of email messages you want to retrieve. This field is available only when the Retrieve all emails? check box is cleared.</td>
</tr>
<tr>
<td><strong>Newer email first</strong></td>
<td>Select this check box to retrieve the most recent email messages according to the number specified in the Number of emails to retrieve field, and the email messages will be returned in chronological order. This check box is available only when the Retrieve all emails? check box, which is selected by default, is cleared.</td>
</tr>
<tr>
<td><strong>Delete emails from server</strong></td>
<td>Select this check box if you do not want to keep the retrieved email messages on the server.</td>
</tr>
<tr>
<td>Choose the protocol</td>
<td>From the list, select the protocol to be used to retrieve the email messages from the server. This protocol is the one used by the email server. If you choose the imap protocol, you will be able to select the folder from which you want to retrieve your emails.</td>
</tr>
<tr>
<td>---------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| Use SSL             | Select this check box if your email server uses this protocol for authentication and communication confidentiality.  
**Note:**  
This option is obligatory for users of Gmail. |

**Advanced settings**

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
<th>Select this check box to gather the job processing metadata at a job level as well as at each component level.</th>
</tr>
</thead>
</table>
| Filter                  | Click the plus button to add as many lines as needed to filter email messages and retrieve only a specific selection:  
**Filter item:** select one of the following filter types from the list:  
**From:** email messages are filtered according to the sender email address.  
**To:** email messages are filtered according to the recipient email address.  
**Subject:** email messages are filtered according to the message subject matter.  
**Before date:** email messages are filtered by the sending or receiving date. All messages before the set date are retrieved.  
**After date:** email messages are filtered by the sending or receiving date. All messages after the set date are retrieved.  
**Pattern:** press Ctrl+Space to display the list of available values. Select the value to use for each filter. |

**Filter condition relation**

Select the type of logical relation you want to use to combine the specified filters:  
**and:** the conditions set by the filters are combined together, the research is more restrictive.  
**or:** the conditions set by the filters are independent, the research is large. 

**Global Variables**

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable |

Note:  
For Gmail servers, this option does not work for the pop3 protocol. Select the imap protocol and ensure that the Gmail account is configured to use imap.
and it returns a string. This variable functions only if the
Die on error check box is cleared, if the component has this
check box.

**NB_EMAIL**: the number of emails received. This is an After
variable and it returns an integer.

**CURRENT_FILE**: the current file name. This is a Flow
variable and it returns a string.

**CURRENT_FILEPATH**: the current file path. This is a Flow
variable and it returns a string.

A Flow variable functions during the execution of a
component while an After variable functions after the
execution of the component.

To fill up a field or expression with a variable, press Ctrl +
Space to access the variable list and choose the variable to
use from it.

For further information about variables, see Talend Studio
User Guide.

---

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component does not handle data flow, it can be used alone.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limitation</td>
<td>When the Use SSL check box or the imap protocol is selected, tPOP cannot work with IBM Java 6.</td>
</tr>
</tbody>
</table>

---

### Retrieving a selection of email messages from an email server

This scenario is a one-component Job that retrieves a predefined number of email messages from an
email server.

- Drop the tPOP component from the Palette to the design workspace.
- Double click tPOP to display the Basic settings view and define the component properties.
- Enter the email server IP address and port number in the corresponding fields.
- Enter the username and password for your email account in the corresponding fields. In this
  example, the email server is called Free.
In the **Output directory** field, enter the path to the output directory manually, or click the three-dot button next to the field and browse to the output directory where the email messages retrieved from the email server are to be stored.

In the **Filename pattern** field, define the syntax you want to use to name the output files that will hold the messages retrieved from the email server, or press **Ctrl+Space** to display a list of predefined patterns. The syntax used in this example is the following:

```
TalendDate.get
Date("yyyyMMdd-hhmmss") + "_" + (counter_tPOP_1 + 1) + ".txt".
```

The output files will be stored as .txt files and are defined by date, time and arrival chronological order.

Clear the **Retrieve all emails?** field and in the **Number of emails to retrieve** field, enter the number of email messages you want to retrieve, 10 in this example.

Select the **Delete emails from server** check box to delete the email messages from the email server once they are retrieved and stored locally.

In the **Choose the protocol** field, select the protocol type you want to use. This depends on the protocol used by the email server. Certain email suppliers, like *Gmail*, use both protocols. In this example, the protocol used is *pop3*.

Save your Job and press **F6** to execute it.

The **tPOP** component retrieves the 10 recent messages from the specified email server. In the **tPOP** directory stored locally, a .txt file is created for each retrieved message. Each file holds the metadata of the email message headings (sender's address, recipient's address, subject matter) in addition to the message content.
tPostgresPlusBulkExec

Improves performance during Insert operations to a DB2 database.

The tPostgresPlusBulkExec executes the Insert action on the data provided.

The tPostgresPlusOutputBulk and tPostgresPlusBulkExec components are generally used together as part of a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tPostgresPlusOutputBulkExec component, detailed in a separate section. The advantage of using two separate components is that the data can be transformed before it is loaded in the database.

tPostgresPlusBulkExec Standard properties

These properties are used to configure tPostgresPlusBulkExec running in the Standard Job framework.

The Standard tPostgresPlusBulkExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
<td></td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
<table>
<thead>
<tr>
<th><strong>DB Version</strong></th>
<th>List of database versions.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Host</strong></td>
<td>Database server IP address</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database</td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>Name of the DB schema.</td>
</tr>
</tbody>
</table>

**Username and Password**

DB user authentication data.
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

**Table**

Name of the table to be written. Note that only one table can be written at a time.

**Action on table**

On the table defined, you can perform one of the following operations:

- **None**: No operation is carried out.
- **Drop and create table**: The table is removed and created again.
- **Create table**: The table does not exist and gets created.
- **Create table if not exists**: The table is created if it does not exist.
- **Drop table if exists and create**: The table is removed if it already exists and created again.
- **Clear table**: The table content is deleted.
- **Truncate table**: The table content is deleted. You do not have the possibility to rollback the operation.

**File Name**

Name of the file to be loaded.

**Warning:**
This file is located on the machine specified by the URI in the **Host** field so it should be on the same machine as the database server.

**Schema and Edit Schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate...
the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

<table>
<thead>
<tr>
<th>Built-In:</th>
<th>You create and store the schema locally for this component only.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Repository:</td>
<td>You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually. You can find more details about how to verify default values in retrieved schema in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
</tbody>
</table>

**Advanced settings**

**Action**
Select the action to be carried out
- Bulk insert
- Bulk update
Depending on the action selected, the required information varies.

**Field terminated by**
Character, string or regular expression to separate fields.

**tStat Catcher Statistics**
Select this check box to collect log data at the component level.

**Usage**

**Usage rule**
This dedicated component offers performance and flexibility of DB2 query handling.

**Dynamic settings**
Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.
**Related scenarios**

For `tPostgresPlusBulkExec` related topics, see:

- Inserting transformed data in MySQL database on page 2493.
- Truncating and inserting file data into an Oracle database on page 2700.
tPostgresPlusClose

Closes the transaction committed in the connected PostgresPlus database.

**tPostgresPlusClose Standard properties**

These properties are used to configure tPostgresPlusClose running in the Standard Job framework.

The Standard tPostgresPlusClose component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tPostgresPlusConnection component in the list if more than one connection are planned for the current Job.</td>
</tr>
</tbody>
</table>

### Advanced settings

**tStat Catcher Statistics**

Select this check box to collect log data at the component level.

### Usage

**Usage rule**

This component is to be used along with PostgresPlus components, especially with tPostgresPlusConnection and tPostgresPlusCommit.

**Dynamic settings**

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.
Related scenarios

No scenario is available for the Standard version of this component yet.
**tPostgresPlusCommit**

Commits in one go a global transaction, using a unique connection, instead of doing that on every row or every batch and thus improves performance.

The tPostgresPlusCommit validates the data processed through the Job into the connected DB.

**tPostgresPlusCommit Standard properties**

These properties are used to configure tPostgresPlusCommit running in the Standard Job framework.

The Standard tPostgresPlusCommit component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tPostgresPlusConnection component in the list if more than one connection are planned for the current Job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Warning:**
If you want to use a **Row > Main** connection to link tPostgresPlusCommit to your Job, your data will be committed row by row. In this case, do not select the Close connection check box or your connection will be closed before the end of your first row commit.

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is more commonly used with other tPostgresPlus* components, especially with the tPostgresPlusConnection and tPostgresPlusRollback components.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic settings</td>
<td>Click the [+ ] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned</td>
</tr>
</tbody>
</table>
in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

### Related scenario

For tPostgresPlusCommit related scenario, see Inserting data in mother/daughter tables on page 2437
tPostgresPlusConnection

Opens a connection to the specified database that can then be reused in the subsequent subjob or subjobs.

The tPostgresPlusConnection opens a connection to the database for a current transaction.

### tPostgresPlusConnection Standard properties

These properties are used to configure tPostgresPlusConnection running in the Standard Job framework.

The Standard tPostgresPlusConnection component belongs to the Databases and the ELT families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

#### Basic settings

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td><strong>Property type</strong></td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><strong>DB Version</strong></td>
<td>List of database versions.</td>
</tr>
<tr>
<td><strong>Host</strong></td>
<td>Database server IP address</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database</td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>Exact name of the schema</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>Enter your DB authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td><strong>Use or register a shared DB Connection</strong></td>
<td>Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the <strong>Shared DB Connection Name</strong> field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connections.</td>
</tr>
</tbody>
</table>
connection components from different Job levels that can be either parent or child.

This option is incompatible with the Use dynamic job and Use an independent process to run subjob options of the tRunJob component. Using a shared connection together with a tRunJob component with either of these two options enabled will cause your Job to fail.

**Advanced settings**

**Auto Commit**
Select this check box to commit any changes to the database automatically upon the transaction.

With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component.

Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component.

**tStatCatcher Statistics**
Select this check box to gather the job processing metadata at a Job level as well as at each component level.

**Usage**

**Usage rule**
This component is more commonly used with other tPostgresPlus* components, especially with the tPostgresPlusCommit and tPostgresPlusRollback components.

**Related scenario**

For tPostgresPlusConnection related scenario, see tMysqlConnection on page 2436.
tPostgresPlusInput

Executes a DB query with a strictly defined order which must correspond to the schema definition. Then it passes on the field list to the next component via a Main row link.

The tPostgresPlusInput reads a database and extracts fields based on a query.

**tPostgresPlusInput Standard properties**

These properties are used to configure tPostgresPlusInput running in the Standard Job framework. The Standard tPostgresPlusInput component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>

**Username and Password**

DB user authentication data.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

**Schema and Edit Schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word **line** when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Built-in**: The schema is created and stored locally for this component only. Related topic: see [Talend Studio User Guide](#).

**Repository**: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see [Talend Studio User Guide](#).
### Table name
Name of the table to be read.

### Query type and Query
Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.

### Advanced settings

<td>Action on data</td>
<td>On the data of the table defined, you can perform:</td>
</tr>
<tr>
<td></td>
<td><strong>Insert</strong>: Add new entries to the table. If duplicates are found, Job stops.</td>
</tr>
<tr>
<td></td>
<td><strong>Update</strong>: Make changes to existing entries</td>
</tr>
<tr>
<td></td>
<td><strong>Insert or update</strong>: Insert a new record. If the record with the given reference already exists, an update would be made.</td>
</tr>
</tbody>
</table>
**Update or insert**: Update the record with the given reference. If the record does not exist, a new record would be inserted.

**Delete**: Remove entries corresponding to the input flow.

**Warning:**

*It is necessary to specify at least one column as a primary key on which the Update and Delete operations are based. You can do that by clicking Edit Schema and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the Advanced settings view where you can simultaneously define primary keys for the Update and Delete operations. To do that: Select the Use field options check box and then in the Key in update column, select the check boxes next to the column names you want to use as a base for the Update operation. Do the same in the Key in delete column for the Delete operation.*

---

**Schema and Edit Schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

**Built-In**: You create and store the schema locally for this component only.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

**Die on error**

This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a Row > Rejects link.
### Advanced settings

</tr>
</tbody>
</table>
Global Variables

Global Variables

| NB_LINE | the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer. |
| NB_LINE_UPDATED | the number of rows updated. This is an After variable and it returns an integer. |
| NB_LINE_INSERTED | the number of rows inserted. This is an After variable and it returns an integer. |
| NB_LINE_DELETED | the number of rows deleted. This is an After variable and it returns an integer. |
| NB_LINE_REJECTED | the number of rows rejected. This is an After variable and it returns an integer. |
| QUERY | the query statement processed. This is an After variable and it returns a string. |

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

Usage

Usage rule

This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible.

This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in a PostgresPlus database. It also allows you to create a reject flow using a Row > Rejects link to filter data in error. For an example of tMySqlOutput in use, see Retrieving data in error with a Reject link on page 2485.

Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic...
Related scenarios

For **tPostgresPlusOutput** related topics, see:

- Inserting a column and altering data using **tMysqlOutput** on page 2477.
tPostgresPlusOutputBulk

Prepares the file to be used as parameter in the INSERT query to feed the PostgresPlus database.

The tPostgresPlusOutputBulk writes a file with columns based on the defined delimiter and the PostgresPlus standards.

The tPostgresPlusOutputBulk and tPostgresPlusBulkExec components are generally used together as part of a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tPostgresPlusOutputBulkExec component, detailed in a separate section. The advantage of using two separate components is that the data can be transformed before it is loaded in the database.

tPostgresPlusOutputBulk Standard properties

These properties are used to configure tPostgresPlusOutputBulk running in the Standard Job framework.

The Standard tPostgresPlusOutputBulk component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

Usage

| Usage rule | This component is to be used along with `tPostgresPlusBulkExec` component. Used together they offer gains in performance while feeding a PostgresPlus database. |

Related scenarios

For use cases in relation with `tPostgresPlusOutputBulk`, see the following scenarios:

- Inserting transformed data in MySQL database on page 2493.
- Inserting data in bulk in MySQL database on page 2500.
- Truncating and inserting file data into an Oracle database on page 2700.
tPostgresPlusOutputBulkExec

Improves performance during Insert operations to a PostgresPlus database.

The tPostgresPlusOutputBulkExec executes the Insert action on the data provided.

The tPostgresplusOutputBulk and tPostgresplusBulkExec components are generally used together as part of a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tPostgresPlusOutputBulkExec component.

**tPostgresPlusOutputBulkExec Standard properties**

These properties are used to configure tPostgresPlusOutputBulkExec running in the Standard Job framework.

The Standard tPostgresPlusOutputBulkExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

</tbody>
</table>
password between double quotes and click **OK** to save the settings.

### Table
Name of the table to be written. Note that only one table can be written at a time and that the table must exist for the insert operation to succeed.

### Action on table
On the table defined, you can perform one of the following operations:

- **None**: No operation is carried out.
- **Drop and create a table**: The table is removed and created again.
- **Create a table**: The table does not exist and gets created.
- **Create a table if not exists**: The table is created if it does not exist.
- **Clear a table**: The table content is deleted.

### File Name
Name of the file to be generated and loaded.

**Warning:**
This file is generated on the machine specified by the URI in the **Host** field so it should be on the same machine as the database server.

### Schema and Edit Schema
A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

- **Built-In**: You create and store the schema locally for this component only.

- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is more commonly used with other tPostgresPlus* components, especially with the tPostgresPlusConnection and tPostgresPlusCommit components. |

Dynamic settings

Click the **[+]** button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different...
Related scenarios

For tPostgresPlusRollback related scenario, see Rollback from inserting data in mother/daughter tables on page 2440.
tPostgresPlusRow

Acts on the actual DB structure or on the data (although without handling data), depending on the nature of the query and the database. The SQLBuilder tool helps you write easily your SQL statements.

The tPostgresPlusRow is the specific component for the database query. It executes the SQL query stated onto the specified database. The row suffix means the component implements a flow in the job design although it doesn't provide output.

tPostgresPlusRow Standard properties

These properties are used to configure tPostgresPlusRow running in the Standard Job framework.

The Standard tPostgresPlusRow component belongs to the Databases family.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

| **Use memory saving Mode** | Select this check box to maximize system performance. |
| **Source keys include Null** | Select this check box to allow the source key columns to have Null values. **Warning:** Special attention should be paid to the uniqueness of the source key(s) values when this option is selected. |
Die on error

This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

Advanced settings

End date time details

Specify the time value of the SCD end date time setting in the format of HH:mm:ss. The default value for this field is 12:00:00.

This field appears only when SCD Type 2 is used and Fixed year value is selected for creating the SCD end date.

Debug mode

Select this check box to display each step during processing entries in a database.

tStatCatcher Statistics

Select this check box to collect log data at the component level.

Global Variables

Global Variables

NB_LINE_UPDATED: the number of rows updated. This is an After variable and it returns an integer.

NB_LINE_INSERTED: the number of rows inserted. This is an After variable and it returns an integer.

NB_LINE_REJECTED: the number of rows rejected. This is an After variable and it returns an integer.

ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule

This component is used as Output component. It requires an Input component and Row main link as input.

Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.
The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

| Limitation | This component does not support using SCD type 0 together with other SCD types. |

**Related scenario**

For related topics, see **tMysqlSCD** on page 2519.
tPostgresPlusSCDELT

Addresses Slowly Changing Dimension needs through SQL queries (server-side processing mode), and logs the changes into a dedicated PostgresPlus SCD table.

The tPostgresPlusSCDELT reflects and tracks changes in a dedicated Oracle SCD table.

tPostgresPlusSCDELT Standard properties

These properties are used to configure tPostgresPlusSCDELT running in the Standard Job framework.

The Standard tPostgresPlusSCDELT component belongs to the Business Intelligence and the Databases families.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td></td>
<td>Built-in: No property data stored centrally. Enter properties manually.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file where Properties are stored. The fields that come after are pre-filled in using the fetched data.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

DB Version | List of database versions. |
<table>
<thead>
<tr>
<th><strong>Host</strong></th>
<th>The IP address of the database server.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of database server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database.</td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>Exact name of the schema</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>User authentication data for a dedicated database. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Source table</strong></td>
<td>Name of the input DB2 SCD table.</td>
</tr>
<tr>
<td><strong>Table</strong></td>
<td>Name of the table to be written. Note that only one table can be written at a time</td>
</tr>
</tbody>
</table>
| **Action on table** | Select to perform one of the following operations on the table defined:  
  - **None**: No action carried out on the table.  
  - **Drop and create table**: The table is removed and created again  
  - **Create table**: A new table gets created.  
  - **Create table if not exists**: A table gets created if it does not exist.  
  - **Clear table**: The table content is deleted. You have the possibility to rollback the operation.  
  - **Truncate table**: The table content is deleted. You don't have the possibility to rollback the operation. |
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When creating a Spark Job, avoid the reserved word line when naming the fields. Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
  - **View schema**: choose this option to view the schema only.  
  - **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
  - **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.  
  - **Built-in**: The schema is created and stored locally for this component only. Related topic: see **Talend Studio User Guide**. |
**PostgresPlusSCDELT**

<table>
<thead>
<tr>
<th><strong>Repository</strong></th>
<th>The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide.</th>
</tr>
</thead>
</table>

**Surrogate Key**

Select the surrogate key column from the list.

**Creation**

Select the method to be used for the surrogate key generation.

For more information regarding the creation methods, see SCD management methodology on page 2522.

**Source Keys**

Select one or more columns to be used as keys, to ensure the unicity of incoming data.

**Use SCD Type 1 fields**

Use type 1 if tracking changes is not necessary. SCD Type 1 should be used for typos corrections for example. Select the columns of the schema that will be checked for changes.

**Use SCD Type 2 fields**

Use type 2 if changes need to be tracked down. SCD Type 2 should be used to trace updates for example. Select the columns of the schema that will be checked for changes.

**Start date**

Specify the column that holds the start date for type 2 SCD.

This list is available only when the **Use SCD type 2 fields** option is selected.

**End date**

Specify the column that holds the end date for type 2 SCD.

This list is available only when the **Use SCD type 2 fields** option is selected.

**Log active status**

Select this check box and from the **Active field** drop-down list displayed, select the column that holds the true or false status value, which helps to spot the active record for type 2 SCD.

This option is available only when the **Use SCD type 2 fields** option is selected.

**Log versions**

Select this check box and from the **Version field** drop-down list displayed, select the column that holds the version number of the record for type 2 SCD.

This option is available only when the **Use SCD type 2 fields** option is selected.

**Advanced settings**

**Debug mode**

Select this check box to display each step during processing entries in a database.

**tStatCatcher Statistics**

Select this check box to collect log data at the component level.
Global Variables

**ERROR_MESSAGE:** the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is used as an output component. It requires an input component and Row main link as input.</th>
</tr>

</table>

Dynamic settings

Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see [Reading data from databases through context-based dynamic connections on page 2457](#) and [Reading data from different MySQL databases using dynamically loaded connection parameters on page 491](#). For more information on **Dynamic settings** and context variables, see [Talend Studio User Guide](#).

Related scenario

For related scenarios, see:

- Tracking data changes in a Snowflake table using the tJDBCSCDELT component on page 1859.
- Tracking data changes in a PostgreSQL table using the tPostgreSQLSCDELT component on page 3039.
tPostgresqlBulkExec

Improves performance while carrying out the Insert operations to a Postgresql database.

The tPostgresqlBulkExec executes the Insert action on the data provided.

The tPostgresqlOutputBulk and tPostgresqlBulkExec components are used together to first output the file that will be then used as parameter to execute the SQL query stated. These two steps compose the tPostgresqlOutputBulkExec component, detailed in a separate section. The interest in having two separate elements lies in the fact that it allows transformations to be carried out before the data loading in the database.

tPostgresqlBulkExec Standard properties

These properties are used to configure tPostgresqlBulkExec running in the Standard Job framework.

The Standard tPostgresqlBulkExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository</td>
</tr>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
<table>
<thead>
<tr>
<th>DB Version</th>
<th>List of database versions.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>Database server IP address</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database.</td>
</tr>
<tr>
<td>Schema</td>
<td>Name of the schema.</td>
</tr>
</tbody>
</table>

**Username and Password**

DB user authentication data.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

| Table       | Name of the table to be written. Note that only one table can be written at a time and that the table must exist for the insert operation to succeed. |

**Action on table**

On the table defined, you can perform one of the following operations:

- **None**: No operation is carried out.
- **Drop and create table**: The table is removed and created again.
- **Create table**: The table does not exist and gets created.
- **Create table if not exists**: The table is created if it does not exist.
- **Drop table if exists and create**: The table is removed if it already exists and created again.
- **Clear table**: The table content is deleted.
- **Truncate table**: The table content is deleted. You don’t have the possibility to rollback the operation.

| File Name   | Name of the file to be loaded. |

**Warning:**

This file is located on the machine specified by the URI in the Host field so it should be on the same machine as the database server.

**Schema and Edit Schema**

A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either Built-in or stored remotely in the Repository.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the
Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

**Built-In:** You create and store the schema locally for this component only.

**Repository:** You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

### Advanced settings

**Action on data**

On the data of the table defined, you can perform:

- **Bulk Insert:** Add multiple entries to the table. If duplicates are found, job stops.
- **Bulk Update:** Make simultaneous changes to multiple entries.

**Copy the OID for each row**

Retrieve the ID item for each row.

**Contains a header line with the names of each column in the file**

Specify that the table contains header.

**File type**

Select the type of file being handled.

**Null string**

String displayed to indicate that the value is null.

**Fields terminated by**

Character, string or regular expression to separate fields.

**Escape char**

Character of the row to be escaped.

**Text enclosure**

Character used to enclose text.

**Activate standard_conforming_string**

Activate the variable.

**Force not null for columns**

Define the columns nullability.

- **Force not null:** Select the check box next to the column you want to define as not null.

**tStatCatcher Statistics**

Select this check box to collect log data at the component level.

### Usage

**Usage rule**

This component is to be used along with **tPostgresqlOut putBulk** component. Used together, they can offer gains in performance while feeding a Postgresql database.
Dynamic settings

Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

Related scenarios

For use cases in relation with **tPostgresqlBulkExec**, see the following scenarios:

- Inserting transformed data in MySQL database on page 2493.
- Inserting data in bulk in MySQL database on page 2500.
- Truncating and inserting file data into an Oracle database on page 2700.
tPostgresqlClose

Closes the transaction committed in the connected Postgresql database.

**tPostgresqlClose Standard properties**

These properties are used to configure tPostgresqlClose running in the Standard Job framework.

The Standard tPostgresqlClose component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tPostgresqlConnection component in the list if more than one connection are planned for the current Job.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is to be used along with Postgresql components, especially with tPostgresqlConnection and tPostgresqlCommit. |

| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |
Related scenarios

No scenario is available for the Standard version of this component yet.
**tPostgresqlCommit**

Commits in one go a global transaction, using a unique connection, instead of doing that on every row or every batch and thus improves performance.

The tPostgresqlCommit validates the data processed through the Job into the connected DB

**tPostgresqlCommit Standard properties**

These properties are used to configure tPostgresqlCommit running in the Standard Job framework.

The Standard tPostgresqlCommit component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the <strong>tPostgresqlConnection</strong> component in the list if more than one connection are planned for the current Job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Warning:**

If you want to use a **Row > Main** connection to link tPostgresqlCommit to your Job, your data will be committed row by row. In this case, do not select the **Close connection** check box or your connection will be closed before the end of your first row commit.

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is more commonly used with other tPostgresql* components, especially with the tPostgresqlConnection and tPostgresqlRollback components. |
| Dynamic settings | Click the [*] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned |
in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

**Related scenario**

For tPostgresqlCommit related scenario, see Inserting data in mother/daughter tables on page 2437.
tPostgresqlConnection

Opens a connection to the specified database that can then be reused in the subsequent subjob or subjobs.

The tPostgresqlConnection opens a connection to the database for a current transaction.

**tPostgresqlConnection Standard properties**

These properties are used to configure tPostgresqlConnection running in the Standard Job framework. The Standard tPostgresqlConnection component belongs to the Databases and the ELT families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td><strong>Property type</strong></td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong></td>
</tr>
<tr>
<td><strong>Built-in</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><strong>DB Version</strong></td>
<td>List of database versions.</td>
</tr>
<tr>
<td><strong>Host</strong></td>
<td>Database server IP address</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of database server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database.</td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>Exact name of the schema.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>Database user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td><strong>Use or register a shared DB Connection</strong></td>
<td>Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the <strong>Shared DB Connection Name</strong> field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child.</td>
</tr>
</tbody>
</table>
This option is incompatible with the **Use dynamic job** and **Use an independent process to run subjob** options of the **tRunJob** component. Using a shared connection together with a **tRunJob** component with either of these two options enabled will cause your Job to fail.

This check box is not available when the **Specify a data source alias** check box is selected.

### Specify a data source alias

Select this check box and specify the alias of a data source created on the **Talend Runtime** side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in **Talend Runtime**.

This check box is not visible when the **Use or register a shared DB Connection** check box is selected.

### Data source alias

Enter the alias of the data source created on the **Talend Runtime** side.

This field is available only when the **Specify a data source alias** check box is selected.

### Advanced settings

#### Auto Commit

Select this check box to commit any changes to the database automatically upon the transaction.

With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component.

Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component.

### tStatCatcher Statistics

Select this check box to collect log data at the component level.

#### Usage

**Usage rule**

This component is more commonly used with other **tPostgresql** components, especially with the **tPostgresqlCommit** and **tPostgresqlRollback** components.

### Related scenario

For **tPostgresqlConnection** related scenario, see **tMysqlConnection** on page 2436
tPostgresqlInput

Executes a DB query with a strictly defined order which must correspond to the schema definition. Then it passes on the field list to the next component via a Main row link.
The tPostgresqlInput reads a database and extracts fields based on a query.

**tPostgresqlInput Standard properties**

These properties are used to configure tPostgresqlInput running in the Standard Job framework.
The Standard tPostgresqlInput component belongs to the Databases family.
The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>

<td>Exact name of the schema.</td>
</tr>
</tbody>
</table>

**Username and Password**

DB user authentication data.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

**Schema and Edit Schema**

A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either **Built-in** or stored remotely in the **Repository**.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Built-In**: You create and store the schema locally for this component only.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.
<table>
<thead>
<tr>
<th><strong>Table name</strong></th>

**Advanced settings**

| **Use cursor** | When selected, helps to decide the row set to work with at a time and thus optimize performance. |
| **Trim all the String/Char columns** | Select this check box to remove leading and trailing whitespace from all the String/Char columns. |
| **Trim column** | Remove leading and trailing whitespace from defined columns. |
| **tStat Catcher Statistics** | Select this check box to collect log data at the component level. |

**Global Variables**

<table>
<thead>
<tr>
<th><strong>Global Variables</strong></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE</strong></td>
<td>the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>QUERY</strong></td>
<td>the query statement being processed. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td><strong>ERROR_MESSAGE</strong></td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td><strong>Die on error</strong></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
</tbody>
</table>

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

*For further information about variables, see *Talend Studio User Guide*. |
Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component covers all possible SQL queries for Postgresql databases.</th>
</tr>
</thead>
</table>

Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

Related scenarios

For related scenarios, see:

- Reading data from different MySQL databases using dynamically loaded connection parameters on page 491.
tPostgresqlOutput

Executes the action defined on the table and/or on the data contained in the table, based on the flow incoming from the preceding component in the job.

The tPostgresqlOutput writes, updates, makes changes or suppresses entries in a database.

tPostgresqlOutput Standard properties

These properties are used to configure tPostgresqlOutput running in the Standard Job framework.

The Standard tPostgresqlOutput component belongs to the Databases family.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
<td></td>
</tr>
</tbody>
</table>

Click this icon to open a database connection wizard and store the database connection parameters you set in the component Basic settings view.

For more information about setting up and storing database connection parameters, see Talend Studio User Guide.

Use an existing connection | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. |
Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>DB Version</th>
<th>List of database versions.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>Database server IP address</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database</td>
</tr>
<tr>
<td>Schema</td>
<td>Exact name of the schema.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Table</td>
<td>Name of the table to be written. Note that only one table can be written at a time</td>
</tr>
<tr>
<td>Action on table</td>
<td>On the table defined, you can perform one of the following operations:</td>
</tr>
<tr>
<td></td>
<td><strong>None</strong>: No operation is carried out.</td>
</tr>
<tr>
<td></td>
<td><strong>Drop and create table</strong>: The table is removed and created again.</td>
</tr>
<tr>
<td></td>
<td><strong>Create table</strong>: The table does not exist and gets created.</td>
</tr>
<tr>
<td></td>
<td><strong>Create table if not exists</strong>: The table is created if it does not exist.</td>
</tr>
<tr>
<td></td>
<td><strong>Drop table if exists and create</strong>: The table is removed if already exists and created again.</td>
</tr>
<tr>
<td></td>
<td><strong>Clear table</strong>: The table content is deleted.</td>
</tr>
<tr>
<td></td>
<td><strong>Truncate table</strong>: The table content is deleted. You do not have the possibility to rollback the operation.</td>
</tr>
<tr>
<td>Action on data</td>
<td>On the data of the table defined, you can perform:</td>
</tr>
<tr>
<td></td>
<td><strong>Insert</strong>: Add new entries to the table. If duplicates are found, job stops.</td>
</tr>
<tr>
<td></td>
<td><strong>Update</strong>: Make changes to existing entries</td>
</tr>
<tr>
<td></td>
<td><strong>Insert or update</strong>: Insert a new record. If the record with the given reference already exists, an update would be made.</td>
</tr>
</tbody>
</table>
**Update or insert**: Update the record with the given reference. If the record does not exist, a new record would be inserted.

**Delete**: Remove entries corresponding to the input flow.

**Warning**: It is necessary to specify at least one column as a primary key on which the Update and Delete operations are based. You can do that by clicking **Edit Schema** and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the **Advanced settings** view where you can simultaneously define primary keys for the Update and Delete operations.

To do that: Select the **Use field options** check box and then in the **Key in update column**, select the check boxes next to the column names you want to use as a base for the Update operation. Do the same in the **Key in delete column** for the Delete operation.

### Schema and Edit Schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Built-In**: You create and store the schema locally for this component only.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

### Use spatial options

**Note**: This check box is available when you selected the table creation related option from the **Action on table** list.

Select this check box to use the PostgreSQL database as a spatial database for geographic information system (GIS). When this check box is selected, two other check boxes are displayed:
### Advanced settings

<table>
<thead>
<tr>
<th>Commit every</th>
<th>Enter the number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and, above all, better performance at execution.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Additional Columns</strong></td>
<td>This option is not offered if you create (with or without drop) the DB table. This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing.</td>
</tr>
<tr>
<td><strong>Name:</strong></td>
<td>Type in the name of the schema column to be altered or inserted as new column</td>
</tr>
<tr>
<td><strong>SQL expression:</strong></td>
<td>Type in the SQL statement to be executed in order to alter or insert the relevant column data.</td>
</tr>
<tr>
<td><strong>Position:</strong></td>
<td>Select <strong>Before</strong>, <strong>Replace</strong> or <strong>After</strong> following the action to be performed on the reference column.</td>
</tr>
<tr>
<td><strong>Reference column:</strong></td>
<td>Type in a column of reference that the tDBoutput can use to place or replace the new or altered column.</td>
</tr>
<tr>
<td><strong>Use save point</strong></td>
<td>Select this check box to use savepoints in the transaction. This check box will not be available if you select:</td>
</tr>
<tr>
<td></td>
<td>• the <strong>Die on error</strong> check box in the <strong>Basic settings</strong> view, or</td>
</tr>
<tr>
<td></td>
<td>• the <strong>Use Batch Size</strong> check box in the <strong>Advanced settings</strong> view.</td>
</tr>
</tbody>
</table>

This check box will not work if you:
• type in 0 in the **Commit every** field, or
• select the **Use an existing connection** check box in the **Basic settings** view while the **Auto Commit** mode is activated in the database connection component.

**Use field options**
Select this check box to customize a request, especially when there is double action on data.

**Enable debug mode**
Select this check box to display each step during processing entries in a database.

**Support null in “SQL WHERE” statement**
Select this check box if you want to deal with the Null values contained in a DB table.

**Note:** Ensure that the Nullable check box is selected for the corresponding columns in the schema.

**Use Batch**
Select this check box to activate the batch mode for data processing.

**Note:** This check box is available only when you have selected the **Insert**, the **Update** or the **Delete** option in the **Action on data** field.

**Batch Size**
Specify the number of records to be processed in each batch.
This field appears only when the **Use batch mode** check box is selected.

**tStat Catcher Statistics**
Select this check box to collect log data at the component level.

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_LINE: the number of rows processed. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>NB_LINEUPDATED: the number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>NB_LINEINSERTED: the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>NB_LINEDELETED: the number of rows deleted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>NB_LINE_REJECTED: the number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>QUERY: the query statement processed. This is an After variable and it returns a string.</td>
</tr>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

#### Usage rule

This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible.

This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in a Postgresql database. It also allows you to create a reject flow using a **Row > Rejects** link to filter data in error. For an example of **tMysqlOutput** in use, see *Retrieving data in error with a Reject link* on page 2485.

#### Dynamic settings

Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List box** in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see *Reading data from databases through context-based dynamic connections* on page 2457 and *Reading data from different MySQL databases using dynamically loaded connection parameters* on page 491. For more information on **Dynamic settings** and context variables, see *Talend Studio User Guide*.

#### Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

### Related scenarios

For **tPostgresqlOutput** related topics, see:

- Inserting a column and altering data using **tMysqlOutput** on page 2477.
tPostgresqlOutputBulk

Prepares the file to be used as parameters in the INSERT query to feed the Postgresql database.

The tPostgresqlOutputBulk writes a file with columns based on the defined delimiter and the Postgresql standards.

The tPostgresqlOutputBulk and tPostgresqlBulkExec components are generally used together as part of a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tPostgresqlOutputBulkExec component, detailed in a separate section. The advantage of having two separate steps is that it makes it possible to transform data before it is loaded in the database.

**tPostgresqlOutputBulk Standard properties**

These properties are used to configure tPostgresqlOutputBulk running in the Standard Job framework.

The Standard tPostgresqlOutputBulk component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>

<td></td>
</tr>
<tr>
<td>File Name</td>
<td>Name of the file to be generated.</td>
</tr>
<tr>
<td><strong>Warning:</strong></td>
<td>This file is generated on the local machine or a shared folder on the LAN.</td>
</tr>
<tr>
<td>Append</td>
<td>Select this check box to add the new rows at the end of the file.</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either Built-in or stored remotely in the Repository. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:</td>
</tr>
</tbody>
</table>
- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

<table>
<thead>
<tr>
<th><strong>Built-In</strong></th>
<th>You create and store the schema locally for this component only.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Repository</strong></td>
<td>You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually. You can find more details about how to verify default values in retrieved schema in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
</tbody>
</table>

**Advanced settings**

| **Row separator** | String (ex: "\n" on Unix) to distinguish rows. |
| **Field separator** | Character, string or regular expression to separate fields. |
| **Include header** | Select this check box to include the column header to the file. |
| **Encoding** | Select the encoding from the list or select Custom and define it manually. This field is compulsory for DB data handling. |
| **tStatCatcher Statistics** | Select this check box to collect log data at the component level. |

**Global Variables**

| **Global Variables** | **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer. **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. |

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

**Usage**

| Usage rule | This component is to be used along with tPostgresqlBulkExec component. Used together they offer gains in performance while feeding a Postgresql database. |

**Related scenarios**

For use cases in relation with tPostgresqlOutputBulk, see the following scenarios:

- Inserting transformed data in MySQL database on page 2493.
- Inserting data in bulk in MySQL database on page 2500.
- Truncating and inserting file data into an Oracle database on page 2700.
tPostgresqlOutputBulkExec

Improves performance during Insert operations to a Postgresql database.

The tPostgresqlOutputBulkExec executes the Insert action on the data provided.

The tPostgresqlOutputBulk and tPostgresqlBulkExec components are generally used together as part of a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tPostgresqlOutputBulkExec component.

**tPostgresqlOutputBulkExec Standard properties**

These properties are used to configure tPostgresqlOutputBulkExec running in the Standard Job framework.

The Standard tPostgresqlOutputBulkExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

</thead>
</table>

**Warning:**

This file is generated on the machine specified by the URI in the **Host** field and it should be on the same machine as the database server.

| **Schema and Edit Schema** | A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either **Built-in** or stored remotely in the **Repository**.  
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
- **View schema**: choose this option to view the schema only.  
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window. |
|-------------------------|------------------------------------------------------------------------------------------------|

**Built-In**: You create and store the schema locally for this component only.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.  
When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.
You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

**Advanced settings**

| Action on data                                                                 | On the data of the table defined, you can perform:  
| Bulk Insert: Add multiple entries to the table. If duplicates are found, job stops.  
| Bulk Update: Make simultaneous changes to multiple entries.  |
| Copy the OID for each row | Retrieve the ID item for each row. |
| Contains a header line with the names of each column in the file | Specify that the table contains header. |
| Use local file for copy(for DB server 8.2 or newer) | Select this check box to copy files from the PostgreSQL client machine. |
| Encoding | Select the encoding from the list or select CUSTOM and define it manually. This field is compulsory for DB data handling. |
| File type | Select the type of file being handled. |
| Null string | String displayed to indicate that the value is null. |
| Row separator | String (ex: 
\n\n on Unix) to distinguish rows. |
| Fields terminated by | Character, string or regular expression to separate fields. |
| Escape char | Character of the row to be escaped. |
| Text enclosure | Character used to enclose text. |
| Activate standard_conforming_string | Activate the variable. |
| Force not null for columns | Define the columns nullability.  
| Force not null: Select the check box next to the column you want to define as not null.  |
| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is mainly used when no particular transformation is required on the data to be loaded onto the database. |
| Limitation | The database server must be installed on the same machine where the Studio is installed or where the Job using tPostgresqlOutputBulkExec is deployed, so that the component functions properly. |
Related scenarios

For use cases in relation with `tPostgresqlOutputBulkExec`, see the following scenarios:

- Inserting transformed data in MySQL database on page 2493.
- Inserting data in bulk in MySQL database on page 2500.
- Truncating and inserting file data into an Oracle database on page 2700.
tPostgresqlRollback

Avoids to commit part of a transaction involuntarily.
The tPostgresqlRollback cancels the transaction commit in the connected DB.

tPostgresqlRollback Standard properties

These properties are used to configure tPostgresqlRollback running in the Standard Job framework.
The Standard tPostgresqlRollback component belongs to the Databases family.
The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related
to database settings vary depending on your database type selection. For more information about
dynamic database connectors, see Dynamic database components on page 598.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection... |
Related scenario

For **tPostgresqlRollback** related scenario, see **tMysqlRollback** on page 2502
tPostgresqlRow

Acts on the actual DB structure or on the data (although without handling data), depending on the nature of the query and the database. The SQLBuilder tool helps you write easily your SQL statements.

The tPostgresqlRow is the specific component for the database query. It executes the SQL query stated onto the specified database. The row suffix means the component implements a flow in the job design although it doesn't provide output.

**tPostgresqlRow Standard properties**

These properties are used to configure tPostgresqlRow running in the Standard Job framework.

The Standard tPostgresqlRow component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

</tr>
<tr>
<td><strong>Repository:</strong> Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
<td></td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
<table>
<thead>
<tr>
<th>DB Version</th>
<th>List of database versions.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>Database server IP address.</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>

</tr>
</thead>
</table>
**Usage**

**Usage rule**
This component offers the flexibility benefit of the DB query and covers all possible SQL queries.

**Dynamic settings**
Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

**Related scenarios**

For related topics, see:

- **Combining two flows for selective output** on page 2514
- **Procedure** on page 625.
- **Removing and regenerating a MySQL table index** on page 2508.
tPostgresqlSCD

Addresses Slowly Changing Dimension needs, reading regularly a source of data and logging the changes into a dedicated SCD table.

The tPostgresqlSCD reflects and tracks changes in a dedicated Postgresql SCD table.

### tPostgresqlSCD Standard properties

These properties are used to configure tPostgresqlSCD running in the Standard Job framework.

The Standard tPostgresqlSCD component belongs to the Business Intelligence and the Databases families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

#### Basic settings

<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td><strong>Table</strong></td>
<td>Name of the table to be written. Note that only one table can be written at a time.</td>
</tr>
</tbody>
</table>
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `LINE` when naming the fields. Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
  - **View schema**: choose this option to view the schema only.  
  - **Change to built-in property**: choose this option to change the schema to Built-in for local changes.  
  - **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.  
  - **Built-in**: The schema is created and stored locally for this component only. Related topic: see *Talend Studio User Guide*.  
  - **Repository**: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see *Talend Studio User Guide*.  
| **SCD Editor** | The SCD editor helps to build and configure the data flow for slowly changing dimension outputs. For more information, see SCD management methodology on page 2522. |
| **Use memory saving Mode** | Select this check box to maximize system performance. |
| **Source keys include Null** | Select this check box to allow the source key columns to have Null values. **Warning:** Special attention should be paid to the uniqueness of the source key(s) values when this option is selected. |
### Die on error

This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

### Advanced settings

#### End date time details

Specify the time value of the SCD end date time setting in the format of `HH:mm:ss`. The default value for this field is `12:00:00`.

This field appears only when SCD Type 2 is used and **Fixed year value** is selected for creating the SCD end date.

#### Debug mode

Select this check box to display each step during processing entries in a database.

#### tStatCatcher Statistics

Select this check box to collect log data at the component level.

### Global Variables

**Global Variables**

- **NB_LINE_UPDATED**: the number of rows updated. This is an After variable and it returns an integer.
- **NB_LINE_INSERTED**: the number of rows inserted. This is an After variable and it returns an integer.
- **NB_LINE_REJECTED**: the number of rows rejected. This is an After variable and it returns an integer.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

### Usage

**Usage rule**

This component is used as Output component. It requires an Input component and Row main link as input.

**Dynamic settings**

Click the `[+]` button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.
The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

| Limitation | This component does not support using SCD type 0 together with other SCD types. |

### Related scenario

For related topics, see **tMysqlSCD** on page 2519.
**tPostgresqlSCDELT**

Addresses Slowly Changing Dimension needs through SQL queries (server-side processing mode), and logs the changes into a dedicated DB2 SCD table.

The tPostgresqlSCDELT reflects and tracks changes in a dedicated Postgresql SCD table.

**tPostgresqlSCDELT Standard properties**

These properties are used to configure tPostgresqlSCDELT running in the Standard Job framework.

The Standard tPostgresqlSCDELT component belongs to the Business Intelligence and the Databases families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>

Usage

Usage rule

This component is used as an output component. It requires an input component and Row main link as input.

Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Tracking data changes in a PostgreSQL table using the tPostgreSQLSCDELT component

This scenario describes a Job that captures the employee data changes in a PostgreSQL table using SCD (Slowly Changing Dimensions) Type 1 and Type 2 methods implemented by the tPostgreSQLSCDELT component, and writes both the current and historical data in a SCD dimension table.

The input data contains various employee details including name, role, salary, and another id column is added to help ensuring the unicity of the input data.

At first, the following employee data is inserted to a new Snowflake table.

```
#id;name;role;salary
1;Mark Smith;tester;11000.00
2;Thomas Johnson;developer;12000.00
3;Teddy Brown;tester;13000.00
```
Later, the table is updated with the following renewed employee data.

<table>
<thead>
<tr>
<th>#</th>
<th>id; name; role; salary</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Mark Smith; tester; 15000.00</td>
</tr>
<tr>
<td>2</td>
<td>Thomas Johnson; tester; 18000.00</td>
</tr>
<tr>
<td>3</td>
<td>Teddy Brown; writer; 17000.00</td>
</tr>
<tr>
<td>4</td>
<td>John Clinton; developer; 19000.00</td>
</tr>
</tbody>
</table>

You can see the role of Thomas Johnson is changed from developer to tester, the role of Teddy Brown is changed from tester to writer, and his salary is raised from 13000.00 to 17000.00. Besides, a new employee record with id 4 is inserted. In this scenario,

- the existing name and role data will be overwritten by the new data, so SCD Type 1 method will be performed on them, and
- the full history of the salary data will be retained, and a new record with the changed data will be always created and the previous record will be closed, so SCD Type 2 method will be performed on it.

For more information about SCD types, see SCD management methodology on page 2522.

**Creating a Job for tracking data changes in a PostgreSQL table using tPostgresqlSCDELT**

**Procedure**

1. Create a new Job and add a `tPostgreSQLConnection` component, a `tCreateTable` component, two `tFixedFlowInput` components, two `tPostgreSQL Input` components, two `tPostgreSQLOutput` components, two `tPostgreSQLSCDELT` components, and two `tLogRow` components to the Job.
2. Link the first tFixedFlowInput component to the first tPostgreSQLOutput component using a Row > Main connection.

3. Do the same to link the first tPostgreSQLInput component to the first tLogRow component, the second tFixedFlowInput component to the second tPostgreSQLOutput component, and the second tPostgreSQLInput component to the second tLogRow component.

4. Link the tPostgreSQLConnection component to the tCreateTable component using a Trigger > On Subjob Ok connection.

5. Do the same to link the first tFixedFlowInput component to the first tPostgreSQLSCDELT component, the first tPostgreSQLSCDELT component to the first tPostgreSQLInput component, the first tPostgreSQLInput component to the second tFixedFlowInput component, the second tFixedFlowInput component to the second tPostgreSQLSCDELT component, the second tPostgreSQLSCDELT component to the second tPostgreSQLInput component.

Opening a connection to a PostgreSQL database
Procedure

1. Double-click the `tPostgreSQLConnection` component to open its **Basic settings** view.

2. In the **Host**, **Port**, **Database**, **Schema**, **Username**, and **Password** fields, enter the information required for the connection to the PostgreSQL database.

**Creating a PostgreSQL table**

Procedure

1. Double-click the `tCreateTable` component to open its **Basic settings** view.

2. In the **Basic settings** view, and from the **Database Type** list, select Postgresql for this scenario.

3. Select the **Use an existing connection** check box and from the **Component List** drop-down list displayed, select the connection component to reuse the connection created by it, `tPostgreSQLConnection_1` in this example.

4. In the **Table Name** field, fill in a name for the table to be created, `employee` in this example.

5. From the **Table Action** list, select **Create table if not exist**.

6. Click the `[...]` button next to **Edit schema** and in the pop-up dialog box, define the schema by adding four columns: `id` of Integer type as the primary key, `name` and `role` of String type, and `salary` of Double type.

   In the end, a new table `employee` is created to store the employee data.
Inserting data into the new PostgreSQL table

Procedure

1. Double-click the first tFixedFlowInput component to open its Basic settings view.
2. Click the [...] button next to Edit schema and in the pop-up dialog box, define the schema by adding four columns: id of Integer type as the primary key, name and role of String type, and salary of Double type.

3. Click OK to save the schema changes. In the pop-up dialog box, click Yes to propagate the schema to the next component.
4. Select Use Inline Content in the Mode area. Then in the Content field displayed, enter the following employee data to be inserted.

<table>
<thead>
<tr>
<th>Id</th>
<th>Name</th>
<th>Role</th>
<th>Salary</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Mark Smith</td>
<td>tester</td>
<td>11000.00</td>
</tr>
<tr>
<td>2</td>
<td>Thomas Johnson</td>
<td>developer</td>
<td>12000.00</td>
</tr>
<tr>
<td>3</td>
<td>Teddy Brown</td>
<td>tester</td>
<td>13000.00</td>
</tr>
</tbody>
</table>

5. Double-click the first tPostgreSQLOutput component to open its Basic settings view.

6. Select the Use an existing connection check box and from the Component List drop-down list displayed, and then select the connection component to reuse the connection created by it, tPostgreSQLConnection_1 in this example.

7. In the Table field, enter the name of the table into which the employee data will be written, employee in this example.

8. In the Action on table drop-down list, select Default.

9. In the Action on data drop-down list, select Insert to insert the employee data transferred from the first tFixedFlowInput component.

10. Click the [...] button next to Edit schema to check whether the schema of tPostgreSQLOutput is the same as the schema of tFixedFlowInput.

Tracking inserted data changes and writing the changes into a SCD dimension table

Procedure

1. Double-click the first tPostgreSQLSCDELT component to open its Basic settings view.
2. Select the **Use an existing connection** check box and from the **Component List** drop-down list displayed, select the connection component to reuse the connection created by it, `tPostgreSQLConnection_1` in this example.

3. In the **Source table** field, enter the name of the table whose data changes will be captured, `employee` in this example.

4. In the **Table** field, enter the name of the SCD dimension table that will store both the current and historical employee data, `employee_scd` in this example.

5. Select **Create table** from the **Action on table** drop-down list to create the SCD dimension table.

6. Click the [...] button next to **Edit schema** and in the pop-up dialog box, define the schema by adding nine columns: `sk` (as the primary key) and `id` of Integer type, `name` and `role` of String type, `salary` of Double type, `start_date` and `end_date` of Date type with the Date Pattern `dd-MM-yyyy`, and `active_status` and `version` of Integer type. When done, click **OK** to save the changes and close the dialog box.
7. From the Surrogate key drop-down list, select the name of the column that will be used as the primary key of the SCD dimension table, sk in this example.

8. Select DB sequence from the Creation drop-down list and in the Sequence field displayed, enter the name of the PostgreSQL sequence used to generate the surrogate key for the SCD Type 2 method, employee_sequence in this example.

9. Click the [+]-button below the Source keys table to add a new line, and click the Name cell and select the key column of the source table from the drop-down list, id in this example.

10. Select the Use SCD type 1 fields check box, click the [+]-button below the SCD type 1 fields table twice to add two lines. Then click each cell and from the drop-down list, select the column on which the SCD Type 1 method will be performed. In this example, they are name and role.

11. Select the Use SCD type 2 fields check box, click the [+]-button below the SCD type 2 fields table to add a line. Then click the cell and select the column on which the SCD Type 2 method will be performed. In this example, it is salary.

12. From the Start date and End date drop-down lists, select the columns used to hold the start date and end date values for the SCD Type 2 method respectively, start_date and end_date in this example.

13. Select the Log active status check box and from the Active field drop-down list displayed, select the column used to hold the active status value for the SCD Type 2 method, which helps identify the active records, active_status in this example.

14. Select the Log versions check box and from the Version field drop-down list, select the column used to hold the version number of the records for the SCD Type 2 method, version in this example.

Retrieving the data updates from the SCD dimension table

Procedure

1. Double-click the first tPostgreSQLInput component to open its Basic settings view.
2. Select the Use an existing connection check box and from the Component List drop-down list displayed, select the connection component to reuse the connection created by it, tPostgreSQLConnection_1 in this example.

3. Click the [...] button next to Edit schema and in the pop-up dialog box, define the schema by adding nine columns: sk and id of Integer type as the primary key, name and role of String type, salary of Double type, start_date and end_date of Date type with the Date Pattern yyyy-MM-dd, and active_status and version of Integer type. When done, click OK to save the changes and close the dialog box.

The schema of the first tPostgreSQLInput component is the same as the schema of the tPostgreSQLSCDELT1 component, you can just copy and paste it.

4. In the Query field, enter the SQL command used to retrieve data from the SCD dimension table, select * from employee_scd in this example.

5. In the Table Name field, enter the name of the SCD dimension table where you will retrieve the data updates, employee_scd in this example.

6. Double-click the first tLogRow component and in the Mode area on its Basic settings view, select Table to display the retrieved data in a table.

**Updating data in the Postgresql table**

**Procedure**

1. Double-click the second tFixedFlowInput component to open its Basic settings view.

2. Click the [...] button next to Edit schema and in the pop-up dialog box, define the schema by adding four columns: id of Integer type as the primary key, name and role of String type, and salary of Double type.

   This schema is the same as the schema of the first tFixedFlowInput component, you can just copy and paste it.

3. Click OK to save the schema changes. In the pop-up dialog box, click Yes to propagate the schema to the next component.

4. Select Use Inline Content in the Mode area. Then in the Content field displayed, enter the following employee data to update the existing data.

   1;Mark Smith;tester;15000.00
   2;Thomas Johnson;tester;18000.00
   3;Teddy Brown;writer;17000.00
   4;John Clinton;developer;19000.00

5. Double-click the second tPostgreSQLOutput component to open its Basic settings view.

6. Select the Use an existing connection check box and from the Component List drop-down list displayed, select the connection component to reuse the connection created by it, tPostgreSQLConnection_1 in this example.

7. In the Table field, enter the name of the table, in which the data will be updated, employee in this example.

8. Select Default from the Action on table drop-down list.

9. Select Insert or update from the Action on data drop-down list.

**Tracking data update changes and writing the changes into the SCD dimension table**
Procedure
1. Double-click the second `tPostgreSQLSCDELT` component to open its Basic settings view.
2. Repeat 2 on page 3045 through 14 on page 3046 in the procedure Tracking inserted data changes and writing the changes into a SCD dimension table on page 3044 to configure the second `tPostgreSQLSCDELT` component.

Retrieve the data update changes from the SCD dimension table

Procedure
1. Double-click the second `tPostgreSQLInput` component to open its Basic settings view.
2. Repeat 2 on page 3047 through 5 on page 3047 in the procedure Retrieving the data updates from the SCD dimension table on page 3046 to configure the second `tPostgreSQLInput` component.
3. Double-click the second `tLogRow` component and in the Mode area on its Basic settings view, select Table to display the retrieved data in a table.

Executing the Job to track data changes in a PostgreSQL table using `tPostgreSQLSCDELT`

Procedure
1. Press Ctrl + S to save the Job.
2. Press F6 to execute the Job.

As shown above, the old role developer for Thomas Johnson is overwritten directly by the new role tester because SCD Type 1 is performed on the role column, and a new record with the surrogate key value set to 26 is created for Teddy Brown's salary update from 13000.00 to 17000.00 because SCD Type 2 is performed on the salary column.
Related Scenario

For related topics, see tMysqlSCD on page 2519 and Tracking data changes in a Snowflake table using the tJDBCSCDELT component on page 1859.
tPostjob

Triggers a task required after the execution of a Job

tPostjob starts the execution of a postjob.

**tPostjob Standard properties**

These properties are used to configure tPostjob running in the Standard Job framework.
The Standard tPostjob component belongs to the Orchestration family.
The component in this framework is available in all Talend products.

**Global Variables**

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

**Usage**

| Usage rule | tPostjob is a start component and can only be used with an iterate connection to the next component. |

**Connections**

| Connections | Outgoing links (from this component to another): Trigger: On Component Ok. Incoming links (from one component to this one): Trigger: Synchronize; Parallelize. For further information regarding connections, see Talend Studio User Guide. |

For more information about the tPostjob component, see Talend Studio User Guide.

**Related scenarios**

- Handling files before and after the execution of a data Job on page 3051
- Creating a bar chart from the input data on page 344
**tPrejob**

Triggers a task required for the execution of a Job
tPrejob starts the execution of a prejob.

**tPrejob Standard properties**

These properties are used to configure tPrejob running in the Standard Job framework.
The Standard tPrejob component belongs to the Orchestration family.
The component in this framework is available in all Talend products.

**Global Variables**

| Global Variables |  
| --- | --- |
|  
| ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>tPrejob is a start component and can only be used with an iterate connection to the next component.</th>
</tr>
</thead>
</table>
| Connections | Outgoing links (from this component to another):

Incoming links (from one component to this one): 
**Trigger:** Synchronize; Parallelize. 
For further information regarding connections, see Talend Studio User Guide. |

For more information about the tPrejob component, see Talend Studio User Guide.

**Handling files before and after the execution of a data Job**

In this scenario, a pre-job and a post-job are added to the Job describes in Finding duplicate files between two folders on page 1097 to handle files before and after the execution of the main data Job.
As described in the above-mentioned scenario, when the main data Job is started, it creates a temporary text file to store the fetched filenames. If the specified temporary file already exists, it will be overwritten.

To prevent possible loss of data, the pre-job saves a backup copy of the specified file by renaming it, if it exists, before the main Job is executed.

After the execution of the main data Job, the post-job deletes the temporary file created by the data Job and restores the backup file, if any.

Adding and linking components

Procedure

1. With the main Job open on the design workspace, add a `tPrejob`, a `tPostjob`, a `tFileDelete`, and two `tFileCopy` components to the Job.

2. Link the `tPrejob` component to the first `tFileCopy` component using a `Trigger > On Component Ok` connection to build the pre-job.

3. Link the `tPostjob` component the `tFileDelete` component using a `Trigger > On Component Ok` connection, and link the `tFileDelete` component to the other `tFileCopy` component to build the post-job.

4. Label the relevant components to better identify their roles.

Configuring the components

Configuring the pre-job

About this task

In the pre-job, the `tPrejob` component does not have any parameter or property to configure; it just triggers the `tFileCopy` component before the execution of the main data Job to rename the specified file, so all the required configurations are made in the `tFileCopy` component.

Procedure

1. Double-click the `tFileCopy` component to show its Basic settings view.
2. Fill the **File Name** field with the path and filename of the temporary text file to be renamed, `D:/temp/tempdata.csv` in this example.

3. In the **Destination directory** field, specify or browse to destination directory. In this example, we will save the backup copy in the same directory, `D:/temp/`.

4. Select the **Rename** check box, and specify the new filename in the **Destination filename** field, `backup-tempdata.csv`. Leave the other parameters as they are.

**Configuring the post-job**

**About this task**

In the post-job, the **tPostjob** component does not have any parameter or property to configure; it just triggers the **tFileDelete** component after the execution of the main data Job to delete the temporary file used to store the fetched filenames, which then triggers the **tFileCopy** component to name the backup file back to its original name.

**Procedure**

1. In the **Basic settings** view of the **tFileDelete** component, fill the **File Name** field with the path and filename of the temporary file to be deleted, `D:/temp/tempdata.csv` in this example, and leave the other parameters as they are.

2. Double-click the **tFileCopy** component to open its **Basic settings** view.
3. Fill the **File Name** field with the path and filename of the backup file, `D:/temp/backup-tempdata.csv` in this example.

4. In the **Destination directory** field, specify or browse to destination directory, `D:/temp/` in this example.

5. Select the **Rename** check box, and specify the original name of the temporary file in the **Destination filename** field, `tempdata.csv`.

6. Select the **Remove source file** check box to remove the backup file after the renaming action. Leave the other parameters as they are.

**Expected execution result**

If the specified temporary file exists, its data will be saved in a backup copy before the main data Job is executed and restored thereafter.

If the temporary file does not exist, the two **tFileCopy** components will generate an error, but this does not prevent the main data Job from being executed.

For the execution result of the main data Job, see *Finding duplicate files between two folders* on page 1097.

**Related scenario**

For another scenario that uses the **tPrejob** component, see *Creating a bar chart from the input data* on page 344.
tPubSubOutput

Receives messages serialized into byte arrays by its preceding component and issues these messages into a given PubSub service.
tRedshiftBulkExec

Loads data into Amazon Redshift from Amazon S3, Amazon EMR cluster, Amazon DynamoDB, or remote hosts.

The tRedshiftOutputBulk and tRedshiftBulkExec components can be used together in a two step process to load data to Amazon Redshift from a delimited/CSV file on Amazon S3. In the first step, a delimited/CSV file is generated. In the second step, this file is used in the INSERT statement used to feed Amazon Redshift. These two steps are fused together in the tRedshiftOutputBulkExec component. The advantage of using two separate steps is that the data can be transformed before it is loaded to Amazon Redshift.

tRedshiftBulkExec loads data into an Amazon Redshift table from an Amazon DynamoDB table or from data files located in an Amazon S3 bucket, an Amazon EMR cluster, or a remote host that is accessed using an SSH connection.

**tRedshiftBulkExec Standard properties**

These properties are used to configure tRedshiftBulkExec running in the Standard Job framework. The Standard tRedshiftBulkExec component belongs to the Cloud and the Databases families. The component in this framework is available in all Talend products.

*Note:* This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td></td>
</tr>
<tr>
<td>Property Type</td>
<td>Either <strong>Built-In</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Built-In:</strong> No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Repository:</strong> Select the repository file where the</td>
</tr>
<tr>
<td></td>
<td>properties are stored.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td>Host</td>
<td>Type in the IP address or hostname of the database server.</td>
</tr>
<tr>
<td>Port</td>
<td>Type in the listening port number of the database server.</td>
</tr>
<tr>
<td>Database</td>
<td>Type in the name of the database.</td>
</tr>
<tr>

<td>Type in the name of the schema.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>Type in the database user authentication data.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the</td>
</tr>
</tbody>
</table>
**Additional JDBC Parameters**

Specify additional JDBC properties for the connection you are creating. The properties are separated by ampersand & and each property is a key-value pair. For example, `ssl=true & sslfactory=com.amazon.redshift.ssl.NonValidatingFactory`, which means the connection will be created using SSL.

**Table Name**

Specify the name of the table to be written. Note that only one table can be written at a time.

**Action on table**

On the table defined, you can perform one of the following operations:

- **None**: No operation is carried out.
- **Drop and create table**: The table is removed and created again.
- **Create table**: The table does not exist and gets created.
- **Create table if not exists**: The table is created if it does not exist.
- **Drop table if exists and create**: The table is removed if it already exists and created again.
- **Clear table**: The table content is deleted. You have the possibility to rollback the operation.

**Schema and Edit schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

- **Built-In**: You create and store the schema locally for this component only.
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Data source type**

Select the location of the source data to be loaded.

- **S3**: load data from a file in an Amazon S3 bucket.
- **EMR**: load data from an Amazon EMR cluster.
- **DynamoDB**: load data from an existing DynamoDB table.
- **Remote host**: load data from one or more remote hosts, such as Amazon Elastic Compute Cloud (Amazon EC2) instances or other computers.
For more information, see Data Sources.

<table>
<thead>
<tr>
<th><strong>Access Key/S3 Access Key</strong></th>
<th>Specify the Access Key ID that uniquely identifies an AWS account. For how to get your Access Key and Access Secret Key, visit Getting Your AWS Access Keys.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Secret Key/S3 Secret Key</strong></td>
<td>Specify the Secret Access Key, constituting the security credentials in combination with the Access Key. To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
</tbody>
</table>

**Note:** This field appears as **S3 Access Key** if you select Remote host from the Data source type drop-down list.

<table>
<thead>
<tr>

<th>Specify the name of the Amazon S3 bucket in which the file is located. This field is available only when S3 or Remote host is selected from the Data source type drop-down list.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Note:</strong> This field appears as <strong>Bucket</strong> if you select S3 from the Data source type drop-down list; it appears as <strong>S3 bucket</strong> if you select Remote host from the drop-down list.</td>
</tr>
<tr>
<td></td>
<td>The bucket and the Redshift database to be used must be in the same region on Amazon. This could avoid the S3ServiceException errors known to Amazon. For further information about these errors, see S3ServiceException Errors.</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Cluster id</strong></td>
<td>Specify the ID of the cluster that stores the data to be loaded. This field is available only when EMR is selected from the Data source type drop-down list.</td>
</tr>
</tbody>
</table>

| **Key** | Specify the path to the file that contains the data to be loaded. This field is available only when S3 is selected from the Data source type drop-down list. |
### HDFS path
Specify the HDFS file path that references the data file.
This field is available only when **EMR** is selected from the **Data source type** drop-down list.

### Table
Specify the name of the DynamoDB table that contains the data to be loaded.
This field is available only when **DynamoDB** is selected from the **Data source type** drop-down list.

### Read ratio
Specify the percentage of the DynamoDB table’s provisioned throughput to use for the data load.
This field is available only when **DynamoDB** is selected from the **Data source type** drop-down list.

### SSH manifest file
Specify the object key for the SSH manifest file that provides the information used to open SSH connections and execute remote commands.
This field is available only when **Remote host** is selected from the **Data source type** drop-down list.

### Advanced settings

<table>
<thead>
<tr>
<th><strong>File type</strong></th>
<th>Select the type of the file that contains the data to be loaded.</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Delimited file or CSV: a delimited/CSV file.</td>
<td></td>
</tr>
<tr>

<td></td>
</tr>
<tr>
<td>• AVRO: an Avro file.</td>
<td></td>
</tr>
<tr>
<td>• Fixed width: a fixed-width file.</td>
<td></td>
</tr>
<tr>
<td>This list is available when <strong>S3</strong>, <strong>EMR</strong>, or <strong>Remote host</strong> is selected from the <strong>Data source type</strong> drop-down list.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Fields terminated by</strong></th>
<th>Enter the character used to separate fields.</th>
</tr>
</thead>
<tbody>
<tr>
<td>This field is available only when <strong>Delimited file or CSV</strong> is selected from the <strong>File type</strong> list.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Enclosed by</strong></th>
<th>Select the character in which the fields are enclosed.</th>
</tr>
</thead>
<tbody>
<tr>
<td>This list is available only when <strong>Delimited file or CSV</strong> is selected from the <strong>File type</strong> list.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>JSON mapping</strong></th>
<th>Specify how to map the data elements in the source file to the columns in the target table on Amazon Redshift. The valid values are:</th>
</tr>
</thead>
<tbody>
<tr>
<td>• auto: Map the data by matching object keys or names in the source name/value pairs for a JSON file or field names in the Avro schema for an Avro file to the names of columns in the target table. The argument is case-sensitive and must be enclosed in double quotation marks.</td>
<td></td>
</tr>
<tr>
<td>• s3://jsonpaths_file: Map the data using the named JSONPaths file. The parameter must be an Amazon S3 object key that is enclosed in double quotation marks and explicitly references a single file, for example, s3://mybucket/jsonpaths.txt. For more information, see Data Format Parameters.</td>
<td></td>
</tr>
</tbody>
</table>
### Fixed width mapping
Enter a string that specifies a user-defined column label and column width between double quotation marks. The format of the string is:

```
ColumnLabel1:ColumnWidth1,ColumnLabel2:ColumnWidth2,...
```

Note that the column label in the string has no relation to the table column name and it can be either a text string or an integer. The order of the label/width pairs must match the order of the table columns exactly.

This field is available only when **Fixed width** is selected from the **File type** list.

### Compressed by
Select this check box and from the list displayed select the compression type of the source file.

This check box is available when **S3**, **EMR**, or **Remote host** is selected from the **Data source type** drop-down list.

### Decrypt
Select this check box if the file is encrypted using Amazon S3 client-side encryption. In the **Encryption key** field displayed, specify the encryption key used to encrypt the file. Note that only a base64 encoded AES 128-bit or AES 256-bit envelope key is supported. For more information, see Loading Encrypted Data Files from Amazon S3.

This check box is available when **S3**, **EMR**, or **Remote host** is selected from the **Data source type** drop-down list.

### Encoding
Select the encoding type of the data to be loaded from the list.

This list is available when **S3**, **EMR**, or **Remote host** is selected from the **Data source type** drop-down list.

### Date format
Select one of the following items from the list to specify the date format in the source data:

- **NONE**: No date format is specified.
- **PATTERN**: Select this item and specify the date format in the field displayed. The default date format is YYYY-MM-DD.
- **AUTO**: Select this item if you want Amazon Redshift to recognize and convert automatically the date format.

### Time format
Select one of the following items from the list to specify the time format in the source data:

- **NONE**: No time format is specified.
- **PATTERN**: Select this item and specify the time format in the field displayed. The default time format is YYYY-MM-DD HH:MI:SS.
- **AUTO**: Select this item if you want Amazon Redshift to recognize and convert automatically the time format.
- **EPOCHSECS**: Select this item if the source data is represented as epoch time, the number of seconds since Jan 1, 1970 00:00:00 UTC.
- **EPOCHMILLISECS**: Select this item if the source data is represented as epoch time, the number of milliseconds since Jan 1, 1970 00:00:00 UTC.
### Settings

Click the [+] button below the table to specify more parameters for loading the data.

- **Parameter:** Click the cell and select a parameter from the drop-down list.
- **Value:** Set the value for the corresponding parameter. Note that you cannot set the value for a parameter (such as `IGNOREBLANKLINES`) that does not need a value.

For more information about the parameters, see [http://docs.aws.amazon.com/redshift/latest/dg/r_COPY.html](http://docs.aws.amazon.com/redshift/latest/dg/r_COPY.html).

### JDBC url

Select a way to access to an Amazon Redshift database from the **JDBC url** drop-down list.

- **Standard:** Use the standard way to access the Redshift database.
- **SSO:** Use the IAM Single Sign-ON (SSO) authentication way to access the Redshift Database. Ensure that the IAM role added to your Redshift cluster has appropriate access rights and permissions to this cluster. You can ask the administrator of your AWS services for more details.

This property is available only when **Use an existing connection** check box is not selected from the **Basic settings**. Once enabled, the **Username** and **Password** properties in **Basic settings** will be hidden, and then you should go to **Additional JDBC Parameters** to specify parameters for access.

### tStatCatcher Statistics

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Note:

This component does not support the **Row > Reject** link.

### Global Variables

**Global Variables**

**ERROR_MESSAGE:** the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.
**Usage**

| Usage rule | The tRedshiftBulkExec component supports loading data to Amazon Redshift from a delimited/CSV, JSON, or fixed-width file on Amazon S3, but the tRedshiftOutputBulk component now only supports generating and uploading a delimited/CSV file to Amazon S3. When you need to load data from a JSON or fixed-width file, you can use the tFileOutputJSON or tFileOutputPositional component together with the tS3Put component instead of using the tRedshiftOutputBulk component to generate and upload the file to Amazon S3. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |

**Loading/unloading data from/to Amazon S3**

This scenario describes a Job that generates a delimited file and uploads the file to S3, loads data from the file on S3 to Redshift and displays the data on the console, then unloads the data from Redshift to files on S3 per slice of the Redshift cluster, and finally lists and gets the unloaded files on S3.
Prerequisites:

The following context variables have been created and saved in the Repository tree view. For more information about context variables, see Talend Studio User Guide.

- **redshift_host**: the connection endpoint URL of the Redshift cluster.
- **redshift_port**: the listening port number of the database server.
- **redshift_database**: the name of the database.
- **redshift_username**: the username for the database authentication.
- **redshift_password**: the password for the database authentication.
- **redshift_schema**: the name of the schema.
- **s3_accesskey**: the access key for accessing Amazon S3.
- **s3_secretkey**: the secret key for accessing Amazon S3.
- **s3_bucket**: the name of the Amazon S3 bucket.
Adding and linking components

Procedure
1. Create a new Job and apply all context variables listed above to the new Job.
2. Add the following components by typing their names in the design workspace or dropping them from the Palette: a tRowGenerator component, a tRedshiftOutputBulk component, a tRedshiftBulkExec component, a tRedshiftInput component, a tLogRow component, a tRedshiftUnload component, a tS3List component, and a tS3Get component.
3. Link tRowGenerator to tRedshiftOutputBulk using a Row > Main connection.
4. Do the same to link tRedshiftInput to tLogRow.
5. Link tS3List to tS3Get using a Row > Iterate connection.
6. Link tRowGenerator to tRedshiftBulkExec using a Trigger > On Subjob Ok connection.
7. Do the same to link tRedshiftBulkExec to tRedshiftInput, link tRedshiftInput to tRedshiftUnload, link tRedshiftUnload to tS3List.

Configuring the components

Preparing a file and uploading the file to S3

Procedure
1. Double-click tRowGenerator to open its RowGenerator Editor.
2. Click the \([+]\) button to add two columns: \textit{ID} of Integer type and \textit{Name} of String type.

3. Click the cell in the \textbf{Functions} column and select a function from the list for each column. In this example, select \texttt{Numeric.sequence} to generate sequence numbers for the \textit{ID} column and select \texttt{TalendDataGenerator.getFirstName} to generate random first names for the \textit{Name} column.

4. In the \textbf{Number of Rows for RowGenerator} field, enter the number of data rows to generate. In this example, it is 20.

5. Click \textbf{OK} to close the schema editor and accept the propagation prompted by the pop-up dialog box.

6. Double-click \texttt{tRedshiftOutputBulk} to open its \textbf{Basic settings} view on the \textbf{Component} tab.

7. In the \textbf{Data file path at local} field, specify the local path for the file to be generated. In this example, it is \texttt{E:/Redshift/redshift_bulk.txt}.

8. In the \textbf{Access Key} field, press \texttt{Ctrl + Space} and from the list select \texttt{context.s3_accesskey} to fill in this field.

   Do the same to fill the \textbf{Secret Key} field with \texttt{context.s3_accesskey} and the \textbf{Bucket} field with \texttt{context.s3_bucket}.

9. In the \textbf{Key} field, enter a new name for the file to be generated after being uploaded on Amazon S3. In this example, it is \texttt{person_load}. 
Loading data from the file on S3 to Redshift

Procedure

1. Double-click `tRedshiftBulkExec` to open its Basic settings view on the Component tab.

2. In the Host field, press Ctrl + Space and from the list select `context.redshift_host` to fill in this field. Do the same to fill:
   - the Port field with `context.redshift_port`,
   - the Database field with `context.redshift_database`,
   - the Schema field with `context.redshift_schema`,
   - the Username field with `context.redshift_username`,
   - the Password field with `context.redshift_password`,
   - the Access Key field with `context.s3_accesskey`,
   - the Secret Key field with `context.s3_secretkey`, and
   - the Bucket field with `context.s3_bucket`.

3. In the Table Name field, enter the name of the table to be written. In this example, it is `person`.

4. From the Action on table list, select Drop table if exists and create.

5. In the Key field, enter the name of the file on Amazon S3 to be loaded. In this example, it is `person_load`.

6. Click the [...] button next to Edit schema and in the pop-up window define the schema by adding two columns: ID of Integer type and Name of String type.
Retrieving data from the table on Redshift

Procedure

1. Double-click tRedshiftInput to open its Basic settings view on the Component tab.

2. Fill the Host, Port, Database, Schema, Username, and Password fields with their corresponding context variables.

3. In the Table Name field, enter the name of the table to be read. In this example, it is person.

4. Click the [...] button next to Edit schema and in the pop-up window define the schema by adding two columns: ID of Integer type and Name of String type.

5. In the Query field, enter the following SQL statement based on which the data are retrieved.

   "SELECT * FROM" + context.redshift_schema + "person ORDER BY \"ID\"

6. Double-click tLogRow to open its Basic settings view on the Component tab.
7. In the Mode area, select Table (print values in cells of a table) for a better display of the result.

**Unloading data from Redshift to file(s) on S3**

**Procedure**

1. Double-click tRedshiftUnload to open its Basic settings view on the Component tab.

2. Fill the Host, Port, Database, Schema, Username, and Password fields with their corresponding context variables. Fill the Access Key, Secret Key, and Bucket fields also with their corresponding context variables.

3. In the Table Name field, enter the name of the table from which the data will be read. In this example, it is person.

4. Click the [...] button next to Edit schema and in the pop-up window define the schema by adding two columns: ID of Integer type and Name of String type.

5. In the Query field, enter the following SQL statement based on which the result will be unloaded.

   "SELECT * FROM person"

6. In the Key prefix field, enter the name prefix for the unload files. In this example, it is person_unload_.

   

3068
Retrieving files unloaded to Amazon S3

**Procedure**

1. Double-click **tS3List** to open its **Basic settings** view on the **Component** tab.

![tS3List](Image)

   - **Connection**: Use an existing connection
   - **Access Key**: `context.s3_accesskey`
   - **Secret Key**: `context.s3_secretkey`
   - **Region**: US Standard
   - **List all buckets objects**
   - **Bucket name**: `context.s3_bucket`
   - **Key prefix**: `person_unload_`

2. Fill the **Access Key** and **Secret Key** fields with their corresponding context variables.

3. From the **Region** list, select the AWS region where the unload files are created. In this example, it is **US Standard**.

4. Clear the **List all buckets objects** check box, and click the **[+]** button under the table displayed to add one row.

   - Fill in the **Bucket name** column with the name of the bucket in which the unload files are created. In this example, it is the context variable `context.s3_bucket`.
   - Fill in the **Key prefix** column with the name prefix for the unload files. In this example, it is `person_unload_`.

5. Double-click **tS3Get** to open its **Basic settings** view on the **Component** tab.

![tS3Get](Image)

   - **Connection**: Use an existing connection
   - **Access Key**: `context.s3_accesskey`
   - **Secret Key**: `context.s3_secretkey`
   - **Region**: US Standard
   - **Encrypt**
   - **Bucket**: `context.s3_bucket`
   - **File**: `E:/Redshift/` + ((String)globalMap.get("tS3List_1_CURRENT_KEY"))

6. Fill the **Access Key** field and **Secret Key** field with their corresponding context variables.

7. From the **Region** list, select the AWS region where the unload files are created. In this example, it is **US Standard**.
8. In the **Bucket** field, enter the name of the bucket in which the unload files are created. In this example, it is the context variable `context.s3_bucket`.

   In the **Key** field, enter the name of the unload files by pressing **Ctrl + Space** and from the list selecting the global variable `(((String)globalMap.get("tS3List_1_CURRENT_KEY")))`.

9. In the **File** field, enter the local path where the unload files are saved. In this example, it is `"E:/Redshift/ + ((String)globalMap.get("tS3List_1_CURRENT_KEY"))`.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl + S** to save the Job.
2. Execute the Job by pressing **F6** or clicking **Run** on the **Run** tab.

   ![Image of saved and executed job](image)

   ![Image of S3 bucket contents](image)
As shown above, the generated data is written into the local file `redshift_bulk.txt`, the file is uploaded on S3 with the new name `person_load`, and then the data is loaded from the file on S3 to the table `person` in Redshift and displayed on the console. After that, the data is unloaded from the table `person` in Redshift to two files `person_unload_0000_part_00` and `person_unload_0001_part_00` on S3 per slice of the Redshift cluster, and finally the unloaded files on S3 are listed and retrieved in the local folder.
tRedshiftClose

Closes the transaction committed in the connected DB.

This component is used together with tRedShiftConnection and tRedshiftCommit to ensure the integrity of the transaction performed into the database.

tRedshiftClose Standard properties

These properties are used to configure tRedshiftClose running in the Standard Job framework.

The Standard tRedshiftClose component belongs to the Cloud and the Databases families.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tRedshiftConnection component in the list if more than one connection are planned for the current Job.</td>
</tr>
</tbody>
</table>

Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

Usage

| Usage rule | This component is to be used along with Amazon Redshift components, especially with tRedshiftConnection and tRedshiftCommit. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic |
Related scenario

For a related scenario, see Handling data with Redshift on page 3083.
tRedshiftCommit

Provides gain in performance.

Using a unique connection, this component commits in one go a global transaction instead of doing that on every row or every batch.

tRedshiftCommit validates the data processed through the Job into the connected database.

**tRedshiftCommit Standard properties**

These properties are used to configure tRedshiftCommit running in the Standard Job framework.

The Standard tRedshiftCommit component belongs to the Cloud and the Databases families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tRedshiftConnection component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Warning:**

*If you want to use a Row > Main connection to link tRedshiftCommit to your Job, your data will be committed row by row. In this case, do not select the Close Connection check box or your connection will be closed before the end of your first row commit.*

**Advanced settings**

| tStat Catcher Statistics                              | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule                                             | This component is more commonly used with other tRedshift* components, especially with the tRedshiftConnection and tRedshiftRollback components. |
| Dynamic settings                                       | Click the [*] button to add a row in the table and fill the Code field with a context variable to choose your database. |
connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

**Related scenario**

For a similar scenario, see Inserting data in mother/daughter tables on page 2437.
tRedshiftConnection

Opens a connection to the specified database that can then be reused in the subsequent subjob or subjobs.

tRedshiftConnection opens a connection to the database for a current transaction.

**tRedshiftConnection Standard properties**

These properties are used to configure tRedshiftConnection running in the Standard Job framework.

The Standard tRedshiftConnection component belongs to the Cloud and the Databases families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Host</td>
<td>Host name or IP address of DB server.</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database. The bucket and the Redshift database to be used must be in the same region on Amazon. This could avoid the S3ServiceException errors known to Amazon. For further information about these errors, see S3ServiceException Errors.</td>
</tr>
<tr>
<td>Schema</td>
<td>Name of the schema.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Additional JDBC Parameters</td>
<td>Specify additional JDBC properties for the connection you are creating. The properties are separated by ampersand &amp; and each property is a key-value pair. For example, ssl=true &amp; ssifactory=com.amazon.redshift.ssl.NonValidatingFactory, which means the connection will be created using SSL.</td>
</tr>
</tbody>
</table>
### Use or register a shared DB Connection

Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the **Shared DB Connection Name** field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child.

This option is incompatible with the **Use dynamic job** and **Use an independent process to run subjob** options of the tRunJob component. Using a shared connection together with a tRunJob component with either of these two options enabled will cause your Job to fail.

### Advanced settings

#### Log file

Specify the path to the log file to be generated during the data retrieval process.

Note that if the logging information needs to be saved and this component reuses the connection created by a tRedshiftConnection component, you must specify the property `loglevel=1/2/3` in the **Additional JDBC Parameters** field of the tRedshiftConnection component.

There is no limitation on the size of the log file. If the specified log file already exists, it will be overwritten.

#### Logging level

Select a logging level from the drop-down list to specify which kind of events will be logged in the log file.

#### Auto Commit

Select this check box to commit any changes to the database automatically upon the transaction.

With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component.

Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component.

#### JDBC url

Select a way to access to an Amazon Redshift database from the JDBC url drop-down list.

- **Standard**: Use the standard way to access the Redshift database.
- **SSO**: Use the IAM Single Sign-On (SSO) authentication way to access the Redshift Database. Ensure that the IAM role added to your Redshift cluster has appropriate access rights and permissions to this cluster. You can ask the administrator of your AWS services for more details.
This property is available only when **Use an existing connection** check box is not selected from the **Basic settings**. Once enabled, the **Username** and **Password** properties in **Basic settings** will be hidden, and then you should go to **Additional JDBC Parameters** to specify parameters for access.

<table>

</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Limitation</th>
<th>Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the <strong>Install</strong> button on the <strong>Component</strong> tab view. You can also find out and add all missing JARs easily on the <strong>Modules</strong> tab in the <strong>Integration</strong> perspective of your studio. You can find more details about how to install external modules in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</th>
</tr>
</thead>
</table>

**Related scenario**

For a related scenario, see **Handling data with Redshift** on page 3083.
tRedshiftInput

Reads data from a database and extracts fields based on a query so that you may apply changes to the extracted data.

tRedshiftInput executes a DB query with a strictly defined order which must correspond to the schema definition. Then it passes on the field list to the next component through a **Main row** link.

**tRedshiftInput Standard properties**

These properties are used to configure tRedshiftInput running in the Standard Job framework.

The Standard tRedshiftInput component belongs to the Cloud and the Databases families.

The component in this framework is available in all **Talend products**.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see **Dynamic database components on page 598**.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-in</strong>: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><img src="image" alt="Icon" /></td>
<td>Click this icon to open a database connection wizard and store the database connection parameters you set in the component <strong>Basic settings</strong> view. For more information about setting up and storing database connection parameters, see <strong>Talend Studio User Guide</strong>.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>Host</th>
<th>Hostname or IP address of the database server.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>Listening port number of the database server.</td>

**Advanced settings**

| Log file | Specify the path to the log file to be generated during the data retrieval process. Note that if the logging information needs to be saved and this component reuses the connection created by a tRedshiftConnection component, you must specify the property loglevel=1/2/3 in the Additional JDBC Parameters field of the tRedshiftConnection component. There is no limitation on the size of the log file. If the specified log file already exists, it will be overwritten. |
| Logging level | Select a logging level from the drop-down list to specify which kind of events will be logged in the log file. |
| Use cursor | Select this check box to help to decide the row set to work with at a time and thus optimize performance. |
| Trim all the String/Char columns | Select this check box to remove leading and trailing whitespace from all the String/Char columns. |
| Trim column | Remove leading and trailing whitespace from defined columns. |
| JDBC url | Select a way to access to an Amazon Redshift database from the JDBC url drop-down list.  
• **Standard**: Use the standard way to access the Redshift database.  
• **SSO**: Use the IAM Single Sign-ON (SSO) authentication way to access the Redshift Database. Ensure that the IAM role added to your Redshift cluster has appropriate access rights and permissions to this cluster. You can ask the administrator of your AWS services for more details.  
This property is available only when Use an existing connection check box is not selected from the Basic settings. Once enabled, the Username and Password properties in Basic settings will be hidden, and then you should go to Additional JDBC Parameters to specify parameters for access. |
| tStatCatcher Statistics | Select this check box to collect log data at the component level. |
### Global Variables

| Global Variables | **NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.  
**QUERY**: the query statement being processed. This is a Flow variable and it returns a string.  
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
For further information about variables, see [Talend Studio User Guide](https://help.talend.com). |

### Usage

| Usage rule | This component covers all possible SQL queries for Amazon Redshift databases. |

| Dynamic settings | Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.  
The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.  
For examples on using dynamic parameters, see [Reading data from databases through context-based dynamic connections](https://help.talend.com) on page 2457 and [Reading data from different MySQL databases using dynamically loaded connection parameters](https://help.talend.com) on page 491. For more information on **Dynamic settings** and context variables, see [Talend Studio User Guide](https://help.talend.com). |

| Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center ([https://help.talend.com](https://help.talend.com)). |
Handling data with Redshift

This scenario describes a Job that writes the personal information into Redshift, then retrieves the information in Redshift and displays it on the console.

![Diagram of components]

The scenario requires the following six components:

- **tRedshiftConnection**: opens a connection to Redshift.
- **tFixedFlowInput**: defines the personal information data structure, and sends the data to the next component.
- **tRedshiftOutput**: writes the data it receives from the preceding component into Redshift.
- **tRedshiftInput**: reads the data from Redshift.
- **tLogRow**: displays the data it receives from the preceding component on the console.
- **tRedshiftClose**: closes the connection to Redshift.

**Dropping and linking the components**

**Procedure**

1. Drop the six components listed previously from the Palette onto the design workspace.
2. Connect **tFixedFlowInput** to **tRedshiftOutput** using a **Row > Main** connection.
3. Connect **tRedshiftInput** to **tLogRow** also using a **Row > Main** connection.
4. Connect **tRedshiftConnection** to **tFixedFlowInput** using a **Trigger > OnSubjobOk** connection.
5. Connect **tFixedFlowInput** to **tRedshiftInput** and **tRedshiftInput** to **tRedshiftClose** also using a **Trigger > OnSubjobOk** connection.
Configuring the components

Opening a connection to Redshift

Procedure

1. Double-click `tRedshiftConnection` to open its Basic settings view.
   
   ![tRedshiftConnection_1](image)

   2. Select Built-In from the Property Type drop-down list.

      In the Host, Port, Database, Schema, Username, and Password fields, enter the information required for the connection to Redshift.

3. In Advanced settings view, select Auto Commit check box to commit any changes to Redshift upon each transaction.

Defining the input data

Procedure

1. Double-click `tFixedFlowInput` to open its Basic settings view.

   ![tFixedFlowInput_1](image)

   2. Click the [...] button next to Edit schema to open the schema editor.
3. In the schema editor, click the [+] button to add three columns: id of the integer type, name of the string type, and age of the integer type.

4. Click OK to validate the changes and accept the propagation prompted by the pop-up [Propagate] dialog box.

5. In the Mode area, select Use Inline Content (delimited file) and enter the following personal information in the Content field.

   1;Arthur;16
   2;Ford;18
   3;Jackson;17

Writing the data into Redshift

Procedure

1. Double-click tRedshiftOutput to open its Basic settings view.

2. Select the Use an existing connection check box, and then select the connection you have already configured for tRedshiftConnection from the Component List drop-down list.

3. In the Table field, enter or browse to the table into which you want to write the data, redshiftexample in this scenario.

4. Select Drop table if exists and create from the Action on table drop-down list, and select Insert from the Action on data drop-down list.

5. Click Sync columns to retrieve the schema from the preceding component tFixedFlowInput.
Retrieving the data from Redshift

Procedure
1. Double-click **tRedshiftInput** to open its **Basic settings** view.

   ![tRedshiftInput](image)

2. Select the **Use an existing connection** check box, and then select the connection you have already configured for **tRedshiftConnection** from the **Component List** drop-down list.
3. Click the [...] button next to **Edit schema** to open the schema editor.
4. In the schema editor, click the [+ ] button to add three columns: **id** of the integer type, **name** of the string type, and **age** of the integer type. The data structure is same as the structure you have defined for **tFixedFlowInput**.
5. Click **OK** to validate the changes and accept the propagation prompted by the pop-up [Propagate] dialog box.
6. In the **Table Name** field, enter or browse to the table into which you write the data, **redshiftexample** in this scenario.
7. Click the **Guess Query** button to generate the query. The **Query** field will be filled with the automatically generated query.

Displaying the defined information

Procedure
1. Double-click **tLogRow** to open its **Basic settings** view.

   ![tLogRow](image)

2. In the **Mode** area, select **Table (print values in cells of a table)** for a better view of the results.
Closing the connection to Redshift

Procedure

1. Double-click tRedshiftClose to open its **Basic settings** view.

   ![tRedshiftClose](image)

2. From **Component List**, select the connection you have already configured for tRedshiftConnection.

Saving and executing the Job

Procedure

1. Press Ctrl+S to save the Job.
2. Press F6 to execute the Job.

   ```
   Starting job DOC3191_tRedshift_S01 at 17:18 19/03/2014
   [statistics] connecting to socket on port 3000
   [statistics] connected
<table>
<thead>
<tr>
<th>tLogRow_1</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
</tr>
<tr>
<td>---</td>
</tr>
<tr>
<td>1</td>
</tr>
<tr>
<td>2</td>
</tr>
<tr>
<td>3</td>
</tr>
</tbody>
</table>
   [statistics] disconnected
   Job DOC3191_tRedshift_S01 ended at 17:18 19/03/2014. [exit code=0]
   ```

The personal information is written to the specified target Redshift database, and then the data is retrieved from the database and displayed on the console.
tRedshiftOutput

Writes, updates, modifies or deletes the data in a database.
tRedshiftOutput executes the action defined on the table and/or on the data of a table, according to the input flow from the previous component.

tRedshiftOutput Standard properties

These properties are used to configure tRedshiftOutput running in the Standard Job framework.
The Standard tRedshiftOutput component belongs to the Cloud and the Databases families.
The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
<td></td>
</tr>
<tr>
<td><img src="image" alt="Icon" /> Click this icon to open a database connection wizard and store the database connection parameters you set in the component Basic settings view.</td>
<td></td>
</tr>
<tr>
<td>Click this icon to open a database connection wizard and store the database connection parameters you set in the component Basic settings view. For more information about setting up and storing database connection parameters, see Talend Studio User Guide.</td>
<td></td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
### tRedshiftOutput

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see [Talend Studio User Guide](#).

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>Hostname or IP address of the database server.</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of the database server.</td>
</tr>
<tr>
<td>Database</td>
<td>Database name. The bucket and the Redshift database to be used must be in the same region on Amazon. This could avoid the S3ServiceException errors known to Amazon. For further information about these errors, see <a href="#">S3ServiceException Errors</a>.</td>
</tr>
<tr>
<td>Schema</td>
<td>Exact name of the schema.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>Database user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Additional JDBC Parameters</td>
<td>Specify additional JDBC properties for the connection you are creating. The properties are separated by ampersand &amp; and each property is a key-value pair. For example, <code>ssl=true &amp; sslfactory=com.amazon.redshift.ssl.NonValidatingFactory</code>, which means the connection will be created using SSL.</td>
</tr>
<tr>
<td>Table</td>
<td>Name of the table to which the data will be written. Note that only one table can be written at a time.</td>
</tr>
<tr>
<td>Action on table</td>
<td>On the table defined, you can perform one of the following operations:</td>
</tr>
<tr>
<td></td>
<td><strong>None:</strong> No operation is carried out.</td>
</tr>
<tr>
<td></td>
<td><strong>Drop and create a table:</strong> The table is removed and created again.</td>
</tr>
<tr>
<td></td>
<td><strong>Create a table:</strong> The table does not exist and gets created.</td>
</tr>
<tr>
<td></td>
<td><strong>Create a table if not exists:</strong> The table is created if it does not exist.</td>
</tr>
<tr>
<td></td>
<td><strong>Drop a table if exists and create:</strong> The table is removed if already exists and created again.</td>
</tr>
<tr>
<td></td>
<td><strong>Clear a table:</strong> The table content is deleted.</td>
</tr>
</tbody>
</table>
### Action on data

On the data of the table defined, you can perform:

- **Insert**: Add new entries to the table. If duplicates are found, the operation will stop.

- **Update**: Make changes to existing entries.

- **Insert or update**: Insert a new record. If the record with the given reference already exists, an update would be made.

- **Update or insert**: Update the record with the given reference. If the record does not exist, a new record would be inserted.

- **Delete**: Remove entries corresponding to the input flow.

**Warning:**

It is necessary to specify at least one column as a primary key on which the **Update** and **Delete** operations are based. You can do that by clicking **Edit Schema** and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the **Advanced settings** view where you can simultaneously define primary keys for the **Update** and **Delete** operations. To do that: Select the **Use field options** check box and then in the **Key in update column**, select the check boxes next to the column names you want to use as a base for the **Update** operation. Do the same in the **Key in delete column** for the **Delete** operation.

### Schema and Edit Schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

- **Built-In**: You create and store the schema locally for this component only.

- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

  When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

  You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

  Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

  - **View schema**: choose this option to view the schema only.
  - **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
  - **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No upon**
Completion and choose this schema metadata again in the Repository Content window.

| **Die on error** | This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error through a Row > Rejects link. |

**Advanced settings**

| **Extend Insert** | Select this check box to carry out a bulk insert of a defined set of lines instead of inserting lines one by one. The gain in system performance is considerable.  
**Number of rows per insert:** enter the number of rows to be inserted per operation. Note that the higher the value specified, the lower performance levels shall be due to the increase in memory demands.  
Amazon Redshift requires the number of rows per insert to be less than 32767. For this reason, if the number you enter exceeds this maximum limit, the Studio automatically resets this number below this limit. |

| **Use Batch** | Select this check box to activate the batch mode for data processing.  
**Note:** This check box is available only when you have selected the Update or the Delete option in the Action on data field. |

| **Batch Size** | Specify the number of records to be processed in each batch.  
This field appears only when the Use batch mode check box is selected. |

| **Commit every** | Enter the number of rows to be completed before committing batches of rows together into the database. This option ensures transaction quality (but not rollback) and, above all, better performance at execution. |

| **Additional Columns** | This option is not offered if you create (with or without drop) the DB table. This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing.  
**Name:** Type in the name of the schema column to be altered or inserted as new column.  
**SQL expression:** Type in the SQL statement to be executed in order to alter or insert the relevant column data.  
**Position:** Select Before, Replace or After following the action to be performed on the reference column. |
**Reference column:** Type in a column of reference that the `tDBOutput` can use to place or replace the new or altered column.

**Use field options**
Select this check box to customize a request, especially when there is double action on data.

**JDBC url**
Select a way to access to an Amazon Redshift database from the `JDBC url` drop-down list.
- **Standard**: Use the standard way to access the Redshift database.
- **SSO**: Use the IAM Single Sign-ON (SSO) authentication way to access the Redshift Database. Ensure that the IAM role added to your Redshift cluster has appropriate access rights and permissions to this cluster. You can ask the administrator of your AWS services for more details.

This property is available only when **Use an existing connection** check box is not selected from the `Basic settings`. Once enabled, the `Username` and `Password` properties in `Basic settings` will be hidden, and then you should go to `Additional JDBC Parameters` to specify parameters for access.

**tStat Catcher Statistics**
Select this check box to collect log data at the component level.

---

**Note:**
The Row > Reject link is not available if any of these three options is selected: **Die on error**, **Extend Insert**, and **Use Batch**. Also, to make sure your job runs properly, do not select any of these three options with the presence of the Row > Reject link.

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE</strong>: the number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_UPDATED</strong>: the number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_INSERTED</strong>: the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_DELETED</strong>: the number of rows deleted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_REJECTED</strong>: the number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.
To fill up a field or expression with a variable, press \texttt{Ctrl + Space} to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

\begin{tabular}{|p{0.5\textwidth}|p{0.5\textwidth}|}
\hline
\textbf{Usage} & \\
\hline
\textbf{Usage rule} & This component covers all possible SQL database queries. It allows you to carry out actions on a table or on the data of a table in an Amazon Redshift database. It enables you to create a reject flow, with a \texttt{Row > Rejects} link filtering the data in error. For a usage example, see Retrieving data in error with a Reject link on page 2485. \\
\textbf{Dynamic settings} & Click the \texttt{[+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. 

The \textit{Dynamic settings} table is available only when the \textit{Use an existing connection} check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. 

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide. \\
\textbf{Limitation} & Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). \\
\hline
\end{tabular}

Related scenarios

For a related scenario, see Handling data with Redshift on page 3083.
tRedshiftOutputBulk

Prepares a delimited/CSV file that can be used by tRedshiftBulkExec to feed Amazon Redshift.

The tRedshiftOutputBulk and tRedshiftBulkExec components can be used together in a two step process to load data to Amazon Redshift from a delimited/CSV file on Amazon S3. In the first step, a delimited/CSV file is generated. In the second step, this file is used in the INSERT statement used to feed Amazon Redshift. These two steps are fused together in the tRedshiftOutputBulkExec component. The advantage of using two separate steps is that the data can be transformed before it is loaded to Amazon Redshift.

This component receives data from the preceding component, generates a single delimited/CSV file and then uploads the file to Amazon S3.

**tRedshiftOutputBulk Standard properties**

These properties are used to configure tRedshiftOutputBulk running in the Standard Job framework. The Standard tRedshiftOutputBulk component belongs to the Cloud and the Databases families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

<tr>
<td>-------</td>
<td>--------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>

### Usage

#### Usage rule

This component is more commonly used with the tRedshiftBulkExec component to feed Amazon Redshift with a delimited/CSV file. Used together they offer gains in performance while feeding Amazon Redshift.

### Related scenario

For a related scenario, see [Loading/unloading data from/to Amazon S3](#) on page 3062.
tRedshiftOutputBulkExec

Executes the Insert action on the data provided.

As a dedicated component, it allows gains in performance during Insert operations to Amazon Redshift.

The tRedshiftOutputBulk and tRedshiftBulkExec components can be used together in a two step process to load data to Amazon Redshift from a delimited/CSV file on Amazon S3. In the first step, a delimited/CSV file is generated. In the second step, this file is used in the INSERT statement used to feed Amazon Redshift. These two steps are fused together in the tRedshiftOutputBulkExec component. The advantage of using two separate steps is that the data can be transformed before it is loaded to Amazon Redshift.

This component receives data from the preceding component, generates a single delimited/CSV file and uploads the file to Amazon S3, finally it loads the data from Amazon S3 to Redshift.

tRedshiftOutputBulkExec Standard properties

These properties are used to configure tRedshiftOutputBulkExec running in the Standard Job framework.

The Standard tRedshiftOutputBulkExec component belongs to the Cloud and the Databases families.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td>Property Type</td>
<td>Either <strong>Built-In</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-In</strong>: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: Select the repository file in which the properties are stored.</td>
</tr>
<tr>
<td></td>
<td>The database connection fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>

<tr>
<td>Host</td>
<td>Type in the IP address or hostname of the database server.</td>
</tr>
<tr>
<td>Port</td>
<td>Type in the listening port number of the database server.</td>
</tr>
<tr>
<td>Database</td>
<td>Type in the name of the database.</td>
</tr>
<tr>
<td>Schema</td>
<td>Type in the name of the schema.</td>
</tr>
</tbody>
</table>
**Username and Password**
Type in the database user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

**Additional JDBC Parameters**
Specify additional JDBC properties for the connection you are creating. The properties are separated by ampersand & and each property is a key-value pair. For example, ssl=true & sslfactory=com.amazon.redshift.ssl.NonValidatingFactory, which means the connection will be created using SSL.

**Table Name**
Specify the name of the table to be written. Note that only one table can be written at a time.

**Action on table**
On the table defined, you can perform one of the following operations:
- **None**: No operation is carried out.
- **Drop and create table**: The table is removed and created again.
- **Create table**: The table does not exist and gets created.
- **Create table if not exists**: The table is created if it does not exist.
- **Drop table if exists and create**: The table is removed if it already exists and created again.
- **Clear table**: The table content is deleted. You have the possibility to rollback the operation.

**Schema and Edit schema**
A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.
- **Built-In**: You create and store the schema locally for this component only.
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:
- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

**Data file path at local**
Specify the local path to the file to be generated.
<table>
<thead>
<tr>
<th><strong>Append the local file</strong></th>
<th>Note that the file is generated on the same machine where the Studio is installed or where the Job using this component is deployed.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Create directory if not exists</strong></td>
<td>Select this check box to append data to the specified local file if it already exists, instead of overwriting it.</td>
</tr>
<tr>
<td><strong>Access Key</strong></td>
<td>Select this check box to create the directory specified in the <strong>Data file path at local</strong> field if it does not exist. By default, this check box is selected.</td>
</tr>
<tr>
<td><strong>Secret Key</strong></td>
<td>Specify the Access Key ID that uniquely identifies an AWS Account. For how to get your Access Key and Access Secret, visit Getting Your AWS Access Keys.</td>
</tr>
</tbody>
</table>
| **Inherit credentials from AWS role** | Specify the Secret Access Key, constituting the security credentials in combination with the access Key.  
To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| **STS Endpoint** | Select this check box to obtain AWS security credentials from Amazon EC2 instance metadata. To use this option, the Amazon EC2 instance must be started and your Job must be running on Amazon EC2. For more information, see Using an IAM Role to Grant Permissions to Applications Running on Amazon EC2 Instances. |
| **Region** | Select this check box and in the field displayed, specify the AWS Security Token Service endpoint, for example, st.s.amazonaws.com, where session credentials are retrieved from.  
This check box is available only when the Assume role check box is selected. |
| **Bucket** | Specify the AWS region by selecting a region name from the list or entering a region between double quotation marks (e.g. “us-east-1”) in the list. For more information about the AWS Region, see Regions and Endpoints. |
| **Key** | Type in the name of the Amazon S3 bucket, namely the top level folder, to which the file is uploaded.  
The bucket and the Redshift database to be used must be in the same region on Amazon. This could avoid the S3ServiceException errors known to Amazon. For further information about these errors, see S3ServiceException Errors. |
| **Key** | Type in an object key to assign to the file uploaded to Amazon S3. |
### Redshift Assume Role

Select this check box and specify the values for the following parameters used to create a new assumed role session.

- **IAM Role ARNs chains**: a series of chained roles, which may belong to other accounts, that your cluster can assume to access resources.
  
  You can chain a maximum of 10 roles.

- **Role ARN**: the Amazon Resource Name (ARN) of the role to assume.

For more information on IAM Role ARNs chains, see [Authorizing Redshift service](#).

### Advanced settings

<table>
<thead>

<tr>
<td><strong>Encrypt</strong></td>
<td>Select this check box to generate and upload the data file to Amazon S3 using client-side encryption. In the Encryption key field displayed, specify the encryption key used to encrypt the file. Note that only a base64 encoded AES 128-bit or AES 256-bit envelope key is supported. For more information, see Loading Encrypted Data Files from Amazon S3. By default, this check box is cleared and the data file will be uploaded to Amazon S3 using server-side encryption. For more information about the client-side and server-side encryption, see Protecting Data Using Encryption.</td>
</tr>
<tr>
<td><strong>Encoding</strong></td>
<td>Select an encoding type for the data in the file to be generated.</td>
</tr>
<tr>
<td><strong>Delete local file after putting it to s3</strong></td>
<td>Select this check box to delete the local file after being uploaded to Amazon S3. By default, this check box is selected.</td>
</tr>
</tbody>
</table>
| **Date format**                            | Select one of the following items from the list to specify the date format in the source data:  
  
  - **NONE**: No date format is specified.  
  - **PATTERN**: Select this item and specify the date format in the field displayed. The default date format is YYYY-MM-DD.  
  - **AUTO**: Select this item if you want Amazon Redshift to recognize and convert automatically the date format. |
| **Time format**                             | Select one of the following items from the list to specify the time format in the source data:  
  
  - **NONE**: No time format is specified. |
• **PATTERN**: Select this item and specify the time format in the field displayed. The default time format is YYYY-MM-DD HH:MI:SS.
• **AUTO**: Select this item if you want Amazon Redshift to recognize and convert automatically the time format.
• **EPOCHSECS**: Select this item if the source data is represented as epoch time, the number of seconds since Jan 1, 1970 00:00:00 UTC.
• **EPOCHMILLISECS**: Select this item if the source data is represented as epoch time, the number of milliseconds since Jan 1, 1970 00:00:00 UTC.

**Settings**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Parameter</strong></td>
<td>Click the cell and select a parameter from the drop-down list.</td>
</tr>
<tr>
<td><strong>Value</strong></td>
<td>Set the value for the corresponding parameter. Note that you cannot set the value for a parameter (such as IGNOREBLANKLINES) that does not need a value.</td>
</tr>
</tbody>
</table>

For more information about the parameters, see [http://docs.aws.amazon.com/redshift/latest/dg/r_COPY.html](http://docs.aws.amazon.com/redshift/latest/dg/r_COPY.html).

**Config client**

Select this check box to configure client parameters for Amazon S3. Click the [+] button below the table displayed to add as many rows as needed, each row for a client parameter, and set the following attributes for each parameter:

<table>
<thead>
<tr>
<th>Client Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Client Parameter</strong></td>
<td>Click the cell and select a parameter from the drop-down list.</td>
</tr>
<tr>
<td><strong>Value</strong></td>
<td>Enter the value for the corresponding client parameter.</td>
</tr>
</tbody>
</table>

**JDBC url**

Select a way to access to an Amazon Redshift database from the **JDBC url** drop-down list.

<table>
<thead>
<tr>
<th>Standard</th>
<th>SSO</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Standard</strong>: Use the standard way to access the Redshift database.</td>
<td></td>
</tr>
<tr>
<td><strong>SSO</strong>: Use the IAM Single Sign-ON (SSO) authentication way to access the Redshift Database. Ensure that the IAM role added to your Redshift cluster has appropriate access rights and permissions to this cluster. You can ask the administrator of your AWS services for more details.</td>
<td></td>
</tr>
</tbody>
</table>

This property is available only when **Use an existing connection** check box is not selected from the **Basic settings**. Once enabled, the **Username** and **Password** properties in **Basic settings** will be hidden, and then you should go to **Additional JDBC Parameters** to specify parameters for access.

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the</th>
</tr>
</thead>
</table>
**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is mainly used when no particular transformation is required on the data to be loaded to Amazon Redshift.</th>
</tr>
</thead>
</table>
| Dynamic settings | Click the \[+\] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.  

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.  

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |

**Related scenario**

For a related scenario, see Loading/unloading data from/to Amazon S3 on page 3062.
tRedshiftRollback

Cancels the transaction commit in the Redshift database to avoid committing part of a transaction involuntarily.

tRedshiftRollback Standard properties

These properties are used to configure tRedshiftRollback running in the Standard Job framework. The Standard tRedshiftRollback component belongs to the Cloud and the Databases families. The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tRedshiftConnection component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

Usage

| Usage rule | This component is more commonly used with other tRedshift* components, especially with the tRedshiftConnection and tRedshiftCommit components. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection |
Related scenario

For a similar scenario, see Rollback from inserting data in mother/daughter tables on page 2440.
tRedshiftRow

Acts on the actual DB structure or on the data (although without handling data), depending on the nature of the query and the database.

The SQLBuilder tool helps you write easily your SQL statements.

tRedshiftRow is the specific component for this database query. It executes the SQL query stated onto the specified database. The row suffix means the component implements a flow in the job design although it does not provide output.

**tRedshiftRow Standard properties**

These properties are used to configure tRedshiftRow running in the Standard Job framework.

The Standard tRedshiftRow component belongs to the Cloud and the Databases families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see **Talend Studio User Guide**.
<table>
<thead>
<tr>
<th><strong>Host</strong></th>
<th>Hostname or IP address of the database server.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of the database server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database. The bucket and the Redshift database to be used must be in the same region on Amazon. This could avoid the S3ServiceException errors known to Amazon. For further information about these errors, see S3ServiceException Errors.</td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>Exact name of the schema.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>Database user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Additional JDBC Parameters</strong></td>
<td>Specify additional JDBC properties for the connection you are creating. The properties are separated by ampersand &amp; and each property is a key-value pair. For example, ssl=true &amp; sslfactory=com.amazon.redshift.ssl.NonValidatingFactory, which means the connection will be created using SSL.</td>
</tr>
<tr>
<td><strong>Schema and Edit Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <strong>line</strong> when naming the fields. <strong>Built-In</strong>: You create and store the schema locally for this component only. <strong>Repository</strong>: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
</tr>
</tbody>
</table>
|             | Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
\- **View schema**: choose this option to view the schema only.  
\- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.  
\- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |
| **Table Name** | Name of the table from which the data will be read. |
| **Query type** | Either Built-in or Repository.  
Built-in: Fill in manually the query statement or build it graphically using SQLBuilder. |
**Repository:** Select the relevant query stored in the Repository. The **Query** field gets accordingly filled in.

<table>
<thead>
<tr>
<th><strong>Guess Query</strong></th>
<th>Click the <strong>Guess Query</strong> button to generate the query which corresponds to your table schema in the Query field.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Query</strong></td>
<td>Enter your database query paying particularly attention to properly sequence the fields in order to match the schema definition. <strong>Note:</strong> All statements in this field will be executed in a single transaction. To have multiple statements executed in different transactions, put each of them in a separate tRedShiftRow component.</td>
</tr>
<tr>
<td><strong>Die on error</strong></td>
<td>This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error through a Row &gt; Rejects link.</td>
</tr>
</tbody>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th><strong>Propagate QUERY’s recordset</strong></th>
<th>Select this check box to insert the result of the query into a COLUMN of the current flow. Select this column from the <strong>use column</strong> list. <strong>Note:</strong> This option allows the component to have a different schema from that of the preceding component. Moreover, the column that holds the QUERY’s recordset should be set to the type of Object and this component is usually followed by tParseRecordSet.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Use PreparedStatement</strong></td>
<td>Select this check box if you want to query the database using a PreparedStatement. In the Set PreparedStatement Parameter table, define the parameters represented by &quot;?&quot; in the SQL instruction of the <strong>Query</strong> field in the <strong>Basic Settings</strong> tab. <strong>Parameter Index:</strong> Enter the parameter position in the SQL instruction. <strong>Parameter Type:</strong> Enter the parameter type. <strong>Parameter Value:</strong> Enter the parameter value. <strong>Note:</strong> This option is very useful if you need to execute the same query several times. Performance levels are increased.</td>
</tr>
<tr>
<td><strong>Commit every</strong></td>
<td>Number of rows to be completed before committing batches of rows together into the database. This option ensures transaction quality (but not rollback) and above all better performance on executions.</td>
</tr>
<tr>
<td><strong>JDBC url</strong></td>
<td>Select a way to access to an Amazon Redshift database from the <strong>JDBC url</strong> drop-down list.</td>
</tr>
</tbody>
</table>
• **Standard**: Use the standard way to access the Redshift database.

• **SSO**: Use the IAM Single Sign-ON (SSO) authentication way to access the Redshift Database. Ensure that the IAM role added to your Redshift cluster has appropriate access rights and permissions to this cluster. You can ask the administrator of your AWS services for more details.

This property is available only when Use an existing connection check box is not selected from the Basic settings. Once enabled, the Username and Password properties in Basic settings will be hidden, and then you should go to Additional JDBC Parameters to specify parameters for access.

<table>
<thead>
<tr>
<th>tStat Catcher Statistics</th>
<th>Select this check box to collect log data at the component level.</th>
</tr>
</thead>
</table>

**Global Variables**

| Global Variables | **QUERY**: the query statement being processed. This is a Flow variable and it returns a string. **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it. For further information about variables, see [Talend Studio User Guide](#). |

**Usage**

| Usage rule | This component offers the flexibility benefit of the database query and covers all possible SQL queries. |

| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see [Reading data from databases through context-based dynamic](#). |
**Related scenarios**

For similar scenarios, see:

- Combining two flows for selective output on page 2514
- Procedure on page 625
- Removing and regenerating a MySQL table index on page 2508
tRedshiftUnload

Unloads data on Amazon Redshift to files on Amazon S3.

This component runs a specified query in Amazon Redshift and then unloads the result of the query to one or more files on Amazon S3.

**tRedshiftUnload Standard properties**

These properties are used to configure tRedshiftUnload running in the Standard Job framework.

The Standard tRedshiftUnload component belongs to the Cloud and the Databases families.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Either Built-In or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Built-In</strong>: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: Select the repository file in which the properties are stored. The database connection fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined.

**Host**

Type in the IP address or hostname of the database server.

**Port**

Type in the listening port number of the database server.

**Database**

Type in the name of the database.

**Schema**

Type in the name of the schema.

**Username and Password**

Type in the database user authentication data.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

**Additional JDBC Parameters**

Specify additional JDBC properties for the connection you are creating. The properties are separated by ampersand & and each property is a key-value pair. For example, `ssl=true & sslfactory=com.amazon.redshift.ssl.NonValidatingFactory`, which means the connection will be created using SSL.

**Table Name**

Type in the name of the table from which the data will be read.

**Schema and Edit schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.
<table>
<thead>
<tr>
<th><strong>Built-In</strong></th>
<th>You create and store the schema locally for this component only.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Repository</strong></td>
<td>You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
</tr>
</tbody>
</table>

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-In** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Query Type** and **Query**

Enter the database query paying particularly attention to the proper sequence of the fields in order to match the schema definition.

Double-escape each simple quotation marks in the query. For example,

```
SELECT name, birth, "Add" FROM my_table WHERE birth between "2018-01-01 00:00:00\" and "2019-01-01 00:00:00\"
```

**Guess Query**

Click the button to generate the query which corresponds to the table schema in the **Query** field.

**Access Key**

Specify the Access Key ID that uniquely identifies an AWS Account. For how to get your Access Key and Access Secret, visit [Getting Your AWS Access Keys](#).

**Secret Key**

Specify the Secret Access Key, constituting the security credentials in combination with the access Key.

To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

**Assume Role**

Select this check box and specify the values for the following parameters used to create a new assumed role session.

- **IAM Role ARNs chains**: a series of chained roles, which may belong to other accounts, that your cluster can assume to access resources.
  
  You can chain a maximum of 10 roles.

- **Role ARN**: the Amazon Resource Name (ARN) of the role to assume.

For more information on IAM Role ARNs chains, see [Authorizing Redshift service](#).
<table>
<thead>
<tr>
<th>Bucket</th>
<th>Type in the name of the Amazon S3 bucket, namely the top level folder, to which the data is unloaded.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Key prefix</td>
<td>Type in the name prefix for the unload files on Amazon S3. By default, the unload files are written per slice of the Redshift cluster and the file names are written in the format <code>&lt;object_path&gt;/&lt;name_prefix&gt;&lt;slice-number&gt;_part_&lt;file-number&gt;</code>.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| File type | Select the type of the unload files on Amazon S3 from the list:  
|---|---|
| • Delimited file or CSV: a delimited/CSV file.  
| • Fixed width: a fixed-width file. |
| Fields terminated by | Enter the character used to separate fields.  
This field appears only when Delimited file or CSV is selected from the File type list. |
| Enclosed by | Select the character in a pair of which the fields are enclosed.  
This list appears only when Delimited file or CSV is selected from the File type list. |
| Fixed width mapping | Enter a string that specifies a user-defined column label and column width between double quotation marks. The format of the string is:  
ColumnLabel1:ColumnWidth1,ColumnLabel2:ColumnWidth2,...  
Note that the column label in the string has no relation to the table column name and it can be either a text string or an integer. The order of the label/width pairs must match the order of the table columns exactly.  
This field appears only when Fixed width is selected from the File type list. |
<p>| Compressed by | Select this check box and from the list displayed select the compression type of the files. |
| Encrypt | Select this check box to encrypt unload file(s) using Amazon S3 client-side encryption. In the Encryption key field displayed, enter the encryption key used to encrypt the unload file(s). Note that only a base64 encoded AES 128-bit or AES 256-bit envelope key is supported. For more information, see Unloading Encrypted Data Files. |
| Specify null string | Select this check box and from the list displayed select a string that represents a null value in unload files. |
| Escape | Select this check box to place an escape character () before every occurrence of the following characters for CHAR and VARCHAR columns in the delimited unload files: linefeed (\n), carriage return (\r), the delimiter character specified for the unloaded data, the escape character (), a quote character (&quot; or &quot;). |</p>
<table>
<thead>
<tr>
<th>Overwrite s3 object if exist</th>
<th>Select this check box to overwrite the existing Amazon S3 object files.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parallel</td>
<td>Select this check box to write data in parallel to multiple unload files on Amazon S3 according to the number of slices in the Redshift cluster.</td>
</tr>
<tr>
<td>JDBC url</td>
<td>Select a way to access to an Amazon Redshift database from the JDBC url drop-down list.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Standard</strong>: Use the standard way to access the Redshift database.</td>
</tr>
<tr>
<td></td>
<td>• <strong>SSO</strong>: Use the IAM Single Sign-ON (SSO) authentication way to access the Redshift Database. Ensure that the IAM role added to your Redshift cluster has appropriate access rights and permissions to this cluster. You can ask the administrator of your AWS services for more details.</td>
</tr>
<tr>
<td></td>
<td>This property is available only when <strong>Use an existing connection</strong> check box is not selected from the <strong>Basic settings</strong>. Once enabled, the <strong>Username</strong> and <strong>Password</strong> properties in <strong>Basic settings</strong> will be hidden, and then you should go to <strong>Additional JDBC Parameters</strong> to specify parameters for access.</td>
</tr>
<tr>
<td>tStatCatcher Statistics</td>
<td>Select this check box to gather the Job processing metadata at the Job level as well as at each component level.</td>

</tbody>
</table>

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press <strong>Ctrl + Space</strong> to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td></td>
<td>For further information about variables, see <a href="#">Talend Studio User Guide</a>.</td>
</tr>
</tbody>
</table>

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component covers all possible SQL queries for the Amazon Redshift database.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic settings</td>
<td>Click the [+] button to add a row in the table and fill the <strong>Code</strong> field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.</td>
</tr>
</tbody>
</table>
The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

### Related Scenario

For a related scenario, see Loading/unloading data from/to Amazon S3 on page 3062.
**tReplace**

Cleanses all files before further processing.
Carries out a Search & Replace operation in the input columns defined.

**tReplace Standard properties**

These properties are used to configure tReplace running in the Standard Job framework.
The Standard tReplace component belongs to the Processing family.
The component in this framework is available in all Talend products.

**Basic settings**

| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
• View schema: choose this option to view the schema only.  
• Change to built-in property: choose this option to change the schema to Built-in for local changes.  
• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.  
Two read-only columns, Value and Match are added to the output schema automatically. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Built-In: You create and store the schema locally for this component only.</td>
<td></td>
</tr>
<tr>
<td>Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
<td></td>
</tr>
</tbody>
</table>
| Simple Mode Search / Replace | Click the button to add as many conditions as needed. The conditions are performed one after the other for each row.  
Input column: Select the column of the schema the search & replace is to be operated on  
Search: Type in the value to search in the input column  
Replace with: Type in the substitution value.  
Whole word: Select this check box if the searched value is to be considered as whole.  
Case sensitive: Select this check box to care about the case. |
Note that you cannot use regular expression in these columns.

Use advanced mode
Select this check box when the operation you want to perform cannot be carried out through the simple mode. In the text field, type in the regular expression as required.

Advanced settings
Select this check box to gather the job processing metadata at a job level as well as at each component level.

Global Variables

Global Variables
ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

NB_LINE: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule
This component is not startable as it requires an input flow. And it requires an output component.

Multiple replacements and column filtering

This following Job searches and replaces various typos and defects in a csv file then operates a column filtering before producing a new csv file with the final output.
• Drop the following components from the Palette onto the design workspace: tFileInputDelimited, tReplace, tFilterColumn and tFileOutputDelimited.
• Connect the components using Main Row connections via a right-click each component.
• Select the tFileInputDelimited component and set the input flow parameters.

<table>

</tr>
<tr>
<td>Encoding Type</td>
<td>ISO-8859-15</td>
</tr>
</tbody>
</table>

• The File is a simple csv file stored locally. The Row Separator is a carriage return and the Field Separator is a semi-colon. In the Header is the name of the column, and no Footer nor Limit are to be set.
• The file contains characters such as: *t, . or Nikson which we want to turn into Nixon, and streat, which we want to turn into Street.

<table>
<thead>
<tr>
<th>Street</th>
<th>FirstName</th>
<th>Name</th>
<th>Amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>streat</td>
<td>John</td>
<td>Kennedy</td>
<td>98.30$</td>
</tr>
<tr>
<td>streat</td>
<td>Richad</td>
<td>Nikson</td>
<td>78.23$</td>
</tr>
<tr>
<td>streat</td>
<td>Richard</td>
<td>Nikson</td>
<td>78.23$</td>
</tr>
<tr>
<td>streat</td>
<td>toto</td>
<td>Nikson</td>
<td>78.23$</td>
</tr>
<tr>
<td>streat</td>
<td>Richard</td>
<td>Nikson</td>
<td>78.23$</td>
</tr>
<tr>
<td>streat</td>
<td>Georges</td>
<td>bush</td>
<td>99.99$</td>
</tr>
</tbody>
</table>

• The schema for this file is built in also and made of four columns of various types (string or int).
• Now select the tReplace component to set the search & replace parameters.

<table>
<thead>
<tr>
<th>InputColumn</th>
<th>Search</th>
<th>Replace with</th>
<th>Whole w...</th>
<th>Case Sens...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amount</td>
<td>&quot;.&quot;</td>
<td>&quot;,&quot;</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Street</td>
<td>&quot;streat&quot;</td>
<td>'Street'</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Amount</td>
<td>&quot;$&quot;</td>
<td>&quot;$&quot;</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Name</td>
<td>&quot;Nikson&quot;</td>
<td>'Nixon'</td>
<td></td>
<td></td>
</tr>
<tr>
<td>FirstName</td>
<td>&quot;t&quot;</td>
<td>&quot;&quot;</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

• The schema can be synchronized with the incoming flow.
• Select the Simple mode check box as the search parameters can be easily set without requiring the use of regexp.
• Click the plus sign to add some lines to the parameters table.
• On the first parameter line, select Amount as InputColumn. Type "." in the Search field, and "," in the Replace field.
On the second parameter line, select Street as **InputColumn**. Type "street" in the **Search** field, and "Street" in the **Replace** field.

On the third parameter line, select again Amount as **InputColumn**. Type "$" in the **Search** field, and "£" in the **Replace** field.

On the fourth parameter line, select Name as **InputColumn**. Type "Nikson" in the **Search** field, and "Nixon" in the **Replace** field.

On the fifth parameter line, select Firstname as **InputColumn**. Type "*t" in the **Search** field, and replace them with nothing between double quotes.

The advanced mode isn’t used in this scenario.

Select the next component in the Job, **tFilterColumn**.

The **tFilterColumn** component holds a schema editor allowing to build the output schema based on the column names of the input schema. In this use case, add one new column named **empty_field** and change the order of the input schema columns to obtain a schema as follows: **empty_field, Firstname, Name, Street, Amount**.

Click **OK** to validate.

Set the **tFileOutputDelimited** properties manually.

The schema is built-in for this scenario, and comes from the preceding component in the Job.

Save the Job and press **F6** to execute it.

<table>
<thead>
<tr>
<th>Firstname</th>
<th>Surname</th>
<th>Street</th>
<th>Amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>John</td>
<td>Kennedy</td>
<td>Street</td>
<td>98,30£</td>
</tr>
<tr>
<td>Richad</td>
<td>Nixon</td>
<td>Street</td>
<td>78,23£</td>
</tr>
<tr>
<td>Richard</td>
<td>Nixon</td>
<td>Street</td>
<td>78,2£</td>
</tr>
<tr>
<td>toto</td>
<td>Nixon</td>
<td>Street</td>
<td>78,23£</td>
</tr>
<tr>
<td>Richard</td>
<td>Nixon</td>
<td>Street</td>
<td>78,23£</td>
</tr>
<tr>
<td>Georges</td>
<td>bush</td>
<td>street</td>
<td>99,99£</td>
</tr>
</tbody>
</table>
The first column is empty, the rest of the columns have been cleaned up from the parasitical characters, and Nikson was replaced with Nixon. The street column was moved and the decimal delimiter has been changed from a dot to a comma, along with the currency sign.
tReplaceList

Cleanses all files before further processing.
Carries out a Search and Replace operation in the input columns defined based on an external lookup.

**tReplaceList Standard properties**

These properties are used to configure tReplaceList running in the Standard Job framework.
The Standard tReplaceList component belongs to the Data Quality family.
The component in this framework is available in all Talend products.

**Basic settings**

| **Schema and Edit schema** | A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either **Built-in** or stored remotely in the **Repository**.
Two read-only columns, Value and Match are added to the output schema automatically.

**Warning:**
The data Type defined in the schemas must be consistent, i.e., an integer can only be replaced by another integer using an integer as a look up field. Values of one type cannot be replaced by values of another type.

| **Built-in**: The schema will be created and stored locally for this component only. Related topic: see Talend Studio User Guide.

| **Repository**: The schema already exists and is stored in the Repository, hence can be reused in various projects and job designs. Related topic: see Talend Studio User Guide.

| **Lookup search column** | Select the column to be searched in the lookup schema.

| **Lookup replacement column** | Select the column where the replacement values are stored.

| **Column options** | Select the columns of the main flow where the replacement is to be carried out.

**Advanced settings**

| **tStat Catcher Statistics** | Select this check box to collect log data at the component level. |
Global Variables

ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule

tReplaceList is an intermediary component. It requires an input flow and an output component.

Replacing state names with their two-letter codes

The following Job searches and replaces a list of states with their corresponding two-letter codes. The relevant codes are taken from a reference file placed as lookup flow in the Job.

Setting up the Job

Procedure

1. Drop the following components from the Palette onto the design workspace: two tFileInputDelimited components, a tReplaceList and a tLogRow.
2. Connect the two tFileInputDelimited components to the tReplaceList component using Row > Main connections. Note that the link between the reference input component (the second tFileInputDelimited) and the tReplaceList component appears as a lookup row.
3. Connect the tReplaceList component to the tLogRow component using a Row > Main connection.
Configuring the components

Procedure

1. Double-click the first tFileInputDelimited component to open its Basic settings view and set the parameters of the main input flow, including the path and name of the file to read and the number of header rows to skip.

In this example, the main input file provides a list of people names and US state names. The following shows an extract of the file content:

<table>
<thead>
<tr>
<th>name</th>
<th>state</th>
</tr>
</thead>
<tbody>
<tr>
<td>Andrew Kennedy</td>
<td>Mississippi</td>
</tr>
<tr>
<td>Benjamin Carter</td>
<td>Louisiana</td>
</tr>
<tr>
<td>Benjamin Monroe</td>
<td>West Virginia</td>
</tr>
<tr>
<td>Bill Harrison</td>
<td>Tennessee</td>
</tr>
<tr>
<td>Calvin Grant</td>
<td>Virginia</td>
</tr>
<tr>
<td>Chester Harrison</td>
<td>Rhode Island</td>
</tr>
<tr>
<td>Chester Hoover</td>
<td>Kansas</td>
</tr>
<tr>
<td>Chester Kennedy</td>
<td>Maryland</td>
</tr>
<tr>
<td>Chester Polk</td>
<td>Indiana</td>
</tr>
<tr>
<td>Dwight Nixon</td>
<td>Nevada</td>
</tr>
<tr>
<td>Dwight Roosevelt</td>
<td>Mississippi</td>
</tr>
<tr>
<td>Franklin Grant</td>
<td>Nebraska</td>
</tr>
</tbody>
</table>

2. Click the [...] button next to Edit schema to open the Schema dialog box and set the input schema. According to the structure of the main input file, the input schema should contain two columns: name and state.
When done, click **OK** to close the dialog box and propagate the changes to the next component.

3. Define the properties of the second **tFileInputDelimited** component similarly.

In this example, the reference input file provides a list of states and their two-letter codes. Accordingly, the reference input schema should have two columns: **state** and **code**.

4. Double-click the **tReplaceList** component to open its **Basic settings** view to set the operation to carry out.
5. From the **Lookup search column** list, select the column to be searched. In this use case, we want to carry out a search on the *state* column.

6. From the **Lookup replacement column** list, select the column containing the replacement values, code for the two-letter state codes in this example.

7. In the **Column options** table, select **Replace** check box for the *states* column, to replace the state names with their corresponding codes.

8. In the **tLogRow** component, select the **Table** check box for a better readability of the output.

**Executing the Job**

**Procedure**

Save the Job and press **F6** to execute it.

The state names have been replaced with their respective two-letter codes.
tReplicate

Duplicates the incoming schema into two identical output flows.
This component performs different operations on the same schema.

**tReplicate Standard properties**

These properties are used to configure tReplicate running in the Standard Job framework.
The Standard tReplicate component belongs to the Orchestration family.
The component in this framework is available in all Talend products.

**Basic settings**

| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.
Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:
- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.
Click Sync columns to retrieve the schema from the previous component in the Job. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-In</strong>: You create and store the schema locally for this component only.</td>
<td></td>
</tr>
<tr>
<td><strong>Repository</strong>: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
<td></td>
</tr>
</tbody>
</table>

**Global Variables**

| **Global Variables** | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. |
|---|---|
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is not startable (green background), it requires an Input component and an output component.</th>
</tr>
</thead>
</table>

| Connections | Outgoing links (from this component to another): 
Row: Main. 
Trigger: Run if; On Component Ok; On Component Error. |
|-------------|----------------------------------------------------------------------------------------------------------|

Incoming links (from one component to this one): 
Row: Main; Reject; 
For further information regarding connections, see Talend Studio User Guide.

### Replicating a flow and sorting two identical flows respectively

The scenario describes a Job that reads an input flow which contains names and states from a CSV file, replicates the input flow, then sorts the two identical flows based on name and state respectively, and displays the sorted data on the console.

### Setting up the Job

**Procedure**

1. Drop the following components from the Palette to the design workspace: one tFileInputDelimited component, one tReplicate component, two tSortRow components, and two tLogRow components.
2. Connect tFileInputDelimited to tReplicate using a Row > Main link.
3. Repeat the step above to connect tReplicate to two tSortRow components respectively and connect tSortRow to tLogRow.
4. Label the components to better identify their functions.

**Configuring the components**

**Procedure**

1. Double-click the `tFileInputDelimited` component to open its **Basic settings** view in the **Component** tab.

   ![Basic settings view of tFileInputDelimited component]

   - **File name/Stream**: D:/Input/Names&States.csv
   - **Row Separator**: \n
   - **Header**: 1
   - **Footer**: 0

2. Click the [...] button next to the **File name/Stream** field to browse to the file from which you want to read the input flow. In this example, the input file is *Names&States.csv*, which contains two columns: *name* and *state*.

   ```
   name;state
   Andrew Kennedy;Mississippi
   Benjamin Carter;Louisiana
   Benjamin Monroe;West Virginia
   Bill Harrison;Tennessee
   Calvin Grant;Virginia
   Chester Harrison;Rhode Island
   Chester Hoover;Kansas
   Chester Kennedy;Maryland
   Chester Polk;Indiana
   Dwight Nixon;Nevada
   Dwight Roosevelt;Mississippi
   Franklin Grant;Nebraska
   ```

3. Fill in the **Header**, **Footer** and **Limit** fields according to your needs. In this example, type in 1 in the **Header** field to skip the first row of the input file.
4. Click **Edit schema** to define the data structure of the input flow.

5. Double-click the first **tSortRow** component to open its **Basic settings** view.

6. In the **Criteria** panel, click the [+ ] button to add one row and set the sorting parameters for the schema column to be processed. To sort the input data by name, select **name** under **Schema column**. Select **alpha** as the sorting type and **asc** as the sorting order.
   For more information about those parameters, see **tSortRow Standard properties** on page 3540.

7. Double-click the second **tSortRow** component and repeat the step above to define the sorting parameters for the state column.
8. In the **Basic settings** view of each **tLogRow** component, select **Table** in the **Mode** area for a better view of the Job execution result.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl+S** to save your Job.
2. Execute the Job by pressing **F6** or clicking **Run** on the **Run** tab.

The data sorted by name and state are both displayed on the console.
tREST

Serves as a REST Web service client.

The tREST component sends HTTP requests to a REpresentational State Transfer (REST) Web service provider and gets responses correspondingly.

**tREST Standard properties**

The Standard tREST component belongs to the Internet family.

**Note:**

To build Jobs that need to be deployed into the Talend Runtime, it is recommended to use the tRESTClient component which is best suited for the Talend Runtime.

For more information about the tRESTClient component, see tRESTClient on page 3135.

The component in this framework is available in all Talend products.

**Basic settings**

| Schema and Edit Schema | A schema is a row description, it defines the number of fields that will be processed and passed on to the next component. This component always uses a built-in, read-only schema that contains two columns:
- **Body**: stores the result from the server end.
- **ERROR_CODE**: stores the HTTP status code from the server end when an error occurs during the invocation process.
The specific meanings of the errors codes are subject to definitions of your Web service provider. For reference information, visit en.wikipedia.org/wiki/List_of_HTTP_status_codes.
Click **Edit Schema** to view the schema structure.

**Warning:**
Changing the schema type may result in loss of the schema structure and therefore failure of the component.

| URL | Type in the URL address of the REST Web server to be invoked.

| HTTP Method | From this list, select an HTTP method that describes the desired action. The specific meanings of the HTTP methods are subject to definitions of your Web service provider. Listed below are the generally accepted HTTP method definitions:
- **GET**: retrieves data from the server end based on the given parameters.
- **POST**: creates and uploads data based on the given parameters.
- **PUT**: updates data based on the given parameters, or if the data does not exist, creates it.
- **DELETE**: removes data based on the given parameters.

### HTTP Headers

Type in the name-value pair(s) for HTTP headers to define the parameters of the requested HTTP operation.

For the specific definitions of HTTP headers, consult your REST Web service provider. For reference information, visit [en.wikipedia.org/wiki/List_of_HTTP_headers](http://en.wikipedia.org/wiki/List_of_HTTP_headers).

### HTTP Body

Type in the payload to be uploaded to the server end when the **POST** or **PUT** action is selected.

### Advanced settings

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

**Global Variables**

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

**Usage rule**

Use this component as a REST Web service client to communicate with a REST Web service provider. It must be linked to an output component.

**Limitation**

JRE 1.6 must be running for this component to work properly.

### Creating and retrieving data by invoking REST Web service

This scenario describes a simple Job that invokes a REST Web service to create a new customer record on the server end and then retrieve the customer information. When executed, the Job displays relevant information on the **Run** console.

- Drop the following components from the **Palette** onto the design workspace: two **tREST** components and two **tLogRow** components, and label the two **tREST** components to best describe the actions to perform.
- Connect each **tREST** to one **tLogRow** using a **Row > Main** connection.
• Connect the first tREST to the second tREST using a Trigger > OnSubjobOK connection.

• Double click the first tREST component to open its Basic settings view.

• Fill the URL field with the URL of the Web service you are going to invoke. Note that the URL provided in this use case is for demonstration purposes only and is not a live address.

• From the HTTP Method list, select POST to send an HTTP request for creating a new record.

• Click the plus button to add a line in the HTTP Headers table, and type in the appropriate name-value key pair, which is subject to definition of your service provider, to indicate the media type of the payload to send to the server end. In this use case, type in Content-Type and application/xml. For reference information about Internet media types, visit www.w3.org/Protocols/rfc2616/rfc2616-sec3.html#sec3.7.

• Fill the HTTP Body field with the payload to be uploaded to the server end. In this use case, type in <Customer><name>Steven</name></Customer> to create a record for a new customer named Steven.

  Note:

  If you want to include double quotation marks in your payload, be sure to use a backslash escape character before each of the quotation marks. In this use case, for example, type in <Customer><name>\"Steven\"</name></Customer> if you want to enclose the name Steven in a pair of double quotation marks.

• Double click the second tREST component to open its Basic settings view.
• Fill the **URL** field with the same URL.
• From the **HTTP Method** list, select **GET** to send an HTTP request for retrieving the existing records.
• In the **Basic settings** view of each **tLogRow**, select the **Print component unique name in front of each output row** and **Print schema column name in front of each value** check boxes for better identification of the output flows.

• Save your Job and press **F6** to launch it.

The console shows that the first **tREST** component sends an HTTP request to the server end to create a new customer named *Steven*, and the second **tREST** component successfully reads data from the server end, which includes the information of the new customer you just created.
tRESTClient

Interacts with RESTful Web service providers by sending HTTP and HTTPS requests using CXF (JAX-RS) getting the corresponding responses.

This component integrates well with *Talend Runtime* to get HTTPS support, with more QoS features to be supported in time.

**tRESTClient Standard properties**

These properties are used to configure tRESTClient running in the Standard Job framework.

The Standard tRESTClient component belongs to the ESB family.

The component in this framework is available in all *Talend products*.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>URL</strong></td>
<td>Type in the URL address of the REST server to be invoked. When the <em>Use Service Locator</em> check box is selected, this field will not show and the URL of the REST server will be obtained from the Service Locator server automatically.</td>
</tr>
<tr>
<td><strong>Relative Path</strong></td>
<td>Enter the relative path of the REST server to be invoked. For example, if you want to access <a href="http://localhost:8888/services/Customers/list">http://localhost:8888/services/Customers/list</a>: If <em>Use Service Locator</em> is disabled: You can enter any of the first part of the address in the URL field, and the second part in the Relative Path field. For example, you can enter <a href="http://localhost:8888/services">http://localhost:8888/services</a> in URL and /Customers/list in Relative Path. You can also enter the full path of the REST server in URL and leave Relative Path blank. If <em>Use Service Locator</em> is enabled: The URL part will be given by the Service Locator. In this case, you need to know the URL part, and specify the rest part in Relative Path. This depends on the service you request. For example, on tRESTRequest, you specify REST Endpoint as <a href="http://localhost:8888/services">http://localhost:8888/services</a> and enable Use Service Locator. Then, if you want to use this service, on tRESTClient side, you should specify /customers/list in Relative Path.</td>
</tr>
<tr>
<td><strong>HTTP Method</strong></td>
<td>From this list, select an HTTP method that describes the desired action. The specific meanings of the HTTP methods are subject to definitions of your Web service provider. Listed below are the generally accepted HTTP method definitions: - GET: retrieves data from the server end based on the given parameters.</td>
</tr>
</tbody>
</table>

*Warning:* When using relative path, you should specify at least one sub-directory in the URL field instead of only host:port to avoid compiling issues. For example, use http://localhost:8888/services instead of http://localhost:8888.
- **POST**: uploads data to the server end based on the given parameters.
- **PUT**: updates data based on the given parameters, or if the data does not exist, creates it.
- **PATCH**: modifies data partially based on the given parameters.
- **DELETE**: removes data based on the given parameters.

<table>
<thead>
<tr>
<th>Content Type</th>
<th>Select XML, JSON, or FORM according to the media type of the content to be uploaded to the server end. This list appears only when you select the POST, PUT, or PATCH HTTP method.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept Type</td>
<td>Select the media type the client end is prepared to accept for the response from the server end. Available options are XML, JSON, and ANY. When ANY is selected, the response message can be of any type and will be transformed into a string.</td>
</tr>
<tr>
<td>Query parameters</td>
<td>Specify the URI query parameters in the form of name-value pairs. This option is mostly used with the GET method.</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description, it defines the number of fields that will be processed and passed on to the next component. This component uses three built-in, read-only schemas. Click Edit Schema to view the schema structure.</td>
</tr>
<tr>
<td>Warning:</td>
<td>Changing the schema type may result in loss of the schema structure and therefore failure of the component.</td>
</tr>
</tbody>
</table>
| Input Schema | Schema for the input data. This schema contains two columns:  
  - **body**: stores the content of structured input data  
  - **string**: stores the input content when it is, or is handled as, a string. |
| Response Schema | Schema for server response. This schema is passed onto the next component via a Row > Response link, and it contains three columns:  
  - **statusCode**: stores the HTTP status code from the server end.  
  - **body**: stores the content of a structured response from the server end.  
  - **string**: stores the response content from the server end when it is, or is handled as, a string. |
| Error Schema | Schema for error information. This schema is passed onto the next component via a Row > Error link, and it contains two columns:  
  - **errorCode**: stores the HTTP status code from the server end when an error occurs during the invocation
process. The specific meanings of the errors codes are subject to definitions of your Web service provider. For reference information, visit [en.wikipedia.org/wiki/List_of_HTTP_status_codes](en.wikipedia.org/wiki/List_of_HTTP_status_codes).

- **errorMessage**: stores the error message corresponding the error code.

### Use Service Locator
Select this check box to enable the Service Locator. It maintains the availability of the service to help meet demands and service level agreements (SLAs). Specify the Service namespace and the Service name in the corresponding fields.

### Use Service Activity Monitor
Select this check box to enable the Service Activity Monitor. It captures events and stores this information to facilitate in-depth analysis of service activity and track-and-trace of messages throughout a business transaction. This can be used to analyze service response times, identify traffic patterns, perform root cause analysis and more.

### Use Authentication
Select this check box if authentication is required on the REST server end. Select the authentication type from:

- **Basic HTTP**: Fill the **Username** and **Password** fields with your credentials.
- **HTTP Digest**: Fill the **Username** and **Password** fields with your credentials.
- **SAML Token (ESB runtime only)**: Fill the **Username** and **Password** fields with your credentials.
- **OAuth2 Bearer**: Fill the **Bearer Token** field with a base64-encoded credential string.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

### Use Business Correlation
Select this check box to create a correlation ID in this component.

You can specify a correlation ID in the **Correlation Value** field. In this case the correlation ID will be passed on to the service it calls so that chained service calls will be grouped under this correlation ID. If you leave this field empty, this value will be generated automatically at runtime.

When this option is enabled, **tRESTClient** will also extract the correlation ID from the response header and store it in the component variable for further use in the flow.

### Die on error
This check box is selected to kill the Job when an error occurs. Clear the check box to skip the row on error and complete the process for error-free rows.

### Advanced settings

<table>
<thead>
<tr>
<th><strong>Log messages</strong></th>
<th>Select this check box to log the message exchange between the service provider and the consumer.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Enable WebClient Operation Reporting</strong></td>
<td>If this check box is selected, a CXF endpoint property will be set on the client side which may be used by some outgoing</td>
</tr>
</tbody>
</table>
CXF metrics interceptors, to track requests to services using their URL's.

The property set is `org.apache.cxf.resource.operation.name` and it contains service URL together with the HTTP method name, for example `GET:http://example.com:8080/service/`.

If this check box is not selected, the property will not be set and some metrics will not be counted, which may increase the performance.

<table>
<thead>
<tr>
<th>Convert Response To DOM Document</th>
<th>Select this check box to convert the response from the server to document type. Clear this check box if you want the response to be handled as a string.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Convert Types To Strings</td>
<td>This option appears when Content Type is JSON, or Accept Type is JSON or any. Select this check box to convert all values in JSON to string between quotation marks. For example, with this option enabled, the JSON data:</td>
</tr>
<tr>
<td></td>
<td>&quot;root&quot;: {</td>
</tr>
<tr>
<td></td>
<td>&quot;test&quot;: 111</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td>will be changed to:</td>
<td>&quot;root&quot;: {</td>
</tr>
<tr>
<td></td>
<td>&quot;test&quot;: &quot;111&quot;</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td>Drop JSON Request Root</td>
<td>This option appears when HTTP Method is POST, PUT or PATCH and Content Type is JSON. Select this check box to drop root JSON elements.</td>
</tr>
<tr>
<td>Wrap JSON Response</td>
<td>This option appears and is enabled by default when JSON is selected from the Accept Type list in the Basic settings view. With this check box selected, the response is wrapped with a root element. Clear this check box to remove the root element from the response.</td>
</tr>
<tr>
<td>HTTP Headers</td>
<td>Type in the name-value pair(s) for HTTP headers to define the parameters of the requested HTTP operation. For the specific definitions of HTTP headers, consult your REST Web service provider. For reference information, visit en.wikipedia.org/wiki/List_of_HTTP_headers.</td>
</tr>
<tr>
<td>Disable chunked encoding</td>
<td>This option appears when HTTP Method is POST, PUT or PATCH. Select this check box to disable encoding the payload as chunks.</td>
</tr>
<tr>
<td>Service Locator Customer Properties</td>
<td>This option appears when Use Service Locator is enabled in the Basic settings tab. Click [+] to add as many properties as needed to the table. Enter the name and the value of each property in the Property Name field and the Property Value field respectively to identify the service.</td>

<tr>
<td>Service Activity Customer Properties</td>
<td>This option appears when Use Service Activity Monitor is enabled in the Basic settings tab. Click [+] to add as many properties as needed to the table. Enter the name and the</td>
</tr>
</tbody>
</table>
Connection timeout

Set the amount of time, in seconds, that the client will attempt to establish a connection before it times out. If set to 0, the client will continue to attempt to open a connection indefinitely. (default: 30)

This option only works in the Studio and for DI Job use cases. For ESB Deployments to Talend Runtime, this parameter will have no effect when the component is deployed in runtime. In the configuration file `<TalendRuntimePath>/container/etc/org.apache.cxf.http.conduits-common.cfg`, you need a URL which covers your service, for example, `url = http://./*` to handle both HTTP and HTTPS requests, and specify the `client.ConnectionTimeout` parameter in milliseconds in this HTTP Conduit file. If you need to use the `Receive timeout` option, specify the `client.ReceiveTimeout` in milliseconds too.

Receive timeout

Set the amount of time, in seconds, that the client will wait for a response before it times out. If set to 0, the client will wait indefinitely. (default: 60) This option works similar to the `Connection timeout` for Studio, DI Use cases and ESB Runtime (OSGi / Microservice Deployments). For how to use it after the component is deployed in runtime or in the `Talend Administration Center`, see the `Connection timeout` option.

Use HTTP proxy

Select this check box if you are using a proxy server. Once selected, you need to provide the connection details: host, port, username and password.

tStatCatcher Statistics

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

Global Variables

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_LINE: the number of rows processed. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>HEADERS: the HTTP response headers. This is a Flow variable and it returns a list of HTTP response header values.</td>
</tr>
<tr>
<td></td>
<td>CORRELATION_ID: the correlation ID by which chained service calls will be grouped. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.</td>
</tr>
</tbody>
</table>
### Usage

#### Usage rule
This component is used as a RESTful Web service client to communicate with a RESTful service provider, with the ability to input a request to a service into a Job and return the Job result as a service response. Depending on the actions to perform, it usually works as a start or middle component in a Job or subjob.

#### Dynamic settings
Click the [+ ] button to add a row in the table and fill the Code field with a context variable to turn on or off the Use Authentication or Use HTTP proxy option dynamically at runtime. You can add two rows in the table to set both options.

Once a dynamic parameter is defined, the corresponding option becomes highlighted and unusable in the Basic settings view or Advanced settings view.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

#### Connections
Outgoing links:
- **Row**: Response; Error.
- **Trigger**: On Subjob Ok; On Subjob Error; Run if; On Component Ok; On Component Error.

Incoming links:
- **Row**: Main; Reject.
- **Trigger**: Run if; On Subjob Ok; On Subjob Error; On component Ok; On Component Error.

For further information regarding connections, see Talend Studio User Guide.

#### Limitation
Using context variables for dynamic endpoint or Service Locator namespace works in the Studio only. It is not supported in Runtime.

---

### Getting user information by interacting with a RESTful service

This scenario describes a three-component Job that retrieves user information based on the user ID from a REST service via HTTP GET and displays the retrieved user information, as well as the message exchange between the client and the server, on the Run console.

#### Prerequisites:
If you are a Talend Open Studio for ESB user, create a Job as described in Using URI Query parameters to explore the data of a database on page 3162, run the Job to expose a REST service, and enter the
REST service URL in your Web browser, http://localhost:8088/users in this example. You should see information like the following:

```
- <users>
  - <user id="1">  
    <first_name>Ronald</first_name>  
    <last_name>Johnson</last_name>  
  </user>
  - <user id="2">  
    <first_name>Theodore</first_name>  
    <last_name>Harding</last_name>  
  </user>
  - <user id="3">  
    <first_name>Bill</first_name>  
    <last_name>Roosevelt</last_name>  
  </user>
</users>
```

If you are not a Talend Open Studio for ESB user, then you need to get from your REST service provider the URL, the data structure, and the required parameters of the REST service you are going to call and make necessary modifications in the scenario configurations accordingly.

**Setting up the Job**

**Procedure**

1. Drop the following components from the Palette onto the design workspace:
   - tRESTClient, used to call the REST service and retrieve user information from the server end,
   - tXMLMap, used to adapt the tree structure of the REST service, and
   - tLogRow, to display the retrieved user information on the Run console.
2. Connect the tRESTClient to the tXMLMap using a Row > Response connection.
3. Connect the tXMLMap to the tLogRow using a Row > Main connection, and give it a name, out in this example.
4. Label the components to best describe the actions to perform.

**Configuring the components**

**Configuring the service call**

**Procedure**

1. Double-click the tRESTClient component to open its Basic settings view.
2. Fill the URL field with the URL of the REST service you are going to invoke, “http://localhost:8088/users” in this example. Note that the URL provided in this use case is for demonstration purposes only and not a live address.

3. From the HTTP Method list, select GET to send an HTTP request for retrieving the existing records.
   From the Accept Type list, select the type the client end is prepared to accept for the response from the server end, XML. Leave the rest of the settings as they are.

4. Click the [+] button beneath the Query parameters table to add two parameters, from and to, and set both parameters to 2, to get the information of the user with the ID of 2.
   Alternatively, you can query the information of the user with the ID of 2 by adding ?from=2&to=2 to the service URL.

5. In the Advanced settings view of the tRESTClient component, select the Log messages and the Convert Response To DOM Document check boxes to log the message exchange to the server and convert the response from the server to document type.

Mapping the service structure and displaying the retrieved user information

Procedure

1. Double-click the tXMLMap component to open the Map Editor.

2. If you selected XML in the Accept Type list of the tRESTClient component, define the input XML tree structure according to the service structure.
   a) In the input table, right-click the default root node of the body column, select Rename from the contextual menu, and rename it to users.
b) Right-click the *users* node, select **Create Sub-Element** from the contextual menu, and create sub-element named *user*. Set *user* as the loop element because the XML structure of the Web service to be invoked is looped on this element.

c) Right-click the *user* node, select **Create Attribute** from the contextual menu, and enter *id* in the **Create New Attribute** dialog box to create an attribute named *id* for the *user* node.

d) Right-click the *user* node again, select **Create Sub-Element** from the contextual menu, and enter *first_name* in the **Create New Element** dialog box to create an sub-element named *first_name* for the *user* node. Repeat this operation to create another sub-element under the *user* node, *last_name*.

e) Drop the *id*, *first_name* and *last_name* columns from the input table to the output table, and then click **OK** to validate the mapping and close the Map Editor.

If you selected **JSON** in the **Accept Type** list of the tRESTClient component, the response from the server end will be sent back in JSON format and converted to document type. In this example, the converted response structure looks like the following:

```xml
<root>
  <users>
    <user>
      <id>2</id>
      <first_name>Theodore</first_name>
      <last_name>Harding</last_name>
    </user>
  </users>
</root>
```
Note that the `<root>` element is removed if the **Wrap JSON Response** check box is cleared in the **Advanced settings** of the tRESTClient component.

Define the input XML tree structure accordingly and map it with the output data flow in a similar manner as described above.

3. Double-click the **tLogRow** component to open its **Basic settings** view.

4. Click the **Sync columns** button to make sure the component schema is synchronized with the output schema of the tXMLMap component.

5. In the **Mode** field, select the **Table** option to display the GET result in table cells.
Saving and executing the Job

Procedure

1. Press **Ctrl+S** to save your Job.
2. Press **F6** or click **Run** on the **Run** console to launch the Job.

   The console shows that the **tRESTClient** component successfully reads the user information from the server end corresponding to the specified user ID.

   If you selected **XML** in the **Accept Type** list of the **tRESTClient** component, the execution result will be:

   ```
   [statistics] connecting to socket on port 3496
   [statistics] connected
   May 26, 2014 5:38:17 PM
   org.apache.cxf.interceptor.LoggingOutInterceptor

   +-------+
   | id | first_name | last_name |
   +-------+
   | 2 | Theodore   | Harding   |
   +-------+
   [statistics] disconnected
   ```

   If you selected **JSON** in the **Accept Type** list of the **tRESTClient** component, the execution result will be:
Updating user information by interacting with a RESTful service

This scenario describes a three-component Job that updates the information of a list of users to a remote database through a REST service using the HTTP POST method. When executed, the Job displays the client-server message exchange information on the Run console.
The user information to be updated to the server is stored in a CSV file, which looks like the following:

<table>
<thead>
<tr>
<th>id</th>
<th>first_name</th>
<th>last_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>John</td>
<td>Smith</td>
</tr>
<tr>
<td>2</td>
<td>Martin</td>
<td>Reagan</td>
</tr>
<tr>
<td>3</td>
<td>James</td>
<td>White</td>
</tr>
<tr>
<td>4</td>
<td>Jenny</td>
<td>Jackson</td>
</tr>
<tr>
<td>5</td>
<td>Robert</td>
<td>Thomson</td>
</tr>
</tbody>
</table>

**Prerequisites:**

If you are a *Talend Open Studio for ESB* user, create a Job as described in REST service accepting HTTP POST requests on page 3170 and run the Job as a REST server to expose a REST service that accepts HTTP POST requests. Upon execution of the Job, the console displays the service implementation information, including the service endpoint URL, which is http://localhost:8045/users in this example. If you enter http://localhost:8045/users?_wadl in your Web browser, you should see the service definition information like the following:

```
<application>
  <grammars/>
  <resources base="http://localhost:8045/users">
    <resource path="/"/>
      <resource path="post/(id)/(first_name)/(last_name)">
        <param name="last_name" style="template" type="xs:string"/>
        <param name="id" style="template" type="xs:int"/>
        <param name="first_name" style="template" type="xs:string"/>
      </resource>
    <method name="POST">
      <request/>
      <response>
        <representation mediaType="application/xml"/>
        <representation mediaType="text/xml"/>
        <representation mediaType="application/json"/>
      </response>
    </method>
  </resource>
  </resources>
</application>
```

If you are not a *Talend Open Studio for ESB* user, then you need to get the service-related information from your REST service provider including the URL, the resource path, and the data structure, and make necessary modifications in the scenario configurations accordingly.
Setting up the Job

Procedure

1. Create a Job and add the following components by typing their names in the design workspace or drop them from the Palette:
   - `tFileInputDelimited`, to read user information of a local file,
   - `tXMLMap`, to adapt the input structure to the REST service structure, and
   - `tRESTClient`, used to call the REST service to send data to the remote database.

2. Connect the `tFileInputDelimited` to the `tXMLMap` using a `Row > Main` connection.

3. Connect the `tXMLMap` to the `tRESTClient` using a `Row > Main` connection, and give the output flow a name, `request` in this example.

4. Label the components to best describe the actions to perform.

Configuring the components

Configuring the input data and the structure mappings

Procedure

1. Double-click the `tFileInputDelimited` component to open its Basic settings view.

2. Specify the input file in the `File name` field, fill the `Header` field with 1 to skip the header row, and keep the rest parameters as they are.

3. Click the `[...]` button next to `Edit schema` to open the Schema dialog box, and edit the input schema as follows:
   - `id`, type Integer, 2 characters long, set as the key column
   - `first_name`, type String
   - `last_name`, type String
4. Double-click the tXMLMap component to open the Map Editor.
5. Rename the root node in the output table: right-click the node, select Rename from the contextual menu, and specify a new name in the pop-up dialog box, user in this example.
6. Select all the three columns in the input table and drop them onto the user node, and select the Create as sub-element of target node option from the pop-up dialog box to set these columns as sub-elements of the user node. When done, click OK to validate the mappings and close the Map Editor.
**Configuring the service call**

**Procedure**

1. Double-click the `tRESTClient` component to open its **Basic settings** view.

   ![Image of tRESTClient component configuration](image)

   **Basic settings**
   - **URL**: "http://localhost:8088/users"
   - **Relative Path**: "/post/" + row1.id + "/" + row1.first_name + "/" + row1.last_name
   - **HTTP Method**: POST
   - **Content Type**: XML
   - **Accept Type**: XML

2. Fill the **URL** field with the URI location where the REST service is accessible, "http://localhost:8088/users" in this example.

3. In the **Relative Path** field, enter the resource path, "/post/" + row1.id + "/" + row1.first_name + "/" + row1.last_name in this example. This will send the data from the input row to the server end via the resource path.

4. From the **HTTP Method** list, select **GET** to send an HTTP request for retrieving the existing records.
   - From the **Accept Type** list, select the type the client end is prepared to accept for the response from the server end, **XML**.

5. In the **Advanced settings** view of the `tRESTClient` component, select the **Log messages** check box to log the message exchange information with the server.
   - Leave the rest of the settings as they are.

**Running the Job and checking the result**

Press **Ctrl+S** to save your Job, and press **F6** to execute it.

The console displays the client-server exchange information:
The console of the server Job displays the exchange information and the database update result.

tRESTRequest

Receives GET/POST/PUT/PATCH/DELETE requests from the clients on the server end.

tRESTRequest accepts the HTTP and/or HTTPS requests from the clients and supports GET, POST, PUT, PATCH and DELETE HTTP methods.

Note:
To enable the HTTPS support, you have to generate a keystore and add some HTTPS security configuration properties in the `org.ops4j.pax.web.cfg` file of your Runtime container before deploying the service on it. For more information, see the Talend ESB Container Administration Guide.

**tRESTRequest Standard properties**

These properties are used to configure tRESTRequest running in the Standard Job framework.

The Standard tRESTRequest component belongs to the ESB family.

This component is relevant only when used with one of the Talend solutions with ESB, as it should be used with the Service Repository node and the Data Service creation related wizard(s).

**Basic settings**

| REST Endpoint | Fill this field with the URI location where REST-ful web service will be accessible for requests. You can either specify an explicit port number, for example, "http://localhost:8088/services/customers", or use the default port of Talend and specify the relative path only, for example, "/services/customers". The default port is different depending on the build type or where you run the service:  
• To run the service inside Talend Studio: 8090  
• To run the service in a Talend Runtime Container: for HTTP 8040 is used for all services, and if HTTPS is enable on Talend Runtime Container the service is also exposed on 9001.  
• To run the service as a Microservice: 8065 |
|----------------|---------------------------------------------------------------|
| REST API Mapping | Click the [+] button beneath the mapping table to add lines to specify HTTP request:  
**Output Flow:** Click the [...] button to specify the name of an output flow and set the schema for that output flow in the dialog box afterwards.  
The schema is not mandatory, so if you do not need to pass additional parameters to the tRESTRequest component, you can leave the schema empty. However, you will have to populate the schema if you have URI Path parameters set in the URI Pattern field or if you need to add optional request parameters such as URI Query, HTTP Header or Form parameters, to the URI specified in the REST Endpoint field. |
Add a schema with the name `body` to get the request body of `POST` and `PUT` methods. It supports `Document`, `String`, and `Byte` types.

If you specify URI parameters in the output flow schema, you might need to define what type of parameter it is in the `Comment` field of the schema. By default, if you leave the `Comment` field empty, the parameter is considered as a Path parameter. Below is a list of supported `Comment` values:

- empty or `path` corresponds to the default `@PathParam`,
- `query` corresponds to `@QueryParam`,
- `form` corresponds to `@FormParam`,
- `header` corresponds to `@HeaderParam`,
- `matrix` corresponds to `@MatrixParam`.
- `multipart` corresponds to the CXF specific `@Multipart`, representing the request body. It can be used only with `POST` and `PUT` HTTP methods.

**Note:**
We recommend you to set the default values of your optional parameters (Header, Query, Form). To do so, fill in the `Default` columns of the schema.

**HTTP Verb:** Select a HTTP method (GET/POST/PUT/PATCH/DELETE/OPTIONS/HEAD) from the list.

**URI pattern:** Fill this field with REST-ful URIs that describe the resource.

**Consumes:** Select the format type of the consume content that the component will use from XML or JSON, XML, JSON, Form, Multipart and Any in the list when the HTTP method is POST, PUT or PATCH.

**Produces:** When the HTTP method is GET, POST, PUT, PATCH, or DELETE, select the format type of the produce content that the component will use from XML or JSON, XML, JSON, HTML and Any, or select `<oneway>` in the list to accept one way requests.

**Streaming:** Select this check box to stream the response data by chunks so that the large volumes of data can be processed efficiently.

**Use Service Locator**
Select this check box to enable the Service Locator. It maintains the availability of the service to help meet demands and service level agreements (SLAs). Specify the Service namespace and the Service name in the corresponding fields.

**Use Service Activity Monitor**
Select this check box to enable the Service Activity Monitor. It captures events and stores this information to facilitate in-depth analysis of service activity and track-and-trace of messages throughout a business transaction. This can be used to analyze service response times, identify traffic patterns, perform root cause analysis and more.

**Use Authentication (ESB runtime only)**
Select this check box to enable the authentication option for the current service. This option works in runtime only. Select the authentication type from:

- **Basic HTTP:** The simplest technique for enforcing access controls to web resources using standard fields in the HTTP header.
- **SAML Token**: An XML-based, open-standard data format for exchanging authentication and authorization data between an identity provider and a service provider.

### Use Business Correlation

Select this check box to enable the correlation option so that chained service calls will be grouped under the same correlation ID. `tRESTRequest` will extract the correlation ID from the request header and store it in the component variable for further use in the flow.

If this option is not enabled on the client side, a correlation ID will be generated automatically in `tRESTRequest`.

### Advanced settings

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Log messages</td>
<td>Select this check box to log the message exchange between the service provider and the consumer.</td>
</tr>
<tr>
<td>Wrap JSON Request</td>
<td>Select this check box to wrap the JSON request with a root element.</td>
</tr>
<tr>
<td>Convert JSON values to String in response</td>
<td>Select this check box to convert the JSON values to string format in the response.</td>
</tr>
</tbody>
</table>

#### Service Locator Customer Properties

This option appears when **Use Service Locator** is enabled in the Basic settings tab. Click `[+]` to add as many properties as needed to the table. Enter the name and the value of each property in the **Property Name** field and the **Property Value** field respectively to identify the service.

#### Service Activity Customer Properties

This option appears when **Use Service Activity Monitor** is enabled in the Basic settings tab. Click `[+]` to add as many properties as needed to the table. Enter the name and the value of each property in the **Property Name** field and the **Property Value** field respectively to identify the service.

#### tStatCatcher Statistics

Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE</strong></td>
<td>the number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>URI</strong></td>
<td>the URI of the REST request. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td><strong>URI_BASE</strong></td>
<td>the base URI of the REST request. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td><strong>URI_ABSOLUTE</strong></td>
<td>the absolute URI of the REST request. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td><strong>HTTP_METHOD</strong></td>
<td>the http method. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td><strong>ATTACHMENT_HEADERS</strong></td>
<td>the attachment headers from the REST request. This is a Flow variable and it returns a list of attachment header values.</td>
</tr>
</tbody>
</table>
ATTACHMENT_FILENAMES: the attachment filenames from the REST request. This is a Flow variable and it returns all attachment filenames.

PRINCIPAL_NAME: the principal name of the REST request. This is a Flow variable and it returns a string.

CORRELATION_ID: the correlation ID by which chained service calls will be grouped. This is a Flow variable and it returns a string.

ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

| Usage rule | This component covers the possibility that a Talend Job can be wrapped as a service, with the ability to input a request to a service into a Job and return the Job result as a service response.

The tRESTRequest component should be used with the tRESTResponse component to provide a Job result as a response, in case of a request-response communication style. |

| Limitation | Using context variables for dynamic endpoint or Service Locator namespace works in the Studio only. It is not supported in Runtime. |

Using a REST service to accept HTTP GET requests and send responses

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

This scenario describes the process of accepting an HTTP request from the client, processing it and sending the response back.
Configuring the tRESTRequest component

Procedure

1. Drop the following components from the Palette onto the design workspace: a tRESTRequest, two tXMLMap and two tRESTResponse.

2. Double-click tRESTRequest in the design workspace to display its Basic settings view.

3. Fill the REST Endpoint field with the URI location where the REST-ful web service will be accessible for requests. For example, "http://192.168.0.235:8088/user".

   Note:
   If you want your service to be available on both HTTP and HTTPS, fill the field with a relative path. For example, if you type in "/test", your service will be available on both http://<DefaultHTTPEndpointAddress>/test and https://<DefaultHTTPSEnpointAddress>/test, provided that you have configured your Runtime container to support HTTPS. For more information, see the Talend ESB Container Administration Guide.

4. Click the [+] button to add one line in the REST API Mapping table.
5. Select the newly-added line and click the [...] button in the Output Flow column to add a schema for the output flow.
   In this scenario, the output flow will be named as GetOneUser.

<table>
<thead>
<tr>
<th>Column</th>
<th>Key</th>
<th>Type</th>
<th>N.</th>
<th>Date Patt.</th>
<th>Length</th>
<th>Pre.</th>
<th>D.</th>
<th>Co.</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td></td>
<td>String</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Then click the [+ ] button to add a new line id to the schema in the dialog box.

6. Click OK to save the schema.

7. Select GET from the list in the HTTP Verb column.

8. Fill the field in the URI Pattern column with "/{id}/".

9. In the same way, add another line in the REST API Mapping table and name this schema GetUserNumber. Add a line string of String type to the schema. Enter query in the Comment field to get the number parameter in the request.

Select GET from the list in the HTTP Verb column. Fill the field in the URI Pattern column with " / number".

**Configuring the first tXMLMap component**

**Procedure**

1. Connect tRESTRequest to a tXMLMap using the Row > GetOneUser connection.
2. Double-click tXMLMap in the design workspace to open the Map Editor.
3. Click the [+] button on the top right to add an output and name it as \textit{ResponseUsers}.

4. Click the [+] button on the bottom right to add two columns for the output.
   Name the first column as \textit{body} and set the \textbf{Type} to Document.
   Name the second column as \textit{string} and set the \textbf{Type} to String.

5. Right-click on the node \textit{root} and select \textbf{Create Sub-Element} to create a sub-element. Name the sub-element as \textit{foo} in the popup dialog box.

6. Right-click on the \textit{foo} node created in the previous step and select \textbf{As loop element}.

7. Select the \textit{id} column of the \textit{GetOneUser} table to the left and drop it onto the Expression field of the \textit{foo} node of the \textit{ResponseUsers} table to the right.

8. Click \textbf{OK} to save the settings.

**Configuring the second \texttt{tXMLMap} component**

**Procedure**

1. Connect \texttt{tRESTRequest} to the other \texttt{tXMLMap} using the \textbf{Row} > \texttt{GetUserNumber} connection.

2. Double-click the first \texttt{tXMLMap} in the design workspace to open the Map Editor.
3. Click the [+] button on the top right to add an output and name it as ResponseUserNumber.
4. Click the [+] button on the bottom right to add one column for the output. Name the first column as body and set the Type to Document.
5. Right-click on the node root and select Create Sub-Element to create a sub-element. Name the sub-element as number in the popup dialog box.
6. Right-click on the number node created in the previous step and select As loop element.
7. Select the string column of the GetUserNumber table to the left and drop it onto the Expression field of the number node of the ResponseUserNumber table to the right.
8. Click OK to save the settings.

Configuring the tRESTResponse component

Procedure
1. Connect tXMLMap to a tRESTResponse using Row > ResponseUsers connection. The schema defined in tXMLMap is retrieved in tRESTResponse automatically.
2. Select OK(200) from the Return status code list.
3. Leave the rest of the settings as they are.
4. Connect **tRESTRequest** to the other **tRESPonse** using the Row > **GetUserNumber** connection.

### Saving and executing the Job

**Procedure**

1. Save the Job and press **F6** to execute it.

   ```
   [statistics] connecting to socket on port 3888
   [statistics] connected
   [INFO ]: org.apache.cxf.endpoint.ServerImpl - Setting the server's publish address to be http://localhost:8088/user
   [INFO ]: org.eclipse.jetty.server.AbstractConnector - Started
   SelectChannelConnector@localhost:8088
   ```
   
   2. Go to your browser if you want to test the service.

   ![Browser Screenshot](image)

   The HTTP request for a user id is accepted by the REST service and the HTTP response is sent back to the server.

   3. Repeat this step and type in **http://localhost:8088/user/number?string=123** in the address bar. Press Enter.

   ![Browser Screenshot](image)

   You can see that 123 is returned in the response.
Using URI Query parameters to explore the data of a database

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

This scenario describes how to use URI query parameters in tRESTRequest to explore data of a database, and send the response via the tRESTResponse.

To do so, you can create two subjobs linked together by an OnSubjobOk connection; this way the two subjobs will be executed sequentially. For more information on Trigger connection, see the Talend Studio User Guide. The first subjob will create and populate the database and the second one will allow to explore the database through the REST service.

Creating the first subJob

About this task

To do this, proceed as follows:

Procedure

1. Drop the following components from the Palette onto the design workspace: tFixedFlowInput from the Misc family and tMysqlOutput from the Databases > Mysql family.
2. Link tFixedFlowInput to tMysqlOutput using a Row > Main connection.
3. Double-click **tFixedFlowInput** to display its **Basic settings** view:

![Basic settings view of tFixedFlowInput](image1)

4. Click the [...] button next to **Edit schema** to open the schema editor.

![Schema editor](image2)

5. In the schema editor, click the [+ ] button three times to add three lines and set them as displayed in the above screenshot.

6. Click **Ok**.

7. Back to **tFixedFlowInput** Basic settings view, in the **Mode** area, select the **Use inline table** option.

8. Under the inline table, click the [+ ] button three times to add three rows in the table.

9. In the inline table, click the **id** field of the first row and type in **1**.

10. Click the **firstname** field of the first row, press **Ctrl+Space** to display the autocompletion list and select the **TalendDataGenerator.getFirstName()** variable in the list.

11. Click the **lastname** field of the first row, press **Ctrl+Space** to display the autocompletion list and select the **TalendDataGenerator.getLastName()** variable in the list.

12. Do the same for the two following rows to obtain the settings displayed in the screenshot.
13. Double-click **tMysqlOutput** to display its **Basic settings** view:

![Image of tMysqlOutput settings](image)

14. From the **Property Type** list, leave **Built-in** and fill in the **Host**, **Port**, **Database**, **Username** and **Password** fields manually. If you centralized your connection information to the database in the **Metadata > DB Connections** node of the **Repository**, you can select **Repository** from the list and the fields will be automatically filled in.

For more information about storing metadata, see *Talend Studio User Guide*.

15. In the **Table** field, type in the name of the table in which the data will be loaded, for example: `users`.

16. From the **Action on table** list, select **Drop table if exists and create**, select **Insert** from the **Action on data** list.

17. Click **Sync columns** to retrieve the schema coming from the previous component.

**Creating the second subJob**

The following components are used as displayed in the first screenshot:

- **tRESTRequest** and **tRESTResponse** from the **ESB > REST** family,
- **tFlowToIterate** from the **Orchestration** family,
- **tMysqlInput** from the **Databases > MySql** family,
- **tXMLMap** from the **Processing** family.

**Configuring the tRESTRequest component**

**About this task**

To do this, proceed as follows:
Procedure

1. Double-click tRESTRequest in the design workspace to display its Basic settings view:

   ![REST Request Basic Settings](image1)

2. Fill the REST Endpoint field with the URI location where the REST-ful web service will be accessible for requests. For example, "http://localhost:8088/users".

3. Click the [+] button to add one line in the REST API Mapping table.

4. Select the newly-added line and click the [...] button in the Output Flow column to add a schema for the output flow.

5. In the dialog box, name the output flow getUsers. A schema editor dialog box appears.

   ![Schema Editor](image2)

6. In the schema editor, click the [+] button twice to add two lines and set them as displayed in the above screenshot.

7. Click OK.

8. Back to tRESTRequest Basic settings view, select GET from the list in the HTTP Verb column.

9. Leave the URI Pattern column as is.

10. Use the corresponding link to connect to the following component: connect tRESTRequest to tFlowToIterate using Row > getUsers connection.
11. Leave the tFlowToIterate settings as is.
12. Connect tFlowToIterate to tMysqlInput using Row > Iterate connection.

Configuring the tMysqlInput component

About this task

To do this, proceed as follows:

Procedure

1. Double-click tMysqlInput to display its Basic settings view:

   ![tMysqlInput settings](image)

2. From the Property Type list, leave Built-in and fill in the Host, Port, Database, Username and Password fields manually. If you centralized your connection information to the database in the Metadata > DB Connections node of the Repository, you can select Repository from the list and the fields will be automatically filled in.

   For more information about storing metadata, see Talend Studio User Guide.

3. Leave the Schema list as Built-in and click the [...] button next to the Edit schema field.

4. In the schema editor, define the schema exactly like the one of the tFixedFlowInput.

5. In the Table Name field, fill in the name of the table in which the data are stored: users.

6. Leave the Query Type list as Built-in and fill in the Query field with the following SQL query allowing to explore the database data with the URI query set in the tRESTRequest component:

   ```
   "select * from users where id >= " + globalMap.get("getUsers.from") + " and id <= " + globalMap.get("getUsers.to")
   ```

Configuring the tXMLMap component

Procedure

1. Right-click tMysqlInput, hold and drag to tXMLMap to connect the two components together.
2. Double-click `tXMLMap` in the design workspace to open the **Map Editor**.

3. Click the `[+]` button on the top right to add an output and name it as `ResponseUsers`.
4. Click the `[+]` button on the bottom right to add two columns for the output.
   - Name the first column as `body` and set the **Type** to `Document`.
   - Name the second column as `string` and set the **Type** to `String`.
5. Right-click on the root node, select **Rename** in the list and rename it `users`.
6. Right-click on the `users` node and select **Create Sub-Element** to create a sub-element. Name the sub-element `user` in the popup dialog box.
7. Right-click on the `user` node created in the previous step and select **As loop element**.
8. Select the `id` column of the `row2` table to the left and drop it onto the `user` node of the `ResponseUsers` table to the right.
9. In the **Selection** dialog box, select the **Create as attribute of target** node option and click **OK**.
10. Select the `firstname` and `lastname` columns of the `row2` table to the left and drop it onto the `user` node of the `ResponseUsers` table to the right.
11. In the **Selection** dialog box, select the **Create as sub-element of target node** option and click **OK**.

12. Click the wrench icon on the top of the **ResponseUsers** table to open the setting panel.

13. Set the **All in one** feature as **true**, this way all XML data is outputted in one single flow.

14. Click **OK** to save the settings.

**Configuring the tRESTResponse component**

**Procedure**

1. Connect **tXMLMap** to **tRESTResponse** using **Row > ResponseUsers** connection.

2. The schema defined in **tXMLMap** is retrieved in **tRESTResponse** automatically. Leave the other settings as they are.
## Connecting the two subJobs

### About this task

Now that the two subJobs are created, you can connect them together:

### Procedure

1. Right-click the `tFixedFlowInput` component of the first subJob.
2. Select **Trigger > OnSubjobOk** on the list.
3. Click the `tRESTRequest` component of the second subjob.

### Results

This way, when executing the job, the second subjob will be executed only if the first one’s execution succeeded.

## Saving and executing the Job

### Procedure

1. Save the Job and press **F6** to execute it.

```
[statistics] connecting to socket on port 4020
[statistics] connected
[INFO ]: org.apache.cxf.endpoint.ServerImpl - Setting the server's publish address to be http://localhost:8080/users
[INFO ]: org.eclipse.jetty.server.AbstractConnector - Started
  SelectChannelConnector@localhost:8088
```

2. Go to your browser if you want to test the service.
   For example, use the URI query `?to=2` to retrieve the data of the two first users.
The HTTP request for a user id is accepted by the REST service and the HTTP response is sent back to the server.

For a use case that calls this REST service using Talend Open Studio for ESB components, see Getting user information by interacting with a RESTful service on page 3140.

**REST service accepting HTTP POST requests**

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

This scenario describes a Job composed of two subJobs: the first subJob exposes a REST service that accepts HTTP POST requests from REST clients, writes data to a database upon receiving an HTTP request, and displays the server-client exchange information on the Run console; the second subJob displays the results of database updates.
Setting up the Job

Procedure

1. Create a Job and add the following components to the Job by typing their names in the design workspace or dropping them from the Palette: a tRESTRequest, a tMysqlOutput, a tXMLMap, and a tRESTResponse.
2. Connect the tRESTRequest to the tMysqlOutput component using a Row > Main connection, and give the output flow a name, request in this example.
3. Connect the tMysqlOutput component to the tXMLMap component using a Row > Main connection.
4. Connect the tXMLMap component to the tRESTResponse component using a Row > Main connection, and give it a name, response in this example. Click OK in the pop-up dialog box to accept the schema propagation from the tRESTResponse component.
5. Add a tMysqlInput component and a tLogRow component to the Job by typing their names in the design workspace or dropping them from the Palette, and connect the tMysqlInput to the tLogRow using a Row > Main connection.
6. Connect the tMysqlOutput to the tMysqlInput using a Trigger > OnComponentOk connection to link the two subjobs.

Configuring the components

Configuring REST request parameters

Procedure

1. Double-click the tRESTRequest component to open its Basic settings view.

2. Fill the REST Endpoint field with the URI location where the REST service will be accessible for requests, "http://localhost:8045/users" in this example.
3. Click the output flow name, which is request in this example, in the Output Flow column of the REST API Mapping table to show the [...] button, and click the button to open the Schema dialog box. Then define the schema for the request flow as follows:
   - id, type Integer, 2 characters long, set as the key column
   - first_name, type String
   - last_name, type String
When done, click **OK** to validate the schema setting and close the dialog box.

4. Click the **HTTP Verb** column and select **POST** from the list.

5. In the **URI Pattern** column, enter the acceptable URI pattern of POST requests, "/post/{id}/{first_name}/{last_name}" in this example. Leave the rest parameters as they are.

6. Click the **Advanced settings** tab, and select the **Log messages** check box.

**Configuring the database and the response parameters**

**Procedure**

1. Double-click the **tMysqlOutput** component to open its **Basic settings** view.

2. Leave the **Property Type** as **Built-in** and fill in the database connection details manually in the Host, Port, Database, Username and Password fields.

   If you have centralized your connection information to the database in the **Metadata > DB Connections** node of the Repository, you can select **Repository** from the **Property Type** list and browse to the centralized connection to have the fields automatically filled in. For more information about storing metadata, see  *Talend Studio User Guide*. 
3. Fill in the **Table** field with the target database table name, *users* in this example.

4. Select the actions to be carried out on the database table and data according to your needs from the corresponding lists. In this example, the target table will be created if it does not exist in the specified database, and data from client requests will be inserted, or updated if it already exists, to the database table.

5. Click the **Sync columns** button to synchronize the table schema with the input schema.

6. Double-click the **tXMLMap** component to open the Map Editor.

7. Rename the *root* node in the output table: right-click the node, select **Rename** from the contextual menu, and specify a new name in the pop-up dialog box, *user* in this example.

8. Select all the three columns in the input table and drop them onto the *user* node, and select the **Create as sub-element of target node** option from the pop-up dialog box to set these columns as sub-elements of the *user* node. When done, click **OK** to validate the mappings and close the Map Editor.

9. Double-click the **tRESTResponse** component and set the response parameters according to your needs. In this example, we keep the default settings for all the parameters.

**Configuring result display**

**Procedure**

1. Double-click the **tMysqlInput** component to open its **Basic settings** view.
2. Specify the database connection details, table name and table schema, which are the same as in the `tMysqlOutput` component.

3. Click the `Guess Query` button to fill the `Query` field with the query statement.

4. Double-click the `tLogRow` component and select the `Table` option to display the content of the database in table cells.

### Saving the executing the Job

**Procedure**

1. Press `Ctrl+S` to save your Job.

2. Click the `Run` button on the `Run` tab or press `F6` to run it.

   The console displays the service implementation information, including the service URL.

   ```
   [statistics] connecting to socket on port 3360
   [statistics] connected
   [INFO ]: org.apache.cxf.endpoint.ServerImpl - Setting the server's publish address to be http://localhost:8045/users
   [INFO ]: org.eclipse.jetty.server.AbstractConnector - Started
   SelectChannelConnector@localhost:8045
   ```

When an HTTP POST request is received from a client, the console displays the relevant exchange information and the database update result.
For a use case that calls this REST service using the HTTP POST method, see [Updating user information by interacting with a RESTful service](#) on page 3146.

**REST service accepting HTTP POST requests and sending responses**

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

This scenario describes how to build a REST service that accepts HTTP POST requests of Document type from the client, processes it and sends the response back. To do this, two Jobs are built: one to create the REST service and the other to call it.

**Creating the REST service Job**

Drag and drop the following components from the Palette onto the design workspace: a `tRESTRequest`, a `tXMLMap` and a `tRESTResponse`. 
Configuring the tRESTRequest component

Procedure

1. Double-click tRESTRequest in the design workspace to display its Basic settings view.

2. In the REST Endpoint field, keep the default URI "http://localhost:8088/" where the REST-ful web service will be accessible for requests.

3. Click the [+] button to add one line in the REST API Mapping table.

4. Select the newly-added line and click the [...] button in the Output Flow column to add a schema for the output flow. Give the name for the schema UserInfo in this scenario.

   The schema editor opens. Click the [+] button to add a new line body of Document type and click OK to save the schema.
5. Back to **tRESTRequest Basic settings** view, select **POST** from the list in the **HTTP Verb** column.
6. Fill the field in the **URI Pattern** column with ‘/UserInfo’. Keep the default settings of the other options.

**Configuring the body of the response**

**Procedure**

1. Connect **tRESTRequest** to **tXMLMap** using the **Row > UserInfo** connection.
2. Double-click **tXMLMap** in the design workspace to open the **Map Editor**.
3. Right-click on the root node of the input table and select Create Sub-Element. Name the sub-element as person in the popup dialog box.
4. Right-click on the person node created in the previous step and select As loop element.
5. Create two sub-elements to the person node by selecting Create Sub-Element in the contextual menu, id and name in this use case.
6. Click the [+] button on the top right to add an output and name it as Response.
7. Click the [+] button on the bottom right to add a column body of Document type for the output.
8. Right-click the node root in the output table and select Create Sub-Element. Name the sub-element as person in the popup dialog box.
9. Right-click the person node created in the previous step and select As loop element.
10. Create three sub-elements to the person node by selecting Create Sub-Element in the contextual menu, id, name and company in this use case.
11. Select the id column from the input table and drop it onto the Expression field of the id node of the output table.
12. Select the name column from the input table and drop it onto the Expression field of the name node in the output table.
   Click the Expression field of the name node in the output table, and click [...] in this field to show the Expression Builder wizard.
   In the Expression area, enter StringHandling.UPCASE([UserInfo.body:/root/person/name]) to convert the name of the user to upper case. Click OK to close the wizard.

   For further information about using the Expression Builder, see Talend Studio User Guide.
13. In the Expression field of the company node, enter “Talend”.
14. Click OK to save the settings.

Configuring the tRESTResponse component

Procedure

1. Connect tXMLMap to a tRESTResponse using Row > Response connection.
   The schema defined in tXMLMap is retrieved in tRESTResponse automatically.
2. Select **OK(200)** from the **Return status code** list.
3. Leave the rest of the settings as they are.

### Launching the service

Save the Job and press **F6** to execute it. The service is started.

### Creating the consumer Job

Drag and drop the following components from the Palette onto the design workspace: a **tFixedFlowInput**, a **tXMLMap**, a **tRESTClient** and a **tLogRow**.

### Configuring the tFixedFlowInput component

#### Procedure

1. Double-click **tFixedFlowInput** in the design workspace to display its **Basic settings** view.
2. Click **Edit schema** to show the schema editor. In the schema editor, click the [] button to add two columns of **String** type, *id* and *name*. Click **Ok** to close the schema editor.

3. Back to **tFixedFlowInput Basic settings** view, in the **Mode** area, select the **Use Inline Content** option.

4. In the **Content** box, enter the *id* and *name* of three users, for example:

   1;ford
   2;smith
   3;thomson

**Configuring the tXMLMap component**

**Procedure**

1. Connect **tFixedFlowInput** to **tXMLMap** using the **Row > Main** connection.
2. Connect **tXMLMap** to **tRESTClient** using the **Row > Main** connection, and name the output flow *request* in this example.
3. Double-click **tXMLMap** in the design workspace to open the **Map Editor**.
4. Right-click on the node root in the output table and select Create Sub-Element. Name the sub-element as person in the popup dialog box.

5. Right-click on the person node created in the previous step and select As loop element.

6. Create two sub-elements to the person node by selecting Create Sub-Element in the contextual menu, id, and name in this use case.

7. Select the id column from the input table and drop it onto the Expression field of the id node of the output table.

8. Select the name column from the input table and drop it onto the Expression field of the name node in the output table.

9. Click OK to save the settings.

**Configuring the tRESTClient component**

**Procedure**

1. Double-click the tRESTClient component to open its Basic settings view.
2. Fill the **URL** field with the URL of the REST service built in the service Job, "http://localhost:8088/".

3. Fill the **Relative Path** with the "UserInfo".

4. From the **HTTP Method** list, select **POST**.

5. Leave the rest of the settings as they are.

6. Connect **tRESTClient** to **tLogRow** using the **Row > Response** connection. Keep the default settings of the **tLogRow** to monitor the message exchanges.

**Saving and executing the Job**

Save the Job and press **F6** to execute it. The user information is shown in the console, including *id*, *name*, and *company*. The name of the user has been converted to upper case.
REST service accepting HTTP POST requests in an HTML form

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

This scenario describes how to upload data to a REST service using HTTP POST in an HTML form file. To do so, a Job is created to accept HTTP POST requests using the tRESTRequest component.

A predefined HTML form UploadFile.html is used to upload data to the REST service:

```
<form action="http://localhost:8088/UserInfo" method="post" enctype="multipart/form-data">
  <input type="file" name="id" />
  <button>upload</button>
</form>
```

The customer.xml that contains a user ID will be uploaded:

```
<customer>
  <id>100</id>
</customer>
```

Setting up the Job

Drop the following components from the Palette onto the design workspace: a tRESTRequest, a tJavaRow, a tXMLMap and a tRESTResponse.
Configuring the tRESTRequest component

Procedure

1. Double-click tRESTRequest in the design workspace to display its Basic settings view.

   ![tRESTRequest component](image)

   - **REST Endpoint**: Keep the default URI "http://localhost:8088/" where the REST-ful web service will be accessible for requests.
   - **REST API Mapping**: Add a line in the table.
   - **Output Flow**: Add a schema for the output flow. Name it "UserInfo".
   - **HTTP Verb**: Select POST.
   - **URI Pattern**: Enter "/UserInfo".
   - **Consumes**: Select Multipart. Keep other options default.

2. In the REST Endpoint field, keep the default URI "http://localhost:8088/" where the REST-ful web service will be accessible for requests.

3. Click the [+] button to add one line in the REST API Mapping table.

4. Select the newly-added line and click the [...] button in the Output Flow column to add a schema for the output flow. Give the name for the schema UserInfo in this scenario.

   The schema editor opens. Click the [+] button to add a new line id of byte[] type and enter multipart in the Comment field. Click OK to save the schema.

5. Back to tRESTRequest Basic settings view, select POST from the list in the HTTP Verb column.

6. Fill the field in the URI Pattern column with "/UserInfo".

7. Select Multipart in the Consumes list. Keep the default settings of the other options.
Configuring the tJavaRow component

Procedure

1. Connect tRESTRequest to tJavaRow using the Row > UserInfo connection.
2. Double-click tJavaRow in the design workspace to display its Basic settings view.

```
String result = new String(input_row.id, 0, input_row.id.length);
String input_row = new String(input_row.id, 0, input_row.id.length);
System.out.println(result);
```

3. Enter the following code in the Code box to convert the message into Document type and print it in the console.

```
String result = new String(input_row.id, 0, input_row.id.length);
String input_row = new String(input_row.id, 0, input_row.id.length);
System.out.println(result);
```

Configuring the tXMLMap component

Procedure

1. Connect tJavaRow to tXMLMap using the Row > Main connection.
2. Double-click tXMLMap in the design workspace to open the Map Editor.
3. Click the [+] button on the bottom left to add a column \textit{id} of \textit{Document} type for the input.

4. Right-click the \textbf{root} node of the input table and select \textit{Rename} in the contextual menu and rename it \textit{customer}.

5. Create a sub-element to the \textit{customer} node by selecting \textbf{Create Sub-Element} in the contextual menu. Name the sub-element as \textit{id} in the pop-up dialog box.

6. Click the [+] button on the top right to add an output and name it as \textit{response}.

7. Click the [+] button on the bottom right to add a column \textit{body} of \textit{Document} type for the output.

8. Right-click the \textbf{root} node of the input table and select \textit{Rename} in the contextual menu and rename it \textit{customer}.

9. Create a sub-element to the \textit{customer} node by selecting \textbf{Create Sub-Element} in the contextual menu. Name the sub-element as \textit{id} in the pop-up dialog box.

10. Select the \textit{id} column from the input table and drop it onto the \textit{Expression} field of the \textit{id} node of the output table.

11. Click \textit{OK} to save the settings.

\textbf{Configuring the tRESTResponse component}

\textbf{Procedure}

1. Connect \textbf{tXMLMap} to a \textbf{tRESTResponse} using \textit{Row} > \textit{response} connection.
   The schema defined in \textbf{tXMLMap} is retrieved in \textbf{tRESTResponse} automatically.
2. Select **OK(200)** from the Return status code list.

3. Leave the rest of the settings as they are.

**Saving and executing the Job**

**Procedure**

1. Save the Job and press **F6** to execute it.

2. Run the UploadFile.html using a web browser.

3. Click the **Browse** button to navigate to the **customer.xml** that contains the user ID and click **upload**.
4. The HTTP POST request is accepted by the REST service and the user ID is sent back to the server.

You can also view the response in the page source.

5. The content of the input file is printed in the execution console.
<customer>
  <id>100</id>
</customer>
tRESTResponse

Returns a specific HTTP status code to the client end as a response to the HTTP and/or HTTP requests.

Note:
To enable the HTTPS support, you have to generate a keystore and add some HTTPS security configuration properties in the `org.ops4j.pax.web.cfg` file of your Runtime container. For more information, see the Talend ESB Container Administration Guide.

## tRESTResponse Standard properties

These properties are used to configure tRESTResponse running in the Standard Job framework.

The Standard tRESTResponse component belongs to the ESB family.

*This component is relevant only when used with one of the Talend solutions with ESB, as it should be used with the Service Repository node and the Data Service creation related wizard(s).*

### Basic settings

<table>
<thead>
<tr>
<th>Return Body Type</th>
<th>Select a response body type from Document, String, and Byte in the list.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Return status code</td>
<td>Select a status code from the list to indicate the request status.</td>
</tr>
<tr>
<td>- &lt;&lt;Custom&gt;&gt;: This option allows you to customize the status code. Enter the status code of your choice in the field.</td>
<td></td>
</tr>
<tr>
<td>- Bad Request (400): The request had bad syntax or was inherently impossible to be satisfied.</td>
<td></td>
</tr>
<tr>
<td>- Internal Server Error (500): The server encountered an unexpected condition which prevented it from fulfilling the request.</td>
<td></td>
</tr>
<tr>
<td>- OK (200): The request was fulfilled.</td>
<td></td>
</tr>
<tr>
<td>- Resource Not Found (404): The server has not found anything matching the URI given.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Schema and Edit schema</th>
<th>A schema is a row description, that is, it defines the number of fields to be processed and passed on to the next component.</th>
</tr>
</thead>
<tbody>
<tr>
<td>The schema mode is Built-in: it is created and stored locally for this component.</td>
<td></td>
</tr>
<tr>
<td>Click Edit schema to make changes to the schema.</td>
<td></td>
</tr>
<tr>
<td>The input flow is retrieved from the previous component connected to tRESTResponse. Any change of the input flow in tRESTResponse will also be propagated to the previous component automatically.</td>
<td></td>
</tr>
<tr>
<td>The output flow of tRESTResponse is a hard-coded field named body, the type of which is defined in the Return Body Type list.</td>
<td></td>
</tr>
</tbody>
</table>
Advanced settings

<table>
<thead>
<tr>
<th>Response Headers</th>
<th>Type in the name-value pair(s) to pass additional information about the response. For more information about response headers, see the site <a href="http://www.w3.org/Protocols/rfc2616/rfc2616-sec6.html#sec6.2">http://www.w3.org/Protocols/rfc2616/rfc2616-sec6.html#sec6.2</a>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Drop JSON Response Root</td>
<td>Select this check box to drop the root JSON element in the response.</td>
</tr>
<tr>
<td>JSON Array Keys</td>
<td>Type in the keywords for the JSON result to be formatted as a JSON array.</td>
</tr>
<tr>
<td>tStatCatcher Statistics</td>
<td>Select this check box to gather the Job processing metadata at a Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_LINE: the number of rows processed. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td></td>
<td>For further information about variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component covers the possibility that a Talend Job can be wrapped as a service, with the ability to input a request to a service into a Job and return the Job result as a service response.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>The tRESTResponse component should only be used with the tRESTRequest component to provide a Job result as response for a web service provider, in case of a request-response communication style.</td>
</tr>
</tbody>
</table>

Related scenario

For a scenario in which tRESTResponse is used, see Using a REST service to accept HTTP GET requests and send responses on page 3156.
tRiakBucketList

Retrieves a list of buckets from a Riak cluster and iterates on it.

**tRiakBucketList Standard properties**

These properties are used to configure tRiakBucketList running in the Standard Job framework.

The Standard tRiakBucketList component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| Use an existing connection | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.
If you select the **Use an existing connection** check box, the Nodes table will not be available. |
|-----------------------------|--------------------------------------------------------------------------------------------------|
| Nodes                      | Fill in the information required for a connection to a Riak cluster.  
• **Host**: enter the IP address or hostname of a Riak node in the Riak cluster that you want to connect to.  
• **Port**: enter the listening port number of a Riak node. You can leave this field empty to use its default value 8098.  
• **Riak path**: enter the Riak path for accessing a Riak node. You can leave this field empty to use its default value riak.  
One example of the URL for accessing a Riak node is http://127.0.0.1:8098/riak.  
For more information about the concepts related to Riak, see https://docs.basho.com/riak/kv/2.2.0/learn/concepts/. |

**Advanced settings**

| **tStatCatcher Statistics** | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global Variables**

| **Global Variables** | **CURRENT_BUCKET_NAME**: the current bucket name. This is a Flow variable and it returns a string.  
**NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.  
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. |

3192
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

### Usage

| Usage rule | This component can be used as a standalone component. |

### Related scenarios

No scenario is available for the Standard version of this component yet.
tRiakClose

Closes an active connection to a Riak cluster so as to release occupied resources.

**tRiakClose Standard properties**

These properties are used to configure tRiakClose running in the Standard Job framework.

The Standard tRiakClose component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| Component List | Select an active connection to a Riak cluster to be closed. |

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global Variables**

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

**Usage**

| Usage rule | This component is generally used with other Riak components, particularly tRiakConnection. |

**Related Scenario**

For a scenario in which tRiakClose is used, see Exporting data from a Riak bucket to a local file on page 3198.
tRiakConnection

Opens and reuses of the connection it creates to a Riak cluster.

**tRiakConnection Standard properties**

These properties are used to configure tRiakConnection running in the Standard Job framework.

The Standard tRiakConnection component belongs to the Big Data and the Databases NoSQL families. The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Nodes</th>
<th>Fill in the information required for a connection to a Riak cluster.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• <strong>Host</strong>: enter the IP address or hostname of a Riak node in the Riak cluster that you want to connect to.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Port</strong>: enter the listening port number of a Riak node. You can leave this field empty to use its default value 8098.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Riak path</strong>: enter the Riak path for accessing a Riak node. You can leave this field empty to use its default value <code>riak</code>.</td>
</tr>
<tr>
<td></td>
<td>One example of the URL for accessing a Riak node is <code>http://127.0.0.1:8098/riak</code>.</td>
</tr>
<tr>
<td></td>
<td>For more information about the concepts related to Riak, see <a href="https://docs.basho.com/riak/kv/2.2.0/learn/concepts/">https://docs.basho.com/riak/kv/2.2.0/learn/concepts/</a>.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press <strong>Ctrl + Space</strong> to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td></td>
<td>For further information about variables, see <a href="https://docs.talend.com/">Talend Studio User Guide</a>.</td>
</tr>
</tbody>
</table>
Usage

| Usage rule | This component is generally used with other Riak components, particularly **tRiakClose**. |

**Related scenario**

For a scenario in which **tRiakConnection** is used, see *Exporting data from a Riak bucket to a local file* on page 3198.
tRiaKInput

Extracts the desired data from a bucket in a Riak node so as to store or apply changes to the data. tRiaKInput reads data from a Riak bucket and send data in the Talend flow.

tRiaKInput Standard properties

These properties are used to configure tRiaKInput running in the Standard Job framework.

The Standard tRiaKInput component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

Basic settings

| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:
• View schema: choose this option to view the schema only.
• Change to built-in property: choose this option to change the schema to Built-in for local changes.
• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Use existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. If you select the Use an existing connection check box, the Nodes table will not be available.</td>
</tr>
</tbody>
</table>
| Nodes | Fill in the information required for a connection to a Riak cluster.
• Host: enter the IP address or hostname of a Riak node in the Riak cluster that you want to connect to.
• Port: enter the listening port number of a Riak node. You can leave this field empty to use its default value 8098.
• Riak path: enter the Riak path for accessing a Riak node. You can leave this field empty to use its default value riak. One example of the URL for accessing a Riak node is http://127.0.0.1:8098/riak. |
For more information about the concepts related to Riak, see https://docs.basho.com/riak/kv/2.2.0/learn/concepts/.

<table>
<thead>
<tr>
<th>Bucket</th>
<th>Type in the name of the bucket from which you want to read data.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Key</td>
<td>Type in the key which is associated with the data that you want to read.</td>
</tr>
<tr>
<td>Output key to column</td>
<td>Select this check box and from the list select the desired column to which the keys will be output.</td>
</tr>
<tr>
<td>Values column</td>
<td>Customize the columns to which the values will be output.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global Variables**

| Global Variables | **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer. **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

**Usage**

| Usage rule | This component always needs an output link. |

**Exporting data from a Riak bucket to a local file**

This scenario applies only to Talend products with Big Data.

The following scenario describes a Job which reads data from a Riak bucket and writes it into a local txt file.
Prerequisites: The Riak bucket from which you want to export data already exists. In this example, the data from the bucket *computer* will be exported and the bucket has already imported the following data:

```
001; Dell; Inspiron 15; 299; Amanda
002; Dell; Inspiron 15R; 549; Linda
003; HP; Pavilion 500-210qe; 539; Marina
004; HP; Pavilion 500-075; 599; Diana
```

Dropping and linking components

Procedure

1. Drop the following components from the Palette to the design workspace: `tRiakConnection`, `tRiakInput`, `tFileOutputDelimited`, and `tRiakClose`.
2. Connect `tRiakConnection` to `tRiakInput` using a Trigger > On Subjob Ok link.
3. Connect `tRiakInput` to `tFileOutputDelimited` using a Row > Main link.
4. Connect `tFileOutputDelimited` to `tRiakClose` using a Trigger > On Component Ok link.

Configuring the components

Opening a connection to Riak

Procedure

1. Double-click `tRiakConnection` to open its Basic settings view in the Component tab.
2. In the Nodes table, enter the information of a Riak cluster you want to connect to.
Exporting data from a Riak bucket to a local file

Procedure

1. Double-click `tRiakInput` to open its **Basic settings** view in the Component tab.

2. Click **Edit schema** to define the structure of exported data. In this example, three columns are defined: `id`, `company`, and `price`.

3. Select the **Use an existing connection** check box and then select the connection you have configured earlier. In this example, it is `tRiakConnection_1`.

4. In the **Bucket** field, enter the name of the bucket from which the data will be exported, `computer` in this example.
5. Select the **Output key to column** check box, and select the desired column from the list. *id* is selected in this example.

6. In the **Value columns** table, click twice the button and select *company* and *price* from the list respectively.

**Writing data into a local file**

**Procedure**

1. Double-click **tFileOutputDelimited** to open its **Basic settings** view in the **Component** tab.

![tFileOutputDelimited](image)

2. In the **File Name** field, enter the full path to the local file in which you want to store the exported data, *D:/Output/computer.txt* in this example.

3. Select the **Include Header** check box.

4. Leave other settings as they are.

**Closing the connection to Riak**

**Procedure**

1. Double-click **tRiakClose** to open its **Basic settings** view in the **Component** tab.

![tRiakClose](image)

2. Select the connection you want to close from the **Component List**, *tRiakConnection_1* in this example.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl+S** to save your Job.

2. Execute the Job by pressing **F6** or clicking **Run** on the **Run** tab.

3. Go to the local directory where the file is stored and check the exported data from the Riak bucket.
<table>
<thead>
<tr>
<th>id</th>
<th>company</th>
<th>price</th>
</tr>
</thead>
<tbody>
<tr>
<td>003</td>
<td>HP</td>
<td>539</td>
</tr>
<tr>
<td>004</td>
<td>HP</td>
<td>599</td>
</tr>
<tr>
<td>001</td>
<td>Dell</td>
<td>299</td>
</tr>
<tr>
<td>002</td>
<td>Dell</td>
<td>549</td>
</tr>
</tbody>
</table>
tRiakKeyList

Retrieves a list of keys and iterates on it within a Riak bucket for analysis or development purposes.

**tRiakKeyList Standard properties**

These properties are used to configure tRiakKeyList running in the Standard Job framework.

The Standard tRiakKeyList component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

### Basic settings

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. If you select the Use an existing connection check box, the Nodes table will not be available.</th>
</tr>
</thead>
</table>

**Nodes**

Fill in the information required for a connection to a Riak cluster.

- **Host**: enter the IP address or hostname of a Riak node in the Riak cluster that you want to connect to.
- **Port**: enter the listening port number of a Riak node. You can leave this field empty to use its default value 8098.
- **Riak path**: enter the Riak path for accessing a Riak node. You can leave this field empty to use its default value riak.

One example of the URL for accessing a Riak node is http://127.0.0.1:8098/riak.

For more information about the concepts related to Riak, see https://docs.basho.com/riak/kv/2.2.0/learn/concepts/.

**Bucket**

Type in the name of the bucket from which you want to retrieve all keys.

### Advanced settings

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th><strong>CURRENT_KEY</strong>: the current key. This is a Flow variable and it returns a string. <strong>NB_LINE</strong>: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer. <strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable</th>
</tr>
</thead>
</table>
and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

| Usage rule         | This component can be used as a standalone component. |

### Related scenarios

No scenario is available for the Standard version of this component yet.
tRiakOutput

Receives data from the preceding component and writes data into or deletes data from a bucket in a Riak cluster.

### tRiakOutput Standard properties

These properties are used to configure tRiakOutput running in the Standard Job framework.

The Standard tRiakOutput component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

#### Basic settings

| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields. 
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:
- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window. |
| **Built-In**: You create and store the schema locally for this component only. | |
| **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.
When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.
You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)). | |
| **Use existing connection** | Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined.
If you select the **Use an existing connection** check box, the **Nodes** table will not be available. |
### Nodes
Fill in the information required for a connection to a Riak cluster.

- **Host**: enter the IP address or hostname of a Riak node in the Riak cluster that you want to connect to.
- **Port**: enter the listening port number of a Riak node. You can leave this field empty to use its default value `8098`.
- **Riak path**: enter the Riak path for accessing a Riak node. You can leave this field empty to use its default value `riak`.

One example of the URL for accessing a Riak node is `http://127.0.0.1:8098/riak`.

For more information about the concepts related to Riak, see [https://docs.basho.com/riak/kv/2.2.0/learn/concepts/](https://docs.basho.com/riak/kv/2.2.0/learn/concepts/).

### Bucket
Specify the name of the bucket to which you want to apply changes.

### Action on data
In the specified bucket, you can perform:

- **Upsert**: Insert data if they do not exist or update the existing data.
- **Delete**: Remove values associated with the specified key.

If you select **Delete** from the **Action on data** list, only the **Key column** list is available in the **Key area**.

### Auto generate the key
Select this check box to let the Riak system generate keys for the values automatically.

### Key column
Select one column from the list to write its data into the Riak bucket as keys. Note that the key must be unique across one bucket.

### Value columns
Customize the columns to write their data into the Riak bucket as values.

### Advanced settings

#### tStatCatcher Statistics
Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

#### Global Variables
- **UPSER'T_NB_LINE**: the number of rows inserted and updated. This is an After variable and it returns an integer.
- **DELETE_NB_LINE**: the number of rows deleted. This is an After variable and it returns an integer.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

| Usage rule | This component is used as an output component and it always needs an incoming link. |

### Related scenarios

No scenario is available for the Standard version of this component yet.
tRouteFault

Sends messages from a Data Integration Job to a Mediation Route and mark the message as fault.

**tRouteFault Standard properties**

These properties are used to configure tRouteFault running in the Standard Job framework.

The Standard tRouteFault component belongs to the ESB family.

*This component is relevant only when used with one of the Talend solutions with ESB, as it should be used with the Service Repository node and the Data Service creation related wizard(s).*

**Basic settings**

| Output Schema and Edit schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click **Edit schema** to make changes to the schema. If the current schema is of the Repository type, three options are available:  
• **View schema**: choose this option to view the schema only.  
• **Change to built-in property**: choose this option to change the schema to Built-in for local changes.  
• **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the Repository Content window. Click **Sync columns** to retrieve the schema from the previous component connected in the Job. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-in</strong>: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td><strong>Repository</strong>: Select the Repository file where Properties are stored.</td>
<td></td>
</tr>
<tr>
<td><strong>Camel</strong></td>
<td>Enter the message parameters corresponding to the columns you defined in the schema dialog box via the <strong>Edit schema</strong> button.</td>
</tr>
</tbody>
</table>
| **Type** | Select between:  
• **Body**: Used to set the body of a Route, equals the code `exchange.getOut().setBody(...)`.
• **Property**: Used to set the property of a Route, equals the code `exchange.setProperty(name, value)`.  
• **System**: Used to set the system property, equals the code `System.setProperty(name, value)`.  
• **Header**: Used to set the output header, equals the code `exchange.getOut().setHeader(name, value)`. |
Name | This column is used to set the name for the parameter when its type is either Property, System or Header. This column is ignored when the type is Body.

Advanced settings

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.
For further information about variables, see Talend Studio User Guide.

Usage

| Usage rule | This component can be used as the end component and thus requires an input component.

Limitation | The Job using a tRouteFault must be launched only within a Route using the cTalendJob component.

Exchanging messages between a Job and a Route

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

This scenario describes how to exchange messages between a Job and a Route using the tRouteInput and the tRouteFault component. To do this, a Job is created to receive the message from the Route and mark the message as fault. Then a Route is built to send the message to the Job and handle the fault message.

Creating an Data Integration Job

In this section, a Job named RouteCommunication_tRouteFault is built.
Arranging the flow of the message

About this task

![Diagram showing the flow of the message]

Procedure

1. Drag and drop a **tRouteInput** and a **tRouteFault** from the Palette onto the design workspace.
2. Right-click the **tRouteInput** component, select **Row > Main** from the contextual menu and click the **tRouteFault** component.

Configuring how the message is processed

Procedure

1. Double-click the **tRouteInput** component to open its **Basic settings** view in the **Component** tab.

   ![Basic settings view]

   - Click the three-dot button next to **Edit Schema**. In the schema dialog box, click the plus button to add a new line of **String** type and name it **body**. Click **OK** to close the dialog box.
3. In the **Simple Expression** field for the *body* element, enter "${in.body}" to get the body of the input message from the Route.

4. Double-click the **tRouteFault** component to display its **Basic settings** view in the **Component** tab.

![tRouteFault_1](image)

The "Name" with "Body" type will be ignored

5. Make sure that **tRouteFault** has one element *body*. Set its type to **Body**.

6. Press **Ctrl+S** to save your Job.

**Creating a Mediation Route**

In this section, we will create a Route to send a message to the Job and handle the fault message.

**Dropping and linking the components**

**About this task**

![Diagram](image)

**Procedure**

1. Drag and drop a **cTimer**, a **cSetBody**, a **cJavaDSLProcessor**, a **cTalendJob**, a **cOnException** and a **cProcessor** component from the **Palette** onto the design workspace.

2. Link the components with the **Row > Route** connection as shown above.

3. Label the components for better identification of their roles.

**Configuring the components**

**Procedure**

1. Double-click the **cTimer** component to open its **Basic settings** view in the **Component** tab.
2. Enter 1 in the Repeat field to trigger a message exchange one time.

3. Double-click the cSetBody component to display its Basic settings view in the Component tab.

4. Select Simple from the Language list and enter Hello! in the Expression field.

5. Double-click the cJavaDSLProcessor component to open its Basic settings view in the Component tab.

6. Enter .handleFault() in the Code box so that the fault message will be caught as an exception.

7. Double-click the cTalendJob component to display its Basic settings view in the Component tab.
8. Select Job `RouteCommunication_tRouteFault` from the repository to call the Job that is created in the previous section.

9. Double click the `cOnException` component to display its Basic settings view in the Component tab.

10. Click `[*]` to add a line to the Exceptions table, and enter `org.apache.camel.CamelException` in the Exception field to handle the exceptions.

11. Double-click the `cProcessor` component to display its Basic settings view in the Component tab.
12. Customize the code in the **Code** area to show the message body:

```
System.out.println(exchange.getIn());
```

13. Press **Ctrl+S** to save your Route.

**Executing the Route**

Click the **Run** view to display it and click the **Run** button to launch the execution of your Route. You can also press **F6** to execute it.

The message *Hello!* is sent from the Route to the Job and caught as exception:
[statistics] connecting to socket on port 3763
[statistics] connected

Processed by failure processor: FallbackErrorHandler[Channel[DelegateSync[local_project.troutefault_0_1.tRouteFault$1@2511045b]]]

tRouteInput

Accepts messages in a Data Integration Job from a Mediation Route.

**tRouteInput Standard properties**

These properties are used to configure tRouteInput running in the Standard Job framework.

The Standard tRouteInput component belongs to the ESB family.

*This component is relevant only when used with one of the Talend solutions with ESB, as it should be used with the Service Repository node and the Data Service creation related wizard(s).*

### Basic settings

| Input Schema and Edit schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
  • View schema: choose this option to view the schema only.  
  • Change to built-in property: choose this option to change the schema to Built-in for local changes.  
  • Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Built-in: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td>Repository: Select the Repository file where Properties are stored.</td>
<td></td>
</tr>
<tr>
<td>Camel</td>
<td>Enter the message parameters corresponding to the columns you defined in the schema dialog box via the Edit schema button using the Simple Expression Language. For more information about the Simple Expression Language, see the site <a href="http://camel.apache.org/simple.html">http://camel.apache.org/simple.html</a>.</td>
</tr>
</tbody>
</table>

### Advanced settings

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

### Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable |
and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

## Usage

**Usage rule**

This component can be used as starter component and has an output. It is mandatory that a *tRouteInput* component is used in the Data Integration Job to be called by a Route using the *cTalendJob* component. The reason for it is that this will prevent the referenced Job from starting automatically when deployed in Talend Runtime. Instead it will only start when it gets called by the Route.

For more information about how to use the *cTalendJob* component, see Talend Help Center (https://help.talend.com).

**Limitation**

The Job using a *tRouteInput* must be launched only within a Route using the *cTalendJob* component.

## Exchanging messages between a Job and a Route

This scenario applies only to *Talend Open Studio for ESB, Talend Data Services Platform* and *Talend Data Fabric*.

This scenario describes how to accept messages from a Route using the *tRouteInput* component and send messages to a Route using the *tRouteOutput* component. To do this, we need to build a Job and a Route to call the Job using the *cTalendJob* component.

For more information about how to use the *cTalendJob* component, see Talend Help Center (https://help.talend.com).

### Creating an Data Integration Job

In this section, we will build a Job named *RouteCommunication* to accept the message from a Route, change the message body and send the message back to the Route.

**Arranging the flow of the message**

**About this task**

![Diagram of the flow of the message]
**Procedure**

1. Drag and drop a `tRouteInput`, a `tLogRow`, a `tReplace` and a `tRouteOutput` from the Palette onto the design workspace.
2. Link the components using the Row > Main connection as shown above.

**Configuring how the message is processed**

**Procedure**

1. Double-click the `tRouteInput` component to open its Basic settings view in the Component tab.

   ![Basic settings view for tRouteInput](image)

2. Click the three-dot button next to Edit Schema. In the schema dialog box, click the plus button to add a new line of String type and name it body. Click OK to close the dialog box.

   ![Schema dialog box for tRouteInput](image)

3. In the Simple Expression field for the body element, enter "${in.body}" to get the body of the input message from the Route.

4. The `tLogRow` component will monitor the message exchanges and does not need any configuration.

5. Double-click the `tReplace` component to open its Basic settings view in the Component tab.
6. Click **Sync columns** to retrieve the schema from the **tLogRow**. In the pop-up dialog box, click **Yes** to propagate the schema to the subsequent component.

Click `[+]` to add a row to the **Search/Replace** table. Enter *World* in the **Search** column and *Talend* in the **Replace with** column. Clear the **Whole word** check box.

7. Double-click the **tRouteOutput** component to display its **Basic settings** view in the **Component** tab.

8. Make sure that **tRouteOutput** has one element *body*. Set its type to **Body**.

9. Press **Ctrl+S** to save your Job.

**Creating a Mediation Route**

In this section, we will create a Route to send a message to the Job and receive the message sent back to the Route.
Dropping and linking the components

About this task

![Diagram showing components]

Procedure

1. Drag and drop a `cTimer`, a `cSetBody`, a `cTalendJob`, and a `cLog` from the Palette onto the design workspace.
2. Link the components with the `Row > Route` connection as shown above.
3. Label the components for better identification of their roles.

Configuring the components

Procedure

1. Double-click the `cTimer` component to open its Basic settings view in the Component tab.

   ![Component settings]
   
   **Basic settings**
   
<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Period</td>
<td>1000</td>
</tr>
<tr>
<td>Repeat</td>
<td>1</td>
</tr>
<tr>
<td>Delay</td>
<td>1000</td>
</tr>
<tr>
<td>Fixed Rate</td>
<td></td>
</tr>
<tr>
<td>Daemon</td>
<td></td>
</tr>
<tr>
<td>Set Schedule Time</td>
<td></td>
</tr>
</tbody>
</table>

2. In the Repeat field, enter 1 to generate the message exchange one time. Keep the default settings of the other options.
3. Double-click the `cSetBody` component to display its Basic settings view in the Component tab.

   ![Component settings]
   
   **Basic settings**
   
<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Language</td>
<td>SIMPLE</td>
</tr>
<tr>
<td>Expression</td>
<td>'Hello World!'</td>
</tr>
</tbody>
</table>

4. Select Simple from the Language list and enter Hello World! in the Expression field.
5. Double-click the `cTalendJob` component to display its Basic settings view in the Component tab.
6. Select Job RouteCommunication from the repository.
7. The cLog component will monitor the message exchanges and does not need any configuration.
8. Press Ctrl+S to save your Route.

**Executing the Route**

Click the Run view to display it and click the Run button to launch the execution of your Route. You can also press F6 to execute it. In the execution log you can see that the message *Hello World!* is sent to the Job. The message body is changed to *Hello Talend!* and sent back to the Route.
tRouteOutput

Sends messages from a Data Integration Job to a Mediation Route.

**tRouteOutput Standard properties**

These properties are used to configure tRouteOutput running in the Standard Job framework.

The Standard tRouteOutput component belongs to the ESB family.

*This component is relevant only when used with one of the Talend solutions with ESB, as it should be used with the Service Repository node and the Data Service creation related wizard(s).*

**Basic settings**

| Output Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:
|              | • View schema: choose this option to view the schema only.
|              | • Change to built-in property: choose this option to change the schema to Built-in for local changes.
|              | • Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.
|              | Click Sync columns to retrieve the schema from the previous component connected in the Job. |
| Built-in     | No property data stored centrally. |
| Repository   | Select the Repository file where Properties are stored. |
| Camel        | Enter the message parameters corresponding to the columns you defined in the schema dialog box via the Edit schema button. |
| Type         | Select between:
|              | **Body**: Used to set the body of a Route, equals the code exchange.getOut().setBody(...). |
|              | **Property**: Used to set the property of a Route, equals the code exchange.setProperty(name, value). |
|              | **System**: Used to set the system property, equals the code System.setProperty(name, value). |
|              | **Header**: Used to set the output header, equals the code exchange.getOut().setHeader(name, value). |
Name

This column is used to set the name for the parameter when its type is either Property, System or Header. This column is ignored when the type is Body.

Advanced settings

tStatCatcher Statistics

Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

Global Variables

Global Variables

ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule

This component can be used as the end component and thus requires an input component. It is mandatory that a tRouteInput component is used in the Data Integration Job to be called by a Route using the cTalendJob component. The reason for it is that this will prevent the referenced Job from starting automatically when deployed in Talend Runtime. Instead it will only start when it gets called by the Route.

For more information about how to use the cTalendJob component, see Talend Help Center (https://help.talend.com).

Limitation

The Job using a tRouteOutput must be launched only within a Route using the cTalendJob component.

Related scenario

For a scenario in which tRouteOutput is used, see Exchanging messages between a Job and a Route on page 3217.
tRowGenerator

Creates an input flow in a Job for testing purposes, in particular for boundary test sets. tRowGenerator generates as many rows and fields as are required using random values taken from a list.

**tRowGenerator Standard properties**

These properties are used to configure tRowGenerator running in the Standard Job framework.
The Standard tRowGenerator component belongs to the Misc family.
The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Schema and Edit schema</th>
<th>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. <td></td>
<td>For further information about variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

**Usage**

| Usage rule | The tRowGenerator Editor’s ease of use allows users without any Java knowledge to generate random data for test purposes. |

**Defining the schema**

First you need to define the structure of data to be generated.

- Add as many columns to your schema as needed, using the plus (+) button.
- Type in the names of the columns to be created in the Columns area and select the Key check box if required.
- Make sure you define then the nature of the data contained in the column, by selecting the Type in the list. According to the type you select, the list of Functions offered will differ. This information is therefore compulsory.

<table>
<thead>
<tr>
<th>Column</th>
<th>Key</th>
<th>Type</th>
<th>Nullable</th>
<th>Functions</th>
<th>Preview</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID_employees</td>
<td>✔</td>
<td>int</td>
<td></td>
<td>sequence</td>
<td></td>
</tr>
<tr>
<td>First_Name</td>
<td></td>
<td>String</td>
<td></td>
<td></td>
<td>Phoebe H</td>
</tr>
<tr>
<td>Last_Name</td>
<td></td>
<td>String</td>
<td></td>
<td>getLastName</td>
<td>Eisenhower</td>
</tr>
<tr>
<td>Hire_Date</td>
<td></td>
<td>Date</td>
<td></td>
<td>getRandomDate</td>
<td>2008-09-31</td>
</tr>
</tbody>
</table>

Number of Rows for RowGenerator: 10
Some extra information, although not required, might be useful such as **Length**, **Precision** or **Comment**. You can also hide these columns, by clicking on the **Columns** drop-down button next to the toolbar, and unchecking the relevant entries on the list.

In the **Function** area, you can select the predefined routine/function if one of them corresponds to your needs. You can also add to this list any routine you stored in the **Routine** area of the **Repository**. Or you can type in the function you want to use in the **Function** definition panel.

Related topic: see *Talend Studio User Guide*.

Click **Refresh** to have a preview of the data generated.

Type in a number of rows to be generated. The more rows to be generated, the longer it’ll take to carry out the generation operation.

### Defining the function

Select the [...] under **Function** in the Schema definition panel in order to customize the function parameters.

- Select the **Function parameters** tab
- The **Parameter** area displays **Customized parameter** as function name (read-only)

![Function parameters](image)

- In the **Value** area, type in the Java function to be used to generate the data specified.
- Click on the **Preview** tab and click **Preview** to check out a sample of the data generated.

### Generating random java data

The following scenario creates a two-component Job, generating 50 rows structured as follows: a randomly picked-up ID in a 1-to-3 range, a random ascii First Name and Last Name generation and a random date taken in a defined range.

- Drop a **tRowGenerator** and a **tLogRow** component from the **Palette** to the design workspace.
- Right-click **tRowGenerator** and select **Row > Main**. Drag this main row link onto the **tLogRow** component and release when the plug symbol displays.
- Double click **tRowGenerator** to open the Editor.
- Define the fields to be generated.
The random ID column is of integer type, the First and Last names are of string type and the Date is of date type.

In the **Function** list, select the relevant function or set on the three dots for custom function.

On the **Function parameters** tab, define the Values to be randomly picked up.

The **First_Name** and **Last_Name** columns are to be generated using the getAsciiRandomString function that is predefined in the system routines. By default the length defined is 6 characters long. You can change this if need be.

The **Date** column calls the predefined getRandomDate function. You can edit the parameter values in the **Function parameters** tab.

Set the **Number of Rows** to be generated to 50.

Click **OK** to validate the setting.

Double click **tLogRow** to view the Basic settings. The default setting is retained for this Job.

Press **F6** to run the Job.

The 50 rows are generated following the setting defined in the **tRowGenerator** editor and the output is displayed in the **Run** console.
tRSSInput

Reads RSS-Feeds using URLs. tRSSInput makes it possible to keep track of blog entries on websites to gather and organize information for quick and easy access.

**tRSSInput Standard properties**

These properties are used to configure tRSSInput running in the Standard Job framework.

The Standard tRSSInput component belongs to the Internet family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Schema and Edit Schema</th>

</table>

## Fetching frequently updated blog entries.

This two-component scenario aims at retrieving frequently updated blog entries from a Talend local news RSS feed using the tRSSInput component.

### Procedure

**Procedure**

1. Drop the following components from the Palette onto the design workspace: tRSSInput and tLogRow.
2. Right-click to connect them using a Row > Main link.

![Workflow Diagram](image)

3. In the design workspace, select tRSSInput, and click the Component tab to define the basic settings for tRSSInput.

   ![Component Settings](image)

   - **Basic settings**
     - **Schema Type**: Built-in
     - **RSS URL**: "http://feeds.feedburner.com/Talend"
     - **Read articles from**: "2008-07-20 00:00:00"
     - **Max amount**: 2
     - **Die on error**: unchecked

4. Enter the URL for the RSS_Feed to access. In this scenario, tRSSInput links to the Talend RSS_Feed: [http://feeds.feedburner.com/Talend](http://feeds.feedburner.com/Talend).
5. Select/clear the other check boxes as required. In this scenario, we want to display the information about two articles dated from July 20, 2008.
6. In the design workspace, select tLogRow and click the Component tab to define its basic settings. For more information about tLogRow properties, see tLogRow Standard properties on page 1956.
7. Save the Job and press F6 to execute it.

```
Starting job tRSSInput at 15:17 07/08/2008.

<table>
<thead>
<tr>
<th>key</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>TITLED</td>
<td>Welcome Jean-Luc Solans</td>
</tr>

</tr>
</tbody>
</table>

Job tRSSInput ended at 15:17 07/08/2008. [exit code=0]
```

The **tRSSInput** component accessed the RSS feed of **Talend** website on your behalf and organized the information for you.

Two blog entries are displayed on the console. Each entry has its own title, description, publication date, and the corresponding RSS feed URL address. Blogs show the last entry first, and you can scroll down to read earlier entries.
# tRSSOutput

Creates and writes XML files that hold RSS or Atom feeds.

## tRSSOutput Standard properties

These properties are used to configure tRSSOutput running in the Standard Job framework.

The Standard tRSSOutput component belongs to the Internet family.

The component in this framework is available in all Talend products.

### Basic settings

<table>

<tr>
<td>File name</td>
<td>Name or path to the XML file to be processed and/or the variable to be used. For further information about how to define and use a variable in a Job, see <em>Talend Studio User Guide</em>.</td>
</tr>
<tr>
<td>Encoding</td>
<td>Select an encoding type from the list, or select Custom and define it manually. This field is compulsory for DB data handling.</td>
</tr>
<tr>
<td>Append</td>
<td>Select this check box to add the new rows to the end of the file.</td>
</tr>
<tr>
<td>Mode</td>
<td>Select between RSS or ATOM according to the feed you want to generate.</td>
</tr>
</tbody>
</table>

### Channel (in RSS mode)

**Note:**
The information to be typed in here concerns your entire input data, site etc, rather than a particular item.

- **Title**: Enter a meaningful title.
- **Description**: Enter a description that you think will describe your content.
- **Publication date**: Enter the relevant date.
- **Link**: Enter the relevant URL.

### Feed (in ATOM mode)

- **Title**: Enter a meaningful title.
- **Link**: Enter the relevant URL.
- **Id**: Enter the valid URL corresponding to the Link.
- **Update date**: Enter the relevant date.
- **Author name**: Enter the relevant name.

### Optionnal Channel Elements

Click the [+] button below the table to add new lines and enter the information relative to the RSS flow metadata:

- **Element Name**: name of the metadata.
- **Element Value**: content of the metadata.

### Schema and Edit Schema

A schema is a row description, it defines the number of fields to be processed and passed on to the next
component. The schema is either Built-in or stored remotely in the Repository.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

By default, the schema of tRSSOutput is made of five read-only columns: *id*, *title*, *link*, *updated*, and *summary*. You can add new columns or click Syn columns to retrieve the schema structure from the preceding component.

---

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

**Global Variables**

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. |
| | **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer. |

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

---

**Usage**

| Usage rule | This component must be linked to an input or intermediary component. |

---

**Creating an RSS flow and storing files on an FTP server**

In this scenario we:
• create an RSS flow for files that you would like to share with other people, and
• store the complete files on an FTP server.

This scenario writes an RSS feed XML file about a Mysql table holding information about books. It adds links to the files stored on an FTP server in case users want to have access to the complete files.

**Dropping and linking components**

**Procedure**

1. Drop the following components from the Palette onto the design workspace: **tMysqlInput**, **tRSSOutput**, and **tFTPPut**.
2. Right-click **tMysqlInput** and connect it to **tRSSOutput** using a Row > Main link.
3. Right-click **tMysqlInput** and connect it to **tFTPPut** using a Trigger > OnSubjobOk link.

![Diagram showing the components and connections]

**Defining the data source**

**Procedure**

1. In the design workspace, select **tMysqlInput**, and click the Component tab to define the basic settings for **tMysqlInput**.
2. Set the **Property type** to **Repository** and click the three-dots button [...] to select the relevant DB entry from the list. The connection details along with the schema get filled in automatically.

3. In the **Table Name** field, either type your table name or click the three dots button [...] and select your table name from the list. In this scenario, the Mysql input table is called "rss_talend" and the schema is made up of four columns, **TITLE**, **Description**, **PUBDATE**, and **LINK**.

4. In the **Query** field, enter your DB query paying particular attention to properly sequence the fields in order to match the schema definition, or click **Guess Query**.

**Creating an RSS flow**

**Procedure**

1. In the design workspace, select **tRSSOutput**, and click the **Component** view to define the basic settings for **tRSSOutput**.
2. In the **File name** field, use the by default file name and path, or browse to set your own for the output XML file.

3. Select the encoding type on the **Encoding Type** list.

4. In the **Mode** area, select **RSS**.

5. In the **Channel** panel, enter a title, a description, a publication date, and a link to define your input data as a whole.

6. Click **Edit Schema** to modify the schema if necessary.

   **Note:**

   You can click **Sync columns** to retrieve the generated schema from the preceding component.

7. Save your Job and press **F6** to execute this first part.
The **tRSSOutput** component created an output RSS flow in an XML format for the defined files.

### Writing the complete files to an FTP server

**About this task**

To store the complete files on an FTP server:

**Procedure**

1. In the design workspace, select **FTPPut**, and click the **Component** tab to define the basic settings for **tFTPPut**.
2. Enter the host name and the port number in their corresponding fields.

3. Enter your connection details in the corresponding **Username** and **Password** fields.

4. Browse to the local directory, or enter it manually in the **Local directory** field.

5. Enter the details of the remote server directory.

6. Select the transfer mode from the **Transfer mode** list.

7. On the **Files** panel, click on the plus button to add new lines and fill in the filemasks of all files to be copied onto the remote directory. In this scenario, the files to be saved on the FTP server are all text files.

8. Save your Job and press **F6** to execute it.

Files defined in the Filemask are copied on the remote server.

### Creating an RSS flow that contains metadata

This scenario describes a two-component Job that creates an RSS flow that holds metadata and then redirects the obtained information in an XML file of the output RSS flow.

### Dropping and linking components

**Procedure**

1. Drop **tRSSInput** and **tRSSOutput** from the **Palette** to the design workspace.

2. Connect the two components together using a **Row > Main** link.

### Configuring the components

**Procedure**

1. Double-click **tRSSInput** to open its **Basic settings** view and define the component properties.
2. Enter the URL for the RSS Feed to access. In this scenario, `tRSSInput` links to the Talend RSS Feed: http://feeds.feedburner.com/Talend.

3. In the design workspace, double-click `tRSSOutput` to display its Basic settings view and define the component properties.

4. In the File name field, use the by default file name and path, or browse to set your own for the output XML file.

5. Select the encoding type on the Encoding Type list.

6. In the Mode area, select RSS.

7. In the Channel panel, enter a title, a description, a publication date and a link to define your input data as a whole.

8. In the Optional Channel Elements, define the RSS flow metadata. In this example, the flow has two metadata: `copyright`, which value is `tos`, and `language` which value is `en_us`.

9. Click Edit Schema to modify the schema if necessary.
Saving and executing the Job

Procedure

1. Press Ctrl+S to save your Job.
2. Press F6 or click Run on the Run tab to execute the Job.

Creating an ATOM feed XML file

This scenario describes a two component Job that generates data and writes them in an ATOM feed XML file.
Dropping and linking components

Procedure

1. Drop the following components from the Palette onto the design workspace: tFixedFlowInput of the Misc component group and tRSSOutput of the Internet component group.
2. Right-click tFixedFlowInput and connect it to tRSSOutput using a Row Main link.
3. When asked whether you want to pass on the schema of tRSSOutput to tFixedFlowInput, click Yes.

Configuring the components

Procedure

1. In the design workspace, double-click tFixedFlowInput to display its corresponding Component view and define its basic settings.

   ![Components Configuration](image)

   **Basic settings**
   - **Schema**: Built-In
   - **Number of rows**: 1
   - **Mode**: Use Single Table
   - **Values**
     - Column: id, title, link, updated, summary
     - Value: "urn:uuid:12255:695:-4be-aaaa-a80da344efaa6a", "Job using tRSSOutput in Talend Open Studio", "http://feeds.feedburner.com/Talend/", "2010-09-07T15:43:02Z", "This is a Job made in Talend Open Studio and usn..."

2. In the Number of rows field, leave the default setting to 1 to only generate one line of data.
3. In the Mode area, leave the Use Single Table option selected and fill in the Values table. Note that the Column field of the Values table is filled in by the columns of the schema defined in the component.
4. In the Value field of the Values table, type in the data you want to be sent to the following component.
5. In the design workspace, double-click tRSSOutput to display its corresponding Component view and define its basic settings.
6. Click the [...] button next to the File Name field to set the output XML file directory and name.

7. In the Mode area, select ATOM to generate an ATOM feed XML file.

Warning:
As the ATOM feed format is strict, some default information is required to create the XML file. So, the schema tRSSOutput contains default columns that will contain those information. Those default columns are greyed out to indicate that they must not be modified. If you choose to modify the schema of the component, the ATOM XML file created will not be valid.

8. In the Feed area, enter a title, link, id, update date, author name to define your input data as a whole.

Saving and executing the Job

Procedure
1. Press Ctrl+S to save your Job.
2. Press F6 or click Run on the Run tab to execute the Job.
The `tRSSOutput` component creates an output ATOM flow in an XML format.
**tRunJob**

Manages complex Job systems which need to execute one Job after another.

`tRunJob` executes the Job called in the component’s properties, in the frame of the context defined.

**tRunJob Standard properties**

These properties are used to configure `tRunJob` running in the Standard Job framework.

The Standard `tRunJob` component belongs to the System and the Orchestration families.

The component in this framework is available in all [Talend products](https://www.talend.com).

**Warning:**

The `tRunJob` component is supported with limitations, which means that only S4 (Minor) support cases are accepted and no patches are provided. If you use `tRunJob` within Data Services and Routes (with `cTalendJob`), support is provided on a "best effort" basis only. In most cases, there are class loading issues which can sometimes be resolved but not always.

This is because `tRunJob` is not designed to work in a Service/Route style (ESB) deployment, so regular support is not provided if you decide to use it, even though it may work in many cases. If you used `tRunJob` in the past, it is recommended to change your Job Design to use Joblets instead.

For DI and non-ESB use cases, it is still a valuable component and has support.

**Basic settings**

| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.
Click **Edit schema** to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the Repository Content window.

<p>| <strong>Built-In</strong> | You create and store the schema locally for this component only. |
| <strong>Repository</strong> | You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. |</p>
<table>
<thead>
<tr>
<th>Copy Child Job Schema</th>
<th>Click to fetch the child Job schema.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Use dynamic job</strong></td>
<td>Select this check box to allow multiple Jobs to be called and processed. When this option is enabled, only the latest version of the Jobs can be called and processed. An independent process will be used to run the subJob. The <strong>Context</strong> and the <strong>Use an independent process to run subJob</strong> options disappear.</td>
</tr>
<tr>
<td><strong>Warning:</strong> The <strong>Use dynamic job</strong> option is not compatible with the Jobserver cache. Therefore, the execution may fail if you run a Job that contains <code>tRunJob</code> with this check box selected in Talend Administration Center.</td>
<td></td>
</tr>
<tr>
<td><strong>Warning:</strong> This option is incompatible with the <strong>Use or register a shared DB Connection</strong> option of database connection components. When <code>tRunJob</code> works together with a database connection component, enabling both options will cause your Job to fail.</td>
<td></td>
</tr>
<tr>
<td><strong>Warning:</strong> This option is not supported within ESB Routes or Data Services.</td>
<td></td>
</tr>
<tr>
<td><strong>Context job</strong></td>
<td>This field is visible only when the <strong>Use dynamic job</strong> option is selected. Enter the name of the Job that you want to call from the list of Jobs selected.</td>
</tr>
<tr>
<td><strong>Job</strong></td>
<td>Select the Job to be called in and processed. Make sure you already executed once the Job called, beforehand, in order to ensure a smooth run through <code>tRunJob</code>.</td>
</tr>
<tr>
<td><strong>Version</strong></td>
<td>Select the child Job version that you want to use.</td>
</tr>
<tr>
<td><strong>Context</strong></td>
<td>If you defined contexts and variables for the Job to be run by the <code>tRunJob</code>, select the applicable context entry on the list.</td>
</tr>
<tr>
<td><strong>Use an independent process to run subJob</strong></td>
<td>Select this check box to use an independent process to run the subJob. This helps in solving issues related to memory limits.</td>
</tr>
<tr>
<td><strong>Warning:</strong> This option is not compatible with the Jobserver cache. Therefore, the execution may fail if you run a Job that contains <code>tRunJob</code> with this check box selected in Talend Administration Center.</td>
<td></td>
</tr>
<tr>
<td><strong>Warning:</strong> This option is incompatible with the <strong>Use or register a shared DB Connection</strong> option of database connection components. When <code>tRunJob</code> works together with a database connection component, enabling both options will cause your Job to fail.</td>
<td></td>
</tr>
<tr>
<td><strong>Note:</strong> Child Job logs are not available if you select this option.</td>
<td></td>
</tr>
<tr>
<td><strong>Die on child error</strong></td>
<td>Clear this check box to execute the parent Job even though there is an error when executing the child Job.</td>
</tr>
</tbody>
</table>
**Transmit whole context**

Select this check box to get all the context variables from the parent Job. Deselect it to get all the context variables from the child Job.

If this check box is selected when the parent and child Jobs have the same context variables defined:

- variable values for the parent Job will be used during the child Job execution if no relevant values are defined in the **Context Param** table.
- otherwise, values defined in the **Context Param** table will be used during the child Job execution.

**Context Param**

You can change the value of selected context parameters. Click the [+ ] button to add the parameters defined in the **Context** tab of the child Job. For more information on context parameters, see **Talend Studio User Guide**.

The values defined here will be used during the child Job execution even if **Transmit whole context** is selected.

**Advanced settings**

**Propagate the child result to the output schema**

Select this check box to propagate the output data stored in the buffer memory via the **tBufferOutput** component in the child Job to the output component in the parent Job.

This property takes effect only when there is data coming from an input component such as **tFixedFlowInput**.

This check box is cleared by default. It is invisible when the **Use dynamic job** or **Use an independent process to run subJob** check box is selected.

**Print Parameters**

Select this check box to display the internal and external parameters in the **Console**.

**tStatCatcher Statistics**

Select this check box to gather the processing metadata at the Job level as well as at each component level.

**Global Variables**

**Global Variables**

- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

- **CHILD_RETURN_CODE**: the return code of a child Job. This is an After variable and it returns an integer.

- **CHILD_EXCEPTION_STACKTRACE**: the exception stack trace from a child Job. This is an After variable and it returns a string.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.
For further information about variables, see Talend Studio User Guide.

Usage

| Usage rule | This component can be used as a standalone Job or can help clarifying complex Job by avoiding having too many subjobs all together in one Job. |

Connections

| Outgoing links (from this component to another): | Row: Main. |
| Trigger: On Subjob Ok; On Subjob Error; Run if; On Component Ok; On Component Error |

| Incoming links (from one component to this one): | Row: Main; Reject; Iterate. |
| Trigger: On Subjob Ok; On Subjob Error; Run if; On Component Ok; On Component Error; Synchronize; Parallelize. |

For further information regarding connections, see Talend Studio User Guide.

Calling a Job and passing the parameter needed to the called Job

This scenario describes a two-component Job named ParentJob that calls another Job named ChildJob to display the content of files specified in the ParentJob on the Run console.
Setting up the child Job

Procedure

1. Create a new Job ChildJob and add a `tFileInputDelimited` component and a `tLogRow` component to it.
2. Connect the `tFileInputDelimited` component to the `tLogRow` component using a Row > Main link.
3. Double-click the `tFileInputDelimited` component to open its Basic settings view.
4. Click in the File Name field and then press F5 to open the New Context Parameter dialog box and configure the context variable.
5. In the Name field, enter a name for this new context variable, `FilePath` in this example.
6. In the Default value field, enter the full path to the default input file.
7. Click Finish to validate the context parameter setup and fill the File Name field with the context variable.

You can also create or edit a context parameter in the Context tab view beneath the design workspace. For more information, see Talend Studio User Guide.
8. Click the [...] button next to Edit schema to open the Schema dialog box where you can configure the schema manually.
9. In the dialog box, click the [+] button to add columns and name them according to the input file structure.

In this example, this component will actually read files defined in the parent Job, and these files contain up to five columns. Therefore, add five string type columns and name them Column1, Column2, Column3, Column4, and Column5 respectively, and then click OK to validate the schema configuration and close the Schema dialog box.

10. Double-click the tLogRow component and on its Basic settings view, select the Table option to view displayed content in table cells.

Setting up the parent Job

Procedure

1. Create a new Job ParentJob and add a tFileList component and a tRunJob component to it.
2. Connect the tFileList component to the tRunJob component using a Row > Iterate link.
3. Double-click the tFileList component to open its Basic settings view.

4. In the Directory field, specify the path to the directory that holds the files to be processed, or click the [...] button next to the field to browse to the directory.

In this example, the directory is D:/tRunJob_Input_Files that holds three delimited files with up to five columns.

5. In the FileList Type list, select Files.
6. Select the Use Glob Expressions as Filemask check box, and then click the [+] button to add a line in the Files area and define a filter to match files. In this example, enter "*.csv" to retrieve all delimited files.
7. Double-click the tRunJob component to display its Basic settings view.
8. Click the [...] button next to the Job field and in the pop-up dialog box, select the child Job you want to execute and click OK to close the dialog box. The name of the selected Job appears in the Job field.

9. In the Context Param area, click the [+] button to add a line and define the context parameter. The only context parameter defined in the child Job, named FilePath, appears in the Parameters cell.

10. Click in the Values cell, press Ctrl+Space on your keyboard to access the list of context variables, and select tFileList_1.CURRENT_FILEPATH.

   The corresponding context variable ((String)globalMap.get("tFileList_1_CURREN T_FILEPATH")) appears in the Values cell.

   For more information on context variables, see Talend Studio User Guide.

**Executing the parent Job**

**Procedure**

1. Press Ctrl+S to save your Jobs.
2. Press F6 to execute the parent Job.
The parent Job calls the child Job, which reads the files defined in the parent Job, and the content of the files is displayed on the Run console.

**Running a list of child Jobs dynamically**

This scenario describes a Job that calls two child Jobs dynamically. When called from the parent Job, each of these simple child Jobs displays a message on the console.

**Setting up the child Jobs**

**Procedure**

1. Create a new Job named **ChildJob1**, and add a **tFixedFlowInput** component and a **tLogRow** component to it.

2. Connect the **tFixedFlowInput** component to the **tLogRow** component using a **Row > Main** connection.

3. Double-click the **tFixedFlowInput** component to open its **Basic settings** view.
4. Click the [...] button next to Edit schema and in the pop-up dialog box, define the schema of the input data by adding one column Message of String type. When done, click OK to close the dialog box and click Yes when prompted to propagate the schema to the next component.

5. In the Mode area, select Use Inline Content(delimited file) and enter the message you want to show on the console in the Content field, Hello World! in this example.

6. Double-click the tLogRow component and on its Basic settings view, select the Table mode to display the execution result in table cells.

7. Create copy of this Job and name it ChildJob2, and enter another message in the Content field of the tFixedFlowInput component, Hello Talend! in this example.

Setting up the parent Job

Procedure

1. Create a new Job named ParentJob and add a tFixedFlowInput component, a tFlowToIterate component, and a tRunJob component to it.

2. Connect the tFixedFlowInput component to the tFlowToIterate component using a Row > Main connection and the tFlowToIterate component to the tRunJob component using a Row > Iterate connection.

3. Double-click the tFixedFlowInput component to open its Basic settings view.

4. Click the [...] button next to Edit schema and in the pop-up dialog box, define the schema of the input data by adding one column JobName of String type. When done, click OK to close the dialog box.

5. In the Mode area, select the Use Inline Content(delimited file) option and specify the names of the child Jobs to call from the parent Job in the Content field.

ChildJob1
ChildJob2
6. Double-click the \texttt{tRunJob} component to open its \textbf{Basic settings} view.

7. Select the \textbf{Use dynamic job} check box and in the \textbf{Context job} field displayed, press \texttt{Ctrl+Space} and from the list of variables select the iterative global variable created by the \texttt{tFlowToIterate} component, \texttt{tFlowToIterate_1.JobName} in this example. The \textbf{Context job} field is then filled with \texttt{((String)globalMap.get("row1.JobName")).} Upon each iteration, this variable will be resolved as the name of the Job to be called.

8. Click the [...] button next to the Job field and in the [Select Job] dialog box, select all the Jobs you want to run and click OK to close the dialog box. In this example, they are \texttt{ChildJob1} and \texttt{ChildJob2}.

\textbf{Executing the parent Job to run the child Jobs dynamically}

\textbf{Procedure}

1. Save your child Jobs and parent Job.
2. Press F6 or click the Run button on the Run console to execute the Job.
As shown above, the child Jobs are called one after another and messages specified in the child Jobs are displayed on the console.

**Propagating the buffered output data from the child Job to the parent Job**

In this scenario, a three-component Job calls a two-component child Job and displays the buffered output data of the child Job, instead of the data from the input flow of the parent Job, on the console.

**Setting up the child Job**

**About this task**

**Procedure**

1. Create a Job named *child*, and add two components by typing their names on the design workspace or dropping them from the Palette to the design workspace:
   - a tFixedFlowInput, to generate a message
   - a tBufferOutput, to store the generated message in the buffer memory
2. Connect the tFixedFlowInput component to the tBufferOutput component using a Row > Main connection.
3. Double-click the tFixedFlowInput component to open its Basic settings view.
4. Click the [...] button next to Edit schema to open the Schema dialog box and define the schema of the input data. In this example, the schema has only one column message of the string type.

When done, click OK to validate the changes and then click Yes in the pop-up Propagate dialog box to propagate the schema to the next component.

5. In the Mode area, select Use Single Table option, and define the corresponding value for the message column in the Values table. In this example, the value is "message from the child job".

Setting up the parent Job

About this task

Procedure

1. Create a Job, and add three components by typing their names on the design workspace or dropping them from the Palette to the design workspace:
   - a tFixedFlowInput, to generate a message
   - a tRunJob, to call the Job named child
• a **tLogRow**, to display the execution result on the console

2. Connect the **tFixedFlowInput** component to the **tRunJob** component and the **tRunJob** component to the **tLogRow** component using the **Row > Main** connections.

3. Double-click the **tFixedFlowInput** component to open its **Basic settings** view.

   ![tFixedFlowInput Settings](image)

   4. Click the [...] button next to **Edit schema** to open the **Schema** dialog box and define the schema of the input data. In this example, the schema has only one column **message** of the string type.

   ![Schema Dialog](image)

   When done, click **OK** to validate the changes.

5. In the **Mode** area, select the **Use Single Table** option, and define the corresponding value for the **message** column in the **Values** table. In this example, the value is "message from the parent job".

6. Click the **tRunJob** component and then click the **Component** tab to open its **Basic settings** view.
7. Click the **Sync columns** button and then click **Yes** in the pop-up **Propagate** dialog box to retrieve the schema from the preceding component.

8. Click the [...] button next to the **Job** field to open the **Repository Content** dialog box.

   ![Repository Content dialog box]

   In the **Repository Content** dialog box, select the Job named *child* and then click **OK** to close the dialog box.

9. In the **Advanced settings** view of the **tRunJob** component, select the **Propagate the child result to the output schema** check box. With this check box selected, the buffered output of the child Job will be propagated to the output component.

   ![Advanced settings view]

**Executing the parent Job**

**Procedure**

1. Press **Ctrl+S** to save the Job.
2. Press **F6** or click the **Run** button on the **Run** console to execute the Job.
The child Job is called and the message specified in the child Job, rather than the message defined in the parent Job, is displayed on the console.
**tS3BucketCreate**

Creates a bucket on Amazon S3.

“Bucket” is a term used by AWS for top level folders on S3, which can contain sub folders and store all your data (objects).

**tS3BucketCreate Standard properties**

These properties are used to configure tS3BucketCreate running in the Standard Job framework.

The Standard tS3BucketCreate component belongs to the Cloud family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>

<tr>
<td><strong>Die on error</strong></td>
<td>This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.</td>
</tr>
</tbody>
</table>
### Advanced settings

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
</table>
| **Config client** | Select this check box to configure client parameters.  
**Client parameter:** select client parameters from the list.  
**Value:** enter the parameter value.  
Not available when **Use existing connection** is selected. |
| **STS Endpoint** | Select this check box and in the field displayed, specify the AWS Security Token Service endpoint, for example, `sts.amazonaws.com`, where session credentials are retrieved from.  
This check box is available only when the **Assume role** check box is selected. |
| **tStatCatcher Statistics** | Select this check box to collect log data at the component level. |

### Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>ERROR_MESSAGE</strong></td>
<td>The error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is selected.</td>
</tr>
</tbody>
</table>

### Usage

| Usage rule | This component can be used alone or with other S3 components, e.g. **tS3BucketExist**. |

**Dynamic settings**  
Click the `[+]` button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.  
Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.  
For examples on using dynamic parameters, see [Reading data from databases through context-based dynamic connections](page 2457) and [Reading data from different MySQL databases using dynamically loaded connection parameters](page 491). For more information on **Dynamic settings** and context variables, see [Talend Studio User Guide](#). |

### Related scenario

For **tS3BucketCreate** related scenarios, see [Verifying the absence of a bucket, creating it and listing all the S3 buckets](page 3264).
**tS3BucketDelete**

Deletes an empty bucket from Amazon S3.

"Bucket" is a term used by AWS for top level folders on S3, which can contain sub folders and store all your data (objects).

**tS3BucketDelete Standard properties**

These properties are used to configure tS3BucketDelete running in the Standard Job framework. The Standard tS3BucketDelete component belongs to the Cloud family. The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>

Verifying the absence of a bucket, creating it and listing all the S3 buckets

In this scenario, `tS3BucketExist` is used to verify the absence of a bucket, `tS3BucketCreate` to create that bucket upon confirmation, and `tS3BucketList` to list all the buckets on Amazon S3.

Linking the components

Procedure

1. Drop `tS3Connection`, `tS3BucketExist`, `tS3BucketCreate`, `tS3BucketList`, `tIterateToFlow` and `tLogRow` onto the workspace.
2. Link `tS3Connection` to `tS3BucketExist` using the `OnSubjobOk` trigger.
3. Link `tS3BucketExist` to `tS3BucketCreate` using the `Run if` trigger.
4. Link `tS3BucketCreate` to `tS3BucketList` using the `OnSubjobOk` trigger.
5. Link `tS3BucketList` to `tIterateToFlow` using the `Row > Iterate` connection.
6. Link `tIterateToFlow` to `tLogRow` using the `Row > Main` connection.

Configuring the components

Procedure

1. Double-click `tS3Connection` to open its Basic settings view.

2. In the Access Key and Secret Key fields, enter the authentication credentials.
3. Double-click `tS3BucketExist` to open its Basic settings view.
4. Select the **Use existing connection** check box to reuse the connection.

5. In the **Bucket** field, enter the bucket name to check if it exists.

6. Double-click the **If** link to define the condition.

7. In the **Condition** box, enter the expression:

   ```java
   !((Boolean)globalMap.get("tS3BucketExist_1_BUCKET_EXIST"))
   ```

   This way, the rest of the Job will be executed if the specified bucket does not exist.

8. Double-click **tS3BucketCreate** to open its **Basic settings** view.

   Select the **Use existing connection** check box to reuse the connection.

   In the **Bucket** field, enter the bucket name to create.

9. Double-click **tS3BucketList** to open its **Basic settings** view.

   Select the **Use existing connection** check box to reuse the connection.

10. Double-click **tIterateToFlow** to open its **Basic settings** view.
11. Click **Edit schema** to open the schema editor.

![Schema editor](image)

Click the **[+]** button to add one column, namely **bucket_list** of the String type.

Click **Ok** to validate the setup and close the schema editor.

12. In the **Mapping** area, press **Ctrl + Space** in the **Value** field to choose the variable **tS3BucketList_1_CURRENT_BUCKET_NAME**.

13. Double-click **tLogRow** to open its **Basic settings** view.

![LogRow editor](image)

Select **Table (print values in cells of a table)** for a better display of the results.

**Executing the Job**

**Procedure**

1. Press **Ctrl + S** to save the Job.
2. Press **F6** to run the Job.
As shown above, the bucket is created and all the buckets are listed.

3. Go to the S3 web console:

As shown above, the bucket has been created on the S3 server.

4. Refresh the S3 Browser client:

This shows that the S3 Create action was performed successfully.
tS3BucketList

Lists all the buckets on Amazon S3.

"Bucket" is a term used by AWS for top level folders on S3, which can contain sub folders and store all your data (objects).

**tS3BucketList Standard properties**

These properties are used to configure tS3BucketList running in the Standard Job framework.

The Standard tS3BucketList component belongs to the Cloud family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>

</tbody>
</table>
Global Variables

| ERROR_MESSAGE | The error message generated by the component when an error occurs. This is an After variable and it returns a string. |

Usage

| Usage rule | As a start component, this component is to be used along with other S3 components. |

Dynamic settings

Click the [+ ] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenario

For tS3Connection related scenarios, see Exchange files with Amazon S3 on page 3298.
tS3Copy

Copies an Amazon S3 object from a source bucket to a destination bucket.

tS3Copy Standard properties

These properties are used to configure tS3Copy running in the Standard Job framework.
The Standard tS3Copy component belongs to the Cloud family.
The component in this framework is available in all Talend products.

Basic settings

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access Key</td>
<td>Specify the Access Key ID that uniquely identifies an AWS Account. For how to get your Access Key and Access Secret, visit Getting Your AWS Access Keys.</td>
</tr>
<tr>
<td>Secret Key</td>
<td>Specify the Secret Access Key, constituting the security credentials in combination with the access key. To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Inherit credentials from AWS role</td>
<td>Select this check box to obtain AWS security credentials from Amazon EC2 instance metadata. To use this option, the Amazon EC2 instance must be started and your Job must be running on Amazon EC2. For more information, see Using an IAM Role to Grant Permissions to Applications Running on Amazon EC2 Instances.</td>
</tr>
<tr>
<td>Assume role</td>
<td>If you temporarily need some access permissions associated to an AWS IAM role that is not granted to your user account, select this check box to assume that role. Then specify the values for the following parameters to create a new assumed role session.</td>
</tr>
<tr>
<td>Region</td>
<td>Specify the AWS region by selecting a region name from the list or entering a region between double quotation marks (e.g. ”us-east-1”) in the list. For more information about the AWS Region, see Regions and Endpoints.</td>
</tr>
<tr>
<td>Source Bucket</td>
<td>Specify the name of the source bucket that contains the object to be copied.</td>
</tr>
<tr>
<td>Source Key</td>
<td>Specify the path to the object to be copied. <strong>Warning: This field must not start with a slash (/).</strong></td>
</tr>
<tr>
<td>Destination Bucket</td>
<td>Specify the name of the destination bucket to which the object will be copied.</td>
</tr>
</tbody>
</table>
### Destination Key
Specify the path to the destination object, using slash (/) to separate folders in the path.

If:
- you only specify a file name in this field, the file will be in the bucket;
- the path contains folders that do not exist, the folders will be created;
- the file already exists, it will be overwritten.

**Warning:** This field must not start with a slash (/).

### Server-Side Encryption
Select this check box to enable server-side encryption with Amazon S3-Managed Encryption Keys (SSE-S3) and use the 256-bit Advanced Encryption Standard (AES-256) cipher to encrypt your data.

For more information about the server-side encryption, see [Protecting Data Using Server-Side Encryption](#).

### Use KMS
Select this check box to enable server-side encryption with AWS KMS-Managed Keys (SSE-KMS) instead of Amazon S3-Managed Encryption Keys (SSE-S3).

This property is available when the **Server-Side Encryption** check box is selected.

### Customer Master Key
Specify your own customer master key (CMK) that is created in the IAM console using AWS Key Management Service for SSE-KMS encryption. If not specified, the default CMK, which is created the first time you add an SSE-KMS encrypted object to the defined bucket in your region, will be used for SSE-KMS encryption.

This property is available when the **Use KMS** check box is selected.

### Die on error
Select this check box to stop the execution of the Job when an error occurs.

Clear the check box to skip any rows on error and complete the process for error-free rows.

### Advanced settings

#### Config client
Select this check box and specify the client parameter(s) by clicking the [+] button to add as many rows as needed, each row for a client parameter, and then setting the value of the following fields for each parameter:
- **Client Parameter**: click the cell and from the drop-down list displayed select the client parameter.
- **Value**: enter the value for the selected parameter.

This check box is available only when the **Use an existing connection** check box is cleared.

#### Part size (Mb) for file larger than 5GB
Specify the part size in MB. This parameter takes effect only when you copy an Amazon S3 object that is larger than 5 GB through multiple parts.

Note that in the copy operation, the object’s metadata may drop during transition.
## STS Endpoint

Select this check box and in the field displayed, specify the AWS Security Token Service endpoint, for example, `sts.amazonaws.com`, where session credentials are retrieved from. This check box is available only when the **Assume role** check box is selected.

## tStatCatcher Statistics

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

## Global Variables

<table>
<thead>
<tr>
<th><strong>ERROR_MESSAGE</strong></th>

## Copying an S3 object from one bucket to another

This scenario describes a Job that uploads a new object to an existing empty S3 bucket `bucket-src`, then copies the object from the bucket `bucket-src` to another existing empty S3 bucket `bucket-dst`, finally lists the object in the bucket `bucket-dst` to see whether the object is successfully copied.
Setting up the Job

Procedure

1. Create a new Job and add a `tS3Connection` component, a `tS3Put` component, a `tS3Copy` component, a `tS3List` component, a `tIterateToFlow` component, and a `tLogRow` component by typing their names on the design workspace or dropping them from the Palette.

2. Link the `tS3List` component to the `tIterateToFlow` component using a `Row > Iterate` connection.

3. Link the `tIterateToFlow` component to the `tLogRow` component using a `Row > Main` connection.

4. Link the `tS3Connection` component to the `tS3Put` component using a `Trigger > On Subjob Ok` connection.

5. Do the same to link the `tS3Put` component to the `tS3Copy` component and the `tS3Copy` component to the `tS3List` component.

Configuring the components

Creating a connection to Amazon S3

Procedure

1. Double-click the `tS3Connection` component to open its `Basic settings` view on the `Component` tab.

2. In the `Access Key` and `Secret Key` fields, enter the authentication credentials required to access Amazon S3.

3. From the `Region` drop-down list, select an AWS region where the object will be uploaded and copied. In this example, we keep the default setting.

Uploading an object to an Amazon S3 bucket

Procedure

1. Double-click the `tS3Put` component to open its `Basic settings` view on the `Component` tab.
2. Select the **Use an existing connection** check box to reuse the Amazon S3 connection information you have defined in the **tS3Connection** component.

3. In the **Bucket** field, enter the name of the S3 bucket where the object will be uploaded. In this example, it is `bucket-src` that already exists in Amazon S3.

4. In the **Key** field, enter the key for the object to be uploaded. In this example, it is `tS3Copy_icon32_src.png`.

5. In the **File** field, browse to or enter the path to the object to be uploaded. In this example, it is `D:/tS3Copy_icon32.png`.

**Copying the uploaded object to another Amazon S3 bucket**

**Procedure**

1. Double-click the **tS3Copy** component to open its **Basic settings** view on the **Component** tab.

![tS3Copy_1](image)

2. Select the **Use an existing connection** check box to reuse the Amazon S3 connection information you have defined in the **tS3Connection** component.

3. In the **Bucket** field in the **Source Configuration** area, enter the name of the bucket which contains the object to be copied. In this example, it is `bucket-src`.

4. In the **Key** field in the **Source Configuration** area, enter the key of the object to be copied. In this example, it is `tS3Copy_icon32_src.png`.

5. In the **Bucket** field in the **Destination Configuration** area, enter the name of the bucket to which the object will be copied. In this example, it is the empty one `bucket-dst` that already exists in Amazon S3.

6. In the **Key** field in the **Destination Configuration** area, enter the new key for the object after being copied to the destination bucket. In this example, it is `tS3Copy_icon32_dst.png`.

**Listing the object in the destination bucket**

**Procedure**

1. Double-click the **tS3List** component to open its **Basic settings** view on the **Component** tab.
2. Select the **Use an existing connection** check box to reuse the Amazon S3 connection information you have defined in the **tS3Connection** component.

3. Clear the **List all buckets objects** check box, and then click the [+] button to add one row in the **Bucket** table displayed and set the value for each column. In this example, **bucket-dst** for the **Bucket name** column and empty value for the **Key prefix** column, this way only the objects in the **bucket-dst** bucket will be listed.

4. Double-click the **tIterateToFlow** component to open its **Basic settings** view on the **Component** tab.

5. Click the [...] button next to **Edit schema** and in the pop-up schema dialog box define the schema by adding one column **ObjectList** of **String** type.

6. Click **OK** to save the changes and in the pop-up dialog box click **Yes** to accept the propagation.

7. Double-click the **tLogRow** component to open its **Basic settings** view on the **Component** tab.
8. In the Mode area, select Table (print values in cells of a table) for better readability of the result.

**Saving and executing the Job**

**Procedure**

1. Press Ctrl + S to save the Job.
2. Press F6 to run the Job.

```plaintext
[statistics] connecting to socket on port 3491
[statistics] connected
[----------]
tLogRow_1
[----------]
ObjectList
[----------]
tS3Copy_icon32_dat.png
[----------]

[statistics] disconnected
```

As shown above, the uploaded object has been copied to the destination bucket successfully.
**tS3Delete**

Deletes a file from Amazon S3.

**tS3Delete Standard properties**

These properties are used to configure tS3Delete running in the Standard Job framework.

The Standard tS3Delete component belongs to the Cloud family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Use existing connection</strong></td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td><strong>Access Key</strong></td>
<td>The Access Key ID that uniquely identifies an AWS Account. For how to get your Access Key and Access Secret, visit Getting Your AWS Access Keys.</td>
</tr>
<tr>
<td><strong>Secret Key</strong></td>
<td>The Secret Access Key, constituting the security credentials in combination with the access key. To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Inherit credentials from AWS role</strong></td>
<td>Select this check box to obtain AWS security credentials from Amazon EC2 instance metadata. To use this option, the Amazon EC2 instance must be started and your Job must be running on Amazon EC2. For more information, see Using an IAM Role to Grant Permissions to Applications Running on Amazon EC2 Instances.</td>
</tr>
<tr>
<td><strong>Assume role</strong></td>
<td>If you temporarily need some access permissions associated to an AWS IAM role that is not granted to your user account, select this check box to assume that role. Then specify the values for the following parameters to create a new assumed role session.</td>
</tr>
<tr>
<td><strong>Region</strong></td>
<td>Specify the AWS region by selecting a region name from the list or entering a region between double quotation marks (e.g. &quot;us-east-1&quot;) in the list. For more information about the AWS Region, see Regions and Endpoints.</td>
</tr>
<tr>
<td><strong>Bucket</strong></td>
<td>Specify the name of the bucket, namely the top level folder, on Amazon S3.</td>
</tr>
<tr>
<td><strong>Key</strong></td>
<td>Specify the path to the file to delete. <strong>Warning:</strong> This field must not start with a slash (/).</td>
</tr>
</tbody>
</table>
### Die on error

This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

### Advanced settings

| Config client | Select this check box to configure client parameters.  
| Client parameter: select client parameters from the list.  
| Value: enter the parameter value.  
| Not available when Use existing connection is selected. |

| STS Endpoint | Select this check box and in the field displayed, specify the AWS Security Token Service endpoint, for example, sts.amazonaws.com, where session credentials are retrieved from.  
| This check box is available only when the Assume role check box is selected. |

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

### Global Variables

| ERROR_MESSAGE | The error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is selected. |

### Usage

| Usage rule | This component can be used alone or with other S3 components, e.g. tS3BucketList. |

| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.  
| Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.  
| For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |
Related scenario

For **tS3Delete** related scenarios, see *Verifying the absence of a bucket, creating it and listing all the S3 buckets* on page 3264.
**tS3Get**

Retrieves a file from Amazon S3.

**tS3Get Standard properties**

These properties are used to configure tS3Get running in the Standard Job framework.

The Standard tS3Get component belongs to the Cloud family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th><strong>Use existing connection</strong></th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Access Key</strong></td>
<td>The Access Key ID that uniquely identifies an AWS Account. For how to get your Access Key and Access Secret, visit Getting Your AWS Access Keys.</td>
</tr>
</tbody>
</table>
| **Secret Key**              | The Secret Access Key, constituting the security credentials in combination with the access Key.  
                             | To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| **Inherit credentials from AWS role** | Select this check box to obtain AWS security credentials from Amazon EC2 instance metadata. To use this option, the Amazon EC2 instance must be started and your Job must be running on Amazon EC2. For more information, see Using an IAM Role to Grant Permissions to Applications Running on Amazon EC2 Instances. |
| **Assume role**             | If you temporarily need some access permissions associated to an AWS IAM role that is not granted to your user account, select this check box to assume that role. Then specify the values for the following parameters to create a new assumed role session. |
| **Region**                  | Specify the AWS region by selecting a region name from the list or entering a region between double quotation marks (e.g. "us-east-1") in the list. For more information about the AWS Region, see Regions and Endpoints. |
| **Client-side Encrypt**     | Select this check box and from the Key type drop-down list displayed, select one of the following three options for encrypting the data on the client-side before sending to Amazon S3. For more information, see Protecting Data Using Client-Side Encryption.  
                             | • KMS-managed customer master key: use a KMS-managed customer master key (CMK) for the client-side data encryption. In the Key field, you need to specify the AWS KMS customer master key ID (CMK). |
- **Symmetric Master Key**: use a symmetric master key (256-bit AES secret key) for the client-side data encryption.
  - **Algorithm**: select the algorithm associated with the key from the list. By default, there is only one algorithm named **AES**.
  - **Encoding**: select the encoding type associated with the key from the list, either **Base64** or **X509**.
  - **Key or Key file**: specify the key or the path to the file that stores the key.

- **Asymmetric Master Key**: use an asymmetric master key (a 1024-bit RSA key pair) for the client-side data encryption.
  - **Algorithm**: select the algorithm associated with the key from the list. By default, there is only one algorithm named **RSA**.
  - **Public key file**: specify the path to the public key file.
  - **Private key file**: specify the path to the private key file.

<table>
<thead>
<tr>
<th><strong>Bucket</strong></th>
<th>Specify the name of the bucket, namely the top level folder, on the S3 server.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Key</strong></td>
<td>Specify the path to the file saved on the S3 server.</td>
</tr>
<tr>
<td><strong>Warning</strong>: This field must not start with a slash (/).</td>
<td></td>
</tr>
<tr>
<td><strong>File</strong></td>
<td>Name of the file to be saved locally.</td>
</tr>
<tr>
<td><strong>Die on error</strong></td>
<td>This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| **Config client** | Select this check box to configure client parameters.  
| **Client parameter**: select client parameters from the list.  
| **Value**: enter the parameter value.  
| Not available when **Use existing connection** is selected. |
| **Enable Accelerate Mode** | Select this check box to enable fast, easy and secure transfers of files over long distances between your client and an S3 bucket. To take it into account, you should enable this acceleration mode on the S3 bucket in advance. |
| **Use Select** | Select this check box to customize the way to retrieve a file from Amazon S3.  
| **File Type**: Type of the file to be retrieved  
| **Query**: Query to be used for retrieving the file.  
| **Compressed Type**: Compression type of the file to be compressed  
| **Header Type** and **Field Separator**: Header type and field separator to be used for retrieving the file |
## S3 CSV Input Options

Select this check box to configure the CSV file input settings.
This property is available only when you select the **Use Select** check box.

## Configure Output

Select this check box to configure the settings used to output files.
This property is available only when you select the **Use Select** check box.

## JSON Record Delimiter

Set the delimiter used to separate JSON records.
This property is available only when you select **JSON** from the **Output Type** drop-down list.

## Add the InputStream in Global variables

Select this check box to add InputStream into global variables so that other components in the Job can use this input data.
This property is available only when you select the **Use Select** check box.

## STS Endpoint

Select this check box and in the field displayed, specify the AWS Security Token Service endpoint, for example, `sts.amazonaws.com`, where session credentials are retrieved from.
This check box is available only when the **Assume role** check box is selected.

## tStatCatcher Statistics

Select this check box to collect log data at the component level.

### Global Variables

<table>
<thead>
<tr>
<th>Variable Name</th>
<th>Description</th>

<tr>
<td>Inherit credentials from AWS role</td>
<td>Select this check box to obtain AWS security credentials from Amazon EC2 instance metadata. To use this option, the Amazon EC2 instance must be started and your Job must be running on Amazon EC2. For more information, see Using an IAM Role to Grant Permissions to Applications Running on Amazon EC2 Instances.</td>
</tr>
<tr>
<td>Assume role</td>
<td>If you temporarily need some access permissions associated to an AWS IAM role that is not granted to your user account, select this check box to assume that role. Then specify the values for the following parameters to create a new assumed role session.</td>
</tr>
<tr>
<td>Region</td>
<td>Specify the AWS region by selecting a region name from the list or entering a region between double quotation marks (e.g. &quot;us-east-1&quot;) in the list. For more information about the AWS Region, see Regions and Endpoints.</td>
</tr>
<tr>
<td>List all bucket objects</td>
<td>Select this check box to list all the files on the S3 server. <strong>Key prefix</strong>: enter the prefix of files to be listed. This way, only files with that prefix will be listed.</td>
</tr>
<tr>
<td>Bucket</td>
<td>Click the [...] button to add one or more lines for defining the buckets and file prefixes. <strong>Bucket name</strong>: name of the bucket, namely the top level folder, whose files will be listed. <strong>Key prefix</strong>: prefix of files to be listed.</td>
</tr>
</tbody>
</table>
### Advanced settings

**Die on error**
- Not available when **List all bucket objects** is selected.
- This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

**Config client**
- Select this check box to configure client parameters.
  - **Client parameter**: select client parameters from the list.
  - **Value**: enter the parameter value.
- Not available when **Use existing connection** is selected.

**STS Endpoint**
- Select this check box and in the field displayed, specify the AWS Security Token Service endpoint, for example, `sts.amazonaws.com`, where session credentials are retrieved from.
- This check box is available only when the **Assume role** check box is selected.

**tStatCatcher Statistics**
- Select this check box to collect log data at the component level.

### Global Variables

- **CURRENT_BUCKET_NAME**: The current bucket name. This is a Flow variable and it returns a string.
- **CURRENT_KEY**: The current key. This is a Flow variable and it returns a string.
- **NB_BUCKET**: The number of buckets. This is an After variable and it returns an integer.
- **NB_BUCKET_OBJECT**: The number of objects in all buckets. This is an After variable and it returns an integer.
- **ERROR_MESSAGE**: The error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is selected.

### Usage

**Usage rule**
- This component can be used alone or with other S3 components, e.g. tS3Delete.

**Dynamic settings**
- Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.
Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

### Listing files with the same prefix from a bucket

In this scenario, **tS3List** is used to list all the files in a bucket which have the same prefix.

There are such files in this bucket:

![S3 Browser 3.9.3 - Free Version (for non-commercial use)](image)

For how to create a bucket and put files into it, see Verifying the absence of a bucket, creating it and listing all the S3 buckets on page 3264 and Exchange files with Amazon S3 on page 3298.

### Linking the components

**Procedure**

1. Drop **tS3Connection**, **tS3List**, **tIterateToFlow**, **tLogRow** and **tS3Close** onto the workspace.
2. Link **tS3Connection** to **tS3List** using the **OnSubjobOk** trigger.
3. Link **tS3List** to **tIterateToFlow** using the **Row > Iterate** connection.
4. Link **tIterateToFlow** to **tLogRow** using the **Row > Main** connection.
5. Link **tS3List** to **tS3Close** using the **OnSubjobOk** trigger.
Configuring the components

Procedure

1. Double-click `tS3Connection` to open its **Basic settings** view.

2. In the **Access Key** and **Secret Key** fields, enter the authentication credentials.

3. Double-click `tS3List` to open its **Basic settings** view.
4. Select the **Use existing connection** check box to reuse the connection.
5. In the **Bucket** area, click the [+] button to add one line.
6. In the **Bucket name** and **Key prefix** fields, enter the bucket name and file prefix.
   This way, only files with the specified prefix will be listed.
7. Double-click **tIterateToFlow** to open its **Basic settings** view.

```
<table>
<thead>
<tr>
<th>Column</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>file_list</td>
<td>((String)globalMap.get(&quot;tS3List_1_CURRENT_KEY&quot;))</td>
</tr>
</tbody>
</table>
```

8. Click **Edit schema** to open the schema editor.

Click the [+] button to add one column, namely **file_list** of the String type.
Click **Ok** to validate the setup and close the schema editor.

9. In the **Mapping** area, press **Ctrl + Space** in the **Value** field to choose the variable **tS3List_1_CURR_ENT_KEY**.

10. Double-click **tLogRow** to open its **Basic settings** view.

```
<table>
<thead>
<tr>
<th>Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table (print values in cells of a table)</td>
</tr>
</tbody>
</table>
```

Select **Table (print values in cells of a table)** for a better display of the results.

11. Double-click **tS3Close** to open its **Basic settings** view.
There is no need to select a connection component as the only one is selected by default.

**Executing the Job**

**Procedure**

1. Press **Ctrl + S** to save the Job.
2. Press **F6** to run the Job.

   ![console output]

   As shown above, only the files with the prefix "in" are listed.
**tS3Put**

Uploads data onto Amazon S3 from a local file or from cache memory via the streaming mode.

**tS3Put Standard properties**

These properties are used to configure tS3Put running in the Standard Job framework. The Standard tS3Put component belongs to the Cloud family. The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>

<tr>
<th><strong>Use KMS</strong></th>
<th>Select this check box to enable server-side encryption with AWS KMS-Managed Keys (SSE-KMS) instead of Amazon S3-Managed Encryption Keys (SSE-S3).</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>This property is available when the Server-Side Encryption check box is selected.</td>
</tr>
</tbody>
</table>

| **Customer Master Key**   | Specify your own customer master key (CMK) that is created in the IAM console using AWS Key Management Service for SSE-KMS encryption. If not specified, the default CMK, which is created the first time you add an SSE-KMS |
encrypted object to the defined bucket in your region, will be used for SSE-KMS encryption. This property is available when the **Use KMS** check box is selected.

| Die on error | This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows. |

### Advanced settings

| Config client | Select this check box to configure client parameters. **Client parameter**: select client parameters from the list. **Value**: enter the parameter value. Not available when **Use existing connection** is selected. |
| Enable Accelerate Mode | Select this check box to enable fast, easy and secure transfers of files over long distances between your client and an S3 bucket. To take it into account, you should enable this acceleration mode on the S3 bucket in advance. |
| STS Endpoint | Select this check box and in the field displayed, specify the AWS Security Token Service endpoint, for example, sts.amazonaws.com, where session credentials are retrieved from. This check box is available only when the **Assume role** check box is selected. |
| Part size (Mb) | Specify the part size in MB when uploading a large file in parts. For more information about S3 multipart upload, see **Multipart Upload Overview**. |
| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

### Global Variables

| ERROR_MESSAGE | The error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is selected. |

### Usage

| Usage rule | This component can be used alone or with other S3 components, e.g. **tS3Connection**. |
| Dynamic settings | Click the **[+]** button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. |
Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Exchange files with Amazon S3

In this scenario, **tS3Put** is used to send a file to the Amazon S3 server while **tS3Get** is used to get that file.

**Linking the components**

**Procedure**

1. Drop **tS3Connection**, **tS3Put** and **tS3Get** onto the workspace.
2. Link **tS3Connection** to **tS3Put** using the **OnSubjobOk** trigger.
3. Link **tS3Put** to **tS3Get** using the **OnSubjobOk** trigger.

![Diagram of component flow](attachment:image.jpg)

**Configuring the components**

**Procedure**

1. Double-click **tS3Connection** to open its Basic settings view.
2. In the **Access Key** and **Secret Key** fields, enter the authentication credentials.

3. Double-click **tS3Put** to open its **Basic settings** view.

4. Select the **Use existing connection** check box to reuse the connection.

5. In the **Bucket** field, enter the bucket name.

6. In the **Key** field, enter the name of the file to be saved on the S3 server.

7. In the **File** field, enter the file to be uploaded to the S3 server.

8. Double-click **tS3Get** to open its **Basic settings** view.

9. Select the **Use existing connection** check box to reuse the connection.

10. In the **Bucket** field, enter the bucket name.

11. In the **Key** field, enter the name of the file to be retrieved from the S3 server.

12. In the **File** field, enter the local name of the retrieved file.

**Executing the Job**

**Procedure**

1. Press **Ctrl + S** to save the Job.

2. Press **F6** to run the Job.
3. Go to the S3 web console:

As shown above, the file has been put on to the S3 server.

4. Refresh the S3 Browser client:

This shows that the S3 Put action was performed successfully.

5. Go to the folder where the retrieved file is saved locally:

As shown above, the remote file is retrieved to the local disk, proof that the S3 Get action was performed successfully.
tSageX3Input

Extracts data from a given Sage X3 system.

This component leverages the Web service provided by a given Sage X3 Web server to extract data from the Sage X3 system (the X3 server).

tSageX3Input Standard properties

These properties are used to configure tSageX3Input running in the Standard Job framework.
The Standard tSageX3Input component belongs to the Business family.
The component in this framework is available in all Talend products.

Basic settings

| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
  • View schema: choose this option to view the schema only.  
  • Change to built-in property: choose this option to change the schema to Built-in for local changes.  
  • Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |
<table>
<thead>
<tr>

</tr>
</thead>
<tbody>
<tr>
<td>Action</td>
<td>Select in the list the action to be carried on. • <strong>getAllDetails</strong>: returns the details of all the records. • <strong>getSummary</strong>: returns the summary of each record. • <strong>getDetail</strong>: returns the details of the records that meet the conditions configured in the <strong>Query condition</strong> table.</td>
</tr>
</tbody>
</table>

| Mapping | Complete this table to map the variable elements of the object, the sub-program or the list set in the given Sage X3 Web server. The columns to be completed include: Column: the columns defined in the schema editor for this component. Group ID: the identifier of each variable element group. For example, a variable element group could represent one of attributes of an object. Field name: the field name of each variable element. |

| Conditions | Complete this table to set up the query condition(s). The columns to be completed include: **Key**: the names of the variable elements used as the key for data extraction. **Value**: the value of the given key field used to extract the corresponding data. Available when **getDetail** is selected in the **Action** list. |

| Query condition | Select this check box to set up the query condition(s). The columns to be completed include: **Key**: the names of the variable elements used as the key for data extraction. **Value**: the value of the given key field used to extract the corresponding data. Not available when **getDetail** is selected in the **Action** list. |

| Limit | Type in a number to indicate the maximum row count of the data to be extracted. |
Not available when **getDetail** is selected in the **Action** list.

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

**Global Variables**

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it. For further information about variables, see **Talend Studio User Guide**. |

**Usage**

| Usage rule | Usually used as a Start component. An output component is required. |

**Using query key to extract data from a given Sage X3 system**

This scenario describes a two-component Job used to extract one row of data from a given Sage X3 system. The object method is to be called, that means the variable elements of this object thus are attributes. The data used in this scenario can be found in the example provided by Sage X3.

**Setting up the Job**

**Procedure**

1. Drop the **tSageX3Input** component and the **tLogRow** components onto the workspace from **Palette**.
2. Connect the **tSageX3Input** component to the **tLogRow** component using a **Row > Main** link.
# Configuring the schema of tSageX3Input

**Procedure**

1. Double-click **tSageX3Input** to set its properties in the **Basic Settings** view.

   ![Basic Settings](image)

   - **Schema**: Built-In
   - **Endpoint address**: "http://10.42.20.168:28880/neighbor/services/CA/dx/dxWebService/XMLCloud"  
     
![Basic Settings](image)

   - **User**: "ERP"  
     
   - **Password**: ****  
     
   - **Language**: "IT"  
     
   - **Pool alias**: "TALEND"  

   - **Request config**: ***  
     
   - **Publication name**: "ITMDE1"  
     
   - **Mapping**:

<table>
<thead>
<tr>
<th>Column</th>
<th>Group ID</th>

<td>&quot;WW_MODSTAMP&quot;</td>
</tr>
<tr>
<td>NW_MODUSER</td>
<td>&quot;ADXTEC&quot;</td>
<td>&quot;NW_MODUSER&quot;</td>
</tr>
</tbody>
</table>

2. In the **Schema** field, select **Built-In** and click the three-dot button next to **Edit schema** to open the schema editor.
3. In this editor, click the plus button 12 times beneath the schema table to add 12 rows into this table.

4. Type in the names you want to use for each row. In this example, these rows are named after the publication names of the object attributes set in the Sage X3 Web server. These columns are used to map the corresponding attribute fields in the Sage X3 system.

5. In the **Type** column, click the **IMG** row to display its drop-down list.

6. From the drop-down list, select **List** as this attribute appears twice or even more and do the same to switch the types of the **TIT2NBLIG** row, the **ITMLNK** row and the **ZITMLNK** row to **List** as well for the same reason.

7. Click **OK** to validate this change and accept the propagation prompted by a pop-up dialog box.

**Configuring the connection to the Sage X3 Web server**

**Procedure**

1. In the **Endpoint address** field, type in the URL address of the Web service provided by the Sage X3 Web server. In this example, it is `http://10.42.20.168:28880/adxwsvc/services/CAdxWebServiceXmlCC`.

2. In the **User** field, type in the user name of the given Sage X3. In this example, it is **ERP**.

3. In the **Language** field, type in the name of the X3 language code used to start a connection group. In this example, it is **FRA**.

4. In the **Pool alias** field, type in the name of connection pool to be used. In this example, this connection pool is called **TALEND**.

5. In the **Publication name** field, type in the publication name of the object to be called. In this scenario, the publication name is **ITMDET**.

**Setting up the mapping and configuring the query condition**

**Procedure**

1. In the **Group ID** column and the **Field name** column of the **Mapping** table, type in values corresponding to the attribute group IDs and the attribute publication names defined in the Sage X3 Web server. In this example, the values are presented in the figure below.
### Note:

In the **Mapping** table, the **Column** column has been filled automatically with the columns you created in the schema editor.

2. Select the **Query condition** check box to activate the **Conditions** table.
3. Under the **Conditions** table, click the plus button to add one row into the table.
4. In the **Key** column, type in the publication name associated with the object attribute you need to extract data from.
5. In the **Value** column, type in the value of the attribute you have selected as the key of the data extraction. In this scenario, it is `CONTS00059`, one of the product references.

### Job execution

**Procedure**

1. Press **Ctrl+S** to save your Job.
2. Press **F6** or click **Run** on the **Run** tab to execute the Job.

   The results are displayed on the **Run** console:
**tSageX3Output**

Writes data into a given Sage X3 system.

This component connects to the Web service provided by a given Sage X3 Web server and therefrom insert, update or delete data in the Sage X3 system (the X3 server).

**tSageX3Output Standard properties**

These properties are used to configure tSageX3Output running in the Standard Job framework.

The Standard tSageX3Output component belongs to the Business family.

The component in this framework is available in all Talend products.

**Basic settings**

| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
- **View schema**: choose this option to view the schema only.  
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.  
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. Click Sync columns to retrieve the schema from the previous component connected in the Job. |
<table>

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

**Global Variables**

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the |

3308
Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>Usually used as an output component. An input component is required.</th>
</tr>
</thead>
</table>

### Using a Sage X3 Web service to insert data into a given Sage X3 system

This scenario describes a two-component Job used to generate one row of data and insert the data into a given Sage X3 system. You can find the data used in this scenario in the example provided by Sage X3. The Sage X3 Web service is used to access an object.

### Setting up the Job

**Procedure**

1. Drop the tFixedFlowInput and the tSageX3Output components onto the workspace from Palette.
2. Connect the tFixedFlowInput component to the tSageX3Output component using a Row > Main connection.

### Configuring the schema for the input data

**Procedure**

1. Double-click the tFixedFlowInput component to set its Basic Settings in the Component view
2. Click the three-dot button next to **Edit schema** to open the schema editor.

3. In the schema editor and then under the schema table, click the plus button four times to add four rows.

4. Click **OK** to validate this changes and then accept the propagation prompted by the pop-up dialog box. The four rows appear automatically in the **Values** table of the **Component** view.

5. In the **Values** table within the **Mode** area, type in the values for each of the four rows in the **Value** column. In this scenario, the values downward are: **CONT500059**, Screen 24" standard 16/10, Screen 24" standard 28/10, 2.

   **Warning:**

   *These values in the Value column must be put between quotation marks.*
Setting up the connection to the Sage X3 Web server

Procedure

1. Double-click **tSageX3Output** to set its properties from the **Basic Settings** view.

   ![Screenshot of tSageX3Output settings](image)

   - **Scheme**: `Built-In`
   - **Endpoint address**: `http://10.42.20.168:28880/adxwsvc/services/CAdxWebServiceXmlCC` (Example)
   - **User**: `ERP` (`Password`: `*****`)
   - **Language**: `FRA`
   - **Pool alias**: `TALEND`
   - **Publication name**: `ITMDET`
   - **Action**: `Insert`

<table>
<thead>
<tr>
<th>Column</th>
<th>Key</th>
<th>Group ID</th>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>newColumn</td>
<td></td>
<td>&quot;ITMDET&quot;</td>
<td>&quot;ITMREF&quot;</td>
<td></td>
</tr>
<tr>
<td>newColumn1</td>
<td></td>
<td>&quot;ITMDET&quot;</td>
<td>&quot;ZITMREF&quot;</td>
<td></td>
</tr>
<tr>
<td>newColumn2</td>
<td></td>
<td>&quot;ITMDET&quot;</td>
<td>&quot;INTDES1&quot;</td>
<td></td>
</tr>
<tr>
<td>newColumn3</td>
<td></td>
<td>&quot;ITMDET&quot;</td>
<td>&quot;ENAPLG&quot;</td>
<td></td>
</tr>
</tbody>
</table>

2. In the **Endpoint address** field, type in the URL address of the Web service provided by the Sage X3 Web server. In this example, it is `http://10.42.20.168:28880/adxwsvc/services/CAdxWebServiceXmlCC`.

3. In the **User** field, type in the user name of the given Sage X3. In this example, it is `ERP`.

4. In the **Language** field, type in the name of the X3 language code used to start a connection group. In this example, it is `FRA`.

5. In the **Pool alias** field, type in the name of connection pool to be used. In this example, this connection pool is called `TALEND`.

6. In the **Publication name** field, type in the publication name of the object to be called. In this scenario, the publication name is `ITMDET`.

7. In the **Action** field, select `insert` from the drop-down list.

Setting up the mapping

Procedure

1. In the **Field name** column of the **Mapping** table, type in the field names of the attributes the selected data action is exercised on.

2. In the **Group ID** column of the **Mapping** table, type in values corresponding to group IDs of the selected attributes. These IDs are defined in the Sage X3 Web server.
Note:
In the **Mapping** table, the **Column** column has been filled automatically with the columns retrieved from the schema of the preceding component.

### Job execution

Press CTRL+S to save your Job and press **F6** to execute it.

To verify the data that you inserted in this scenario, you can use the **tSageX3Input** component to read the concerned data from the Sage X3 server.

For further information about how to use the **tSageX3Input** component to read data, see *Using query key to extract data from a given Sage X3 system* on page 3303.
tSalesforceBulkExec

Bulk-loads data in a given file into a Salesforce object.

The tSalesforceOutputBulk and tSalesforceBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used to feed the Salesforce database. These two steps are fused together in the tSalesforceOutputBulkExec component. The advantage of using two separate steps is that the data can be transformed before it is loaded into Salesforce.

tSalesforceBulkExec Standard properties

These properties are used to configure tSalesforceBulkExec running in the Standard Job framework.

The Standard tSalesforceBulkExec component belongs to the Business and the Cloud families.

The component in this framework is available in all Talend products.

Basic settings

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Select the way the connection details will be set.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• <strong>Built-In</strong>: The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Repository</strong>: The connection details stored centrally in Repository &gt; Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up Repository Content dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in.</td>
</tr>
</tbody>
</table>

This property is not available when other connection component is selected from the Connection Component drop-down list.

| Connection Component | Select the component that opens the database connection to be reused by this component. |

<table>
<thead>
<tr>
<th>Connection type</th>
<th>Select the type of the connection from the drop-down list. The connection properties will vary according to the connection type you choose.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• <strong>Basic</strong>: select this option to access Salesforce by entering your Salesforce username and password.</td>
</tr>
</tbody>
</table>
|                 | • **OAuth**: select this option to access Salesforce using OAuth (Open Authorization) 2.0 protocol to authenticate the user. From the OAuth2 flow type drop-down list displayed, you need to choose an OAuth 2.0 authentication flow type, either Json Web Token Flow or Implicit Flow (Deprecated) (User Agent Flow). This way, you need to create a connected app in Salesforce to configure a Salesforce authentication provider. For more information about the OAuth authentication flow, see Authenticate Apps with OAuth. For more information about how to create a connected app in Salesforce, see Create a Connected App.
<table>

Salesforce Connection

The Salesforce Connection will be shown in the API (Enable OAuth Settings) area of the connected app detail page in Salesforce. This property is available only when the OAuth Implicit Flow type is selected.

| Token File | The path to the token file that stores the refresh token used to get the access token without authorization. This property is available only when the OAuth Implicit Flow type is selected. |

**Advanced settings**

| Salesforce URL | The Webservice URL required to connect to Salesforce. |
| API version | The Salesforce API version. This property is available only when the OAuth connection type is selected. |
| Bulk Connection | Select this check box if you need to use bulk data processing function. |
| Use or save the connection session | Select this check box and in the Session directory field displayed, specify the path to the connection session file to be saved or used. This session file can be shared by different Jobs to retrieve a connection session as long as the correct user ID is provided by the component. This way, you do not need to connect to the server to retrieve the session. When an expired session is detected, if the correct connection information (the user ID, password, and security key) is provided, the component will connect to the server to retrieve the new session information and update the connection session file. This property is available only when the Basic connection type is selected. |
| Need compression | Select this check box to activate SOAP message compression, which can result in increased performance levels. |
| Use Http Chunked | Select this check box to use the HTTP chunked data transfer mechanism. This property is available only when the Bulk Connection check box is cleared. |
| Trace HTTP message | Select this check box to output the HTTP interactions on the console. This property is available only when the Bulk Connection check box is selected. |
| Client Id | Enter the ID of the real user to differentiate between those who use the same account and password to access the Salesforce website. |
| Timeout | Enter the intended number of query timeout in milliseconds in Salesforce. |
Use Proxy

Select this check box to use a proxy server, and in the Host, Port, User Id, and Password fields displayed, specify the connection parameters of the proxy server.

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

Global Variables

| Error Message | The error message generated by the component when an error occurs. This is an After variable and it returns a string. |

Usage

| Usage rule | This component is more commonly used with other Salesforce components. |

Connecting to Salesforce using OAuth implicit flow to authenticate the user (deprecated)

In this scenario, the OAuth2 (Open Authorization 2.0) method is adopted to authorize the SalesforceConnection to access the Salesforce resources. This way, better security is achieved as users do not need entering their Salesforce username/password directly on the SalesforceConnection, which is required by the Basic login type instead.

Setting up the Job

**Procedure**

1. Drop a SalesforceConnection component, a FixedFlowInput component and a SalesforceOutput component onto the workspace.
2. Link the FixedFlowInput component to the SalesforceOutput component using a Row > Main connection.
3. Link the SalesforceConnection component to the FixedFlowInput component using a Trigger > OnSubjobOk connection.
Configuring the components

Procedure

1. Double-click the tSalesforceConnection component to open its Basic settings view.

![tSalesforceConnection Basic settings](image)

2. Select OAuth from the Connection type drop-down list and Implicit Flow from the Oauth2 flow type drop-down list.

3. In the Client Id and Client Secret fields, enter the key and secret used by the consumer to access Salesforce respectively.

4. In the Callback Host and Callback Port fields, enter the callback host and port information respectively.

5. In the Token File field, browse to or enter the path to the token file that stores the refresh token used by the OAuth-enabled connected app to obtain new sessions without requiring the user to provide their credentials.

6. Double-click the tFixedFlowInput component to open its Basic settings view.

![tFixedFlowInput Basic settings](image)

7. Click the [...] button next to Edit schema and in the pop-up schema dialog box, define the schema by adding one column Name of String type. When done, click OK to save the changes and close the dialog box.
8. In the Mode area, select Use Inline Content (delimited file). Then in the Content field displayed, enter the data to be written into Salesforce. For example, Talend.

9. Double-click the tSalesforceOutput component to open its Basic settings view.

10. Select the tSalesforceConnection component from the Connection Component drop-down list to reuse the connection created by it.

11. Click the [...] button next to the Module Name field and in the pop-up dialog box, select the object you want to access. In this example, it is Account.

12. Click the [...] button next to Edit schema to open the schema dialog box. On the right side of the panel, remove all the columns except the column Name. When done, click OK to save the changes and close the dialog box.

**Executing the Job**

**Procedure**

1. Press Ctrl + S to save the Job.
2. Press F6 to run the Job. The Studio console gives the URL (in yellow) for OAuth authorization.
3. Copy the URL to the browser's address bar. The Salesforce.com login page appears.

4. Fill up the username and password and click **Log in to Salesforce**.
   The authorization response is then shown on the browser at the callback host.

5. Now is the time for the Job to continue running.
As shown above, the Job is successfully executed.

6. Go to the Salesforce.com and check the Account object. You can find that the account whose name is *Talend* is inserted.

</tbody>
</table>
### Callback Port
The port value in the OAuth authentication callback URL that is defined during the creation of a connected app and will be shown in the **API (Enable OAuth Settings)** area of the connected app detail page in Salesforce.

This property is available only when the OAuth Implicit Flow type is selected.

### Token File
The path to the token file that stores the refresh token used to get the access token without authorization.

This property is available only when the OAuth Implicit Flow type is selected.

### Module Name
Click the [...] button next to the field and in the dialog box displayed, select the module that will be used or select the **Use custom object** check box and specify the module name in the **Object Name** field.

### Schema and Edit schema
A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

Click **Sync columns** to retrieve the schema from the previous component connected in the Job.

### Start Date
Click the [...] button next to the field and in the calendar dialog box displayed, select the date and time to collect only the data deleted since the specified time.

Note that you can collect only the data deleted in the past 30 days.

### End Date
Click the [...] button next to the field and in the calendar dialog box displayed, select the date and time to collect only the data deleted before the specified time.

Recovering deleted data from Salesforce

This scenario describes a two-component Job that collects the account data deleted over the past five days from Salesforce.

Setting up the Job for recovering deleted data from Salesforce

Procedure

1. Create a new Job and add a tSalesforceGetDeleted component and a tLogRow component by typing their names on the design workspace or dropping them from the Palette.
2. Connect the `tSalesforceGetDeleted` component to the `tLogRow` component using a Row > Main connection.

### Configuring the Job for recovering deleted data from Salesforce

#### Procedure

1. Double-click the `tSalesforceGetDeleted` component to open its Basic settings view.

   ![Basic settings view](image)

   2. In the **User Id**, **Password** and **Security Key** fields, enter the user authentication information required to access Salesforce.

   3. Click the `[...]` button next to the **Module Name** field and in the pop-up dialog box, select the object you want to access. In this example, it is **Account**. When done, click **OK** to save the settings and close the dialog box.
4. Click the [...] button next to the Start Date field and in the pop-up calendar dialog box, set the value of the start date and time to collect only the data deleted since the specified time. In this example, it is 2016-06-08 00:00:00.

![Select Date & Time](image)

5. Do the same to set the value of the end date and time in the End Date field to collect only the data deleted before the specified time. In this example, it is 2016-06-13 00:00:00.

6. Double-click the tLogRow component to open its Basic settings view.

7. Click Sync columns to retrieve the schema from the preceding component.

8. In the Mode area, select Vertical (each row is a key/value list) to display the results in a tabular form on the console.

**Executing the Job to recover deleted data from Salesforce**

**Procedure**

1. Press Ctrl + S to save your Job.
2. Press F6 to run your Job.
As shown above, the data deleted during the past five days is collected and displayed in a tabular form on the console.
tSalesforceGetServerTimestamp

Retrieves the current date of the Salesforce server presented in a timestamp format.

**tSalesforceGetServerTimestamp Standard properties**

These properties are used to configure tSalesforceGetServerTimestamp running in the Standard Job framework.

The Standard tSalesforceGetServerTimestamp component belongs to the Business and the Cloud families.

The component in this framework is available in all Talend products.

**Basic settings**

</tr>
<tr>
<td>Client Id</td>
<td>The OAuth Consumer Key, generated when your connected app is created and shown in the connected app detail page in Salesforce. For more information, see <a href="#">Create a Connected App</a>. This property is available only when the OAuth <strong>Implicit Flow</strong> type is selected.</td>
</tr>
<tr>
<td>Client Secret</td>
<td>The OAuth Consumer Secret, generated when your connected app is created and shown in the connected app detail page in Salesforce. For more information, see <a href="#">Create a Connected App</a>. This property is available only when the OAuth <strong>Implicit Flow</strong> type is selected.</td>
</tr>
</tbody>
</table>
### Callback Host
The host value in the OAuth authentication callback URL that is defined during the creation of a connected app and will be shown in the API (Enable OAuth Settings) area of the connected app detail page in Salesforce.
This property is available only when the OAuth Implicit Flow type is selected.

### Callback Port
The port value in the OAuth authentication callback URL that is defined during the creation of a connected app and will be shown in the API (Enable OAuth Settings) area of the connected app detail page in Salesforce.
This property is available only when the OAuth Implicit Flow type is selected.

### Token File
The path to the token file that stores the refresh token used to get the access token without authorization.
This property is available only when the OAuth Implicit Flow type is selected.

### Schema and Edit schema
A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

### Advanced settings

<td>Subject</td>
<td>The Salesforce username. This property is available only when the OAuth Json Web Token Flow type is selected.</td>
</tr>
<tr>
<td>Expiration time (in seconds)</td>
<td>The expiration time of the assertion (in seconds) within five minutes. This property is available only when the OAuth Json Web Token Flow type is selected.</td>
</tr>
<tr>
<td>Key store</td>
<td>The path to the keystore file in Java Keystore (JKS) format. The keystore file can be generated by creating a certificate signed by Salesforce and then exporting it to keystore. For more information, see <a href="#">Generate a Self-Signed Certificate</a>. This property is available only when the OAuth Json Web Token Flow type is selected.</td>
</tr>
<tr>
<td>Key store password</td>
<td>The keystore password. This property is available only when the OAuth Json Web Token Flow type is selected.</td>
</tr>
<tr>
<td>Certificate alias</td>
<td>The unique name of the certificate signed by Salesforce. This property is available only when the OAuth Json Web Token Flow type is selected.</td>
</tr>
<tr>
<td>Client Id</td>
<td>The OAuth Consumer Key, generated when your connected app is created and shown in the connected app detail page in Salesforce. For more information, see <a href="#">Create a Connected App</a>. This property is available only when the OAuth Implicit Flow type is selected.</td>
</tr>
<tr>
<td>Client Secret</td>
<td>The OAuth Consumer Secret, generated when your connected app is created and shown in the connected app detail page in Salesforce. For more information, see <a href="#">Create a Connected App</a>. This property is available only when the OAuth Implicit Flow type is selected.</td>
</tr>
<tr>
<td>Callback Host</td>
<td>The host value in the OAuth authentication callback URL that is defined during the creation of a connected app and will be shown in the API (Enable OAuth Settings) area of the connected app detail page in Salesforce.</td>
</tr>
</tbody>
</table>
This property is available only when the OAuth Implicit Flow type is selected.

**Callback Port**
The port value in the OAuth authentication callback URL that is defined during the creation of a connected app and will be shown in the API (Enable OAuth Settings) area of the connected app detail page in Salesforce.

This property is available only when the OAuth Implicit Flow type is selected.

**Token File**
The path to the token file that stores the refresh token used to get the access token without authorization.

This property is available only when the OAuth Implicit Flow type is selected.

**Module Name**
Click the [...] button next to the field and in the dialog box displayed, select the module that will be used or select the Use custom object check box and specify the module name in the Object Name field.

**Schema and Edit schema**
A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

Click Sync columns to retrieve the schema from the previous component connected in the Job.

**Start Date**
Click the [...] button next to the field and in the calendar dialog box displayed, select the date and time to collect only the data updated since the specified time.

Note that you can collect only the data updated in the past 30 days.

**End Date**
Click the [...] button next to the field and in the calendar dialog box displayed, select the date and time to collect only the data updated before the specified time.

**Advanced settings**

<table>
<thead>
<tr>
<th><strong>Salesforce URL</strong></th>
<th>The Webservice URL required to connect to Salesforce.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>API version</strong></td>
<td>The Salesforce API version.</td>
</tr>
</tbody>
</table>
Use or save the connection session

Select this check box and in the **Session directory** field displayed, specify the path to the connection session file to be saved or used.

This session file can be shared by different Jobs to retrieve a connection session as long as the correct user ID is provided by the component. This way, you do not need to connect to the server to retrieve the session.

When an expired session is detected, if the correct connection information (the user ID, password, and security key) is provided, the component will connect to the server to retrieve the new session information and update the connection session file.

This property is available only when the **OAuth** connection type is selected.

Need compression

Select this check box to activate SOAP message compression, which can result in increased performance levels.

Use Http Chunked

Select this check box to use the HTTP chunked data transfer mechanism.

Client Id

Enter the ID of the real user to differentiate between those who use the same account and password to access the Salesforce website.

Timeout

Enter the intended number of query timeout in milliseconds in Salesforce.

Use Proxy

Select this check box to use a proxy server, and in the **Host**, **Port**, **User Id**, and **Password** fields displayed, specify the connection parameters of the proxy server.

Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>

<tr>
<td>Callback Host</td>
<td>The host value in the OAuth authentication callback URL that is defined during the creation of a connected app and will be shown in the API (Enable OAuth Settings) area of the connected app detail page in Salesforce.</td>
</tr>
</tbody>
</table>
This property is available only when the OAuth Implicit Flow type is selected.

### Callback Port

The port value in the OAuth authentication callback URL that is defined during the creation of a connected app and will be shown in the API (Enable OAuth Settings) area of the connected app detail page in Salesforce.

This property is available only when the OAuth Implicit Flow type is selected.

### Token File

The path to the token file that stores the refresh token used to get the access token without authorization.

This property is available only when the OAuth Implicit Flow type is selected.

### Module Name

Click the [...] button next to the field and in the dialog box displayed, select the module that will be used or select the Use custom object check box and specify the module name in the Object Name field.

### Schema and Edit schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

In this component the schema is related to the Module selected.

To retrieve a column from a linked module it is necessary to define the column in a particular manner in the Edit schema view, otherwise the relationship query will not work. The correct syntax is: `NameofCurrentModule_NameofLinkedModule_NameofColumnofInterest`.

### Query Mode

Select the query mode from the drop-down list, either Query or Bulk.

- **Query**: the ordinary query.
- **Bulk**: the bulk query used to query large data sets efficiently and reduce the number of API requests.

### Condition

Enter the query used to select the data to be extracted between double quotation marks, for example, "name=’Talend’" or "name like ’%talend_user%’".

This property is not available when the Manual Query check box is selected.
### Manual Query
Select this check box and in the **Full SOQL query string** field displayed, enter the full SOQL (Salesforce Object Query Language) statement used to select the data to be retrieved between double quotation marks. For more information about the SOQL, see *Salesforce Object Query Language (SOQL)*.

### Guess schema
Click this button to generate the schema columns based on the query specified in the **Full SOQL query string** field.
This property is available only when the Manual Query check box is selected.
Note that there are some limitations you should be aware of when using this feature. Please refer to the Know Limitations section in Release Notes for more detailed information.

### Guess query
Click this button to generate the query in the **Full SOQL query string** field based on the defined module and schema.
For more information about how to set the module and schema correctly when generating the SOQL queries, see *How to set schema for the guess query feature of tSalesforceInput* on page 3346.
This property is available only when the Manual Query check box is selected.
Note that there are some limitations you should be aware of when using this feature. Please refer to the Know Limitations section in Release Notes for more detailed information.

### Include deleted records
Select this check box to query all the records, including the deleted ones.
This property is available only when Query is selected from the **Query Mode** drop-down list.

### How to set schema for the guess query feature of tSalesforceInput

**tSalesforceInput** allows you to generate SOQL queries, with both standard objects and fields and custom objects and fields, based on the defined module and schema. This section demonstrates how to set the module and schema when generating an SOQL query.

There are two types of SOQL queries: simple query and relationship query.

Simple query retrieves data from only one object. For more information about how to set the module and schema for generating simple queries, see How to set schema for generating the simple query on page 3347.

Relationship query retrieves data from more than a single type of object, including child-to-parent and parent-to-child relationship queries.

For more information about how to set the module and schema for generating child-to-parent relationship queries, see How to set schema for generating the child-to-parent relationship query on page 3347.
For more information about how to set the module and schema for generating parent-to-child relationship queries, see How to set schema for generating the parent-to-child relationship query on page 3349.

Note that before setting the module name and schema columns for generating the relationship query in the Basic settings view of tSalesforceInput, you need to first identify the relationship type (child-to-parent or parent-to-child) of the query to be generated, because the methods of setting the schema column names for these two kinds of relationship queries are somewhat different. The main difference between the child-to-parent and parent-to-child relationship queries is that the parent-to-child relationship query is specified by using the subquery enclosed in parentheses, while the child-to-parent relationship query is not. For more information about the relationship queries in SOQL and how to identify the relationship queries, see Relationship Queries.

**How to set schema for generating the simple query**

This section demonstrates how to set the module name and schema columns for generating the simple query.

The following two simple query examples will be used for demonstration purpose in the following steps.

- SELECT Id, Name, BillingCity FROM Account, a simple query with standard object and fields, and
- SELECT Name__c, LastName__c FROM Mother__c, a simple query with custom object and fields.

**Procedure**

1. Set the module name with the name of the object specified in the FROM clause, Account and Mother__c for above examples.
2. Create a column for each field in the field list (separated by commas) after SELECT in the schema dialog box and set the column name with the field name.
   - For the first example, you need to create three columns Id, Name, and BillingCity for the three fields.
   - For the second example, you need to create two columns Name__c and LastName__c for the two fields.

**How to set schema for generating the child-to-parent relationship query**

This section demonstrates how to set the module name and schema columns for generating a child-to-parent relationship query.

The following two child-to-parent relationship query examples will be used for demonstration purpose in the following steps.

- SELECT Name, Account.Name, Account.Owner.Name FROM Contact, a child-to-parent relationship query with standard object and fields, and
- SELECT Id, FirstName__c, MotherOfDaughter__r.FirstName__c FROM Daughter__c, a child-to-parent relationship query with custom object and fields.

Note that here you must use the relationship name with __r instead of __c. For more information, see Understanding Relationship Names, Custom Objects, and Custom Fields.
Procedure

1. Set the module name with the name of the object specified in the FROM clause, Contact and Daughter__c in above examples.

2. Create a column for each field in the field list (separated by commas) after SELECT in the schema dialog box.

   For the first example, you need to create three columns for the three fields Name, Account.Name, and Account.Owner.Name.

   For the second example, you need to create three columns for the three fields Id, FirstName__c, and MotherOfDaughter__r.FirstName__c.

3. Set the name of each column with the name of each field and replace all dots in the column name with underscore characters.

   For the first example, the names of the three columns are set to Name, Account_Name, and Account_Owner_Name.

   For the second example, the names of the three columns are set to Id, FirstName__c, and MotherOfDaughter__r_FirstName__c.

4. Set the type of each column.

   The schema for the first example should be set like this:

   ![Schema of tSalesforceInput_1](image)

   And the schema for the second example should be set like this:

   ![Schema of tSalesforceInput_1](image)
Note that the underscore character '_' is used as a separator between the relationship name and the field name in Talend schema, so only the underscore character '_' that goes after '__r' or '__c' will be replaced by the dot character '.' when generating the query. If the underscore character '_' is a part of any custom name in the schema, for example, Contact_custom_field__c, which should be Contact.custom_field__c in the query, you need to replace '_' in the generated query with '.' manually.

**How to set schema for generating the parent-to-child relationship query**

This section demonstrates how to set the module name and schema columns for generating a parent-to-child relationship query.

The following two parent-to-child relationship query examples will be used for demonstration purpose in the following steps.

- SELECT Name, Owner.Name (SELECT CreatedBy.Name FROM Notes) FROM Account, a parent-to-child relationship query with standard object and fields, and
- SELECT LastName__c, (SELECT FirstName__c FROM Daughters__r) FROM Mother__c, a parent-to-child relationship query with custom object and fields.

Note that here you must use the relationship name with __r instead of __c. For more information, see *Understanding Relationship Names, Custom Objects, and Custom Fields*.

**Procedure**

1. Set the module name with the name of the object specified in the outer query FROM clause, Account and Mother__c in above examples.

2. Create a column for each field (including the fields in subquery) after `SELECT` in the schema dialog box.

   For the first example, you need to create three columns for the three fields, including two fields Name and Owner.Name after the outer `SELECT`, and one field CreatedBy.Name after the subquery `SELECT`.

   For the second example, you need to create two columns for the two fields, including the field LastName__c after the outer `SELECT`, and the field FirstName__c after the subquery `SELECT`.

3. For the fields in the outer `SELECT` clause, which are outside parentheses, set the name of each column with the name of each field and replace all dots in the column name with underscore characters.

   For the first example, the column names for the two fields Name and Owner.Name in the outer `SELECT` clause are set to Name and Owner_Name.

   For the second example, there is no dot in the field name, so the column name is same as the field name.

4. For the fields in the subquery `SELECT`, construct the column names using the pattern `<$XXX>_records_$YYY>`, where <$XXX> corresponds to the name of the object specified in the subquery FROM clause, and <$YYY> will be the field name with all dots replaced by underscore characters.

   For the first example, the column name for the field CreatedBy.Name in the subquery is set to Notes_records_CreatedBy_Name.
For the second example, the column name for the field FirstName__c in the subquery is set to Daughters__r_records_FirstName__c.

5. Set the type of each column.

The schema for the first example should be set like this:

![Schema of tSalesforceInput_1](image)

And the schema for the second example should be set like this:

![Schema of tSalesforceInput_1](image)

Note that the underscore character ‘_’ is used as a separator between the relationship name and the field name in Talend schema, so only the underscore character ‘_’ that goes after ‘__r’ or ‘__c’ will be replaced by the dot character ‘.’ when generating the query. If the underscore character ‘_’ is a part of any custom name in the schema, for example, Contact_custom_field__c, which should be Contact.custom_field__c in the query, you need to replace ‘_’ in the generated query with ‘.’ manually.

**Related scenario**

Upserting Salesforce data based on external IDs on page 3356
# tSalesforceOutput

Inserts, updates, upserts, or deletes data in a Salesforce object.

## tSalesforceOutput Standard properties

These properties are used to configure tSalesforceOutput running in the Standard Job framework. The Standard tSalesforceOutput component belongs to the Business and the Cloud families. The component in this framework is available in all Talend products.

### Basic settings

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Select the way the connection details will be set.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Built-In</strong>: The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Repository</strong>: The connection details stored centrally in Repository &gt; Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up Repository Content dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in.</td>
</tr>
<tr>
<td>This property is not available when other connection component is selected from the Connection Component drop-down list.</td>
<td></td>
</tr>
</tbody>
</table>

| Connection Component         | Select the component that opens the database connection to be reused by this component.                                                                                                                      |

<table>
<thead>

</tr>
<tr>
<td>Callback Host</td>
<td>The host value in the OAuth authentication callback URL that is defined during the creation of a connected app and will be shown in the API (Enable OAuth Settings) area of the connected app detail page in Salesforce.</td>
</tr>
</tbody>
</table>
This property is available only when the OAuth Implicit Flow type is selected.

**Callback Port**

The port value in the OAuth authentication callback URL that is defined during the creation of a connected app and will be shown in the API (Enable OAuth Settings) area of the connected app detail page in Salesforce.

This property is available only when the OAuth Implicit Flow type is selected.

**Token File**

The path to the token file that stores the refresh token used to get the access token without authorization.

This property is available only when the OAuth Implicit Flow type is selected.

**Module Name**

Click the [...] button next to the field and in the dialog box displayed, select the module that will be used or select the Use custom object check box and specify the module name in the Object Name field.

**Schema and Edit schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

Click Sync columns to retrieve the schema from the previous component connected in the Job.

**Output Action**

Select one of the following operations to be performed from the drop-down list.

- **INSERT**: insert one or more new records into Salesforce.
- **UPDATE**: update one or more existing records in Salesforce.
- **UPSERT**: create new records and update existing records. In the Upsert Key Column field displayed, specify the key column for the upsert operation.
- **DELETE**: delete one or more records in Salesforce.

**Advanced settings**

<table>
<thead>
<tr>
<th>Salesforce URL</th>
<th>The Webservice URL required to connect to Salesforce.</th>
</tr>
</thead>
<tbody>
<tr>
<td>API version</td>
<td>The Salesforce API version.</td>
</tr>
</tbody>
</table>
This property is available only when the **OAuth** connection type is selected.

### Use or save the connection session

Select this check box and in the **Session directory** field displayed, specify the path to the connection session file to be saved or used.

This session file can be shared by different Jobs to retrieve a connection session as long as the correct user ID is provided by the component. This way, you do not need to connect to the server to retrieve the session.

When an expired session is detected, if the correct connection information (the user ID, password, and security key) is provided, the component will connect to the server to retrieve the new session information and update the connection session file.

This property is available only when the **Basic** connection type is selected.

### Need compression

Select this check box to activate SOAP message compression, which can result in increased performance levels.

### Use Http Chunked

Select this check box to use the HTTP chunked data transfer mechanism.

### Client Id

Enter the ID of the real user to differentiate between those who use the same account and password to access the Salesforce website.

### Timeout

Enter the intended number of query timeout in milliseconds in Salesforce.

### Use Proxy

Select this check box to use a proxy server, and in the **Host**, **Port**, **User Id**, and **Password** fields displayed, specify the connection parameters of the proxy server.

### Relationship mapping for upsert

Click the [+ ] button to add lines as needed and specify the external ID fields in the input flow, the lookup relationship fields in the upsert module, the lookup module as well as the external ID fields in the lookup module.

- **Column name of Talend Schema**: the name of the external ID field in the input flow. It refers to the fields in the schema of the preceding component. Such columns are intended to match against the external ID fields specified in the **External id name** column, which are the fields of the lookup module specified in the **Module name** column.

- **Lookup field name**: the name of the lookup field. It refers to the lookup field of the module specified in the **Module Name** field in the **Basic settings** view. This column needs to be specified when there are NULL input values for it and the **Ignore Null** check box is cleared.

- **Lookup relationship field name**: the name of the lookup relationship field. It refers to the lookup relationship fields of the module specified in the **Module Name** field in the **Basic settings** view and is intended to establish relationship with the lookup module specified in the **Module name** column in this table. For how to define the lookup relationship fields and how to
provide their correct names in the **Lookup relationship field name** field, go to the Salesforce website and launch the Salesforce Data Loader application for proper actions and information.

- **Module name**: the name of the lookup module.
- **External id name**: the name of the external ID field in the lookup module specified in the **Module name** column.

This property is available only when **UPSERT** is selected from the **Output Action** drop-down list.

### Extend Insert
Select this check box to transfer the output data in batches. In the **Commit Level** field displayed, specify the number of lines per batch.

### Die on Error
Select the check box to stop the execution of the Job when an error occurs.

This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

### Retrieve Id
Select this check box to allow Salesforce to return the Salesforce ID for the inserted or updated records.

This check box is available only when **INSERT** or **UPSERT** is selected from the **Output Action** drop-down list and the **Extend Insert** check box is cleared.

When this check box is selected and the **tSalesforceOutput** component is linked to another component via a **Row > Main** connection, the following column(s) will be added to the schema of the data flow:

- **salesforce_id**: the Salesforce ID of the created or updated record.
- **salesforce_upsert_status** (only for **UPSERT**): the status of the upsert action to indicate whether the record is created or updated.

### Ignore Null
Select this check box to ignore NULL values.

This property is available only when **UPDATE** or **UPSERT** is selected from the **Output Action** drop-down list.

### Log File Name
Specify the path to the log file that holds all error logs.

### tStatCatcher Statistics
Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE</strong></td>
<td>The number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_SUCCESS</strong></td>
<td>The number of rows successfully processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_REJECT</strong></td>
<td>The number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
</tbody>
</table>
The error message generated by the component when an error occurs. This is an After variable and it returns a string.

Usage

This component can be used as an end component or an intermediate component of a Job or Subjob and it always needs an input link.

Upserting Salesforce data based on external IDs

Here is an example of using Talend components to insert and update Salesforce Contact object data based on the mapping relationship with external IDs of the Account object.

The Job used in this example is composed of the following seven subJobs:

- the first subJob opens a connection to Salesforce,
- the second subJob deletes some Account records based on external IDs,
- the third subJob inserts two Account records with external IDs,
- the fourth subJob inserts three Contact records based on the mapping relationship with the Account object external IDs, and gathers both inserted and erroneous data,
- the fifth subJob updates two inserted Contact records based on the mapping relationship with the Account object external IDs,
- the sixth subJob retrieves the inserted Account records, and
- the seventh subJob retrieves the upserted Contact records.
Creating a Job for upserting Salesforce data based on external IDs

Before you begin

- An external ID custom field `Account_External_ID` has been added for the Account object in your Salesforce, which will be used to map the relationship with the Contact object.
An external ID custom field `Contact_Talend_ID` has been added for the Contact object in Salesforce, which will be used as the key column for upserting Contact object data.

### Procedure

1. Create a new Job and add a `tSalesforceConnection` component, three `tSalesforceInput` components, four `tSalesforceOutput` components, three `tFixedFlowInput` components, and four `tLogRow` components.

2. Connect the first `tSalesforceInput` component to the first `tSalesforceOutput` component using a `Row > Main` connection.

3. Do the same to connect the first `tFixedFlowInput` component to the second `tSalesforceOutput` component, the second `tFixedFlowInput` component to the third `tSalesforceOutput` component, the third `tFixedFlowInput` component to the fourth `tSalesforceOutput` component, the second `tSalesforceInput` component to the third `tLogRow` component, and the third `tSalesforceInput` component to the fourth `tLogRow` component.

4. Connect the third `tSalesforceOutput` component to the first `tLogRow` component using a `Row > Main` connection and to the second `tLogRow` component using a `Row > Reject` connection.

5. Connect the `tSalesforceConnection` component to the first `tSalesforceInput` component using a `Trigger > On Subjob Ok` connection.

6. Do the same to connect the first `tSalesforceInput` component to the first `tFixedFlowInput` component, the first `tFixedFlowInput` component to the second `tFixedFlowInput` component, the second `tFixedFlowInput` component to the third `tFixedFlowInput` component, the third `tFixedFlowInput` component to the second `tSalesforceInput` component, and the second `tSalesforceInput` component to the third `tSalesforceInput` component.

### Opening a connection to Salesforce

#### Procedure

1. Double-click the `tSalesforceConnection` component to open its `Basic settings` view on the `Component` tab.

2. Select `Basic` from the `Connection type` drop-down list to connect to Salesforce using your Salesforce account username, password, and security token.

   In this example, you connect to Salesforce using the basic connection type. You can also connect to Salesforce using the OAuth JWT (JSON Web Token) Flow type. For more information, see the related description of how to connect to Salesforce using OAuth JWT Flow on Talend Help Center ([https://help.talend.com](https://help.talend.com)).

3. In the `User Id` field, enter your Salesforce username.

4. Click the `[...]` button next to the `Password` field and in the pop-up dialog box, enter your Salesforce password between double quotation marks.
5. Click the [...] button next to the **Security Token** field and in the pop-up dialog box, enter your Salesforce security token between double quotation marks.

You can use the Salesforce metadata wizard to create a connection to your Salesforce system, save the connection in the Repository, and then reuse the connection configuration defined in the metadata wizard in Salesforce components. For more information, see the related description of centralizing Salesforce metadata.

**Deleting Salesforce Account records based on external ID**

**Procedure**

1. Double-click the first `tSalesforceInput` component to open its **Basic settings** view on the **Component** tab.
2. Select the component that will create the Salesforce connection from the **Connection Component** drop-down list, `tSalesforceConnection_1` in this example.
3. Click the [...] button next to the **Module Name** field and in the pop-up dialog box, select the object whose data will be deleted, **Account** in this example. The schema of the Account object will be automatically filled.
4. Click **OK** to save the changes and in the pop-up dialog box, click **Yes** to propagate the schema to the next `tSalesforceOutput` component.
5. Select **Query** from the **Query Mode** drop-down list and specify the condition used to filter data to be deleted. In this example, it is `talendlena__Account_External_ID__c like '%talend%'`. All Salesforce Account records whose `talendlena__Account_External_ID__c` field contains `talend` will be deleted.
6. Double-click the first `tSalesforceOutput` component to open its **Basic settings** view on the **Component** tab.
7. Select the component that will create the Salesforce connection from the **Connection Component** drop-down list, `tSalesforceConnection_1` in this example.
8. Click the [...] button next to the **Module Name** field and in the pop-up dialog box, select the object whose data will be deleted, **Account** in this example.
9. Select **DELETE** from the **Output Action** drop-down list to perform the delete operation on the Account objects filtered by the first `tSalesforceInput` component.

**Inserting Salesforce Account records with external IDs**

**Procedure**

1. Double-click the second `tSalesforceOutput` component to open its **Basic settings** view on the **Component** tab.
2. Select the component that will create the Salesforce connection from the **Connection Component** drop-down list, `tSalesforceConnection_1` in this example.
3. Click the [...] button next to the **Module Name** field and in the pop-up dialog box, select the object into which data will be inserted, **Account** in this example. The schema of the Account object will be automatically filled.
4. Click the [...] button next to Edit schema and in the pop-up dialog box, remove all schema columns except the two columns Name and talendlena__Account_External_ID__c. Then click ☐️ to copy these two columns to the first tFixedFlowInput component. When done, click OK to close the dialog box.

5. Select INSERT from the Output Action drop-down list.

6. Double-click the first tFixedFlowInput component to open its Basic settings view on the Component tab.

7. In the Mode area, select Use Inline Table and in the table displayed, enter the data to be inserted into the Salesforce Account object. In this example, the following two records will be inserted.

```
account_talend;account_talend_exid
account_talend_doc;account_talend_doc_exid
```

You can also select Use Inline Content, and then copy and paste the input data into the Content field displayed.

Inserting Salesforce Contact records upon Account external IDs

Procedure

1. Double-click the third tSalesforceOutput component to open its Basic settings view on the Component tab.

2. Select the component that will create the Salesforce connection from the Connection Component drop-down list, tSalesforceConnection_1 in this example.

3. Click the [...] button next to the Module Name field and in the pop-up dialog box, select the object into which data will be inserted, Contact in this example. The schema of the Contact object will be automatically filled. When done, click OK to save the changes and in the pop-up dialog box, click Yes to propagate the schema to the next two tLogRow components.

4. Click the [...] button next to Edit schema and in the pop-up dialog box, remove all schema columns except the three columns LastName, FirstName, and talendlena__Contact_Talend_ID__c. Then add another column Account_External_ID of String type and copy these four columns to the second tFixedFlowInput component. When done, click OK to close
the dialog box and in the pop-up dialog box, click **Yes** to propagate the schema to the next two **tLogRow** components.

5. Select **UPSERT** from the **Output Action** drop-down list and **talendlena__Contact_Talend_ID__c** from the **Upsert Key Column** drop-down list displayed.

6. Go to the **Advanced settings** view and in the **Relationship mapping for upsert** table, specify the relationship mapping for the column **Account_EXTERNAL_ID** by adding one row and setting the value for each table column. In this example, the column **Account_EXTERNAL_ID** is mapped with the external ID field **talendlena__Account_EXTERNAL_ID__c** of the Account object, so the value for **Column name of Talend Schema** is **Account_EXTERNAL_ID**, the value for **Lookup relationship field name** and **Module name** is Account, and the value for **External id name** is **talendlena__Account_EXTERNAL_ID__c**.

7. Clear the **Extend Insert** and **Die on Error** check boxes so that erroneous data can be gathered via the **Row > Reject** connection.

8. Double-click the second **tFixedFlowInput** component to open its **Basic settings** view on the **Component** tab.
9. In the **Mode** area, select **Use Inline Table** and in the table displayed, enter the data to be inserted into the Salesforce Contact object. In this example, the input data is as follows.

<table>
<thead>
<tr>
<th>Name</th>
<th>Last name</th>
<th>Account ID</th>
<th>Talend ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>Beckham</td>
<td>David</td>
<td>2018010001</td>
<td>account_talend_exid</td>
</tr>
<tr>
<td>Taylor</td>
<td>Swift</td>
<td>2018010002</td>
<td>account_talend_exid</td>
</tr>
<tr>
<td></td>
<td></td>
<td>2018010003</td>
<td>account_talend_exid</td>
</tr>
</tbody>
</table>

You can also select **Use Inline Content**, and then copy and paste the input data into the **Content** field displayed.

10. Double-click the first **tLogRow** component and on its **Basic settings** view, select **Table** in the **Mode** area to display the result in a table.

11. Do the same to configure the second **tLogRow** component.

### Updating Salesforce Contact records upon Account external IDs

#### Procedure

1. Double-click the fourth **tSalesforceOutput** component to open its **Basic settings** view on the **Component** tab.
2. Select the component that will create the Salesforce connection from the **Connection Component** drop-down list, **tSalesforceConnection_1** in this example.
3. Click the [...] button next to the **Module Name** field and in the pop-up dialog box, select the object into which data will be inserted, **Contact** in this example. The schema of the Contact object will be automatically filled.
4. Click the [...] button next to **Edit schema** and in the pop-up dialog box, remove all schema columns except the three columns **Phone**, **Email**, and **talendlena__Contact_Talend_ID__c**. Then add another column **Account_External_ID** of String type and copy these four columns to the second **tFixedFlowInput** component. When done, click **OK** to close the dialog box.
5. Select **UPSERT** from the **Output Action** drop-down list and **talendlena__Contact_Talend_ID__c** from the **Upsert Key Column** drop-down list displayed.
6. Go to the **Advanced settings** view and in the **Relationship mapping for upsert** table, specify the relationship mapping for the column **Account_External_ID** by adding one row and setting the value for each table column. In this example, the column **Account_External_ID** is mapped with the external ID field **talendlena__Account_External_ID__c** of the Account object, so the value for **Column name of Talend Schema** is **Account_External_ID**, the value for **Lookup relationship field name** and **Module name** is **Account**, and the value for **External id name** is **talendlena__Account_External_ID__c**.
7. Double-click the third **tFixedFlowInput** component to open its **Basic settings** view on the **Component** tab.
8. In the **Mode** area, select **Use Inline Table** and in the table displayed, enter the data used to update the two records inserted into the Salesforce Contact object. In this example, the updated data is as follows. The phone and email values will be added for both two records and the Account external ID value for the second record is updated to `account_talend_doc_exid`.

```
+86 13666666666;beckham.david@talend.com;2018010001;account_talend_exid
+86 13888888888;taylor.swift@talend.com;2018010002;account_talend_doc_exid
```

You can also select **Use Inline Content**, and then copy and paste the input data into the **Content** field displayed.

### Retriving inserted Salesforce Account records

#### Procedure

1. Double-click the second **tSalesforceInput** component to open its **Basic settings** view on the **Component** tab.
2. Select the component that will create the Salesforce connection from the **Connection Component** drop-down list, **tSalesforceConnection_1** in this example.
3. Click the [...] button next to the **Module Name** field and in the pop-up dialog box, select the object from which data will be retrieved, **Account** in this example. The schema of the Account object will be automatically filled.
4. Click the [...] button next to **Edit schema** and in the pop-up dialog box, remove all schema columns except the three columns **Id**, **Name**, and **talendlena__Account_External_ID__c**. When done, click **OK** to save the changes and in the pop-up dialog box, click **Yes** to propagate the schema to the next **tLogRow** component.
5. Select **Query** from the **Query Mode** drop-down list and specify the condition used to filter data to be retrieved. In this example, it is **Name like '%talend%'**.

   All Salesforce Account records whose **Name** field contains **talend** will be retrieved.

6. Double-click the third **tLogRow** component and on its **Basic settings** view, select **Table** in the **Mode** area to display the result in a table.

### Retrieving updated Salesforce Contact records using SOQL query
Procedure

1. Double-click the third **tSalesforceInput** component to open its **Basic settings** view on the **Component** tab.
2. Select the component that will create the Salesforce connection from the **Connection Component** drop-down list, **tSalesforceConnection_1** in this example.
3. Click the [...] button next to the **Module Name** field and in the pop-up dialog box, select the object from which data will be retrieved, **Contact** in this example. The schema of the Contact object will be automatically filled.
4. Click the [...] button next to **Edit schema** and in the pop-up dialog box, remove all schema columns except the four columns **Name**, **Phone**, **Email**, and **talendlena__Contact_Talend_ID__c**.

![Schema of tSalesforceInput]

5. Add another two columns to retrieve name and external ID of the linked Account object, **Contact.Account.Name** and **Contact.Account_talendlena__Account_External_ID__c** in this example.

To retrieve data of a linked object column, it is necessary to define the name of the column in a particular manner in the schema editor. The correct syntax is `NameofCurrentObject_NameofLinkedObject_NameofColumnofInterest`. If this syntax is not respected, data from the linked object will not be returned. For more information about how to set schema for the relationship query, see **How to set schema for the guess query feature of tSalesforceInput** on page 3346.

6. Click **OK** to save the changes. In the pop-up dialog box, click **Yes** to propagate the schema to the next **tLogRow** component.
7. Select **Query** from the **Query Mode** drop-down list.
8. Select the **Manual Query** check box and click the **Guess query** button to generate the SOQL query based on the defined module name and schema columns. The generated SOQL query will look like below.

```sql
SELECT Name, Phone, Email, talendlena__Contact_Talend_ID__c,
      Contact.Account.Name, Contact.Account_talendlena__Account_External_ID__c
FROM Contact
```

9. In the generated SOQL query string, replace each underscore character after the object name in the column name **Contact.Account_talendlena__Account_External_ID__c** with a dot character. Then add the **WHERE** condition clause used to filter data to be retrieved at the end of the generated SOQL query. In this example, it is **talendlena__Contact_Talend_ID__c**.
D__c like '201801%' and all Salesforce Contact records whose talendlena__Contact_Talend_ID__c field begins with 201801 will be retrieved. The updated SOQL query will look like below.

```sql
SELECT Name, Phone, Email, talendlena__Contact_Talend_ID__c, Contact.Account.Name, Contact.Account.talendlena__Account_External_ID__c FROM Contact WHERE talendlena__Contact_Talend_ID__c like '201801%'
```

10. **Double-click the fourth tLogRow component and on its Basic settings view, select Table in the Mode area to display the result in a table.**

### Executing the Job to upsert Salesforce data based on external ID

**Procedure**

1. Press Ctrl + S to save your Job.
2. Press F6 to execute your Job.

As shown above, two Account records account_talend and account_talend_doc are successfully inserted, two Contact records Beckham David and Taylor Swift are successfully inserted and updated based on the mapping relationship with the external IDs in the Account object, and another Contact record missing the value for the required field LastName is not inserted.

You can also go to the Salesforce website to double-check the Job execution result.
**tSalesforceOutputBulk**

Generates the file to be processed by the tSalesforceBulkExec component for bulk processing.

The tSalesforceOutputBulk and tSalesforceBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used to feed the Salesforce database. These two steps are fused together in the tSalesforceOutputBulkExec component. The advantage of using two separate steps is that the data can be transformed before it is loaded into Salesforce.

**tSalesforceOutputBulk Standard properties**

These properties are used to configure tSalesforceOutputBulk running in the Standard Job framework. The Standard tSalesforceOutputBulk component belongs to the Business and the Cloud families. The component in this framework is available in all Talend products.

**Basic settings**

| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word \_i\_n\_e when naming the fields.
Click **Edit schema** to make changes to the schema. If the current schema is of the Repository type, three options are available:
• **View schema**: choose this option to view the schema only.
• **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
• **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the Repository Content window.
Click **Sync columns** to retrieve the schema from the previous component connected in the Job. |

| **Bulk File Path** | Specify the path to the file to be generated. |

| **Append** | Select this check box to append new data at the end of the file if it already exists, instead of overwriting the existing data. |

| **Ignore Null** | Select this check box to ignore NULL values. |

**Advanced settings**

| **Relationship mapping for upsert** | Click the [+] button to add lines as needed and specify the external ID fields in the input flow, the lookup relationship fields in the upsert module, the lookup module as well as the external ID fields in the lookup module. |
• **Column name of Talend Schema**: the name of the external ID field in the input flow. It refers to the fields in the schema of the preceding component. Such columns are intended to match against the external ID fields specified in the **External id name** column, which are the fields of the lookup module specified in the **Module name** column.

• **Lookup relationship field name**: the name of the lookup relationship field. It refers to the lookup relationship fields of the module specified in the **Module Name** field in the **Basic settings** view of the **tSalesforceBulkExec** component and is intended to establish relationship with the lookup module specified in the **Module name** column in this table. For how to define the lookup relationship fields and how to provide their correct names in the **Lookup relationship field name** field, go to the Salesforce website and launch the Salesforce Data Loader application for proper actions and information.

• **Module name**: the name of the lookup module.

• **Polymorphic**: select this check box when and only when polymorphic fields are used for relationship mapping. You will get an error if you keep this check box cleared for a polymorphic field or select it for a field that is not polymorphic. For more information about the polymorphic fields, search polymorphic at http://www.salesforce.com/us/developer/docs/api_asynch/.

• **External id name**: the name of the external ID field in the lookup module specified in the **Module name** column.

### tStatCatcher Statistics

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

### Global Variables

<table>
<thead>
<tr>
<th>NB_LINE</th>
<th>The number of rows processed. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERROR_MESSAGE</td>
<td>The error message generated by the component when an error occurs. This is an After variable and it returns a string.</td>
</tr>
</tbody>
</table>

### Usage

| Usage rule | This component is more commonly used with the **tSalesforceBulkExec** component. Used together, they gain performance while feeding or modifying information in Salesforce.com. |

### Related scenario

No scenario is available for this component yet.
tSalesforceOutputBulkExec

Bulk-loads data in a given file into a Salesforce object. The tSalesforceOutputBulk and tSalesforceBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used to feed the Salesforce database. These two steps are fused together in the tSalesforceOutputBulkExec component. The advantage of using two separate steps is that the data can be transformed before it is loaded into Salesforce.

tSalesforceOutputBulkExec Standard properties

These properties are used to configure tSalesforceOutputBulkExec running in the Standard Job framework. The Standard tSalesforceOutputBulkExec component belongs to the Business and the Cloud families. The component in this framework is available in all Talend products.

Basic settings

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Select the way the connection details will be set.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• <strong>Built-In</strong>: The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Repository</strong>: The connection details stored centrally in Repository &gt; Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up Repository Content dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in.</td>
</tr>
</tbody>
</table>

This property is not available when other connection component is selected from the Connection Component drop-down list.

<table>
<thead>
<tr>
<th>Connection Component</th>
<th>Select the component that opens the database connection to be reused by this component.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Connection type</th>
<th>Select the type of the connection from the drop-down list. The connection properties will vary according to the connection type you choose.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• <strong>Basic</strong>: select this option to access Salesforce by entering your Salesforce username and password.</td>
</tr>
<tr>
<td></td>
<td>• <strong>OAuth</strong>: select this option to access Salesforce using OAuth (Open Authorization) 2.0 protocol to authenticate the user. From the Oauth2 flow type drop-down list displayed, you need to choose an OAuth 2.0 authentication flow type, either Json Web Token Flow or Implicit Flow (Deprecated) (User Agent Flow). This way, you need to create a connected app in Salesforce to configure a Salesforce authentication provider. For more information about the OAuth authentication flow, see Authenticate Apps with OAuth.</td>
</tr>
</tbody>
</table>

For more information about how to create a connected app in Salesforce, see [Create a Connected App](#).

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>User Id</td>
<td>The Salesforce username. This property is available only when the Basic connection type is selected.</td>

</tr>
<tr>
<td>Token File</td>
<td>The path to the token file that stores the refresh token used to get the access token without authorization. This property is available only when the OAuth <strong>Implicit Flow</strong> type is selected.</td>
</tr>
<tr>
<td>Module Name</td>
<td>Click the [...] button next to the field and in the dialog box displayed, select the module that will be used or select the <strong>Use custom object</strong> check box and specify the module name in the <strong>Object Name</strong> field.</td>
</tr>
<tr>
<td>Schema and Edit schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <strong>line</strong> when naming the fields. Click <strong>Edit schema</strong> to make changes to the schema. If the current schema is of the <strong>Repository</strong> type, three options are available:</td>
</tr>
<tr>
<td></td>
<td>• <strong>View schema</strong>: choose this option to view the schema only.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Change to built-in property</strong>: choose this option to change the schema to <strong>Built-in</strong> for local changes.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Update repository connection</strong>: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select <strong>No upon completion</strong> and choose this schema metadata again in the <strong>Repository Content</strong> window.</td>
</tr>
<tr>
<td></td>
<td>Click <strong>Sync columns</strong> to retrieve the schema from the previous component connected in the Job.</td>
</tr>
<tr>
<td>Output Action</td>
<td>Select one of the following operations to be performed from the drop-down list.</td>
</tr>
<tr>
<td></td>
<td>• <strong>INSERT</strong>: insert one or more new records into Salesforce.</td>
</tr>
<tr>
<td></td>
<td>• <strong>UPDATE</strong>: update one or more existing records in Salesforce.</td>
</tr>
</tbody>
</table>
- **UPSERT**: create new records and update existing records. In the **Upsert Key Column** field displayed, specify the key column for the upsert operation.

- **DELETE**: delete one or more records in Salesforce.

### Bulk File Path
Specify the path to the file that stores the data to be processed.

### Append
Select this check box to append new data at the end of the file if it already exists, instead of overwriting the existing data.

### Ignore Null
Select this check box to ignore NULL values.

### Advanced settings

<table>
<thead>
<tr>
<th><strong>Salesforce URL</strong></th>
<th>The Webservice URL required to connect to Salesforce.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>API version</strong></td>
<td>The Salesforce API version. This property is available only when the <strong>OAuth</strong> connection type is selected.</td>
</tr>
<tr>
<td><strong>Need compression</strong></td>
<td>Select this check box to activate SOAP message compression, which can result in increased performance levels.</td>
</tr>
<tr>
<td><strong>Trace HTTP message</strong></td>
<td>Select this check box to output the HTTP interactions on the console.</td>
</tr>
<tr>
<td><strong>Client Id</strong></td>
<td>Enter the ID of the real user to differentiate between those who use the same account and password to access the Salesforce website.</td>
</tr>
<tr>
<td><strong>Timeout</strong></td>
<td>Enter the intended number of query timeout in milliseconds in Salesforce.</td>
</tr>
<tr>
<td><strong>Use Proxy</strong></td>
<td>Select this check box to use a proxy server, and in the <strong>Host</strong>, <strong>Port</strong>, <strong>User Id</strong>, and <strong>Password</strong> fields displayed, specify the connection parameters of the proxy server.</td>
</tr>
<tr>
<td><strong>Bulk API V2</strong></td>
<td>Select this checkbox to create a Bulk API V2 job, and then select a type of field delimiter from the <strong>Column Delimiter</strong> drop-down list and a way of line ending from the <strong>Line Ending</strong> drop-down list respectively for CSV data. Compared with Bulk API V1, Bulk API v2 simplifies the way of processing data. This property is available only when the <strong>OAuth</strong> connection type is selected.</td>
</tr>
</tbody>
</table>

### Relationship mapping for upsert
Click the [*] button to add lines as needed and specify the external ID fields in the input flow, the lookup relationship fields in the upsert module, the lookup module as well as the external ID fields in the lookup module.

- **Column name of Talend Schema**: the name of the external ID field in the input flow. It refers to the fields in the schema of the preceding component. Such columns are intended to match against the external ID fields specified in the **External id name** column, which
are the fields of the lookup module specified in the **Module name** column.

- **Lookup relationship field name**: the name of the lookup relationship field. It refers to the lookup relationship fields of the module specified in the **Module Name** field in the **Basic settings** view and is intended to establish relationship with the lookup module specified in the **Module name** column in this table. For how to define the lookup relationship fields and how to provide their correct names in the **Lookup relationship field name** field, go to the Salesforce website and launch the Salesforce Data Loader application for proper actions and information.

- **Module name**: the name of the lookup module.

- **Polymorphic**: select this check box when and only when polymorphic fields are used for relationship mapping. You will get an error if you keep this check box cleared for a polymorphic field or select it for a field that is not polymorphic. For more information about the polymorphic fields, search *polymorphic* at [http://www.salesforce.com/us/developer/docs/api_asynch/](http://www.salesforce.com/us/developer/docs/api_asynch/).

- **External id name**: the name of the external ID field in the lookup module specified in the **Module name** column. This property is available only when **UPSERT** is selected from the **Output Action** drop-down list.

### Concurrency Mode

Select the concurrency mode for the job.

- **Parallel**: process batches in parallel mode.
- **Serial**: process batches in serial mode.

### Rows to Commit

Specify the number of lines per data batch to be processed.

### Bytes to Commit

Specify the number of bytes per data batch to be processed.

### Wait Time Check Batch State

Specify the wait time (in milliseconds) for checking whether the batches in a Job have been processed until all batches are finally processed.

### tStatCatcher Statistics

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

**ERROR_MESSAGE**

The error message generated by the component when an error occurs. This is an After variable and it returns a string.

### Usage

**Usage rule**

This component is mainly used when no particular transformation is required on the data to be loaded into Salesforce.

**Limitation**

The bulk data to be processed in Salesforce should be in .csv format.
Inserting bulk data into Salesforce

This scenario describes a four-component Job that bulk-loads data in a file into Salesforce, performs the intended action on the data, and ends up with displaying the Job execution results on the console.

The content of the input file SalesforceAccount.txt used in this example is as follows:

<table>
<thead>
<tr>
<th>Name</th>
<th>ParentId</th>
<th>Phone</th>
<th>Fax</th>
</tr>
</thead>
<tbody>
<tr>
<td>Burlington Textiles Corp of America</td>
<td></td>
<td>(336) 222-7000; (336) 222-8000</td>
<td></td>
</tr>
<tr>
<td>Dickenson plc</td>
<td></td>
<td>(785) 241-6200; (785) 241-6201</td>
<td></td>
</tr>
<tr>
<td>GenePoint</td>
<td></td>
<td>(650) 867-3450; (650) 867-9895</td>
<td></td>
</tr>
<tr>
<td>Edge Communications</td>
<td>talend</td>
<td>(512) 757-6000; (512) 757-9000</td>
<td></td>
</tr>
<tr>
<td>Grand Hotels &amp; Resorts Ltd</td>
<td>talend</td>
<td>(312) 596-1000; (312) 596-1500</td>
<td></td>
</tr>
</tbody>
</table>

Setting up the Job for inserting bulk data into Salesforce

Procedure

1. Create a new Job and add a tFileInputDelimited component, a tSalesforceOutputBulkExec component, and two tLogRow components by typing their names on the design workspace or dropping them from the Palette.
2. Link the tFileInputDelimited component to the tSalesforceOutputBulkExec component using a Row > Main connection.
3. Link the tSalesforceOutputBulkExec component to the first tLogRow component using a Row > Main connection.
4. Link the tSalesforceOutputBulkExec component to the second tLogRow component using a Row > Reject connection.

Configuring the Job for inserting bulk data into Salesforce

Procedure

1. Double-click the tFileInputDelimited component to open its Basic settings view.
2. In the File name/Stream field, browse to or enter the path to the input data file. In this example, it is D:/SalesforceAccount.txt.

3. Click the [...] button next to Edit schema and in the pop-up schema dialog box, define the schema by adding four columns Name, ParentId, Phone and Fax of String type. When done, click OK to save the changes and close the dialog box.

4. Double-click the tSalesforceOutputBulkExec component to open its Basic settings view.
5. In the **User Id**, **Password** and **Security Key** fields, enter the user authentication information required to access Salesforce.

6. Click the [...] button next to the **Module Name** field and in the pop-up dialog box, select the object you want to access. In this example, it is **Account**.

7. In the **Bulk File Path** field, browse to or enter the path to the CSV file that stores the data for bulk processing. The bulk file to be processed must be in csv format.

8. Double-click the first **tLogRow** component to open its **Basic settings** view.

9. In the **Mode** area, select **Table (print values in cells of a table)** for better readability of the results.

10. Do the same to configure the second **tLogRow** component.

**Executing the Job to insert bulk data into Salesforce**

**Procedure**

1. Press **Ctrl + S** to save the Job.

2. Press **F6** to execute the Job.

On the console of the **Run** view, you can check the execution result.

```plaintext
<table>
<thead>
<tr>
<th>statistics</th>
<th>connecting to server on port 4025</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

In the **tLogRow_1** table, you can read the data inserted into Salesforce.

In the **tLogRow_2** table, you can read the rejected data due to the incompatibility with the Account objects you have accessed.

Note that if you want to transform the input data before loading them into Salesforce, you need to use **tSalesforceOutputBulk** and **tSalesforceBulkExec** in cooperation to achieve this purpose.
tSalesforceWaveBulkExec

Loads data into Salesforce Analytics Cloud from a local file.

**tSalesforceWaveBulkExec Standard properties**

These properties are used to configure tSalesforceWaveBulkExec running in the Standard Job framework.

The Standard tSalesforceWaveBulkExec component belongs to the Business and the Cloud families. The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Either Built-In or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Built-In</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The connection fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level.

**User Name and Password**

Enter the Web service authentication details.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

**End Point**

Enter the WebService URL required to connect to Salesforce. For example, https://login.salesforce.com/services/Soap/u/37.0. Note that the version in the URL should be 32.0 or later.

**Schema and Edit schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

- For the fields of numeric type (for example, byte, short, int, long, float, double, and BigDecimal), their length and precision values need to be specified. The default length and precision values are 10 and 2, and you can also specify their custom values in the schema editor.
- For the fields of date type, you need to specify the format of the date in the schema editor. For more information about the supported date format, see Analytics Cloud External Data Format Reference.
The Schema list and the Editor schema button disappear if the Custom JSON Metadata check box is selected.

**Built-In:** You create and store the schema locally for this component only.

**Repository:** You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema:** choose this option to view the schema only.
- **Change to built-in property:** choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection:** choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

### Operation

Select an operation to perform on the dataset:

- **Append:** Append all data to the dataset. Create a dataset if it does not exist.
- **Upsert:** Insert or update rows in the dataset. Create a dataset if it does not exist.
- **Overwrite:** Create a new dataset with the given data, and replace dataset if it already exists.
- **Delete:** Delete the rows from the dataset.

**Note:**

- A metadata JSON file is required for the **Append**, **Upsert**, and **Delete** operations.
- The data and metadata for the **Append** and **Upsert** operations must match the dataset on which the operation is happening. All columns, dimensions, and measures must match exactly.
- The **Append** operation is not allowed if you specify any column as the primary key.
- You must specify one (and only one) column as the primary key on which the **Upsert** or **Delete** operation is based. You can do this by clicking **Edit schema** and selecting the check box next to the column you want to set as the primary key.
- The metadata for the **Delete** operation must be a subset of the dataset columns.

### Name

Type in the name of the dataset into which the data will be loaded.

### CSV File

Specify the path to the local CSV file to be loaded.
### Advanced settings

| **CSV Encoding**          | Enter the encoding type of the CSV file.  
|                          | This field is not visible when the **Custom JSON Metadata** check box is selected. |
| **Fields Delimiter**      | Enter the character that separates the field values in the CSV file.  
|                          | This field is not visible when the **Custom JSON Metadata** check box is selected. |
| **Fields Enclosed By**    | Enter the character used to enclose the field values in the CSV file.  
|                          | This field is not visible when the **Custom JSON Metadata** check box is selected. |
| **Line Terminated By**    | Enter the character indicating the end of a line.  
|                          | This field is not visible when the **Custom JSON Metadata** check box is selected. |
| **Auto Generate JSON Metadata Description** | Select this check box to generate the JSON metadata description automatically. |
| **Header**                | Specify the number of lines to ignore in the CSV file.  
|                          | This field is available only when the **Auto Generate JSON Metadata Description** check box is cleared. |
| **Unique API Name**       | Specify the unique API name for the object in the JSON metadata description.  
|                          | This field is available only when the **Auto Generate JSON Metadata Description** check box is cleared. |
| **Label**                 | Specify the display name for the object in the JSON metadata description.  
|                          | This field is available only when the **Auto Generate JSON Metadata Description** check box is cleared. |
| **Fully Qualified Name**  | Specify the full path that uniquely identifies the record in the JSON metadata description.  
|                          | This field is available only when the **Auto Generate JSON Metadata Description** check box is cleared. |
| **Custom JSON Metadata**  | Select this check box to use a customized JSON metadata file.  
|                          | This check box is available only when the **Auto Generate JSON Metadata Description** check box is cleared. |
| **JSON Metadata**         | Specify the path to the customized JSON metadata file.  
|                          | This field is available only when the **Custom JSON Metadata** check box is selected. |
| **Generate JSON in File**  | Select this check box to write the JSON metadata description into a local file.  
|                          | This check box is not visible when the **Custom JSON Metadata** check box is selected. |
### Generated JSON Folder

Specify the directory where you want to store the generated JSON metadata file.

This field is available only when the **Generate JSON in File** check box is selected.

### Retrieve Upload Status

Select this check box to retrieve the status of the data upload.

### Time to wait for server answer (seconds)

Specify the amount of time in seconds to wait for the upload status response from the server.

This field is available only when the **Retrieve Upload Status** check box is selected.

### tStatCatcher Statistics

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

---

### Global Variables

<table>

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>This component can be used as a standalone component.</td>
</tr>
</tbody>
</table>

### Related scenario

No scenario is available for this component yet.
tSalesforceWaveOutputBulkExec

Gains in performance during data operations to the Salesforce Analytics Cloud.

tSalesforceWaveOutputBulkExec receives data from the preceding component, generates a local CSV file and then loads data from the file to the Salesforce Analytics Cloud.

**tSalesforceWaveOutputBulkExec Standard properties**

These properties are used to configure tSalesforceWaveOutputBulkExec running in the Standard Job framework.

The Standard tSalesforceWaveOutputBulkExec component belongs to the Business and the Cloud families.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Either Built-In or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Built-In: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The connection fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level.

**User Name and Password**

Enter the Web service authentication details.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

**End Point**

Enter the WebService URL required to connect to Salesforce. For example, https://login.salesforce.com/services/Soap/u/37.0. Note that the version in the URL should be 32.0 or later.

**Schema and Edit schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

- For the fields of numeric type (for example, byte, short, int, long, float, double, and BigDecimal), their length and precision values need to be specified. The default length and precision values are 10 and 2, and you can also specify their custom values in the schema editor.
- For the fields of date type, you need to specify the format of the date in the schema editor. For more
For information about the supported date format, see [Analytics Cloud External Data Format Reference](#).

The **Schema** list and the **Editor schema** button disappear if the **Custom JSON Metadata** check box is selected.

| **Built-In**: You create and store the schema locally for this component only. |
| **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. |

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No upon completion** and choose this schema metadata again in the **Repository Content** window.

Click **Sync columns** to retrieve the schema from the previous component connected in the Job.

**Operation**

Select an operation to perform on the dataset:

- **Append**: Append all data to the dataset. Create a dataset if it does not exist.
- **Upsert**: Insert or update rows in the dataset. Create a dataset if it does not exist.
- **Overwrite**: Create a new dataset with the given data, and replace dataset if it already exists.
- **Delete**: Delete the rows from the dataset.

**Note:**

- A metadata JSON file is required for the **Append**, **Upsert**, and **Delete** operations.
- The data and metadata for the **Append** and **Upsert** operations must match the dataset on which the operation is happening. All columns, dimensions, and measures must match exactly.
- The **Append** operation is not allowed if you specify any column as the primary key.
- You must specify one (and only one) column as the primary key on which the **Upsert** or **Delete** operation is based. You can do that by clicking **Edit schema** and selecting the check box next to the column you want to set as the primary key.
- The metadata for the **Delete** operation must be a subset of the dataset columns.

**Name**

Type in the name of the dataset into which the data will be loaded.
<table>
<thead>
<tr>
<th>Generated Temp CSV File</th>
<th>Specify the local path to the CSV file to be generated.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Append</td>
<td>Select this check box to append data to the specified local file if it already exists, instead of overwriting it.</td>
</tr>
<tr>
<td>Include Header</td>
<td>Select this check box to include the column header to the file.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| CSV Encoding | Enter the encoding type of the CSV file.  
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Note that the value of this field should be same as the value defined in the JSON metadata file when the Custom JSON Metadata check box is selected.</td>
</tr>
</tbody>
</table>
| Fields Delimiter | Enter the character that separates the field values in the CSV file.  
|                | Note that the value of this field should be same as the value defined in the JSON metadata file when the Custom JSON Metadata check box is selected. |
| Fields Enclosed By | Enter the character used to enclose the field values in the CSV file.  
|                   | Note that the value of this field should be same as the value defined in the JSON metadata file when the Custom JSON Metadata check box is selected. |
| Line Terminated By  | Enter the character indicating the end of a line.  
|                   | Note that the value of this field should be same as the value defined in the JSON metadata file when the Custom JSON Metadata check box is selected. |
| Create directory if not exists | Select this check box to create the directory specified in the Generated Temp CSV File field if it does not exist. |
| Custom the flush buffer size | Select this check box to specify the number of lines to write before emptying the buffer.  
| Row number | Specify the number of lines to write before emptying the buffer.  
|            | This field is available only when the Custom the flush buffer size check box is selected. |
| Don’t generate empty file | Select this check box if you do not want to generate empty files. |
| Auto Generate JSON Metadata Description | Select this check box to generate the JSON metadata description automatically. |
| Header | Specify the number of lines to ignore in the CSV file.  
|            | This field is available only when the Auto Generate JSON Metadata Description check box is cleared. |
| Unique API Name | Specify the unique API name for the object in the JSON metadata description. |
| **Label** | Specify the display name for the object in the JSON metadata description. This field is available only when the **Auto Generate JSON Metadata Description** check box is cleared. |
| **Fully Qualified Name** | Specify the full path that uniquely identifies the record in the JSON metadata description. This field is available only when the **Auto Generate JSON Metadata Description** check box is cleared. |
| **Custom JSON Metadata** | Select this check box to use a customized JSON metadata file. This check box is available only when the **Auto Generate JSON Metadata Description** check box is cleared. |
| **JSON Metadata** | Specify the path to the customized JSON metadata file. This field is available only when the **Custom JSON Metadata** check box is selected. |
| **Generate JSON in File** | Select this check box to write the JSON metadata description into a local file. This check box is not visible when the **Custom JSON Metadata** check box is selected. |
| **Generated JSON Folder** | Specify the directory where you want to store the generated JSON metadata file. This field is available only when the **Generate JSON in File** check box is selected. |
| **Retrieve Upload Status** | Select this check box to retrieve the status of the data upload. |
| **Time to wait for server answer (seconds)** | Specify the amount of time in seconds to wait for the upload status response from the server. This field is available only when the **Retrieve Upload Status** check box is selected. |
| **tStatCatcher Statistics** | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global Variables**

| **ERROR_MESSAGE** | The error message generated by the component when an error occurs. This is an After variable and it returns a string. |

**Usage**

| **Usage rule** | This component is mainly used when no particular transformation is required on the data to be loaded to Salesforce Analytics Cloud. |
Related scenario

For a similar scenario, see Inserting bulk data into Salesforce on page 3374.
tSampleRow

Selects rows according to a list of single lines and/or a list of groups of lines.
tSampleRow filters rows according to line numbers.

**tSampleRow Standard properties**

These properties are used to configure tSampleRow running in the Standard Job framework.
The Standard tSampleRow component belongs to the Processing family.
The component in this framework is available in all Talend products.

**Basic settings**

| Schema and Edit Schema | A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either Built-in or stored remotely in the Repository. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available: • **View schema**: choose this option to view the schema only. • **Change to built-in property**: choose this option to change the schema to Built-in for local changes. • **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. Click Sync columns to retrieve the schema from the previous component in the Job. |
|——|——|
| **Built-in**: You create the schema and store it locally for the relevant component. Related topic: see Talend Studio User Guide. | |
| **Repository**: The schema already exists and is stored in the Repository, hence can be reused in various projects and Job flowcharts. Related topic: see Talend Studio User Guide. | |
| Range | Enter a range using the relevant syntax to choose a list of single lines and/or a list of groups of lines. |

**Global Variables**

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. |
|——|——|
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

| Usage rule | This component handles flows of data therefore it requires input and output components. |

### Filtering rows and groups of rows

This scenario describes a three-component Job. A `tRowGenerator` is used to create random entries which are directly sent to a `tSampleRow` where they will be filtered according to a defined range. In this scenario, we suppose the input flow contains names of salespersons along with their respective number of sold products and their years of presence in the enterprise. The result of the filtering operation is displayed on the Run console.

### Dropping and linking the components

**Procedure**

1. Drop the following components from the Palette onto the design workspace: `tRowGenerator`, `tSampleRow`, and `tLogRow`.
2. Connect the three components using Row > Main links.

### Results

![Diagram of component connections]

### Configuring the components

**Procedure**

1. In the design workspace, select `tRowGenerator`, and click the Component tab to define the basic settings for `tRowGenerator`.
2. Click the [...] button next to Edit Schema to define the data you want to use as input. In this scenario, the schema is made of five columns.
3. In the Basic settings view, click RowGenerator Editor to define the data to be generated.

4. In the RowGenerator Editor, specify the number of rows to be generated in the Number of Rows for RowGenerator field and click OK. The RowGenerator Editor closes.

5. In the design workspace, select tSampleRow and click the Component tab to define the basic settings for tSampleRow.

6. In the Basic settings view, set the Schema to Built-In and click Sync columns to retrieve the schema from the tRowGenerator component.

7. In the Range panel, set the filter to select your rows using the correct syntax as explained. In this scenario, we want to select the first and fifth lines along with the group of lines between 9 and 12.

8. In the design workspace, select tLogRow and click the Component tab to define its basic settings. For more information about tLogRow, see tLogRow on page 1956.
Saving and executing the Job

Procedure

1. Press Ctrl+S to save your Job.
2. Press F6, or click Run on the Run tab to execute the Job.

Results

The filtering result displayed on the console shows the first and fifth rows and the group of rows between 9 and 12.
tSAPHanaClose

Closes a connection to a SAP HANA database.

**tSAPHanaClose Standard properties**

These properties are used to configure tSAPHanaClose running in the Standard Job framework.

The Standard tSAPHanaClose component belongs to the Databases family.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the <strong>tSAPHanaConnection</strong> component in the list if more than one connection is planned for the current Job.</td>
</tr>
</tbody>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
<th>Select this check box to collect log data at the component level.</th>
</tr>
</thead>
</table>

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is to be used along with SAP HANA components, especially with <strong>tSAPHanaConnection</strong> and <strong>tSAPHanaCommit</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Support</td>
<td>tSAPHanaClose should be used to interact with the ERP part of SAP, including S4/HANA.</td>
</tr>
</tbody>
</table>

**Related scenarios**

No scenario is available for the Standard version of this component yet.
**tSAPHanaCommit**

Commits in one go, using a unique connection, a global transaction instead of doing that on every row or every batch and thus provides gain in performance.

tSAPHanaCommit validates the data processed through the Job into the connected database.

**tSAPHanaCommit Standard properties**

These properties are used to configure tSAPHanaCommit running in the Standard Job framework.

The Standard tSAPHanaCommit component belongs to the Databases family.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tSAPHanaConnection component in the list if more than one connection is planned for the current Job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Warning:**

If you want to use a Row > Main connection to link tSAPHanaCommit to your Job, your data will be committed row by row. In this case, do not select the Close connection check box or your connection will be closed before the end of your first row commit.

**Advanced settings**

| tStatCatcher Statistics   | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule                | This component is more commonly used with other tSAPHana* components, especially with the tSAPHanaConnection and tSAPHanaRollback components. Use this component if the Auto Commit option of the tSAPHanaConnection component is cleared. |
Related scenario

For a related scenario, see Inserting data in mother/daughter tables on page 2437.
tSAPHanaConnection

Establishes a SAP HANA connection to be reused by other SAP HANA components in your Job. tSAPHanaConnection opens a connection to the database for a current transaction.

**tSAPHanaConnection Standard properties**

These properties are used to configure tSAPHanaConnection running in the Standard Job framework. The Standard tSAPHanaConnection component belongs to the Databases and the ELT families. The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>DB Version</strong></td>
<td>Select the SAP HANA Database (HDB) version you are using.</td>
</tr>
<tr>
<td><strong>Host</strong></td>
<td>Database server IP address.</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of database server.</td>
</tr>
<tr>
<td><strong>Table Schema</strong></td>
<td>Name of the database schema.</td>
</tr>
</tbody>
</table>

**Username and Password**

Database authentication data.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

**Additional JDBC Parameters**

Specify additional connection properties in the database connection you are creating.

### Advanced settings

**Auto Commit**

Select this check box to commit any changes to the database automatically upon the transaction.

With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component.

Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does...
not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component.

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

**Usage**

| Usage rule | This component is more commonly used with other tSAPHana* components, especially with the tSAPHanaCommit and tSAPHanaRollback components. |
| Support | tSAPHanaConnection should be used to interact with the ERP part of SAP, including S4/HANA. |

**Related scenarios**

No scenario is available for the Standard version of this component yet.
tSAPHanaInput

Executes a database query with a defined command which must correspond to the schema definition. tSAPHanaInput reads a database and extracts fields based on a query. Then it passes on rows to the next component via a Main row link.

**tSAPHanaInput Standard properties**

These properties are used to configure tSAPHanaInput running in the Standard Job framework. The Standard tSAPHanaInput component belongs to the Databases family. The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

*Note:* This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

*Note:* When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>DB Version</th>
<th>Select the SAP HANA Database (HDB) version you are using.</th>

</tr>
</tbody>
</table>

### Advanced settings

| Additional JDBC Parameters | Specify additional connection properties in the database connection you are creating. This option is not available if you have selected **Use an existing connection** check box in the **Basic settings**. |
## Trim all the String/Char columns

Select this check box to remove leading and trailing whitespaces from all the String/Char columns.

## Trim column

Remove leading and trailing whitespaces from defined columns.

**Note:**
Clear Trim all the String/Char columns check box to enable this option.

## tStatCatcher Statistics

Select this check box to collect log data at the component level.

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_LINE: the number of rows processed. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>QUERY: the query statement being processed. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>

<tr>
<td>Dynamic settings</td>
<td>Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.</td>
</tr>
<tr>
<td></td>
<td>The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the</td>
</tr>
</tbody>
</table>
Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenarios

No scenario is available for the Standard version of this component yet.
tSAPHanaOutput

Executes the action defined on the table and/or on the data contained in the table, based on the flow incoming from the preceding component in the Job.

tSAPHanaOutput writes, updates, makes changes or suppresses entries in a SAP HANA database.

**tSAPHanaOutput Standard properties**

These properties are used to configure tSAPHanaOutput running in the Standard Job framework.

The Standard tSAPHanaOutput component belongs to the Databases family.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
</table>
| Use an existing connection | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. **Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:
  1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
  2. In the child level, use a dedicated connection component to read that registered database connection.
For an example about how to share a database connection across Job levels, see Talend Studio User Guide. |
| DB Version | Select the SAP HANA Database (HDB) version you are using. |
| Host | Database server IP address. |
| Port | Listening port number of database server. |
| Table Schema | Name of the database schema. |
| Username and Password | Database authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the |
Password between double quotes and click **OK** to save the settings.

<table>
<thead>
<tr>
<th><strong>Table</strong></th>
<th><strong>Name of the table to be written. Note that only one table can be written at a time.</strong></th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th><strong>Action on table</strong></th>
<th><strong>On the table defined, you can perform one of the following operations:</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>None</strong>: No operation is carried out.</td>
</tr>
<tr>
<td></td>
<td><strong>Drop and create table</strong>: The table is removed and created again.</td>
</tr>
<tr>
<td></td>
<td><strong>Create table</strong>: The table does not exist and gets created.</td>
</tr>
<tr>
<td></td>
<td><strong>Create table if not exists</strong>: The table is created if it does not exist.</td>
</tr>
<tr>
<td></td>
<td><strong>Drop table if exists and create</strong>: The table is removed if it already exists and created again.</td>
</tr>
<tr>
<td></td>
<td><strong>Clear table</strong>: The table content is deleted.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Type of table storage</strong></th>
<th><strong>This option is only available if you create (with or without drop) the database table. This option allows you to define the way the data is stored in the table. The following types of table storage organization are available:</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• <strong>Row</strong>: Data is stored in rows. It is preferable to use this table type if the majority of table access involves selecting a few records, with all attributes selected.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Column</strong>: Data is stored in columns. It is preferable to use this table type if the majority of table access will be through a large number of tuples, with only a few selected attributes.</td>
</tr>
<tr>
<td></td>
<td>• <strong>History column</strong>: Creates a table with a particular transaction session type called <strong>HISTORY</strong>. Tables with session type <strong>HISTORY</strong> support time travel queries. For more information on <strong>HISTORY</strong> and time travel queries, see <a href="http://help.sap.com/saphelp_hanaplatform/helpdata/en/20/d56cd075191014b7ea9e4e77477aae/content.htm">http://help.sap.com/saphelp_hanaplatform/helpdata/en/20/d56cd075191014b7ea9e4e77477aae/content.htm</a>.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Global temporary</strong>: The table definition and data can be seen by any user and any connection during the current session. The table is truncated at the end of the session.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Local temporary</strong>: The table definition and data can only be seen by the user who created the table during the current session. The table is truncated at the end of the session.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Action on data</strong></th>
<th><strong>On the data of the table defined, you can perform:</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Insert</strong>: Add new entries to the table. If duplicates are found, the Job stops.</td>
</tr>
<tr>
<td></td>
<td><strong>Update</strong>: Make changes to existing entries</td>
</tr>
<tr>
<td></td>
<td><strong>Insert or update</strong>: Insert a new record. If the record with the given reference already exists, an update would be made.</td>
</tr>
<tr>
<td></td>
<td><strong>Update or insert</strong>: Update the record with the given reference. If the record does not exist, a new record would be inserted.</td>
</tr>
<tr>
<td></td>
<td><strong>Delete</strong>: Remove entries corresponding to the input flow.</td>
</tr>
</tbody>
</table>
Note that it is necessary to specify at least one column as a primary key on which the **Update** and **Delete** operations are based. You can do that by clicking **Edit Schema** and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, see **Use field options** in the **Advanced settings** view.

### Schema and Edit Schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

**Built-In**: You create and store the schema locally for this component only.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

### Die on error

This check box is cleared by default. This means that **Die on error** skips the row when an error is encountered and completes the process for rows without errors.

### Advanced settings

#### Additional JDBC Parameters

Specify additional connection properties in the database connection you are creating. This option is not available if you have selected **Use an existing connection** check box in the **Basic settings**.

#### Commit every

Enter the number of rows to be committed before committing batches of rows together into the database. This option ensures transaction quality (but not rollback) and, above all, better performance at execution.

#### Additional Columns

This option is not available if you create (with or without drop) the database table. This option allows you to call SQL.
functions to perform actions on columns, which are not insert, nor update or delete actions, or any other action that requires particular preprocessing.

| Name: | Type in the name of the schema column to be altered or inserted as new column |
| SQL expression: | Type in the SQL statement to be executed in order to alter or insert the relevant column data. |
| Position: | Select Before, Replace or After following the action to be performed on the reference column. |
| Reference column: | Type in a column of reference that tSAPHanaOutput can use to locate or replace the new column or the column to be modified. |

### Use field options
Select this check box to customize a request, especially when there is double action on data. In that table, you can define:

- **Key in update**: define the primary key to use in an update operation.
- **Key in delete**: define the primary key to use in a delete operation.
- **Updatable**: define the column(s) to update.
- **Insertable**: define the column(s) to insert.

### Enable debug mode
Select this check box to display each step during processing entries in a database.

### Support null in “SQL WHERE” statement
Select this check box to validate null in “SQL WHERE” statement.

### Use Batch Size
When selected, enables you to define the number of lines in each processed batch.
This option is available only when you do not use an existing connection in Basic settings.

### tStatCatcher Statistics
Select this check box to collect log data at the component level.

### Global Variables

| Global Variables | NB_LINE: the number of rows processed. This is an After variable and it returns an integer. |
| Global Variables | NB_LINE_UPDATED: the number of rows updated. This is an After variable and it returns an integer. |
| Global Variables | NB_LINE_INSERTED: the number of rows inserted. This is an After variable and it returns an integer. |
| Global Variables | NB_LINE_DELETED: the number of rows deleted. This is an After variable and it returns an integer. |
| Global Variables | NB_LINE_REJECTED: the number of rows rejected. This is an After variable and it returns an integer. |
| Global Variables | QUERY: the query statement processed. This is an After variable and it returns a string. |
**tSAPHanaOutput**

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

**Usage rule**

This component must be connected to an Input component. It allows you to carry out actions on a table or on the data of a table in an SAP HANA database. It also allows you to create reject flows using a **Row > Reject** link to filter erroneous data.

**Support**

tSAPHanaOutput should be used to interact with the ERP part of SAP, including S4/HANA.

### Dynamic settings

Click the **[+]** button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see *Reading data from databases through context-based dynamic connections* on page 2457 and *Reading data from different MySQL databases using dynamically loaded connection parameters* on page 491. For more information on **Dynamic settings** and context variables, see *Talend Studio User Guide*.

### Related scenarios

No scenario is available for the Standard version of this component yet.
**tSAPHanaRollback**

Avoids to commit part of a transaction involuntarily. 
tSAPHanaRollback cancels the transaction in the connected database.

**tSAPHanaRollback Standard properties**

These properties are used to configure tSAPHanaRollback running in the Standard Job framework.
The Standard tSAPHanaRollback component belongs to the Databases family.
The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td>Component list</td>
<td>Select the <strong>tSAPHanaConnection</strong> component in the list if more than one connection is planned for the current Job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

### Advanced settings

<table>

<td>tSAPHanaRollback should be used to interact with the ERP part of SAP, including S4/HANA.</td>
</tr>
</tbody>
</table>

### Related scenarios

No scenario is available for the Standard version of this component yet.
tSAPHanaRow

Acts on the actual database structure or on the data (although without handling data).

tSAPHanaRow is the specific component for this database query. It executes the SQL query stated onto the specified database. The row suffix means the component implements a flow in the Job design although it does not provide output.

The SQLBuilder tool helps you write easily your SQL statements.

**tSAPHanaRow Standard properties**

These properties are used to configure tSAPHanaRow running in the Standard Job framework.

The Standard tSAPHanaRow component belongs to the Databases family.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

<td>Name of the table to be written. Note that only one table can be written at a time.</td>
</tr>
<tr>
<td><strong>Query Type</strong></td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td><strong>Built-in</strong>: Fill in manually the query statement or build it graphically using SQLBuilder.</td>
<td></td>
</tr>
<tr>
<td><strong>Repository</strong>: Select the relevant query stored in the Repository. The Query field gets accordingly filled in.</td>
<td></td>
</tr>
<tr>
<td><strong>Guess Query</strong></td>
<td>Click the Guess Query button to generate the query which corresponds to your table schema in the Query field.</td>
</tr>
<tr>
<td><strong>Query</strong></td>
<td>Enter your database query paying particularly attention to properly sequence the fields in order to match the schema definition.</td>
</tr>
</tbody>
</table>
**Die on error**

This check box is cleared by default. This means that **Die on error** skips the row when an error is encountered and completes the process for rows without errors.

### Advanced settings

<table>
<thead>
<tr>
<th><strong>Additional JDBC Parameters</strong></th>
<th>Specify additional connection properties in the database connection you are creating. This option is not available if you have selected <strong>Use an existing connection</strong> check box in the <strong>Basic settings</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Propagate QUERY’s recordset</strong></td>
<td>Select this check box to insert the result of the query into a column of the current flow. Select this column from the <strong>use column</strong> list.</td>
</tr>
<tr>
<td><strong>Note:</strong></td>
<td>This option allows the component to have a different schema from that of the preceding component. Moreover, the column that holds the QUERY’s recordset should be set to the type of <strong>Object</strong> and this component is usually followed by <strong>tParseRecordSet</strong>.</td>
</tr>
</tbody>
</table>

| **Commit every** | Number of rows to be completed before committing batches of rows together into the database. This option ensures transaction quality (but not rollback) and above all better performance on executions. |

| **Use PreparedStatement** | Select this check box if you want to query the database using a PreparedStatement. In the **Set PreparedStatement Parameter** table, define the parameters represented by ‘?’ in the SQL instruction of the **Query** field in the **Basic Settings** tab. |
| **Parameter Index:** | Enter the parameter position in the SQL instruction. |
| **Parameter Type:** | Enter the parameter type. |
| **Parameter Value:** | Enter the parameter value. |
| **Note:** | This option is very useful if you need to execute the same query several times. Performance levels are increased. |

| **tStatCatcher Statistics** | Select this check box to collect log data at the component level. |

### Global Variables

| **Global Variables** | **QUERY:** the query statement being processed. This is a Flow variable and it returns a string. **ERROR_MESSAGE:** the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. |

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component offers the flexibility of the database query and covers all possible SQL queries.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Support</td>
<td>tSAPHanaRow should be used to interact with the ERP part of SAP, including S4/HANA.</td>
</tr>
</tbody>
</table>

Related scenarios

No scenario is available for the Standard version of this component yet.
tSasInput

Executes a DB query with a strictly defined statement which must correspond to the schema definition.

**Warning:**

Before being able to benefit from all functional objectives of the SAS components, make sure to install the following three modules: sas.core.jar, sas.intrnet.javatools.jar and sas.svc.connection.jar in the path lib > java in your Talend Studio directory. You can later verify, if needed whether the modules are successfully installed through the Modules view of the Studio.

tSasInput reads a database and extracts fields based on a query. Then it passes on the field list to the component that follows via a **Row** > **Main** connection.

### tSasInput Standard properties

These properties are used to configure tSasInput running in the Standard Job framework.

The Standard tSasInput component belongs to the Databases family.

The component in this framework is available in all Talend products.

#### Basic settings

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-in or Repository</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

Click this icon to open a database connection wizard and store the database connection parameters you set in the component **Basic settings** view.

For more information about setting up and storing database connection parameters, see *Talend Studio User Guide*.

- **Host name**
  - SAS server IP address.

- **Port**
  - Listening port number of server.

- **Librefs**
  - Enter the directory name that holds the table to read followed by its access path. For example: "TpSas 'C:/SAS/TpSas'"

- **Username and Password**
  - DB user authentication data.
  - To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.
<table>
<thead>
<tr>
<th><strong>Schema and Edit Schema</strong></th>

</table>
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component covers all possible SQL queries for databases using SAS connections.</th>
</tr>
</thead>
</table>

| Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |

### Related scenarios

For related topics, see:

- Reading data from different MySQL databases using dynamically loaded connection parameters on page 491.
tSasOutput

Executes the action defined on the table and/or on the data contained in the table, based on the incoming flow from the preceding component in the Job.

**Warning:**

*Before being able to benefit from all functional objectives of the SAS components, make sure to install the following three modules: sas.core.jar, sas.intrnet.javatools.jar and sas.svc.connection.jar in the path lib > java in your Talend Studio directory. You can later verify, if needed whether the modules are successfully installed through the Modules view of the Studio.*

tSasOutput writes, updates, makes changes or suppresses entries in a database.

**tSasOutput Standard properties**

These properties are used to configure tSasOutput running in the Standard Job framework.

The Standard tSasOutput component belongs to the Databases family.

The component in this framework is available in all [Talend products](https://www.talend.com/).

**Basic settings**

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
</table>

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

*For an example about how to share a database connection across Job levels, see [Talend Studio User Guide](https://www.talend.com/).*

<table>
<thead>
<tr>
<th>SAS URL</th>
<th>Enter the URL to connect to the desired DB.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Driver JAR</strong></td>
<td>In the drop down list, select a desired available driver, or download one from a local directory through clicking the three-dot button.</td>
</tr>
<tr>
<td><strong>Class Name</strong></td>
<td>Type in the Class name to be pointed to in the driver.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the</td>
</tr>
</tbody>
</table>
password between double quotes and click **OK** to save the settings.

<table>
<thead>
<tr>
<th><strong>Table</strong></th>
<th>Name of the table to read.</th>
</tr>
</thead>
</table>

**Action on data**

On the data of the table defined, you can perform:

- **Insert**: Add new entries to the table. If duplicates are found, job stops.
- **Update**: Make changes to existing entries
- **Insert or update**: Insert a new record. If the record with the given reference already exists, an update would be made.
- **Update or insert**: Update the record with the given reference. If the record does not exist, a new record would be inserted.
- **Delete**: Remove entries corresponding to the input flow.

**Warning:**

It is necessary to specify at least one column as a primary key on which the **Update** and **Delete** operations are based. You can do that by clicking **Edit Schema** and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the **Advanced settings** view where you can simultaneously define primary keys for the **Update** and **Delete** operations. To do that:

Select the **Use field options** check box and then in the **Key in update column**, select the check boxes next to the column names you want to use as a base for the **Update** operation. Do the same in the **Key in delete column** for the **Delete** operation.

<table>
<thead>
<tr>
<th><strong>Clear data in table</strong></th>
<th>Select this check box to delete data in the selected table before any operation.</th>
</tr>
</thead>
</table>

**Schema and Edit Schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word **line** when naming the fields.

<table>
<thead>
<tr>
<th><strong>Built-In</strong></th>
<th>You create and store the schema locally for this component only.</th>
</tr>
</thead>
</table>

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

<table>
<thead>
<tr>
<th><strong>Click <strong>Edit schema</strong> to make changes to the schema. If the current schema is of the <strong>Repository</strong> type, three options are available:</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>• <strong>View schema</strong>: choose this option to view the schema only.</td>
</tr>
</tbody>
</table>
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

### Die on error
This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a **Row > Rejects** link.

### Advanced settings

#### Commit every
Enter the number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and, above all, better performance at execution.

#### Additional Columns
This option is not offered if you create (with or without drop) the DB table. This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing.

- **Name**: Type in the name of the schema column to be altered or inserted as a new column.
- **SQL expression**: Type in the SQL statement to be executed in order to alter or insert the relevant column data.
- **Position**: Select **Before**, **Replace** or **After** following the action to be performed on the reference column.
- **Reference column**: Type in a column of reference that the **tSasOutput** can use to place or replace the new or altered column.

#### Use field options
Select this check box to customize a request, especially when there is double action on data.

#### Enable debug mode
Select this check box to display each step during processing entries in a database.

#### tStatCatcher Statistics
Select this check box to collect log data at the component level.

### Global Variables

- **NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.
- **NB_LINE_UPDATED**: the number of rows updated. This is an After variable and it returns an integer.
- **NB_LINE_INSERTED**: the number of rows inserted. This is an After variable and it returns an integer.
tSasOutput

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
</tr>
</thead>
<tbody>
<tr>
<td>This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible. This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in a SAS database. It also allows you to create a reject flow using a Row &gt; Rejects link to filter data in error. For an example of tMySQLOutput in use, see <a href="#">Retrieving data in error with a Reject link</a> on page 2485.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Limitation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
</tbody>
</table>

**Related scenarios**

For scenarios in which **tSasOutput** might be used, see:

- [Inserting a column and altering data using tMysqlOutput](#) on page 2477.
tSchemaComplianceCheck

Ensures the data quality of any source data against a reference data source.

tSchemaComplianceCheck validates all input rows against a reference schema or check types, nullability, length of rows against reference values. The validation can be carried out in full or partly.
tSCPClose

Closes a connection to an SCP protocol.
tSCPClose closes a connection to a fully encrypted channel.

**tSCPClose Standard properties**

These properties are used to configure tSCPClose running in the Standard Job framework.
The Standard tSCPClose component belongs to the Internet family.
The component in this framework is available in all Talend products.

**Basic settings**

| Component list | If there is more than one connection in the current Job, select tSCPConnection from the list. |

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

**Global Variables**

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

**Usage**

| Usage rule | tSCPClose is generally used as a start component. It requires an output component. |

| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your SCP connection dynamically from multiple connections planned in your Job. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. |
Related scenario

This component is closely related to **tSCPConnection** and **tSCPRollback**. It is generally used with **SCPConnection** as it allows you to close a connection for the transaction which is underway.

For a related scenario, see **Handling a file using SCP** on page 3424.
tSCPConnection

Opens an SCP connection to transfer files in one transaction.

**tSCPConnection Standard properties**

These properties are used to configure tSCPConnection running in the Standard Job framework.

The Standard tSCPConnection component belongs to the Internet family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Host</th>
<th>IP address of the SCP server.</th>
</tr>
</thead>

</table>
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is typically used as a single-component subJob but can also be used with other components.</th>
</tr>
</thead>
</table>

Handling a file using SCP

In this scenario, a six-component Job checks if a defined file exists in a specified directory on a remote SCP server, and returns a message to indicate the result of the verification. If the file doesn’t exist in that directory, the Job will put the local file to the SCP server, and then get the file from the SCP server to another defined local directory to verify that the file has been uploaded correctly.
Dropping and linking the components

Procedure

1. Add the following six components by typing their names on the design workspace or dropping them from the Palette to the design workspace: tSCPConnection, tSCPFileExists, tJava, tSCPPut, tSCPGet, and tSCPClose.

2. Connect the tSCPConnection component to the tSCPFileExists component using a Trigger > On Subjob Ok connection.

3. Connect the tSCPFileExists component to the tJava component using a Trigger > On Component Ok connection, and to the tSCPPut component using a Trigger > Run if connection.

4. Connect the tSCPPut component to the tSCPGet component using a Trigger > On Subjob Ok connection.

5. Connect the tSCPGet component to the tSCPClose component using a Trigger > On Subjob Ok connection.

Configuring the tSCPConnection component

Procedure

1. Double-click the tSCPConnection component to open its Basic settings view.

2. Enter the host name or IP address of the SCP server and the port number in the corresponding field.

3. Enter the user name used for connection in the Username field.

4. Select Password from the Authentication method drop-down list.

5. Click the [...] button next to the Password text box, then in the pop-up Enter a new password dialog box, enter the password between double quotes and click OK to save the change.
Configuring file existence verification

Procedure
1. Double-click the **tSCPFileExists** component to open its **Basic settings** view.

   ![tSCPFileExists Component](image)

   - Select the **Use an existing connection** check box and then select the connection you have configured from the **Component List**.
   - In the **Filename** field, enter the name of the file to be checked between double quotes. In this example, it is "testscp.txt".

2. Double-click the **tJava** component to open its **Basic settings** view.

   ![tJava Component](image)

   - In the **Code** field, enter the following code:
     ```java
     System.out.println((String)globalMap.get("tSCPFileExists_1_FILENAME"));
     System.out.println((String)globalMap.get("tSCPFileExists_1_STATUS"));
     ```

3. Select the **Component** tab and click the **If** connection to open its **Basic settings** view.

   ![If Component](image)

   - In the **Condition** field, enter the following code:
     ```java
     !((String)globalMap.get("tSCPFileExists_1_STATUS")).equals("File exists.")
     ```

   This way, if the file doesn’t exist in the defined directory, the rest of the Job will be executed.

Configuring the **tSCPPut** component

Procedure
1. Double-click the **tSCPPut** component to open its **Basic settings** view.
2. Select the **Use an existing connection** check box and then select the connection you have configured from the **Component List**.

3. Click the [+ ] button to add one row in the **Filelist** table, and enter the full local path of the file to be uploaded in the corresponding **Source** column. In this example, it is “D:/SCPPut/testscp.txt”.

### Configuring the tSCPGet component

**Procedure**

1. Double-click the **tSCPGet** component to open its **Basic settings** view.

2. Select the **Use an existing connection** check box and then select the connection you have configured from the **Component List**.

3. In the **Local directory** field, enter or click the [...] button to browse to the directory under which the file will be stored. In this example, it is “D:/SCPGet”.

4. Select **append** from the **Overwrite or Append** drop-down list.

5. Click the [+ ] button to add one row in the **Filelist** table, and then enter the path of the file to be retrieved from the SCP server in the corresponding **Source** column. In this example, it is “./testscp.txt”.

### Configuring the tSCPClose component

**Procedure**

1. Double-click the **tSCPClose** component to open its **Basic settings** view.
2. Select the connection you have configured from the Component List.

**Executing the Job**

**Procedure**

1. Press Ctrl+S to save the Job.
2. Make sure the file testscp.txt exists in the local directory D:/SCPPut, and does not exist in the local directory D:/SCPGet and the home directory of the SCP server.
3. Press F6 to run the Job.

The file verification information is displayed on the Run console.

4. Go to the local directory D:/SCPGet and the home directory of the SCP server, you will see the file testscp.txt there.
tSCPFileList

Lists files from the defined SCP server.
tSCPFileList iterates, over a fully encrypted channel, on files in a given directory on a remote host.

**tSCPFileList Standard properties**

These properties are used to configure tSCPFileList running in the Standard Job framework.
The Standard tSCPFileList component belongs to the Internet family.
The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specify the host name or IP address of the SCP server.</td>
<td></td>
</tr>
<tr>
<td>Specify the listening port number of the SCP server.</td>
<td></td>
</tr>
<tr>
<td>Fill in the user name to access the SCP server.</td>
<td></td>
</tr>
<tr>
<td>Select one of the SCP authentication methods from the drop-down list, <strong>Public key</strong>, <strong>Password</strong>, or <strong>Keyboard Interactive</strong>.</td>
<td></td>
</tr>
<tr>
<td>Enter the password to access the SCP server. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings. This field appears only when <strong>Password</strong> or <strong>Keyboard Interactive</strong> is selected from the <strong>Authentication method</strong> drop-down list.</td>
<td></td>
</tr>
<tr>
<td>Enter the passphrase for the public key. To enter the passphrase, click the [...] button next to the passphrase field, and then in the pop-up dialog box enter the passphrase between double quotes and click <strong>OK</strong> to save the settings. This field appears only when <strong>Public key</strong> is selected from the <strong>Authentication method</strong> drop-down list.</td>
<td></td>
</tr>
<tr>
<td>Browse to or type in the path to the private key. This field appears only when <strong>Public key</strong> is selected from the <strong>Authentication method</strong> drop-down list.</td>
<td></td>
</tr>
<tr>
<td>Specify the character used to separate multiple commands.</td>
<td></td>
</tr>
</tbody>
</table>
Click the [+] button to add a command or a set of commands to list files in a given directory on the SCP server.

Advanced settings

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

Global Variables

| Global Variables | CURRENT_LINE: the file currently being iterated upon. This is a Flow variable and it returns a string. ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. NB_LINE: the number of files iterated upon so far. This is a Flow variable and it returns an integer. STATUS: the execution result of the component. This is an After variable and it returns a string. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

Usage
