<td>Select the tFirebirdConnection component in the list if more than one connection are planned for the current Job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is more commonly used with other tFirebird* components, especially with the tFirebirdConnection and tFirebirdCommit components. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic |
tFirebirdRollback

settings and context variables, see Talend Studio User Guide.

Related scenario

For tFirebirdRollback related scenario, see Rollback from inserting data in mother/daughter tables on page 2440.
tFirebirdRow

Executes the stated SQL query on the specified Firebird database.

Depending on the nature of the query and the database, tFirebirdRow acts on the actual DB structure or on the data (although without handling data). The SQLBuilder tool helps you write easily your SQL statements.

tFirebirdRow is the specific component for this database query. The row suffix means the component implements a flow in the job design although it doesn’t provide output.

**tFirebirdRow Standard properties**

These properties are used to configure tFirebirdRow running in the Standard Job framework.

The Standard tFirebirdRow component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
<tr>
<td><strong>Property type</strong></td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><strong>Use an existing connection</strong></td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
<table>
<thead>

<td>Enter the data that you want to generate, separated by the separators that you have already defined in the Row and Field Separator fields.</td>
</tr>
<tr>
<td>Number of rows</td>
<td>Enter the number of lines to be generated.</td>
</tr>
</tbody>
</table>
### Values
Between inverted commas, enter the values corresponding to the columns you defined in the schema dialog box via the **Edit schema** button.

### Advanced settings

| **tStat Catcher Statistics** | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

### Global Variables

| **NB_LINE**: the number of rows processed. This is an After variable and it returns an integer. |
| **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. |
| A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. |
| To fill up a field or expression with a variable, press `Ctrl + Space` to access the variable list and choose the variable to use from it. |
| For further information about variables, see [Talend Studio User Guide](#). |

### Usage

| **Usage rule** | This component can be used as a start or intermediate component and thus requires an output component. |

### Related scenarios

For related scenarios, see:

- Buffering output data on the webapp server on page 411.
- Iterating on a DB table and listing its column names on page 2430.
- Filtering a list of names using simple conditions on page 1166.
**tFlowMeter**

Counts the number of rows processed in the defined flow, so this number can be caught by the tFlowMeterCatcher component for logging purposes.

**tFlowMeter Standard properties**

These properties are used to configure tFlowMeter running in the Standard Job framework.

The Standard tFlowMeter component belongs to the Logs & Errors family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Use input connection name as label</th>
<th>Select this check box to reuse the name given to the input main row flow as label in the logged data.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Mode</strong></td>
<td>Select the type of values for the data measured: <strong>Absolute</strong>: the actual number of rows is logged <strong>Relative</strong>: a ratio (%) of the number of rows is logged. When this option is selected, a Connections List shows to let you select a reference connection.</td>
</tr>
<tr>
<td><strong>Thresholds</strong></td>
<td>Adds a threshold to watch proportions in volumes measured. You can decide that the normal flow has to be between low and top end of a row number range, and if the flow is under this low end, there is a bottleneck.</td>
</tr>
</tbody>
</table>

**Global Variables**

| Global Variables                  | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

**Usage**

| Usage rule                        | Cannot be used as a start component as it requires an input flow to operate. |

If you have a need of log, statistics and other measurement of your data flows, see Talend Studio User Guide.
Related scenario

For related scenario, see Catching flow metrics from a Job on page 1197
tFlowMeterCatcher

Operates as a log function triggered by the use of a tFlowMeter component in the Job. Based on a defined schema, the tFlowMeterCatcher catches the processing volumetric from the tFlowMeter component and passes them on to the output component.

tFlowMeterCatcher Standard properties

These properties are used to configure tFlowMeterCatcher running in the Standard Job framework. The Standard tFlowMeterCatcher component belongs to the Logs & Errors family. The component in this framework is available in all Talend products.

Basic settings

<table>
<thead>
<tr>
<th>Schema and Edit Schema</th>
<th>A schema is a row description, it defines the fields to be processed and passed on to the next component. In this particular case, the schema is read-only, as this component gathers standard log information including:</th>

</tr>
</tbody>
</table>
Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | This component is the start component of a secondary Job which triggers automatically at the end of the main Job. |

Limitation

| limitation | The use of this component cannot be separated from the use of the tFlowMeter. For more information, see tFlowMeter on page 1194 |

Catching flow metrics from a Job

The following basic Job aims at catching the number of rows being passed in the flow processed. The measures are taken twice, once after the input component, that is, before the filtering step and once right after the filtering step, that is, before the output component.

- Drop the following components from the Palette to the design workspace: tMysqlInput, tFlowMeter (x2), tMap, tLogRow, tFlowMeterCatcher and tFileOutputDelimited.
- Link components using row main connections and click on the label to give consistent name throughout the Job, such as US_States from the input component and filtered_states for the output from the tMap component, for example.
- Link the tFlowMeterCatcher to the tFileOutputDelimited component using a row main link also as data is passed.
• On the **tMysqlInput** Component view, configure the connection properties as **Repository**, if the table metadata are stored in the Repository. Or else, set the Type as **Built-in** and configure manually the connection and schema details if they are built-in for this Job.

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Repository</th>
<th>DB (MYSQL):U$s_states</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB Version</td>
<td>Mysql 5</td>
<td></td>
</tr>
<tr>
<td>Use an existing connection</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Host</td>
<td>&quot;localhost&quot;</td>
<td>* Port &quot;3306&quot;</td>
</tr>
<tr>
<td>Database</td>
<td>&quot;tbox10&quot;</td>
<td></td>
</tr>
<tr>
<td>Username</td>
<td>&quot;root&quot;</td>
<td>* Password ************</td>
</tr>
<tr>
<td>Schema</td>
<td>Built-In</td>
<td>Edit schema</td>
</tr>
<tr>
<td>Table Name</td>
<td>&quot;states&quot;</td>
<td></td>
</tr>
<tr>
<td>Query Type</td>
<td>Built-In</td>
<td>Guess Query</td>
</tr>
<tr>
<td>Query</td>
<td>&quot;SELECT * FROM states&quot;</td>
<td></td>
</tr>
</tbody>
</table>

• The 50 States of the USA are recorded in the table **states**. In order for all 50 entries of the table to get selected, the query to run onto the Mysql database is as follows:

```sql
select * from states
```

• Select the relevant **encoding type** on the Advanced settings vertical tab.

• Then select the following component which is a **tFlowMeter** and set its properties.

• Select the check box **Use input connection name as label**, in order to reuse the label you chose in the log output file (**tFileOutputDelimited**).

• The mode is **Absolute** as there is no reference flow to meter against, also no **Threshold** is to be set for this example.

• Then launch the **tMap** editor to set the filtering properties.

• For this use case, drag and drop the ID and State columns from the Input area of the **tMap** towards the Output area. No variable is used in this example.
On the Output flow area (labelled `filtered_states` in this example), click the arrow & plus button to activate the expression filter field.

Drag the `State` column from the Input area (row2) towards the expression filter field and type in the rest of the expression in order to filter the state labels starting with the letter `M`. The final expression looks like: `row2.State.startsWith("M")`

Click **OK** to validate the setting.

Then select the second **tFlowMeter** component and set its properties.

- Select the check box **Use input connection name as label**.
- Select **Relative** as **Mode** and in the **Reference connections** list, select US_States as reference to be measured against.
- Once again, no threshold is used for this use case.
- No particular setting is required in the **tLogRow**.
- Neither does the **tFlowMeterCatcher** as this component's properties are limited to a preset schema which includes typical log information.
- So eventually set the log output component (**tFileOutputDelimited**).

Select the **Append** check box in order to log all **tFlowMeter** measures.
• Then save your Job and press **F6** to execute it.

```
19 | Maine
20 | Maryland
21 | Massachusetts
22 | Michigan
23 | Minnesota
24 | Mississippi
25 | Missouri
26 | Montana
Job FlowMeterCatcher ended at 17:56 29/08/2007. [exit code=0]
```

The **Run** view shows the filtered state labels as defined in the Job.

<table>
<thead>
<tr>
<th>A</th>
<th>K</th>
<th>L</th>
<th>M</th>
<th>N</th>
<th>O</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>moment</td>
<td>origin</td>
<td>label</td>
<td>count</td>
<td>reference</td>
</tr>
<tr>
<td>2</td>
<td>08/29/07 05:56 PM</td>
<td>tFlowMeter_1</td>
<td>US_States</td>
<td>50</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>08/29/07 05:56 PM</td>
<td>tFlowMeter_2</td>
<td>filtered_states</td>
<td>8</td>
<td>60</td>
</tr>
</tbody>
</table>

In the delimited csv file, the number of rows shown in column **count** varies between **tFlowMeter1** and **tFlowMeter2** as the filtering has then been carried out. The **reference** column shows also this difference.
tFlowToIterate

Reads data line by line from the input flow and stores the data entries in iterative global variables.

**tFlowToIterate Standard properties**

These properties are used to configure tFlowToIterate running in the Standard Job framework.

The Standard tFlowToIterate component belongs to the Orchestration family.

The component in this framework is available in all Talend products.

**Basic settings**

<td>Trigger: Run if; On Component Ok; On Component Error.</td>
</tr>
</tbody>
</table>
Transforming data flow to a list

The following scenario describes a Job that reads a list of files from a defined input file, iterates on each of the files and displays their content row by row on the Run console.

Setting up the Job

Procedure
1. Drop the following components from the Palette onto the design workspace: two tFileInputDelimited components, a tFlowToIterate, and a tLogRow.
2. Connect the first tFileInputDelimited to tFlowToIterate using a Row > Main link, tFlowToIterate to the second tFileInputDelimited using an Iterate link, and the second tFileInputDelimited to tLogRow using a Row > Main link.

Configuring the Components

Procedure
1. Double-click the first tFileInputDelimited to display its Basic settings view.
2. Click the [...] button next to the File Name field to select the path to the input file.

Note:
The File Name field is mandatory.
The input file used in this scenario is *Customers.txt*. It is a text file that contains a list of names of three other simple text files: *Name.txt*, *E-mail.txt* and *Address.txt*. The first text file, *Name.txt*, is made of one column holding customers’ names. The second text file, *E-mail.txt*, is made of one column holding customers’ e-mail addresses. The third text file, *Address.txt*, is made of one column holding customers’ postal addresses.

Fill in all other fields as needed. For more information, see *tFileInputDelimited Standard properties* on page 1008. In this scenario, the header and the footer are not set and there is no limit for the number of processed rows.

3. Click **Edit schema** to describe the data structure of this input file. In this scenario, the schema is made of one column, *FileName*.

4. Double-click **tFlowToIterate** to display its **Basic settings** view.

Click the plus button to add new parameter lines and define your variables, and click in the **key** cell to enter the variable name as desired. In this scenario, one variable is defined: "Name_of_File".

Alternatively, you can select the **Use the default (key, value) in global variables** check box to use the default in global variables.

5. Double-click the second **tFileInputDelimited** to display its **Basic settings** view.
In the File name field, enter the directory of the files to be read, and then press Ctrl+Space to select the global variable "Name_of_File". In this scenario, the syntax is as follows:

"C:/scenario/flow_to_iterate/*+(String)globalMap.get("Name_of_File")"

Click Edit schema to define the schema column name. In this scenario, it is RowContent.

Fill in all other fields as needed. For more information, see tFileInputDelimited Standard properties on page 1008.

6. In the design workspace, select the last component, tLogRow, and click the Component tab to define its basic settings.

Define your settings as needed. For more information, see tLogRow Standard properties on page 1956.

**Saving and executing the Job**

**Procedure**

1. Save your Job by pressing Ctrl+S.
2. Execute the Job by pressing F6 or clicking Run on the Run tab.
Starting job Practice_8_27 at 16:12 28/08/2012.

Job Practice_8_27 ended at 16:12 28/08/2012. [exit code=0]

Results

Customers' names, customers' e-mails, and customers' postal addresses appear on the console preceded by the schema column name.
tForeach

Creates a loop on a list for an iterate link.

**tForeach Standard properties**

These properties are used to configure tForeach running in the Standard Job framework.

The Standard tForeach component belongs to the Orchestration family.

The component in this framework is available in all Talend products.

**Basic settings**

| Values | Use the [*] button to add rows to the Values table. Then click on the fields to enter the list values to be iterated upon, between double quotation marks. |

**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect the log data at a component level. |

**Global Variables**

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

**CURRENT_VALUE**: the value currently iterated upon. This is a Flow variable and it returns a string.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide. |

**Usage**

| Usage rule | tForeach is an input component and requires an Iterate link to connect it to another component. |

**Iterating on a list and retrieving the values**

This scenario describes a two component Job in which a list is created and iterated upon in a tForeach component. The values are then retrieved in a tJava component.
Setting up the Job

Procedure
1. Drop a \texttt{tForeach} and a \texttt{tJava} component onto the design workspace.
2. Link \texttt{tForeach} to \texttt{tJava} using a Row > Iterate connection.

Results

Configuring the components

Procedure
1. Double-click \texttt{tForeach} to open its Basic settings view:

2. Click the [+] button to add as many rows to the Values list as required.
3. Click on the Value fields to enter the list values, between double quotation marks.
4. Double-click \texttt{tJava} to open its Basic settings view:

5. Enter the following Java code in the Code area: \texttt{System.out.println(globalMap.get("tForeach_1_CURRENT_VALUE") +"_out");}
Saving and executing the Job

Procedure

1. Press Ctrl+S to save your Job.
2. Press F6 to execute the Job.

Results

The **tJava** run view displays the list values retrieved from **tForeach**, each one suffixed with _out:

```
[statistics] connecting to socket on port 3409
[statistics] connected
element_1_out
element_2_out
element_3_out
element_4_out
[statistics] disconnected
Job tForeach_2 ended at 14:28
04/10/2010. [exit code=0]
```
tFTPClose

Closes an active FTP connection to release the occupied resources.

**tFTPClose Standard properties**

These properties are used to configure tFTPClose running in the Standard Job framework. The Standard tFTPClose component belongs to the Internet family. The component in this framework is available in all Talend products.

**Basic settings**

| Component list | Select the component that opens the connection you need to close from the list. |

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global Variables**

| ERROR_MESSAGE | The error message generated by the component when an error occurs. This is an After variable and it returns a string. |

**Usage**

| Usage rule | This component is more commonly used with other FTP components, especially with the tFTPConnection component. |

**Related scenarios**

- Listing and getting files/folders on an FTP directory on page 1222
- Putting files onto an FTP server on page 1238
- Renaming a file located on an FTP server on page 1244
tFTPConnection

Opens an FTP connection to transfer files in a single transaction.

**tFTPConnection Standard properties**

These properties are used to configure tFTPConnection running in the Standard Job framework.

The Standard tFTPConnection component belongs to the Internet family.

The component in this framework is available in all Talend products.

**Basic settings**

**Username and Password**

The user authentication data to access the FTP server.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

**Remote directory**

The directory where the files/folders to be deleted are located.

**Move to the current directory**

Select this check box to change the directory to the one specified in the Remote directory field. The next FTP component in the Job will take this directory as the root of the remote directory when using the same connection.

This property is available only when the Use an existing connection check box is selected.

**SFTP Support**

Select this check box to connect to the FTP server via an SFTP connection.
### tFTPDelete

**Warning:** This option does not work with an HTTP/HTTPS proxy. If you need a proxy, set a SOCKS proxy in the Advanced settings tab.

| Authentication method | Select the SFTP authentication method, either **Public key** or **Password**.  
|                       | • **Public key**: Enter the path to the private key and the passphrase for the key in the **Private key** and **Key Passphrase** fields correspondingly.  
|                       | • **Password**: Enter the password required.  
|                       | This property is available only when the **SFTP Support** check box is selected. |

| Filename encoding | Select this check box to set the encoding used to convert file names from Strings to bytes. It should be the same encoding used on the SFTP server. If the SFTP server’s version is greater than 3, the encoding should be UTF-8, or else an error occurs.  
|                   | This property is available only when the **SFTP Support** check box is selected. |

| FTPS Support | Select this check box to connect to the FTP server via an FTPS connection.  
|              | If you are using an HTTP proxy, via a tSetProxy component for example, you need to select this check box and set the connection mode to **Passive**. |

| Keystore File | The path to your keystore file, a password protected file containing several keys and certificates.  
|              | This property is available only when the **FTPS Support** check box is selected. |

| Keystore Password | The password for your keystore file.  
|                  | This property is available only when the **FTPS Support** check box is selected. |

| Security Mode | Select the security mode from the list, either **Implicit** or **Explicit**.  
|              | This property is available only when the **FTPS Support** check box is selected. |

| Use Perl5 Regex Expression as Filemask | Select this check box to use Perl5 regular expressions in the **Files** field as file filters. This is useful when the name of the file to be processed contains special characters such as parentheses.  
|                                       | For more information about Perl5 regular expression syntax, see Perl5 Regular Expression Syntax. |

| Files | The names of the files/folders or the paths to the files/folders to be deleted. You can specify multiple files/folders in a line by using wildcards or a regular expression. |

| Target Type | Select the type of the target to be deleted, either **File** or **Directory**. |
### Connection mode
Select the connection mode from the list, either **Passive** or **Active**.

### Encoding
Specify the encoding type by selecting an encoding type from the list or selecting **CUSTOM** and enter the encoding type manually.

### Die on error
Select the check box to stop the execution of the Job when an error occurs. Clear the check box to skip any error and continue the Job execution process.

Usage

| Usage rule                    | This component is typically used as a single-component subjob but can also be used with other components.                                      |

Listing and getting files/folders on an FTP directory

Here is an example of using Talend FTP components to iterate and list all files and folders on an FTP server directory, and then get only text files on that directory to a local directory.

Creating a Job for listing and getting files/folders on an FTP directory

Create a Job to connect to an FTP server, iterate and list all files and folders on an FTP root directory, then get only text files on the FTP root directory to a local directory, finally close the connection to the server.
Before you begin

**Prerequisites:** To replicate this scenario, an FTP server must be started and a couple of files/folders must be put onto the root directory of the FTP server.

**Procedure**

1. Create a new Job and add a `tFTPConnection` component, a `tFTPFileList` component, a `tIterateToFlow` component, a `tLogRow` component, a `tFTPGet` component, and a `tFTPClose` component by typing their names in the design workspace or dropping them from the Palette.

2. Link the `tFTPFileList` component to the `tIterateToFlow` component using a Row > Iterate connection.

3. Link the `tIterateToFlow` component to the `tLogRow` component using a Row > Main connection.
4. Link the tFTPConnection component to the tFTPFileList component using a Trigger > OnSubjobOk connection.

5. Do the same to link the tFTPFileList component to the tFTPGet component, and the tFTPGet component to the tFTPClose component.

**Opening a connection to the FTP server**

Configure the tFTPConnection component to open a connection to the FTP server.

**Procedure**

1. Double-click the tFTPConnection component to open its Basic settings view.
2. In the Host and Port fields, enter the FTP server IP address and the listening port number respectively.
3. In the Username and Password fields, enter the authentication details.

**Listing all files/folders on the FTP root directory**

Configure the tFTPFileList component, the tIterateToFlow component, and the tLogRow component to iterate all files and folders on the FTP root directory and display the names and paths of these files and folders on the console of Talend Studio.

**Procedure**

1. Double-click the tFTPFileList component to open its Basic settings view.
2. Specify the connection details required to access the FTP server. In this example, select the Use an existing connection check box and from the Component list drop-down list displayed, select the connection component to reuse its connection details you have already defined.
3. In the Remote directory field, specify the FTP server directory on which the files and folders will be iterated. In this example, it is /, which means the root directory of the FTP server.
4. Clear the Move to the current directory check box.
5. Double-click the tIterateToFlow component to open its Basic settings view.
6. Click the button next to **Edit schema** to open the schema dialog box.

7. Click the **Add columns** button to add two String type columns **filename** and **filepath** that will hold the names and paths of the files to be iterated respectively. When done, click **OK** to close the dialog box.

8. In the **Mapping** table, set the values for the **filename** and **filepath** columns. In this example, the global variable `((String)globalMap.get("tFTPFileList_1_CURRENT_FILE"))` for **filename** and the global variable `((String)globalMap.get("tFTPFileList_1_CURRENT_FILEPATH"))` for **filepath**.

Note that you can fill the values by pressing **Ctrl + Space** to access the global variables list and then selecting **tFTPFileList_1_CURRENT_FILE** and **tFTPFileList_1_CURRENT_FILEPATH** from the list.

9. Double-click the **tLogRow** component to open its **Basic settings** view, and then select **Table (print values in cells of a table)** in the **Mode** area for better readability of the result.
**Getting files on the FTP server directory to a local directory**

Configure the **tFTPGet** component to get only the text files on the FTP root directory to a local directory.

**Procedure**

1. Double-click the **tFTPGet** component to open its **Basic settings** view.

![tFTPGet Component Settings](image1)

2. Specify the connection details required to access the FTP server. In this example, select the **Use an existing connection** check box and from the **Component list** drop-down list displayed, select the connection component to reuse its connection details you have already defined.

3. In the **Local directory** field, specify the local directory to which the files and folders will be downloaded. In this example, it is `D:/FtpDownloads`.

4. In the **Remote directory** field, specify the FTP server directory under which the files and folders will be downloaded. In this example, it is `/`, which means the root directory of the FTP server.

5. In the **Files** table, click the `[+]` button to add a line and in the **Filemask** column field, enter `*.txt` between double quotation marks to get only the text files on the FTP directory to the local directory.

**Closing the connection to the FTP server**

Configure the **tFTPClose** component to close the connection to the FTP server.

**Procedure**

1. Double-click the **tFTPClose** component to open its **Basic settings** view.

![tFTPClose Component Settings](image2)
2. From the Component list drop-down list, select the tFTPConnection component that opens the connection you need to close. In this example, only one tFTPConnection component is used and it is selected by default.

**Executing the Job to list and get files/folders on the FTP directory**

After setting up the Job and configuring the components used in the Job for listing and getting files/folders on the FTP directory, you can then execute the Job and verify the Job execution result.

**Procedure**

1. Press Ctrl + S to save the Job.
2. Press F6 to execute the Job.

```

As shown above, the names and paths of the files and folders on the FTP server root directory are displayed on the console, and only the text files are downloaded to the specified local directory.
tFTPFileProperties

Retrieves the properties of a specified file on an FTP server.

**tFTPFileProperties Standard properties**

These properties are used to configure tFTPFileProperties running in the Standard Job framework.

The Standard tFTPFileProperties component belongs to the Internet family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Select the way the connection details will be set.</th>

### tFTPGet

- **always**: Always overwrite the file.
- **size different**: Overwrite the file when the file size is different.
- **overwrite**: Overwrite the existing file.
- **resume**: Resume downloading the file from the point of interruption.
- **append**: Add data to the end of the file without overwriting data.

*overwrite, resume, and append* are available when the SFTP Support check box is selected.

### Append

Select this check box to append data at the end of the file in order to avoid overwriting data.

### SFTP Support

Select this check box to connect to the FTP server via an SFTP connection.

**Warning**: This option does not work with an HTTP/HTTPS proxy. If you need a proxy, set a SOCKS proxy in the Advanced settings tab.

### Authentication method

Select the SFTP authentication method, either **Public key** or **Password**.

- **Public key**: Enter the path to the private key and the passphrase for the key in the Private key and Key Passphrase fields correspondingly.
- **Password**: Enter the password required.

This property is available only when the SFTP Support check box is selected.

### Filename encoding

Select this check box to set the encoding used to convert file names from Strings to bytes. It should be the same encoding used on the SFTP server. If the SFTP server’s version is greater than 3, the encoding should be UTF-8, or else an error occurs.

This property is available only when the SFTP Support check box is selected.

### FTPS Support

Select this check box to connect to the FTP server via an FTPS connection.

If you are using an HTTP proxy, via a tSetProxy component for example, you need to select this check box and set the connection mode to Passive.

### Keystore File

The path to your keystore file, a password protected file containing several keys and certificates.

This property is available only when the FTPS Support check box is selected.

### Keystore Password

The password for your keystore file.

This property is available only when the FTPS Support check box is selected.

### Security Mode

Select the security mode from the list, either Implicit or Explicit.

This property is available only when the FTPS Support check box is selected.
| **Use Perl5 Regex Expression as Filemask** | Select this check box to use Perl5 regular expressions in the Files field as file filters. This is useful when the name of the file to be processed contains special characters such as parentheses. For more information about Perl5 regular expression syntax, see Perl5 Regular Expression Syntax. |
| **Files** | The names of the files or the paths to the files to be downloaded. You can specify multiple files in a line by using wildcards or a regular expression. |
| **Connection mode** | Select the connection mode from the list, either Passive or Active. |
| **Encoding** | Specify the encoding type by selecting an encoding type from the list or selecting CUSTOM and enter the encoding type manually. |
| **Die on error** | Select the check box to stop the execution of the Job when an error occurs. Clear the check box to skip any error and continue the Job execution process. |

**Advanced settings**

| **Use Socks Proxy** | Select this check box if you are using a proxy, and in the Proxy host, Proxy port, Proxy user and Proxy password fields displayed, specify the proxy server settings information. |
| **Ignore Failure At Quit (FTP)** | Select this check box to ignore library closing errors or FTP closing errors. |
| **Print message** | Select this check box to display the list of files downloaded on the console. |
| **Data Channel Protection Level** | The data channel protection level with which data is transferred between the client and the server. For more information, see RFC 2228: FTP Security Extensions. This property is available only when the FTPS Support check box is selected. |
| **Protection Buffer Size** | The maximum size (in bytes) of the encoded data blocks to be transferred between the client and the server. For more information, see RFC 2228: FTP Security Extensions. This property is available only when the FTPS Support check box is selected. |
| **tStatCatcher Statistics** | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global Variables**

<p>| <strong>ERROR_MESSAGE</strong> | The error message generated by the component when an error occurs. This is an After variable and it returns a string. |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>

<td>Host</td>
<td>The IP address or hostname of the FTP server.</td>
</tr>
<tr>
<td>Port</td>
<td>The listening port number of the FTP server.</td>
</tr>
</tbody>
</table>

| Username and Password       | The user authentication data to access the FTP server. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |

| Local directory             | The local directory from which the files will be uploaded to the FTP server.                                       |
| Remote directory            | The FTP directory where the uploaded files will be placed.                                                        |

| Move to the current directory | Select this check box to change the directory to the one specified in the Remote directory field. The next FTP component in the Job will take this directory as the root of the remote directory when using the same connection. This property is available only when the Use an existing connection check box is selected. |

| Transfer mode               | Select the transfer mode from the list, either ascii or binary.                                                    |
| Overwrite file              | Select the action to be performed when the file already exists.                                                    |
- **never**: Never overwrite the file.
- **always**: Always overwrite the file.
- **size different**: Overwrite the file when the file size is different.
- **overwrite**: Overwrite the existing file.
- **resume**: Resume downloading the file from the point of interruption.
- **append**: Add data to the end of the file without overwriting data.

**overwrite**, **resume**, and **append** are available when the **SFTP Support** check box is selected.

### Append
Select this check box to append data at the end of the file in order to avoid overwriting data.

### SFTP Support
Select this check box to connect to the FTP server via an SFTP connection.

**Warning**: This option does not work with an HTTP/HTTPS proxy. If you need a proxy, set a SOCKS proxy in the **Advanced settings** tab.

### Authentication method
Select the SFTP authentication method, either **Public key** or **Password**.
- **Public key**: Enter the path to the private key and the passphrase for the key in the **Private key** and **Key Passphrase** fields correspondingly.
- **Password**: Enter the password required.

This property is available only when the **SFTP Support** check box is selected.

### Filename encoding
Select this check box to set the encoding used to convert file names from Strings to bytes. It should be the same encoding used on the SFTP server. If the SFTP server’s version is greater than 3, the encoding should be **UTF-8**, or else an error occurs.

This property is available only when the **SFTP Support** check box is selected.

### FTPS Support
Select this check box to connect to the FTP server via an FTPS connection.

If you are using an HTTP proxy, via a tSetProxy component for example, you need to select this check box and set the connection mode to **Passive**.

### Keystore File
The path to your keystore file, a password protected file containing several keys and certificates.

This property is available only when the **FTPS Support** check box is selected.

### Keystore Password
The password for your keystore file.

This property is available only when the **FTPS Support** check box is selected.

### Security Mode
Select the security mode from the list, either **Implicit** or **Explicit**.
### Use Perl5 Regex Expression as Filemask
Select this check box to use Perl5 regular expressions in the **Files** field as file filters. This is useful when the name of the file to be processed contains special characters such as parentheses.

For more information about Perl5 regular expression syntax, see [Perl5 Regular Expression Syntax](#).

### Files
Specify the files to be uploaded.
- **Filemask**: the file names or the path to the files to be uploaded.
- **New name**: the name to give the file after the transfer.

### Connection mode
Select the connection mode from the list, either **Passive** or **Active**.

### Encoding
Specify the encoding type by selecting an encoding type from the list or selecting **CUSTOM** and enter the encoding type manually.

### Die on error
Select the check box to stop the execution of the Job when an error occurs.
Clear the check box to skip any error and continue the Job execution process.

### Advanced settings

#### Use Socks Proxy
Select this check box if you are using a proxy, and in the **Proxy host**, **Proxy port**, **Proxy user** and **Proxy password** fields displayed, specify the proxy server settings information.

#### Ignore Failure At Quit (FTP)
Select this box to ignore library closing errors or FTP closing errors.

#### Data Channel Protection Level
The data channel protection level with which data is transferred between the client and the server. For more information, see [RFC 2228: FTP Security Extensions](#).
This property is available only when the **FTPS Support** check box is selected.

#### Protection Buffer Size
The maximum size (in bytes) of the encoded data blocks to be transferred between the client and the server. For more information, see [RFC 2228: FTP Security Extensions](#).
This property is available only when the **FTPS Support** check box is selected.
**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

---

**Putting files onto an FTP server**

Here is an example of using Talend FTP components to put several files in a local directory onto an FTP server.

**Creating a Job for putting files onto an FTP server**

Create a Job to connect to an FTP server, then put several local files onto the server, finally close the connection to the server.
Procedure

1. Create a new Job and add a tFTPConnection component, a tFTPPut component, and a tFTPClose component by typing their names in the design workspace or dropping them from the Palette.
2. Link the tFTPConnection component to the tFTPPut component using a Trigger > OnSubjobOk connection.
3. Link the tFTPPut component to the tFTPClose component using a Trigger > OnSubjobOk connection.

Opening a connection to the FTP server

Configure the tFTPConnection component to open a connection to the FTP server.

Procedure

1. Double-click the tFTPConnection component to open its Basic settings view.
2. In the Host and Port fields, enter the FTP server IP address and the listening port number respectively.
3. In the Username and Password fields, enter the authentication details.
4. From the Connection Mode drop-down list, select the FTP connection mode you want to use, Active in this example.

Putting files onto the FTP server

Configure the tFTPPut component to put several local files onto the FTP server root directory.

Procedure

1. Double-click the tFTPPut component to open its Basic settings view.
   
   ![tFTPPut Component Settings](image)

   2. Specify the connection details required to access the FTP server. In this example, select the Use an existing connection check box and from the Component list drop-down list displayed, select the connection component to reuse its connection details you have already defined.
3. In the **Local directory** field, specify the local directory that contains the files to be put onto the FTP server. In this example, it is `D:\components`.

4. In the **Remote directory** field, specify the FTP server directory onto which the files will be put. In this example, it is `/`, which means the root directory of the FTP server.

5. Clear the **Move to the current directory** check box.

6. In the **Files** table, click twice the `[+]` button to add two lines, and in the two **Filemask** column fields, enter `*.txt` and `*.png` respectively, which means only the text and png files in the specified local directory will be put onto the FTP server root directory.

### Closing the connection to the FTP server

Configure the **tFTPClose** component to close the connection to the FTP server.

**Procedure**

1. Double-click the **tFTPClose** component to open its **Basic settings** view.

![tFTPClose component](image)

2. From the **Component list** drop-down list, select the **tFTPConnection** component that opens the connection you need to close. In this example, only one **tFTPConnection** component is used and it is selected by default.

### Executing the Job to put files on the FTP server

After setting up the Job and configuring the components used in the Job for putting files onto the FTP server, you can then execute the Job and verify the Job execution result.

**Procedure**

1. Press **Ctrl + S** to save the Job and then **F6** to execute the Job.
2. Connect to the FTP server to verify the result.
As shown above, only the text and png files in the local directory are put onto the FTP server.
tFTPRename

Renames files in an FTP directory.

**tFTPRename Standard properties**

These properties are used to configure tFTPRename running in the Standard Job framework.

The Standard tFTPRename component belongs to the Internet family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>

</tbody>
</table>
| **Authentication method** | Select the SFTP authentication method, either **Public key** or **Password**.  
  - **Public key**: Enter the path to the private key and the passphrase for the key in the **Private key** and **Key Passphrase** fields correspondingly.  
  - **Password**: Enter the password required.  
  This property is available only when the **SFTP Support** check box is selected. |
| **Filename encoding** | Select this check box to set the encoding used to convert file names from Strings to bytes. It should be the same encoding used on the SFTP server. If the SFTP server’s version is greater than 3, the encoding should be **UTF-8**, or else an error occurs.  
  This property is available only when the **SFTP Support** check box is selected. |
| **FTPS Support** | Select this check box to connect to the FTP server via an FTPS connection.  
  If you are using an HTTP proxy, via a tSetProxy component for example, you need to select this check box and set the connection mode to **Passive**. |
| **Keystore File** | The path to your keystore file, a password protected file containing several keys and certificates.  
  This property is available only when the **FTPS Support** check box is selected. |
| **Keystore Password** | The password for your keystore file.  
  This property is available only when the **FTPS Support** check box is selected. |
| **Security Mode** | Select the security mode from the list, either **Implicit** or **Explicit**.  
  This property is available only when the **FTPS Support** check box is selected. |
| **Files** | Specify the files to be renamed and their new names.  
  - **Filemask**: specify the file to be renamed by entering the filename or filemask using wildcharacters or regular expressions.  
  - **New name**: enter the new name of the file. |
| **Connection mode** | Select the connection mode from the list, either **Passive** or **Active**. |
### Encoding
Specify the encoding type by selecting an encoding type from the list or selecting CUSTOM and enter the encoding type manually.

### Die on error
Select the check box to stop the execution of the Job when an error occurs.
Clear the check box to skip any error and continue the Job execution process.

### Advanced settings

#### Use Socks Proxy
Select this check box if you are using a proxy, and in the Proxy host, Proxy port, Proxy user and Proxy password fields displayed, specify the proxy server settings information.

#### Ignore Failure At Quit (FTP)
Select this check box to ignore library closing errors or FTP closing errors.

#### Data Channel Protection Level
The data channel protection level with which data is transferred between the client and the server. For more information, see RFC 2228: FTP Security Extensions.
This property is available only when the FTPS Support check box is selected.

#### Protection Buffer Size
The maximum size (in bytes) of the encoded data blocks to be transferred between the client and the server. For more information, see RFC 2228: FTP Security Extensions.
This property is available only when the FTPS Support check box is selected.

#### tStatCatcher Statistics
Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

#### ERROR_MESSAGE
The error message generated by the component when an error occurs. This is an After variable and it returns a string.

#### NB_FILE
The number of the files processed. This is an After variable and it returns an integer.

#### CURRENT_STATUS
The execution result of the component. This is a Flow variable and it returns a string.

### Usage

#### Usage rule
This component is generally used as a subJob with one component, but it can also be used as an output or end component.

### Renaming a file located on an FTP server
Here is an example of using Talend FTP components to rename a file located on an FTP server.
**Creating a Job for renaming a file on an FTP server**

Create a Job to connect to an FTP server, then rename a file on the server, finally close the connection to the server.

---

**Before you begin**

**Prerequisites:** To replicate this scenario, an FTP server must be started and a file must be put onto the server. In this example, the file `movies.json` has been put into the folder `movies` under the root directory of the FTP server.

---

**Procedure**

1. Create a new Job and add a `tFTPConnection` component, a `tFTPRename` component, and a `tFTPClose` component by typing their names in the design workspace or dropping them from the Palette.
2. Link the `tFTPConnection` component to the `tFTPRename` component using a `Trigger > OnSubjobOk` connection.
3. Link the `tFTPRename` component to the `tFTPClose` component using a `Trigger > OnSubjobOk` connection.

**Opening a connection to the FTP server**

Configure the `tFTPConnection` component to open a connection to the FTP server.
Procedure

1. Double-click the **tFTPConnection** component to open its **Basic settings** view.
2. In the **Host** and **Port** fields, enter the FTP server IP address and the listening port number respectively.
3. In the **Username** and **Password** fields, enter the authentication details.

Renaming the file on the FTP server

Configure the **tFTPRename** component to rename the file on the FTP server.

Procedure

1. Double-click the **tFTPRename** component to open its **Basic settings** view.

   ![Image of tFTPRename component]

   1. **Property Type**: Built-In
   2. **Use an existing connection**: Check box
   3. **Remote directory**: /movies
   4. **Filemask**: movies.json
   5. **New name**: action_movies.json
   6. **Files** table
   7. **Move to the current directory**: Check box

2. Specify the connection details required to access the FTP server. In this example, select the **Use an existing connection** check box and from the **Component list** drop-down list displayed, select the connection component to reuse its connection details you have already defined.
3. In the **Remote directory** field, enter the directory on the FTP server where the file to be renamed exists. In this example, it is /movies.
4. Clear the **Move to the current directory** check box.
5. In the **Files** table, click the `[+]` button to add a line, and then enter the existing file name in the **Filemask** column field and the new file name in the **New name** column field. In this example, they are movies.json and action_movies.json respectively.

Closing the connection to the FTP server

Configure the **tFTPClose** component to close the connection to the FTP server.

Procedure

1. Double-click the **tFTPClose** component to open its **Basic settings** view.

   ![Image of tFTPClose component]
2. From the Component list drop-down list, select the tFTPConnection component that opens the connection you need to close. In this example, only one tFTPConnection component is used and it is selected by default.

**Executing the Job to rename the file on the FTP server**

After setting up the Job and configuring the components used in the Job for renaming the file on the FTP server, you can then execute the Job and verify the Job execution result.

**Procedure**

1. Press Ctrl + S to save the Job and then F6 to execute the Job.
2. Connect to the FTP server to verify the result.

As shown above, the file on the FTP server has been renamed from movies.json to action_movies.json.
tFTPTruncate

Truncates files in an FTP directory.

**tFTPTruncate Standard properties**

These properties are used to configure tFTPTruncate running in the Standard Job framework.

The Standard tFTPTruncate component belongs to the Internet family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Property Type</strong></td>
<td>Select the way the connection details will be set.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Built-In</strong>: The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Repository</strong>: The connection details stored centrally in Repository &gt; Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up Repository Content dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in.</td>
</tr>
<tr>
<td><strong>Use an existing connection</strong></td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td><strong>Host</strong></td>
<td>The IP address or hostname of the FTP server.</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>The listening port number of the FTP server.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>The user authentication data to access the FTP server. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Remote directory</strong></td>
<td>The path to the FTP directory in which the files will be truncated.</td>
</tr>
<tr>
<td><strong>Move to the current directory</strong></td>
<td>Select this check box to change the directory to the one specified in the Remote directory field. The next FTP component in the Job will take this directory as the root of the remote directory when using the same connection. This property is available only when the Use an existing connection check box is selected.</td>
</tr>
<tr>
<td><strong>SFTP Support</strong></td>
<td>Select this check box to connect to the FTP server via an SFTP connection.</td>
</tr>
</tbody>
</table>
**Authenication method**
Select the SFTP authentication method, either **Public key** or **Password**.
- **Public key**: Enter the path to the private key and the passphrase for the key in the **Private key** and **Key Passphrase** fields correspondingly.
- **Password**: Enter the password required.
This property is available only when the **SFTP Support** check box is selected.

**Filename encoding**
Select this check box to set the encoding used to convert file names from Strings to bytes. It should be the same encoding used on the SFTP server. If the SFTP server’s version is greater than 3, the encoding should be **UTF-8**, or else an error occurs.
This property is available only when the **SFTP Support** check box is selected.

**FTPS Support**
Select this check box to connect to the FTP server via an FTPS connection.
If you are using an HTTP proxy, via a tSetProxy component for example, you need to select this check box and set the connection mode to **Passive**.

**Keystore File**
The path to your keystore file, a password protected file containing several keys and certificates.
This property is available only when the **FTPS Support** check box is selected.

**Keystore Password**
The password for your keystore file.
This property is available only when the **FTPS Support** check box is selected.

**Security Mode**
Select the security mode from the list, either **Implicit** or **Explicit**.
This property is available only when the **FTPS Support** check box is selected.

**Use Perl5 Regex Expression as Filemask**
Select this check box to use Perl5 regular expressions in the **Files** field as file filters. This is useful when the name of the file to be processed contains special characters such as parentheses.
For more information about Perl5 regular expression syntax, see [Perl5 Regular Expression Syntax](#).

**Files**
The names of the files or the paths to the files to be truncated. You can specify multiple files in a line by using wildcards or a regular expression.

**Connection mode**
Select the connection mode from the list, either **Passive** or **Active**.
### Encoding

Specify the encoding type by selecting an encoding type from the list or selecting **CUSTOM** and enter the encoding type manually.

### Advanced settings

</tbody>
</table>

### Related scenario

No scenario is available for this component yet.
tFuzzyMatch

Compares a column from the main flow with a reference column from the lookup flow and outputs the main flow data displaying the distance.

**tFuzzyMatch Standard properties**

These properties are used to configure tFuzzyMatch running in the Standard Job framework.

The Standard tFuzzyMatch component belongs to the Data Quality family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Schema and Edit schema</th>
<th>A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either Built-in or stored remotely in the Repository. Two read-only columns, Value and Match are added to the output schema automatically.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Built-in: The schema will be created and stored locally for this component only. Related topic: see Talend Studio User Guide.</td>
<td></td>
</tr>
<tr>
<td>Repository: The schema already exists and is stored in the Repository, hence can be reused in various projects and job designs. Related topic: see Talend Studio User Guide.</td>
<td></td>
</tr>
</tbody>
</table>

**Matching type**

Select the relevant matching algorithm among:

- **Levenshtein**: Based on the edit distance theory. It calculates the number of insertion, deletion or substitution required for an entry to match the reference entry.
- **Metaphone**: Based on a phonetic algorithm for indexing entries by their pronunciation. It first loads the phonetics of all entries of the lookup reference and checks all entries of the main flow against the entries of the reference flow.
- **Double Metaphone**: a new version of the Metaphone phonetic algorithm, that produces more accurate results than the original algorithm. It can return both a primary and a secondary code for a string. This accounts for some ambiguous cases as well as for multiple variants of surnames with common ancestry.

**Min distance**

(Levenshtein only) Set the minimum number of changes allowed to match the reference. If set to 0, only perfect matches are returned.

**Max distance**

(Levenshtein only) Set the maximum number of changes allowed to match the reference.

**Matching column**

Select the column of the main flow that needs to be checked against the reference (lookup) key column.
Unique matching
Select this check box if you want to get the best match possible, in case several matches are available.

Matching item separator
In case several matches are available, all of them are displayed unless the unique match box is selected. Define the delimiter between all matches.

Advanced settings

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_LINE: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td></td>
<td>For further information about variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

Usage

| Usage rule | This component is not startable (green background) and it requires two input components and an output component. |

Checking the Levenshtein distance of 0 in first names

This scenario describes a four-component Job aiming at checking the edit distance between the First Name column of an input file with the data of the reference input file. The output of this Levenshtein type check is displayed along with the content of the main flow on a table.
**Setting up the Job**

**Procedure**

1. Drag and drop the following components from the **Palette** to the design workspace: **tFileInputDelimited** (x2), **tFuzzyMatch**, **tLogRow**.
2. Link the first **tFileInputDelimited** component to the **tFuzzyMatch** component using a **Row > Main** connection.
3. Link the second **tFileInputDelimited** component to the **tFuzzyMatch** using a **Row > Main** connection (which appears as a **Lookup** row on the design workspace).
4. Link the **tFuzzyMatch** component to the standard output **tLogRow** using a **Row > Main** connection.

**Configuring the components**

**Procedure**

1. Define the first **tFileInputDelimited** in its **Basic settings** view. Browse the system to the input file to be analyzed.
2. Define the schema of the component. In this example, the input schema has two columns, **firstname** and **gender**.
3. Define the second **tFileInputDelimited** component the same way.

**Warning:**

*Make sure the reference column is set as key column in the schema of the lookup flow.*

4. Double-click the **tFuzzyMatch** component to open its **Basic settings** view, and check its schema. The **Schema** should match the **Main** input flow schema in order for the main flow to be checked against the reference.
Note that two columns, **Value** and **Matching**, are added to the output schema. These are standard matching information and are read-only.

5. Select the method to be used to check the incoming data. In this scenario, *Levenshtein* is the **Matching type** to be used.

6. Then set the distance. In this method, the distance is the number of char changes (insertion, deletion or substitution) that needs to be carried out in order for the entry to fully match the reference.

In this use case, we set both the minimum distance and the maximum distance to 0. This means only the exact matches will be output.

7. Also, clear the **Case sensitive** check box.

8. Check that the matching column and look up column are correctly selected.

9. Leave the other parameters as default.

### Executing the Job

**Procedure**

Save the Job and press **F6** to execute the Job.
Results

As the edit distance has been set to 0 (min and max), the output shows the result of a regular join between the main flow and the lookup (reference) flow, hence only full matches with Value of 0 are displayed.

A more obvious example is with a minimum distance of 1 and a maximum distance of 2, see Procedure on page 1255

Checking the Levenshtein distance of 1 or 2 in first names

This scenario is based on the scenario described above. Only the minimum and maximum distance settings in the tFuzzyMatch component are modified, which will change the output displayed.

Procedure

Procedure

1. In the Component view of the tFuzzyMatch, change the minimum distance from 0 to 1. This excludes straight away the exact matches (which would show a distance of 0).
2. Change also the maximum distance to 2. The output will provide all matching entries showing a discrepancy of 2 characters at most.

No other changes are required.
3. Make sure the **Matching item separator** is defined, as several references might be matching the main flow entry.

4. Save the new Job and press **F6** to run it.

As the edit distance has been set to 2, some entries of the main flow match more than one reference entry.

**Results**

You can also use another method, the metaphone, to assess the distance between the main flow and the reference, which will be described in the next scenario.

**Checking the Metaphonic distance in first name**

This scenario is based on the scenario described above.

**Procedure**

1. Change the **Matching type** to **Metaphone**. There is no minimum nor maximum distance to set as the matching method is based on the discrepancies with the phonetics of the reference.

2. Save the Job and press **F6**. The phonetics value is displayed along with the possible matches.

**Global Variables**

| **ERROR_MESSAGE** | The error message generated by the component when an error occurs. This is an After variable and it returns a string. |
Usage

| Usage rule | This component is more commonly used with other Google Drive components. In a Job design, it is usually used to open a Google Drive connection that can be reused by other Google Drive components. |

OAuth methods for accessing Google Drive

Talend provides the following four OAuth methods to access Google Drive using Google Drive components and metadata wizard.

- Installed Application (Id & Secret)
- Installed Application (JSON)
- Service Account
- Access Token (deprecated)

How to access Google Drive using client ID and secret

To use client ID and client secret to access Google Drive, you need to first generate the client ID and client secret by completing the following steps using Google Chrome.

Before you begin

A Google account has already been signed up for using Google Drive.

Procedure

1. Go to Google API Console and select an existing project or create a new one. In this example, we create a new project TalendProject.

2. Go to the Library page and in the right panel, find Google Drive API and enable the Google Drive API that allows you to access resources from Google Drive.
3. Go to the Credentials page, click **OAuth consent screen** in the right panel and set a product name in the **Product name shown to users** field. In this example, it is **TalendProduct**. When done, click **Save**.
4. Click Create credentials > OAuth client ID, and in the Create client ID page, create a new client ID TalendApplication with Application type set to Other.
5. Click **Create**. You will be shown your client ID and client secret that can be used by Google Drive components and metadata wizard to access Google Drive using the OAuth method **Installed Application (Id & Secret)**.

**How to access Google Drive using a client secret JSON file**

To use a client secret JSON file to access Google Drive, you need to first download the client secret JSON file from Google API Console by completing the following steps using Google Chrome.
Before you begin

The client ID and client secret have been created in Google API Console. For more information, see How to access Google Drive using client ID and secret on page 1262.

Procedure

1. Go to Google API Console.
2. Go to the Credentials page.
3. Click the Download JSON button to download the client secret JSON file and securely store it in a local folder. This JSON file can then be used by Google Drive components and metadata wizard to access Google Drive via the OAuth method Installed Application (JSON).

How to access Google Drive using a service account JSON file

To use a service account JSON file to access Google Drive, you need to first create a service account in Google API Console, then download the service account JSON file by completing the following steps using Google Chrome.

Before you begin

1. A Google account has already been signed up for using Google Drive.
2. In Google API Console, your project has been created, the Google Drive API has been enabled, and the product name has been set. For more information about how to make these configuration, see How to access Google Drive using client ID and secret on page 1262.

Procedure

1. Go to Google API Console.
2. Open the Service accounts page. If prompted, select your project.
3. Click CREATE SERVICE ACCOUNT.

4. In the Create service account window, type a name for the service account, select Furnish a new private key and then the key type JSON.
5. Click **Create**. In the pop-up window, choose a folder and click **Save** to store your service account JSON file securely. This JSON file can then be used by Google Drive components and metadata wizard to access Google Drive via the OAuth method **Service Account**.

**How to access Google Drive using an access token (deprecated)**

To use an access token to access Google Drive, you need to first generate the access token by completing the following steps using Google Developers OAuth Playground.

**Before you begin**

1. A Google account has already been signed up for using Google Drive.
2. The client ID and client secret have been created in Google API Console. For more information, see **How to access Google Drive using client ID and secret** on page 1262.

**Procedure**

1. Go to Google Developers OAuth Playground.
2. Click **OAuth 2.0 Configuration** and select **Use your own OAuth credentials** check box, enter the OAuth client ID and client secret you have already created in the **OAuth Client ID** and **OAuth Client secret** fields respectively.
3. In OAuth 2.0 Playground Step 1, select the scope https://www.googleapis.com/auth/drive under Drive API v3 for the Google Drive API and click Authorize APIs, then click Allow to generate the authorization code.
4. In OAuth 2.0 Playground Step 2, click Exchange authorization code for tokens to generate the OAuth access token.

The OAuth access token is displayed on the right panel as shown in below figure. It can be used by Google Drive components and metadata wizard to access Google Drive via the OAuth method Access Token.
Note that the access token expires in every 3600 seconds. You can click **Refresh access token** in **OAuth 2.0 Playground Step 2** to refresh it.

</tr>
</tbody>
</table>

For more detailed information about how to access Google Drive using each method, see OAuth methods for accessing Google Drive on page 1262.
| **Access Token** | The access token generated through Google Developers OAuth 2.0 Playground. This property is available only when Access Token is selected from the OAuth Method drop-down list. |
| **Client ID and Client Secret** | The client ID and client secret. These two properties are available only when Installed Application (Id & Secret) is selected from the OAuth Method drop-down list. |
| **Client Secret JSON** | The path to the client secret JSON file. This property is available only when Installed Application (JSON) is selected from the OAuth Method drop-down list. |
| **Service Account JSON** | The path to the service account JSON file. This property is available only when Service Account is selected from the OAuth Method drop-down list. |
| **Use Proxy** | Select this check box when you are working behind a proxy. With this check box selected, you need to specify the value for the following parameters:  
  - **Host**: The IP address of the HTTP proxy server.  
  - **Port**: The port number of the HTTP proxy server. |
| **Use SSL** | Select this check box if an SSL connection is used to access Google Drive. With this check box selected, you need to specify the value for the following parameters:  
  - **Algorithm**: The name of the SSL cryptography algorithm.  
  - **Keystore File**: The path to the certificate TrustStore file that contains the list of certificates the client trusts.  
  - **Password**: The password used to check the integrity of the TrustStore data. |
| **Copy Mode** | Select the type of the item to be copied.  
  - **File**: Select this option when you need to copy a file.  
  - **Folder**: Select this option when you need to copy a folder. |
| **Source** | The name or ID of the source file/folder to be copied. |
| **Source Access Mode** | Select the method by which the source file/folder is specified, either by Name or by Id. |
| **Destination Folder Name** | The name or ID of the destination folder in which the copy of the source file/folder will be saved. |
| **Destination Access Mode** | Select the method by which the destination folder is specified, either by Name or by Id. |
| **Rename (set new title)** | Select this check box to rename the copy of the file/folder in the destination folder. In the Destination Name field displayed, enter the name for the file/folder after being copied to the destination folder. |
Remove Source File

Select this check box to remove the source file after it is copied to the destination folder.

This property is available only when **File** is selected from the **Copy Mode** drop-down list.

Schema and **Edit schema**

A schema is a row description, and it defines the fields to be processed and passed on to the next component.

The schema of this component is read-only. You can click the [...] button next to **Edit schema** to view the predefined schema which contains the following fields:

- **sourceId**: The ID of the source file/folder.
- **destinationId**: The ID of the destination file/folder.

**Advanced settings**

**DataStore Path**

The path to the credential file that stores the refresh token.

**Note**: When your client ID, client secret, or any other configuration related to the Installed Application authentication changes, you need to delete this credential file manually before running your Job again.

This property is available only when **Installed Application (Id & Secret)** or **Installed Application (JSON)** is selected from the **OAuth Method** drop-down list.

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

**Global Variables**

**ERROR_MESSAGE**

The error message generated by the component when an error occurs. This is an After variable and it returns a string.

**SOURCE_ID**

The ID of the source file/folder. This is an After variable and it returns a string.

**DESTINATION_ID**

The ID of the destination file/folder. This is an After variable and it returns a string.

**Usage**

**Usage rule**

This component can be used as a standalone component or as a start component of a Job or Subjob.

**Related scenario**

| **File Name** | The name for the file after being uploaded. |
| **Destination Folder** | The name or ID of the folder in which uploaded data will be stored. |
| **Access Method** | Select the method by which the destination folder is specified, either by Name or by Id. |
| **Replace if Existing** | Select this check box to overwrite any existing file with the newly uploaded one. |
| **Upload Mode** | Select one of the following upload modes from the drop-down list:  
  - **Upload Incoming content as File**: Select this option to upload data from an input flow of the preceding component.  
  - **Upload Local File**: Select this option to upload data from a local file. In the File field displayed, specify the path to the file to be uploaded. |
- **Expose As OutputStream**: Select this option to expose output stream of this component, which can be used by other components to write the file content. For example, you can use the Use OutputStream feature of the `tFileOutputDelimited` component to feed a given `tGoogleDrivePut`'s exposed output stream. For more information, see `tFileOutputDelimited` on page 1106.

### Schema and Edit schema

A schema is a row description, and it defines the fields to be processed and passed on to the next component.

The schema of this component is read-only. You can click the [...] button next to Edit schema to view the predefined schema which contains the following fields:

- **content**: The content of the uploaded data.
- **parentFolderId**: The ID of the parent folder.
- **fileId**: The ID of the file.

### Advanced settings

**DataStore Path**

The path to the credential file that stores the refresh token.

*Note*: When your client ID, client secret, or any other configuration related to the Installed Application authentication changes, you need to delete this credential file manually before running your Job again.

This property is available only when Installed Application (Id & Secret) or Installed Application (JSON) is selected from the OAuth Method drop-down list.

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

</tr>
<tr>
<td><code>FILE_ID</code></td>
<td>The ID of the file. This is an After variable and it returns a string.</td>
</tr>
</tbody>
</table>

### Usage

**Usage rule**

This component can be used as a standalone component to upload a local file to Google Drive or an end component to upload data from an input flow of the preceding component to Google Drive.
Managing files with Google Drive

This scenario describes a Job that uploads two files to an empty folder Talend in the root directory of Google Drive, then creates a new folder Talend Backup in the root directory and copies one of the two files to the new folder Talend Backup, and finally lists and displays all files and folders in the root directory of Google Drive on the console.

Creating a Job for managing files with Google Drive

Procedure
1. Create a new Job and add a tGoogleDriveConnection component, two tGoogleDrivePut components, a tFileInputRaw component, a tGoogleDriveCreate component, a tGoogleDriveCopy component, a tGoogleDriveList component, and five tLogRow components to the Job.
2. Link the first tGoogleDrivePut component to the first tLogRow component using a Row > Main connection.

3. Do the same to link the tFileInputRaw component to the second tGoogleDrivePut component, the second tGoogleDrivePut component to the second tLogRow component, the tGoogleDriveCreate component to the third tLogRow component, the tGoogleDriveCopy component to the fourth tLogRow component, the tGoogleDriveList component to the fifth tLogRow component.

4. Link the tGoogleDriveConnection component to the first tGoogleDrivePut component using a Trigger > On Subjob Ok connection.

5. Do the same to link the first tGoogleDrivePut component to the tFileInputRaw component, the tFileInputRaw component to the tGoogleDriveCreate component, the tGoogleDriveCreate component to the tGoogleDriveCopy component, and the tGoogleDriveCopy component to the tGoogleDriveList component.

**Opening a connection to Google Drive**

Configure the tGoogleDriveConnection component to connect to Google Drive using a client secret JSON file.
Before you begin

- The client secret JSON file has been downloaded into a local folder through Google API Console. For more information, see How to access Google Drive using a client secret JSON file on page 1265.
- An empty folder Talend has been created in the root directory of Google Drive.

Procedure

1. Double-click the tGoogleDriveConnection component to open its Basic settings view in the Component tab.

2. In the Application Name field, enter the application name required by Google Drive to get access to its API. In this example, it is TalendProject.

3. Select Installed Application (JSON) from the OAuth Method drop-down list.

4. In the Client Secret JSON field, specify the path to the client secret JSON file you have generated, D:/client_secret.json in this example.

Uploading files to Google Drive

Procedure

1. Double-click the first tGoogleDrivePut component to open its Basic settings view in the Component tab.
2. Select the component that will create the Google Drive connection from the **Connection Component** drop-down list, `tGoogleDriveConnection_1` in this example.

3. Select **by Name** from the **Access Method** drop-down list and in the **Destination Folder** field, enter the name of the folder in which the file will be uploaded, *Talend* in this example.

   **Note:** When accessing a Google Drive resource by its name, if the name matches more than one resource, an error will be thrown because the resource cannot be identified precisely. In this case, you can specify the Google Drive resource using a pseudo path hierarchy, like `/Talend/Documentation`. This example specifies a folder named *Documentation* under the folder *Talend* under the Google Drive root folder.

4. In the **File Name** field, enter the name for the file after being uploaded. In this example, it is *Talend Customers.csv*.

5. Select **Upload Local File** from the **Upload Mode** drop-down list and in the **File** field, browse to or enter the path to the file to be uploaded. In this example, it is `D:/Downloads/Talend Customers.csv`.

6. Double-click the `tFileInputRaw` component and on its **Basic settings** view, select **Read the file as a bytes array** in the **Mode** area and specify the path to the file whose content will be uploaded in the **Filename** field, `D:/Downloads/Talend Products.txt` in this example.

7. Double-click the second `tGoogleDrivePut` component to open its **Basic settings** view in the **Component** tab.

   ![tGoogleDrivePut](image)

8. Repeat step 2 on page 1293 to step 3 on page 1293 to configure this component.

9. In the **File Name** field, enter the name for the file after being uploaded. In this example, it is *Talend Products.txt*.

10. Select **Upload Incoming content as File** from the **Upload Mode** drop-down list.
Creating a new folder in Google Drive

Procedure
1. Double-click **tGoogleDriveCreate** to open its **Basic settings** view in the **Component** tab.

   ![GoogleDriveCreate](image)

   - **Connection Component**: tGoogleDriveConnection_1
   - **Parent Folder**: root
   - **New Folder Name**: Talend Backup
   - **Access Method**: by Name

2. Select the component that will create the Google Drive connection from the Connection Component drop-down list, **tGoogleDriveConnection_1** in this example.
3. In the **Parent Folder** field, enter the name of the folder in which a new folder will be created. In this example, it is root.
4. In the **New Folder Name** field, enter the name of the folder to be created. In this example, it is Talend Backup.
5. Double-click the third **tLogRow** component to open its **Basic settings** view in the **Component** tab.
6. In the **Mode** area, select **Vertical (each row is a key/value list)** for a better display of the results.

Copying a file to the newly created folder

Procedure
1. Double-click the **tGoogleDriveCopy** component to open its **Basic settings** view in the **Component** tab.

   ![GoogleDriveCopy](image)

   - **Connection Component**: tGoogleDriveConnection_1
   - **Copy Mode**: File
   - **Source**: Talend Customers.csv
   - **Access Method**: by Name
   - **Destination Folder Name**: Talend Backup
   - **Access Method**: by Name
   - **Destination Name**: Talend Customers v1.0.csv
   - **Rename (set new title)**
   - **Remove Source File**
   - **Schema**: Built-In

2. Select the component that will create the Google Drive connection from the Connection Component drop-down list, **tGoogleDriveConnection_1** in this example.
3. Select **File** from the **Copy Mode** drop-down list.
4. In the **Source** field, enter the name of the file to be copied. In this example, it is Talend Customers.csv.
5. In the **Destination Folder Name** field, enter the name of the folder to which the file will be copied. In this example, it is Talend Backup.
6. Select the **Rename (set new title)** check box and in the **Destination Name** field, enter a new name for the file after being copied to the destination folder. In this example, it is Talend Customers v1.0.csv.
7. Double-click the fourth tLogRow component to open its Basic settings view in the Component tab.

8. In the Mode area, select Vertical (each row is a key/value list) for a better display of the results.

Listing files and folders in Google Drive

Procedure

1. Double-click the tGoogleDriveList component to open its Basic settings view in the Component tab.

   ![tGoogleDriveList_1](image)

   - Connection Component: tGoogleDriveConnection_1
   - Folder Name: "root"
   - Access Method: by Name
   - FileList Type: Both
   - Include SubDirectories
   - Schema: Built-In

2. Select the component that will create the Google Drive connection from the Connection Component drop-down list, tGoogleDriveConnection_1 in this example.

3. In the Folder Name field, enter the name of the folder in which the files/folders will be listed. In this example, it is the root directory of Google Drive and you can use the alias root to refer to it.

4. Select Both from the FileList Type drop-down list to list both files and folders in the root directory.

5. Select the Include SubDirectories check box to list also the files/folders in the subdirectories.

6. Double-click the fifth tLogRow component to open its Basic settings view in the Component tab.

   ![tLogRow_3](image)

   - Mode:
     - Basic
     - Table (print values in cells of a table)
     - Vertical (each row is a key/value list)

7. In the Mode area, select Vertical (each row is a key/value list) for a better display of the results.

Saving and executing the Job

Procedure

1. Press Ctrl + S to save the Job.

2. Execute the Job by pressing F6 or clicking Run on the Run tab.
<table>
<thead>
<tr>

</tr>
</tbody>
</table>
As shown above, two files Talend Products.txt and Talend Customers.csv were uploaded to the folder Talend, then a new folder Talend Backup was created in the root folder and the file Talend Customers.csv was copied to the new folder and renamed to Talend Customers v1.0.csv, and finally all files and folders in the root directory are listed on the console.
**tGPGDecrypt**

Calls the `gpg -d` command to decrypt a GnuPG-encrypted file and saves the decrypted file in the specified directory.

**tGPGDecrypt Standard properties**

These properties are used to configure tGPGDecrypt running in the Standard Job framework.

The Standard tGPGDecrypt component belongs to the File family.

The component in this framework is available in all Talend products.

</tr>
</tbody>
</table>
Usage

Usage rule

This component can be used as a standalone component.

Decrypting a GnuPG-encrypted file and display its content

The following scenario describes a three-component Job that decrypts a GnuPG-encrypted file and displays the content of the decrypted file on the Run console.

Dragging and linking the components

Procedure

1. Drop a tGPGDecrypt component, a tFileInputDelimited component, and a tLogRow component from the Palette to the design workspace.

2. Connect the tGPGDecrypt component to the tFileInputDelimited component using a Trigger > OnSubjobOk link, and connect the tFileInputDelimited component to the tLogRow component using a Row > Main link.

Configuring the components

Procedure

1. Double-click the tGPGDecrypt to open its Component view and set its properties:
2. In the **Input encrypted file** field, browse to the file to be decrypted.

3. In the **Output decrypted file** field, enter the path to the decrypted file.

**Warning:**
If the file path contains accented characters, you will get an error message when running the Job.

4. In the **GPG binary path** field, browse to the GPG command file.

5. In the **Passphrase** field, enter the passphrase used when encrypting the input file.

6. Double-click the **tFileInputDelimited** component to open its **Component** view and set its properties:

7. In the **File name/Stream** field, define the path to the decrypted file, which is the output path you have defined in the **tGPGDecrypt** component.

8. In the **Header**, **Footer** and **Limit** fields, define respectively the number of rows to be skipped in the beginning of the file, at the end of the file and the number of rows to be processed.

9. Use a **Built-In** schema. This means that it is available for this Job only.

10. Click **Edit schema** and edit the schema for the component. Click twice the [*+*] button to add two columns that you will call **idState** and **labelState**.

11. Click **OK** to validate your changes and close the editor.
12. Double-click the **tLogRow** component and set its properties:

13. Use a **Built-In** schema for this scenario.

14. In the **Mode** area, define the console display mode according to your preference. In this scenario, select **Table (print values in cells of a table)**.

### Saving and executing the Job

**Procedure**

1. Press **Ctrl+S** to save your Job
2. Press **F6** or click **Run** from the **Run** tab to run it.

```plaintext
Starting job tGPGDecrypt at 18:19 17/11/2010.
[statistics] connecting to socket on port 3990
[statistics] connected
----------
tLogRow_1
----------
iState|labelState
----------
1    |Alabama
2    |Alaska
3    |Arizona
4    |Arkansas
5    |California
6    |Colorado
7    |Connecticut
8    |Delaware
9    |Florida
10   |Georgia
----------
[statistics] disconnected
job tGPGDecrypt ended at 18:49 17/11/2010. [exit code=0]
```
Results

The specified file is decrypted and the defined number of rows of the decrypted file are printed on the Run console.
tGreenplumBulkExec

Improves performance when loading data in a Greenplum database.

The tGreenplumOutputBulk and tGreenplumBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT statement used to feed a database. These two steps are fused together in the tGreenplumOutputBulkExec component, detailed in a separate section. The advantage of using a two step process is that it makes it possible to transform data before it is loaded in the database.

tGreenplumBulkExec performs an Insert action on the data.

**tGreenplumBulkExec Standard properties**

These properties are used to configure tGreenplumBulkExec running in the Standard Job framework. The Standard tGreenplumBulkExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
<td></td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
<table>
<thead>
<tr>
<th><strong>Host</strong></th>
<th>Database server IP address.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database.</td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>Exact name of the schema.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Table</strong></td>
<td>Name of the table to be written. Note that only one table can be written at a time</td>
</tr>
</tbody>
</table>
| **Action on table**      | On the table defined, you can perform one of the following operations:  
  * **None**: No operation is carried out.  
  * **Drop and create a table**: The table is removed and created again.  
  * **Create a table**: The table does not exist and gets created.  
  * **Create a table if not exists**: The table is created if it does not exist.  
  * **Drop a table if exists and create**: The table is removed if it already exists and created again.  
  * **Clear a table**: The table content is deleted. |
| **Filename**             | Name of the file to be loaded. |
| **Warning:**             | This file is located on the machine specified by the URI in the **Host** field so it should be on the same machine as the database server. |
| **Schema and Edit Schema**| A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. |
| **Built-In**             | You create and store the schema locally for this component only. |
| **Repository**           | You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.  
  When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.  
  You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)). |
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

### Advanced settings

</tr>
</thead>
</table>
example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

### Related scenarios

For more information about **tGreenplumBulkExec**, see:

- Inserting transformed data in MySQL database on page 2493.
- Inserting data in bulk in MySQL database on page 2500.
- Truncating and inserting file data into an Oracle database on page 2700.
tGreenplumClose

Closes a connection to the Greenplum database.

**tGreenplumClose Standard properties**

These properties are used to configure tGreenplumClose running in the Standard Job framework.

The Standard tGreenplumClose component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>

For more information on Dynamic settings and context variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

1307
Related scenarios

No scenario is available for the Standard version of this component yet.
tGreenplumCommit

Commits global transaction in one go instead of repeating the operation for every row or every batch and thus provides gain in performance.

tGreenplumCommit validates the data processed through the Job into the connected DB. This component uses an unique connection.

**tGreenplumCommit Standard properties**

These properties are used to configure tGreenplumCommit running in the Standard Job framework.

The Standard tGreenplumCommit component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tGreenplumConnection component in the list if more than one connection are planned for the current Job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Warning:**
If you want to use a `Row > Main` connection to link tGreenplumCommit to your Job, your data will be committed row by row. In this case, do not select the Close connection check box or your connection will be closed before the end of your first row commit.

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is more commonly used with other tGreenplum components, especially with the tGreenplumConnection and tGreenplumRollback components. |
| Dynamic settings | Click the `[+]` button to add a row in the table and fill the Code field with a context variable to choose your database |
connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenarios

For tGreenplumCommit related scenarios, see:

- Mapping data using a simple implicit join on page 680.
- Inserting data in mother/daughter tables on page 2437.
**tGreenplumConnection**

Opens a connection to the specified database that can then be reused in the subsequent subjob or subjobs.

`tGreenplumConnection` opens a connection to the database for a current transaction.

**tGreenplumConnection Standard properties**

These properties are used to configure `tGreenplumConnection` running in the Standard Job framework. The Standard `tGreenplumConnection` component belongs to the Databases and the ELT families.

The component in this framework is available in all **Talend products**.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td><strong>Property type</strong></td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Host</strong></td>
<td>Database server IP address.</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database.</td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>Exact name of the schema.</td>
</tr>
<tr>
<td><strong>Username</strong> and <strong>Password</strong></td>
<td>DB user authentication data.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field,</td>

</tr>
<tr>
<td><strong>Use or register a shared DB Connection</strong></td>
<td>Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the <strong>Shared DB Connection Name</strong> field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child. This option is incompatible with the <strong>Use dynamic job</strong> and <strong>Use an independent process to run subjob</strong> options of the</td>
</tr>
</tbody>
</table>
**tGreenplumConnection**

**tRunJob** component. Using a shared connection together with a **tRunJob** component with either of these two options enabled will cause your Job to fail.

### Advanced settings

| **Auto Commit** | Select this check box to commit any changes to the database automatically upon the transaction. With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component. Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component. |

| **tStatCatcher Statistics** | Select this check box to gather the job processing metadata at a Job level as well as at each component level. |

### Usage

| **Usage rule** | This component is more commonly used with other tGreenplum* components, especially with the **tGreenplumCommit** and **tGreenplumRollback** components. |

### Related scenarios

For **tGreenplumConnection** related scenarios, see:

- Mapping data using a simple implicit join on page 680.
- **tMysqlConnection** on page 2436.
**tGreenplumGPLoad**

Bulk loads data into a Greenplum table either from an existing data file, an input flow, or directly from a data flow in streaming mode through a named-pipe.

*tGreenplumGPLoad* inserts data into a Greenplum database table using Greenplum’s *gpload* utility.

**tGreenplumGPLoad Standard properties**

These properties are used to configure *tGreenplumGPLoad* running in the Standard Job framework. The Standard *tGreenplumGPLoad* component belongs to the Databases family. The component in this framework is available in all *Talend products*.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-in or Repository</th>
</tr>
</thead>
<tbody>
<tr>
<td><em>Host</em></td>
<td>Database server IP address.</td>
</tr>
<tr>
<td><em>Port</em></td>
<td>Listening port number of the DB server.</td>
</tr>
<tr>
<td><em>Database</em></td>
<td>Name of the Greenplum database.</td>
</tr>
<tr>
<td><em>Schema</em></td>
<td>Exact name of the schema.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><em>Table</em></td>
<td>Name of the table into which the data is to be inserted.</td>
</tr>
<tr>
<td><em>Action on table</em></td>
<td>On the table defined, you can perform one of the following operations before loading the data:</td>
</tr>
<tr>
<td></td>
<td><strong>None</strong>: No operation is carried out.</td>
</tr>
<tr>
<td></td>
<td><strong>Clear table</strong>: The table content is deleted before the data is loaded.</td>
</tr>
<tr>
<td></td>
<td><strong>Create table</strong>: The table does not exist and gets created.</td>
</tr>
<tr>
<td></td>
<td><strong>Create table if not exists</strong>: The table is created if it does not exist.</td>
</tr>
<tr>
<td></td>
<td><strong>Drop and create table</strong>: The table is removed and created again.</td>
</tr>
<tr>
<td></td>
<td><strong>Drop table if exists and create</strong>: The table is removed if it already exists and created again.</td>
</tr>
<tr>
<td><strong>Truncate table:</strong></td>
<td>The table content is deleted. You do not have the possibility to rollback the operation.</td>
</tr>
</tbody>
</table>

| **Action on data** | On the data of the table defined, you can perform:  
**Insert:** Add new entries to the table. If duplicates are found, Job stops.  
**Update:** Make changes to existing entries.  
**Merge:** Updates or adds data to the table.  

**Warning:**  
*It is necessary to specify at least one column as a primary key on which the Update and Merge operations are based.*  
You can do that by clicking **Edit Schema** and selecting the check box(es) next to the column(s) you want to set as primary key(s). To define the **Update/Merge options**, select in the **Match Column** column the check boxes corresponding to the column names that you want to use as a base for the Update and Merge operations, and select in the **Update Column** column the check boxes corresponding to the column names that you want to update. To define the **Update condition**, type in the condition that will be used to update the data. |

| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word **line** when naming the fields.  
**Built-In:** You create and store the schema locally for this component only.  
**Repository:** You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.  
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
- **View schema:** choose this option to view the schema only.  
- **Change to built-in property:** choose this option to change the schema to **Built-in** for local changes.  
- **Update repository connection:** choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window. |

| **Data file** | Full path to the data file to be used. If this component is used in standalone mode, this is the name of an existing data file to be loaded into the database. If this component is connected with an input flow, this is the name of the file to be generated and written with the incoming data to later be used with gpload to load into the database. This field is hidden when the **Use named-pipe** check box is selected. |
Use named-pipe

Select this check box to use a named-pipe. This option is only applicable when the component is connected with an input flow. When this check box is selected, no data file is generated and the data is transferred to gpload through a named-pipe. This option greatly improves performance in both Linux and Windows.

**Note:**
This component on named-pipe mode uses a JNI interface to create and write to a named-pipe on any Windows platform. Therefore the path to the associated JNI DLL must be configured inside the java library path. The component comes with two DLLs for both 32 and 64 bit operating systems that are automatically provided in the Studio with the component.

**Named-pipe name**

Specify a name for the named-pipe to be used. Ensure that the name entered is valid.

**Die on error**

This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a Row > Rejects link.

### Advanced settings

#### Use existing control file (YAML formatted)

Select this check box to provide a control file to be used with the gpload utility instead of specifying all the options explicitly in the component. When this check box is selected, **Data file** and the other gpload related options no longer apply. Refer to Greenplum’s gpload manual for details on creating a control file.

**Control file**

Enter the path to the control file to be used, between double quotation marks, or click [...] and browse to the control file. This option is passed on to the gpload utility via the -f argument.

**CSV mode**

Select this check box to include CSV specific parameters such as **Escape char** and **Text enclosure**.

**Field separator**

Character, string, or regular expression used to separate fields.

**Warning:**
This is gpload’s delim argument. The default value is |. To improve performance, use the default value.

**Escape char**

Character of the row to be escaped.

**Text enclosure**

Character used to enclose text.

**Header (skips the first row of data file)**

Select this check box to skip the first row of the data file.

**Additional options**

Set the gpload arguments in the corresponding table. Click [*] as many times as required to add arguments to the table. Click the Parameter field and choose among the
arguments from the list. Then click the corresponding **Value** field and enter a value between quotation marks.

<table>
<thead>
<tr>
<th>LOCAL_HOSTNAME: The host name or IP address of the local machine on which gpload is running. If this machine is configured with multiple network interface cards (NICs), you can specify the host name or IP of each individual NIC to allow network traffic to use all NICs simultaneously. By default, the local machine’s primary host name or IP is used.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>PORT</strong> (gpfdist port): The specific port number that the gpfdist file distribution program should use. You can also specify a <strong>PORT_RANGE</strong> to select an available port from the specified range. If both <strong>PORT</strong> and <strong>PORT_RANGE</strong> are defined, then <strong>PORT</strong> takes precedence. If neither <strong>PORT</strong> or <strong>PORT_RANGE</strong> is defined, an available port between 8000 and 9000 is selected by default. If multiple host names are declared in <strong>LOCAL_HOSTNAME</strong>, this port number is used for all hosts. This configuration is desired if you want to use all NICs to load the same file or set of files in a given directory location.</td>
</tr>
<tr>
<td><strong>PORT_RANGE</strong>: Can be used instead of <strong>PORT</strong> (gpfdist port) to specify a range of port numbers from which gpload can choose an available port for this instance of the gpfdist file distribution program.</td>
</tr>
<tr>
<td><strong>NULL_AS</strong>: The string that represents a null value. The default is '\N' (backslash-N) in TEXT mode, and an empty value with no quotation marks in CSV mode. Any source data item that matches this string will be considered a null value.</td>
</tr>
<tr>
<td><strong>FORCE_NOT_NULL</strong>: In CSV mode, processes each specified column as though it were quoted and hence not a NULL value. For the default null string in CSV mode (nothing between two delimiters), this causes missing values to be evaluated as zero-length strings.</td>
</tr>
<tr>
<td><strong>ERROR_LIMIT</strong> (2 or higher): Enables single row error isolation mode for this load operation. When enabled and the error limit count is not reached on any Greenplum segment instance during input processing, all good rows will be loaded and input rows that have format errors will be discarded or logged to the table specified in <strong>ERROR_TABLE</strong> if available. When the error limit is reached, input rows that have format errors will cause the load operation to abort. Note that single row error isolation only applies to data rows with format errors, for example, extra or missing attributes, attributes of a wrong data type, or invalid client encoding sequences. Constraint errors, such as primary key violations, will still cause the load operation to abort if encountered. When this option is not enabled, the load operation will abort on the first error encountered.</td>
</tr>
<tr>
<td><strong>ERROR_TABLE</strong>: When <strong>ERROR_LIMIT</strong> is declared, specifies an error table where rows with formatting errors will be logged when running in single row error isolation mode. You can then examine this error table to see error rows that were not loaded (if any).</td>
</tr>
<tr>
<td>Log file</td>
</tr>
<tr>
<td>----------</td>

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_LINE: the number of rows processed. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>GPLOAD_OUTPUT: the output information when the gpload utility is the executed. This is an After variable and it returns a string.</td>
</tr>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td></td>
<td>For further information about variables, see <a href="https://help.talend.com">Talend Studio User Guide</a>.</td>
</tr>
</tbody>
</table>

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is mainly used when no particular transformation is required on the data to be loaded on to the database.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>This component can be used as a standalone or an output component.</td>
</tr>
</tbody>
</table>

| Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center ([https://help.talend.com](https://help.talend.com)). |
Related scenario

For a related use case, see Inserting data in bulk in MySQL database on page 2500.
**tGreenplumInput**

Reads a database and extracts fields based on a query.

tGreenplumInput executes a DB query with a strictly defined order which must correspond to the schema definition and then it passes on the field list to the next component via a Main row link.

**tGreenplumInput Standard properties**

These properties are used to configure tGreenplumInput running in the Standard Job framework.

The Standard tGreenplumInput component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td><strong>Property type</strong></td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><strong>Click this icon to open a database connection wizard and store the database connection parameters you set in the component Basic settings view.</strong></td>
<td>For more information about setting up and storing database connection parameters, see Talend Studio User Guide.</td>
</tr>
<tr>
<td><strong>Host</strong></td>
<td>Database server IP address.</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database.</td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>Exact name of the database.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Schema and Edit schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td><strong>Built-In:</strong> You create and store the schema locally for this component only.</td>
<td></td>
</tr>
<tr>
<td><strong>Repository:</strong> You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
<td></td>
</tr>
</tbody>
</table>

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema:** choose this option to view the schema only.
- **Change to built-in property:** choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection:** choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Query type and Query**

Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.

**Guess Query**

Click the **Guess Query** button to generate the query which corresponds to your table schema in the **Query** field.

**Guess schema**

Click the **Guess schema** button to retrieve the table schema.

**Advanced settings**

**Use cursor**

When selected, helps to decide the row set to work with at a time and thus optimize performance.

**Trim all the String/Char columns**

Select this check box to remove leading and trailing whitespace from all the String/Char columns.

**Trim column**

Remove leading and trailing whitespace from defined columns.

**tStat Catcher Statistics**

Select this check box to collect log data at the component level.

**Global Variables**

**Global Variables**

**NB_LINE:** the number of rows processed. This is an After variable and it returns an integer.

**QUERY:** the query statement being processed. This is a Flow variable and it returns a string.

**ERROR_MESSAGE:** the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component covers all possible SQL queries for FireBird databases.</th>
</tr>
</thead>
</table>

Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenarios

For related topics, see:

- Mapping data using a simple implicit join on page 680.

See also related topic: Reading data from different MySQL databases using dynamically loaded connection parameters on page 491.
tGreenplumOutput

Executes the action defined on the table and/or on the data of a table, according to the input flow from the previous component.

tGreenplumOutput writes, updates, modifies or deletes the data in a database.

tGreenplumOutput Standard properties

These properties are used to configure tGreenplumOutput running in the Standard Job framework.
The Standard tGreenplumOutput component belongs to the Databases family.
The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><img src="icon" alt="Icon" /></td>
<td>Click this icon to open a database connection wizard and store the database connection parameters you set in the component Basic settings view. For more information about setting up and storing database connection parameters, see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Host</strong></td>
<td>Database server IP address.</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Table</strong></td>
<td>Name of the table to be written. Note that only one table can be written at a time</td>
</tr>
<tr>
<td><strong>Action on table</strong></td>
<td>On the table defined, you can perform one of the following operations:</td>
</tr>
<tr>
<td></td>
<td><strong>None</strong>: No operation is carried out.</td>
</tr>
<tr>
<td></td>
<td><strong>Drop and create a table</strong>: The table is removed and created again.</td>
</tr>
<tr>
<td></td>
<td><strong>Create a table</strong>: The table does not exist and gets created.</td>
</tr>
<tr>
<td></td>
<td><strong>Create a table if not exists</strong>: The table is created if it does not exist.</td>
</tr>
<tr>
<td></td>
<td><strong>Drop a table if exists and create</strong>: The table is removed if it already exists and created again.</td>
</tr>
<tr>
<td></td>
<td><strong>Clear a table</strong>: The table content is deleted.</td>
</tr>
<tr>
<td><strong>Action on data</strong></td>
<td>On the data of the table defined, you can perform:</td>
</tr>
<tr>
<td></td>
<td><strong>Insert</strong>: Add new entries to the table. If duplicates are found, Job stops.</td>
</tr>
<tr>
<td></td>
<td><strong>Update</strong>: Make changes to existing entries</td>
</tr>
<tr>
<td></td>
<td><strong>Insert or update</strong>: Insert a new record. If the record with the given reference already exists, an update would be made.</td>
</tr>
<tr>
<td></td>
<td><strong>Update or insert</strong>: Update the record with the given reference. If the record does not exist, a new record would be inserted.</td>
</tr>
<tr>
<td></td>
<td><strong>Delete</strong>: Remove entries corresponding to the input flow.</td>
</tr>
</tbody>
</table>
Warning:
It is necessary to specify at least one column as a primary key on which the Update and Delete operations are based. You can do that by clicking Edit Schema and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the Advanced settings view where you can simultaneously define primary keys for the Update and Delete operations. To do that: Select the Use field options check box and then in the Key in update column, select the check boxes next to the column names you want to use as a base for the Update operation. Do the same in the Key in delete column for the Delete operation.

<table>
<thead>
<tr>
<th><strong>Warning:</strong></th>

Do the same in the Key in delete column for the Delete operation.</td>
</tr>
</tbody>
</table>

**Schema and Edit Schema**
A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

**Built-In:** You create and store the schema locally for this component only.

**Repository:** You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.
When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.
You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Die on error**
This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a **Row > Rejects** link.
### Advanced settings

<table>
<thead>
<tr>
<th><strong>Commit every</strong></th>
<th>Enter the number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and, above all, better performance at execution.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Additional Columns</strong></td>
<td>This option is not offered if you create (with or without drop) the DB table. This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing.</td>
</tr>
<tr>
<td>Name</td>
<td>Type in the name of the schema column to be altered or inserted as new column</td>
</tr>
<tr>
<td>SQL expression</td>
<td>Type in the SQL statement to be executed in order to alter or insert the relevant column data.</td>
</tr>
<tr>
<td>Position</td>
<td>Select Before, Replace or After following the action to be performed on the reference column.</td>
</tr>
<tr>
<td>Reference column</td>
<td>Type in a column of reference that the tDBOutput can use to place or replace the new or altered column.</td>
</tr>
<tr>
<td><strong>Use field options</strong></td>
<td>Select this check box to customize a request, especially when there is double action on data.</td>
</tr>
<tr>
<td><strong>Use Batch</strong></td>
<td>Select this check box to activate the batch mode for data processing.</td>
</tr>
<tr>
<td><strong>Note:</strong></td>
<td>This check box is available only when you have selected the Insert, Update, or Delete option in the Action on data option.</td>
</tr>
<tr>
<td><strong>Batch Size</strong></td>
<td>Specify the number of records to be processed in each batch.</td>
</tr>
<tr>
<td><strong>tStat Catcher Statistics</strong></td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

### Global Variables

<table>
<thead>
<tr>
<th><strong>Global Variables</strong></th>
<th><strong>NB_LINE</strong>: the number of rows processed. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>NB_LINE_UPDATED</strong>: the number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td><strong>NB_LINE_INSERTED</strong>: the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td><strong>NB_LINE_DELETED</strong>: the number of rows deleted. This is an After variable and it returns an integer.</td>
</tr>
</tbody>
</table>
**Usage**

This component covers all possible SQL queries for Greenplum databases. It allows you to carry out actions on a table or on the data of a table in a Greenplum database.

It enables you to create a reject flow, with a Row > Rejects link filtering the data in error. For a usage example, see Retrieving data in error with a Reject link on page 2485.

**Dynamic settings**

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

**Related scenarios**

For related scenarios, see:

- Mapping data using a simple implicit join on page 680.
- Inserting a column and altering data using tMysqlOutput on page 2477.
tGreenplumOutputBulk

Prepares the file to be used as parameter in the INSERT query to feed the Greenplum database.

The tGreenplumOutputBulk and tGreenplumBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tGreenplumOutputBulkExec component, detailed in a separate section. The advantage of using a two step process is that it makes it possible to transform data before it is loaded in the database.

 Writes a file with columns based on the defined delimiter and the Greenplum standards

**tGreenplumOutputBulk Standard properties**

These properties are used to configure tGreenplumOutputBulk running in the Standard Job framework. The Standard tGreenplumOutputBulk component belongs to the Databases family. The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

<tr>
<td><strong>Use an existing connection</strong></td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
<table>
<thead>
<tr>
<th>Host</th>
<th>Database server IP address</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database</td>
</tr>
<tr>
<td>Schema</td>
<td>Exact name of the schema.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-In</strong>: You create and store the schema locally for this component only.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
</tr>
<tr>
<td></td>
<td>Click <strong>Edit schema</strong> to make changes to the schema. If the current schema is of the <strong>Repository</strong> type, three options are available:</td>
</tr>
<tr>
<td></td>
<td>• <strong>View schema</strong>: choose this option to view the schema only.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Change to built-in property</strong>: choose this option to change the schema to <strong>Built-in</strong> for local changes.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Update repository connection</strong>: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select <strong>No</strong> upon completion and choose this schema metadata again in the <strong>Repository Content</strong> window.</td>
</tr>
<tr>
<td>Table Name</td>
<td>Name of the table to be read.</td>
</tr>
<tr>
<td>Query type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-in</strong>: Fill in manually the query statement or build it graphically using SQLBuilder.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: Select the relevant query stored in the Repository. The Query field gets accordingly filled in.</td>
</tr>
<tr>
<td>Guess Query</td>
<td>Click the <strong>Guess Query</strong> button to generate the query which corresponds to your table schema in the Query field.</td>
</tr>
<tr>
<td>Query</td>
<td>Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.</td>
</tr>
</tbody>
</table>
### Die on error

This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a Row > Rejects link.

### Advanced settings

<table>
<thead>
<tr>
<th>Propagate QUERY’s recordset</th>
<th>Select this check box to insert the result of the query into a COLUMN of the current flow. Select this column from the use column list.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Note:</strong> This option allows the component to have a different schema from that of the preceding component. Moreover, the column that holds the QUERY’s recordset should be set to the type of Object and this component is usually followed by tParseRecordSet.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Use PreparedStatement</th>
<th>Select this check box if you want to query the database using a PreparedStatement. In the Set PreparedStatement Parameter table, define the represented by ‘?’ in the SQL instruction of the Query field in the Basic Settings tab.</th>
</tr>
</thead>
</table>
|                       | **Parameter Index:** Enter the parameter position in the SQL instruction.  
**Parameter Type:** Enter the parameter type.  
**Parameter Value:** Enter the parameter value. |
|                       | **Note:** This option is very useful if you need to execute the same query several times. Performance levels are increased |

| Commit every | Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions. |

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

### Global Variables

| Global Variables | QUERY: the query statement being processed. This is a Flow variable and it returns a string.  
ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------|

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component offers the flexibility of the DB query and covers all possible SQL queries.</th>
</tr>
</thead>
</table>

Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenarios

For a related scenario, see:

- Combining two flows for selective output on page 2514
- Procedure on page 625.
- Removing and regenerating a MySQL table index on page 2508.
tGreenplumSCD

Addresses Slowly Changing Dimension needs, reading regularly a source of data and logging the changes into a dedicated SCD table.
tGreenplumSCD reflects and tracks changes in a dedicated Greenplum SCD table.

**tGreenplumSCD Standard properties**

These properties are used to configure tGreenplumSCD running in the Standard Job framework.
The Standard tGreenplumSCD component belongs to the Business Intelligence and the Databases families.
The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the Repository file where properties are stored. The following fields are pre-filled in using fetched data.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td>Connection type</td>
<td>Select the relevant driver on the list.</td>
</tr>
<tr>
<td>Host</td>
<td>Database server IP address.</td>
</tr>
</tbody>
</table>

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
<table>
<thead>
<tr>
<th>Port</th>
<th>Listening port number of DB server.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Name of the database.</td>
</tr>
<tr>
<td>Schema</td>
<td>Name of the DB schema.</td>
</tr>
</tbody>
</table>
| Username and Password | DB user authentication data.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings. |
| Table        | Name of the table to be written. Note that only one table can be written at a time. |
| Schema and Edit schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word **line** when naming the fields.  
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
• **View schema**: choose this option to view the schema only.  
• **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
• **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window. |
|            | Built-in: The schema is created and stored locally for this component only. Related topic: see *Talend Studio User Guide*. |
|            | Repository: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see *Talend Studio User Guide*. |
| SCD Editor  | The SCD editor helps to build and configure the data flow for slowly changing dimension outputs.  
For more information, see *SCD management methodology* on page 2522. |
| Use memory saving Mode | Select this check box to maximize system performance. |
| Source keys include Null | Select this check box to allow the source key columns to have Null values.  
**Warning:**  
Special attention should be paid to the uniqueness of the source key(s) value when this option is selected. |
### Die on error

This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

### Advanced settings

<table>
<thead>
<tr>
<th><strong>End date time details</strong></th>
<th>Specify the time value of the SCD end date time setting in the format of HH:mm:ss. The default value for this field is 12:00:00. This field appears only when SCD Type 2 is used and Fixed year value is selected for creating the SCD end date.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Debug mode</strong></td>
<td>Select this check box to display each step during processing entries in a database.</td>
</tr>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

### Global Variables

<table>
<thead>
<tr>
<th><strong>Global Variables</strong></th>
<th><strong>NB_LINE_UPDATED</strong>: the number of rows updated. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>NB_LINE_INSERTED</strong>: the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td><strong>NB_LINE_REJECTED</strong>: the number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press `Ctrl + Space` to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

### Usage

<table>
<thead>
<tr>
<th><strong>Usage rule</strong></th>
<th>This component is used as Output component. It requires an Input component and Row main link as input.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Dynamic settings</strong></td>
<td>Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.</td>
</tr>
</tbody>
</table>
The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see **Reading data from databases through context-based dynamic connections** on page 2457 and **Reading data from different MySQL databases using dynamically loaded connection parameters** on page 491. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

### Limitation

| Limitation | This component does not support using SCD type 0 together with other SCD types. |

**Related scenario**

For related scenarios, see **tMysqlSCD** on page 2519.
**tGroovy**

tGroovy broadens the functionality if the **Talend** Job, using the Groovy language which is a simplified Java syntax.

tGroovy allows you to enter customized code which you can integrate in the **Talend** programme. The code is run only once.

**tGroovy Standard properties**

These properties are used to configure tGroovy running in the Standard Job framework.

The Standard tGroovy component belongs to the Custom Code family.

The component in this framework is available in all **Talend products**.

**Basic settings**

<table>
<thead>
<tr>
<th>Groovy Script</th>
<th>Enter the Groovy code you want to run.</th>

</tr>
</thead>
<tbody>
<tr>
<td>Limitation</td>
<td>Knowledge of the Groovy language is required.</td>
</tr>
</tbody>
</table>
Calling a file which contains Groovy code

This scenario uses `tGroovyFile`, on its own. The Job calls a file containing Groovy code in order to display the file information in the Console.

Setting up the Job

Open the Custom_Code folder in the Palette and drop a `tGroovyFile` component onto the workspace.

Configuring the `tGroovyFile` component

**Procedure**

1. Double-click the component to display the Component view.

   ![Component view](image)

   - **Basic settings**
   - **Groovy File**: D:/Input/Ageducapitaine.txt

   - **Variables**
   - **Name**: age
   - **Value**: 50

2. In the **Groovy File** field, enter the path to the file containing the Groovy code, or browse to the file in your directory. In this example, it is D:/Input/Ageducapitaine.txt, and the file contains the following Groovy codes:

   ```groovy
   println("The captain is "+age+" years old")
   ```

3. In the **Variables** table, add a line by clicking the [+ ] button.

4. In the **Name** column, enter "age", and then in the **Value** column, enter 50.

Executing the Job

**Procedure**

1. Press Ctrl+S to save your Job.
2. Press F6 or click Run on the Run tab to execute the Job.

   The Console displays the information contained in the input file, to which the variable result is added.
Starting job tGroovyFile at 09:49 17/02/2010.

[statistics] connecting to socket on port 4016
[statistics] connected
The captain is 50 years old
[statistics] disconnected
Job tGroovyFile ended at 09:49 17/02/2010. [exit code=0]
tGSBucketCreate

Creates a new bucket which you can use to organize data and control access to data in Google Cloud Storage.

**tGSBucketCreate Standard properties**

These properties are used to configure tGSBucketCreate running in the Standard Job framework.

The Standard tGSBucketCreate component belongs to the Big Data and the Cloud families.

The component in this framework is available in all Talend products.

**Basic settings**

| **Use an existing connection** | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. |
| **Access Key and Secret Key** | Type in the authentication information obtained from Google for making requests to Google Cloud Storage. These keys can be consulted on the Interoperable Access tab view under the Google Cloud Storage tab of the project from the Google APIs Console. To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. For more information about the access key and secret key, go to https://developers.google.com/storage/docs/reference/v1/getting-startedv1?hl=en/ and see the description about developer keys. The **Access Key** and **Secret Key** fields will be available only if you do not select the **Use an existing connection** check box. |
| **Bucket name** | Specify the name of the bucket which you want to create. Note that the bucket name must be unique across the Google Cloud Storage system. For more information about the bucket naming convention, see https://developers.google.com/storage/docs/bucketnaming. |
| **Special configure** | Select this check box to provide the additional configuration for the bucket to be created. |
| **Project ID** | Specify the project ID to which the new bucket belongs. |
| **Location** | Select from the list the location where the new bucket will be created. Currently, Europe and US are available. By default, the bucket location is in the US. Note that once a bucket is created in a specific location, it cannot be moved to another location. |
Acl

Select from the list the desired access control list (ACL) for the new bucket.

Depending on the ACL on the bucket, the access requests from users may be allowed or rejected. If you do not specify a predefined ACL for the new bucket, the predefined project-private ACL applies.

For more information about ACL, see https://developers.google.com/storage/docs/accesscontrol?hl=en.

Die on error

This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

Advanced settings

tStatCatcher Statistics

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

Global Variables

Global Variables

ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule

This component can be used together with the tGSBucketList component to check if a new bucket is created successfully.

Related scenario

For related topics, see Verifying the absence of a bucket, creating it and listing all the S3 buckets on page 3264.
tGSBucketDelete

Deletes an empty bucket in Google Cloud Storage so as to release occupied resources.

Note that bucket deletion cannot be undone, so you need to back up any data that you want to keep before the deletion.

**tGSBucketDelete Standard properties**

These properties are used to configure tGSBucketDelete running in the Standard Job framework.

The Standard tGSBucketDelete component belongs to the Big Data and the Cloud families.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
</table>
| **Access Key** and **Secret Key** | Type in the authentication information obtained from Google for making requests to Google Cloud Storage.
These keys can be consulted on the Interoperable Access tab view under the Google Cloud Storage tab of the project from the Google APIs Console.
To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.
For more information about the access key and secret key, go to https://developers.google.com/storage/docs/reference/v1/getting-startedv1?hl=en/ and see the description about developer keys.
The Access Key and Secret Key fields will be available only if you do not select the Use an existing connection check box. |
| **Bucket name** | Specify the name of the bucket that you want to delete. Make sure that the bucket to be deleted is empty. |
| **Die on error** | This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows. |

**Advanced settings**

| **tStatCatcher Statistics** | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global Variables**

| **Global Variables** | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable |
and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

| Usage rule | This component can be used together with the **tGSBucketList** component to check if the specified bucket is deleted successfully. |

### Related scenarios

No scenario is available for the Standard version of this component yet.
tGSBucketExist

Checks the existence of a bucket in Google Cloud Storage so as to make further operations.

**tGSBucketExist Standard properties**

These properties are used to configure tGSBucketExist running in the Standard Job framework.

The Standard tGSBucketExist component belongs to the Big Data and the Cloud families.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>

**Global Variables**

| Global Variables | CURRENT_BUCKET_NAME: the current bucket name. This is a Flow variable and it returns a string. NB_BUCKET: the number of buckets. This is an After variable and it returns an integer. |
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

---

**Usage**

| Usage rule | The `tGSBucketList` component can be used as a standalone component or as a start component of a process. |

---

**Related scenario**

For related topics, see *Verifying the absence of a bucket, creating it and listing all the S3 buckets* on page 3264.
tGSClose

Closes an active connection to Google Cloud Storage in order to release the occupied resources.

**tGSClose Standard properties**

These properties are used to configure tGSClose running in the Standard Job framework.

The Standard tGSClose component belongs to the Big Data and the Cloud families.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Component List</th>
<th>Select the tGSConnection component in the list if more than one connection is planned for the current Job.</th>
</tr>
</thead>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
<th>Select this check box to gather the Job processing metadata at the Job level as well as at each component level.</th>
</tr>
</thead>
</table>

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. </tr>
</thead>
</table>

**Related scenario**

For a scenario in which tGSClose is used, see Managing files with Google Cloud Storage on page 1369.
tGSConnection

Provides the authentication information for making requests to the Google Cloud Storage system and enables the reuse of the connection it creates to Google Cloud Storage.

**tGSConnection Standard properties**

These properties are used to configure tGSConnection running in the Standard Job framework.

The Standard tGSConnection component belongs to the Big Data and the Cloud families.

The component in this framework is available in all Talend products.

**Basic settings**

| Access Key and Secret Key | Type in the authentication information obtained from Google for making requests to Google Cloud Storage. These keys can be consulted on the Interoperable Access tab view under the Google Cloud Storage tab of the project from the Google APIs Console. To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. For more information about the access key and secret key, go to https://developers.google.com/storage/docs/reference/v1/getting-startedv1?hl=en/ and see the description about developer keys. |

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global Variables**

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide. |
**Usage**

| Usage rule | This component is generally used with other Google Cloud Storage components, particularly `tGSClose`. |

**Related scenario**

For a scenario in which `tGSCConnection` is used, see Managing files with Google Cloud Storage on page 1369.
tGSCopy

Copies or moves objects within a bucket or between buckets in Google Cloud Storage. tGSCopy streamlines processes by automating the copy tasks.

**tGSCopy Standard properties**

These properties are used to configure tGSCopy running in the Standard Job framework. The Standard tGSCopy component belongs to the Big Data and the Cloud families. The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access Key and Secret Key</td>
<td>Type in the authentication information obtained from Google for making requests to Google Cloud Storage. These keys can be consulted on the Interoperable Access tab view under the Google Cloud Storage tab of the project from the Google APIs Console. <td>Specify the target folder to which the objects will be copied or moved.</td>
</tr>
</tbody>
</table>
| Action                      | Select the action that you want to perform on objects from the list.  
  • Copy: copies objects from the source bucket or folder to the target bucket or folder. |
- **Move**: moves objects from the source bucket or folder to the target bucket or folder.

### Rename

Select this check box and in the **New name** field enter a new name for the object to be copied or moved. The **Rename** check box will not be available if you select the **Source is folder** check box.

### Die on error

This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

### Advanced settings

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

### Global Variables

| Global Variables | **SOURCE_BUCKET**: the source bucket name. This is an After variable and it returns a string.  
**SOURCE_OBJECTKEY**: the key of a source object. This is an After variable and it returns a string.  
**DESTINATION_BUCKETNAME**: the destination bucket name. This is an After variable and it returns a string.  
**DESTINATION_FOLDER**: the destination folder. This is an After variable and it returns a string.  
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
For further information about variables, see [Talend Studio User Guide](#). |

### Usage

| Usage rule | This component can be used as a standalone component. |

### Related scenario

For a scenario in which **tGSCopy** is used, see [Managing files with Google Cloud Storage](#) on page 1369.
tGSDelete

Deletes the objects which match the specified criteria in Google Cloud Storage so as to release the occupied resources.

**tGSDelete Standard properties**

These properties are used to configure tGSDelete running in the Standard Job framework.

The Standard tGSDelete component belongs to the Big Data and the Cloud families.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
</table>
| **Access Key and Secret Key** | Type in the authentication information obtained from Google for making requests to Google Cloud Storage. These keys can be consulted on the Interoperable Access tab view under the Google Cloud Storage tab of the project from the Google APIs Console.  
To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.  
For more information about the access key and secret key, go to https://developers.google.com/storage/docs/reference/v1/getting-startedv1?hl=en/ and see the description about developer keys.  
The Access Key and Secret Key fields will be available only if you do not select the Use an existing connection check box. |
| **Key prefix** | Specify the prefix to delete only objects whose keys begin with the specified prefix. |
| **Delimiter** | Specify the delimiter in order to delete only those objects with key names up to the delimiter. |
| **Specify project ID** | Select this check box and in the Project ID field enter the project ID from which you want to delete objects. |
| **Delete object from bucket list** | Select this check box and complete the Bucket table to delete objects in the specified buckets.  
- **Bucket name**: type in the name of the bucket from which you want to delete objects.  
- **Key prefix**: type in the prefix to delete objects whose keys begin with the specified prefix in the specified bucket.  
- **Delimiter**: type in the delimiter to delete those objects with key names up to the delimiter in the specified bucket. |
If you select the Delete object from bucket list check box, the Key prefix and Delimiter fields as well as the Specify project ID check box will not be available.

### Advanced settings

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

### Global Variables

| Global Variables | NB_LINE: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer. ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

### Usage

| Usage rule | This component can be used together with the tGSList component to check if the objects which match the specified criteria are deleted successfully. |

### Related scenario

For a scenario in which tGSDelete is used, see Managing files with Google Cloud Storage on page 1369.
tGSGet

Retrieves objects which match the specified criteria from Google Cloud Storage and outputs them to a local directory.

**tGSGet Standard properties**

These properties are used to configure tGSGet running in the Standard Job framework.

The Standard tGSGet component belongs to the Big Data and the Cloud families.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access Key and Secret Key</td>
<td>Type in the authentication information obtained from Google for making requests to Google Cloud Storage. These keys can be consulted on the Interoperable Access tab view under the Google Cloud Storage tab of the project from the Google APIs Console. To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. For more information about the access key and secret key, go to <a href="https://developers.google.com/storage/docs/reference/v1/getting-startedv1?hl=en/">https://developers.google.com/storage/docs/reference/v1/getting-startedv1?hl=en/</a> and see the description about developer keys. The Access Key and Secret Key fields will be available only if you do not select the Use an existing connection check box.</td>
</tr>
<tr>
<td>Key prefix</td>
<td>Specify the prefix to download only objects which keys begin with the specified prefix.</td>
</tr>
<tr>
<td>Delimiter</td>
<td>Specify the delimiter in order to download only those objects with key names up to the delimiter.</td>

<td>Specify project ID</td>
<td>Select this check box and in the Project ID field enter the project ID from which you want to obtain objects.</td>
</tr>
</tbody>
</table>
| Use keys                    | Select this check box and complete the Keys table to define the criteria for objects to be downloaded from Google Cloud Storage.  
  • Bucket name: type in the name of the bucket from which you want to download objects.  
  • Key: type in the key of the object to be downloaded.  
  • New name: type in a new name for the object to be downloaded.  
If you select the Use keys check box, the Key prefix and Delimiter fields as well as the Specify project ID check box
and the Get files from bucket list check box will not be available.

| Get files from bucket list | Select this check box and complete the Bucket table to define the criteria for objects to be downloaded from Google Cloud Storage.  
• Bucket name: type in the name of the bucket from which you want to download objects.  
• Key prefix: type in the prefix to download objects whose keys start with the specified prefix from the specified bucket.  
• Delimiter: specify the delimiter to download those objects with key names up to the delimiter from the specified bucket.  
If you select the Get files from bucket list check box, the Key prefix and Delimiter fields as well as the Specify project ID check box and the Use keys check box will not be available. |

| Output directory | Specify the directory where you want to store the downloaded objects. |

| Die on error | This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows. |

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global Variables**

| Global Variables | **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.  
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.  
For further information about variables, see Talend Studio User Guide. |

**Usage**

| Usage rule | This component is usually used together with other Google Cloud Storage components, particularly tGSPut. |
Related scenarios

No scenario is available for the Standard version of this component yet.
tGSLList

Retrieves a list of objects from Google Cloud Storage one by one.

tGSLList iterates on a list of objects which match the specified criteria in Google Cloud Storage.

**tGSLList Standard properties**

These properties are used to configure tGSLList running in the Standard Job framework.

The Standard tGSLList component belongs to the Big Data and the Cloud families.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th><strong>Use an existing connection</strong></th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Access Key and Secret Key</strong></td>
<td>Type in the authentication information obtained from Google for making requests to Google Cloud Storage. These keys can be consulted on the Interoperable Access tab view under the Google Cloud Storage tab of the project from the Google APIs Console. To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. For more information about the access key and secret key, go to <a href="https://developers.google.com/storage/docs/reference/v1/getting-startedv1?hl=en">https://developers.google.com/storage/docs/reference/v1/getting-startedv1?hl=en</a> and see the description about developer keys. The Access Key and Secret Key fields will be available only if you do not select the Use an existing connection check box.</td>
</tr>
<tr>
<td><strong>Key prefix</strong></td>
<td>Specify the key prefix so that only the objects whose keys begin with the specified string will be listed.</td>
</tr>
<tr>
<td><strong>Delimiter</strong></td>
<td>Specify the delimiter in order to list only those objects with key names up to the delimiter.</td>
</tr>
<tr>
<td><strong>Specify project ID</strong></td>
<td>Select this check box and in the Project ID field enter the project ID from which you want to retrieve a list of objects.</td>
</tr>
<tr>
<td><strong>List objects in bucket list</strong></td>
<td>Select this check box and complete the Bucket table to retrieve objects in the specified buckets.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Bucket name</strong>: type in the name of the bucket from which you want to retrieve objects.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Key prefix</strong>: type in the prefix to list only objects whose keys begin with the specified string in the specified bucket.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Delimiter</strong>: type in the delimiter to list only those objects with key names up to the delimiter.</td>
</tr>
</tbody>
</table>
If you select the **List objects in bucket list** check box, the **Key prefix** and **Delimiter** fields as well as the **Specify project ID** check box will not be available.

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global Variables**

| Global Variables | **CURRENT_BUCKET**: the current bucket name. This is a Flow variable and it returns a string.  
**CURRENT_KEY**: the current key. This is a Flow variable and it returns a string.  
**NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
For further information about variables, see *Talend Studio User Guide*. |

**Usage**

| Usage rule | The **tGSLList** component can be used as a standalone component or as a start component of a process. |

**Related scenario**

For a scenario in which **tGSLList** is used, see *Managing files with Google Cloud Storage* on page 1369
**tGSPut**

Uploads files from a local directory to Google Cloud Storage so that you can manage them with Google Cloud Storage.

**tGSPut Standard properties**

These properties are used to configure tGSPut running in the Standard Job framework.

The Standard tGSPut component belongs to the Big Data and the Cloud families.

The component in this framework is available in all Talend products.

### Basic settings

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>

</thead>
</table>
| **Access Key and Secret Key** | Type in the authentication information obtained from Google for making requests to Google Cloud Storage. These keys can be consulted on the Interoperable Access tab view under the Google Cloud Storage tab of the project from the Google APIs Console.  
To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.  
For more information about the access key and secret key, go to [https://developers.google.com/storage/docs/reference/v1/getting-startedv1?hl=en](https://developers.google.com/storage/docs/reference/v1/getting-startedv1?hl=en) and see the description about developer keys.  
The Access Key and Secret Key fields will be available only if you do not select the Use an existing connection check box. |
| Bucket name | Type in the name of the bucket into which you want to upload files. |
| Local directory | Type in the full path of or browse to the local directory where the files to be uploaded are located. |
| Google Storage directory | Type in the Google Storage directory to which you want to upload files. |
| Use files list | Select this check box and complete the Files table.  
- **Filemask:** enter the filename or filemask using wildcharacters (*) or regular expressions.  
- **New name:** enter a new name for the file after being uploaded. |
| Die on error | This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows. |
**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global Variables**

| Global Variables | **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.  
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
For further information about variables, see Talend Studio User Guide. |

**Usage**

| Usage rule | This component can be used together with other components, particularly the tGSGet component. |

**Managing files with Google Cloud Storage**

The scenario describes a Job which uploads files from the local directory to a bucket in Google Cloud Storage, then performs copy, move and delete operations on those files, and finally lists and displays the files in relevant buckets on the console.
Prerequisites: You have purchased a Google Cloud Storage account and created three buckets under the same Google Storage directory. In this example, the buckets created are bighouse, bed_room, and study_room.

Dropping and linking the components

About this task

To design the Job, proceed as follows:

Procedure

1. Drop the following components from the Palette to design the workspace: one tGSConnection component, one tGSPut component, two tGSCopy components, one tGSDelete component, one
tGSPut component, one tIterateToFlow component, one tLogRow component and one tGSClose component.

2. Connect tGSConnection to tGSPut using a Trigger > On Subjob Ok link.
3. Connect tGSPut to the first tGSCopy using a Trigger > On Subjob Ok link.
4. Do the same to connect the first tGSCopy to the second tGSCopy, connect the second tGSCopy to tGSDelete, connect tGSDelete to tGSList, and connect tGSList to tGSClose.
5. Connect tGSList to tIterateToFlow using a Row > Iterate link.
6. Connect tIterateToFlow to tLogRow using a Row > Main link.

Configuring the components

Opening a connection to Google Cloud Storage

Procedure

1. Double-click the tGSConnection component to open its Basic settings view in the Component tab.

   ![tGSConnection_1](image)

   Access Key: your_access_key
   Secret Key: ***************

2. Navigate to the Google APIs Console in your web browser to access the Google project hosting the Cloud Storage services you need to use.
3. Click Google Cloud Storage > Interoperable Access to open its view, and copy the access key and secret key.
4. In the Component view of the Studio, paste the access key and secret key to the corresponding fields respectively.

Uploading files to Google Cloud Storage

Procedure

1. Double-click the tGSPut component to open its Basic settings view in the Component tab.

   ![tGSPut_1](image)

   Connection: Use an existing connection
   Component List: tGSConnection_1
   Bucket name: bighouse
   Local directory: D:/Input/House
   Google Storage directory: 
   Use files list: 
   Die on error: 

2. Select the Use an existing connection check box and then select the connection you have configured earlier.
3. In the Bucket name field, enter the name of the bucket into which you want to upload files. In this example, bighouse.
4. In the Local directory field, browse to the directory from which the files will be uploaded, D:/Input/House in this example.
The files under this directory are shown below:

5. Leave other settings as they are.

Copying all files from one bucket to another bucket

Procedure

1. Double-click the first tGSCopy component to open its Basic settings view in the Component tab.

2. Select the Use an existing connection check box and then select the connection you have configured earlier.

3. In the Source bucket name field, enter the name of the bucket from which you want to copy files, bighouse in this example.

4. Select the Source is a folder check box. All files from the bucket bighouse will be copied.

5. In the Target bucket name field, enter the name of the bucket into which you want to copy files, bed_room in this example.

6. Select Copy from the Action list.

Moving a file from one bucket to another bucket and renaming it

Procedure

1. Double-click the second tGSCopy component to open its Basic settings view in the Component tab.
2. Select the **Use an existing connection** check box and then select the connection you have configured earlier.

3. In the **Source bucket name** field, enter the name of the bucket from which you want to move files, *bighouse* in this example.

4. In the **Source object key** field, enter the key of the object to be moved, *computer_01.txt* in this example.

5. In the **Target bucket name** field, enter the name of the bucket into which you want to move files, *study_room* in this example.

6. Select **Move** from the **Action** list. The specified source file *computer_01.txt* will be moved from the bucket *bighouse* to *study_room*.

7. Select the **Rename** check box. In the **New name** field, enter a new name for the moved file. In this example, the new name is *laptop.txt*.

8. Leave other settings as they are.

### Deleting a file in one bucket

#### Procedure

1. Double-click the **tGSDel**ot component to open its **Basic settings** view in the **Component** tab.

2. Select the **Use an existing connection** check box and then select the connection you have configured earlier.
3. Select the **Delete object from bucket list** check box. Fill in the **Bucket** table with the file information that you want to delete.

   In this example, the file *computer_03.csv* will be deleted from the bucket *bed_room* whose files are copied from the bucket *bighouse*.

**Listing all files in the three buckets**

**Procedure**

1. Double-click the **tGSList** component to open its **Basic settings** view in the **Component** tab.

![tGSList component](image)

   - **Basic settings**
     - **Connection**: Use an existing connection
     - **Query configuration**: List objects in bucket list

   - **Bucket**
     - **Bucket name**
       - *bighouse*
       - *study_room*
       - *bed_room*

2. Select the **Use an existing connection** check box and then select the connection you have configured earlier.

3. Select the **List objects in bucket list** check box. In the **Bucket** table, enter the name of the three buckets in the **Bucket name** column, *bighouse*, *study_room*, and *bed_room*.

4. Double-click the **tIterateToFlow** component to open its **Basic settings** view in the **Component** tab.

![tIterateToFlow component](image)

5. Click **Edit schema** to define the data to pass on to **tLogRow**.

   In this example, add two columns *bucketName* and *key*, and set their types to **Object**.
6. The Mapping table will be populated with the defined columns automatically.
   In the Value column, enter `globalMap.get("tGSList_2_CURRENT_BUCKET")` for the bucketName column and `globalMap.get("tGSList_2_CURRENT_KEY")` for the key column. You can also press Ctrl + Space and then choose the appropriate variable.

7. Double-click the tLogRow component to open its Basic settings view in the Component tab.

8. Select Table (print values in cells of a table) for a better view of the results.

Closing the connection to Google Cloud Storage

Procedure

1. Double-click the tGSClose component to open its Basic settings view in the Component tab.
2. Select the connection you want to close from the Component List.

Saving and executing the Job

Procedure

1. Press Ctrl+S to save your Job.
2. Execute the Job by pressing F6 or clicking Run on the Run tab.
The files in the three buckets are displayed. As expected, at first, the files from the bucket `bighouse` are copied to the bucket `bed_room`, then the file `computer_01.txt` from the bucket `bighouse` is moved to the bucket `study_room` and renamed to be `laptop.txt`, finally the file `computer_03.csv` is deleted from the bucket `bed_room`.

tHashInput

Reads from the cache memory data loaded by tHashOutput to offer high-speed data feed, facilitating transactions involving a large amount of data.

The components of the Technical family are normally hidden from the Palette by default. For more information about how to show them on the Palette, see Talend Studio User Guide.

**tHashInput Standard properties**

These properties are used to configure tHashInput running in the Standard Job framework.

The Standard tHashInput component belongs to the Technical family.

The component in this framework is available in all Talend products.

**Basic settings**

| Schema and Edit schema | A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either built-in or remotely stored in the Repository.
Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

| Built-in: The schema is created and stored locally for this component only. Related topic: see the Talend Studio User Guide.
| Repository: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see the Talend Studio User Guide.

| Link with a tHashOutput | Select this check box to connect to a tHashOutput component. It is always selected by default.

| Component list | Drop-down list of available tHashOutput components.

| Clear cache after reading | Select this check box to clear the cache after reading the data loaded by a certain tHashOutput component. This way, the following tHashInput components, if any, will not be able to read the cached data loaded by that tHashOutput component. |
Advanced settings

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. |
| | NB_LINE: the number of rows processed. This is an After variable and it returns an integer. |
| | A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. |
| | To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. |
| | For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | This component is used along with tHashOutput. It reads from the cache memory data loaded by tHashOutput. Together, these twin components offer high-speed data access to facilitate transactions involving a massive amount of data. |

Reading data from the cache memory for high-speed data access

The following Job reads from the cache memory a huge amount of data loaded by two tHashOutput components and pass it to a tFileOutputDelimited. The goal of this scenario is to show the speed at which mass data is read and written. In practice, data feed generated in this way can be used as lookup table input for some use cases where a big amount of data needs to be referenced.

Dropping and linking the components

Procedure

1. Drag and drop the following components from the Palette to the workspace: tFixedFlowInput (X2), tHashOutput (X2), tHashInput and tFileOutputDelimited.
2. Connect the first tFixedFlowInput to the first tHashOutput using a Row > Main link.
3. Connect the second tFixedFlowInput to the second tHashOutput using a Row > Main link.
4. Connect the first subjob (from tFixedFlowInput_1) to the second subjob (to tFixedFlowInput_2) using an OnSubjobOk link.
5. Connect tHashInput to tFileOutputDelimited using a Row > Main link.
6. Connect the second subjob to the last subjob using an **OnSubjobOk** link.

![Diagram of subjob connections]

### Configuring the components

#### Configuring data inputs and hash cache

**Procedure**

1. Double-click the first **tFixedFlowInput** component to display its **Basic settings** view.

   ![Basic settings view of tFixedFlowInput]

   - **Schema**: Built-In
   - **Number of rows**: 50000
   - **Values**:
     - ID: 1
     - ID_Insurance: 3

2. Select **Built-In** from the **Schema** drop-down list.

   **Note:**
   
   You can select **Repository** from the **Schema** drop-down list to fill in the relevant fields automatically if the relevant metadata has been stored in the **Repository**. For more information about **Metadata**, see the **Talend Studio User Guide**.
3. Click **Edit schema** to define the data structure of the input flow. In this case, the input has two columns: *ID* and *ID_Insurance*, and then click **OK** to close the dialog box.

4. Fill in the **Number of rows** field to specify the entries to output, e.g. 50000.

5. Select the **Use Single Table** check box. In the **Values** table and in the **Value** column, assign values to the columns, e.g. 1 for *ID* and 3 for *ID_Insurance*.

6. Perform the same operations for the second **tFixedFlowInput** component, with the only difference in the values. That is, 2 for *ID* and 4 for *ID_Insurance* in this case.

7. Double-click the first **tHashOutput** to display its **Basic settings** view.

8. Select **Built-In** from the **Schema** drop-down list and click **Sync columns** to retrieve the schema from the previous component. Select **Keep all** from the **Keys management** drop-down list and keep the **Append** check box selected.

9. Perform the same operations for the second **tHashOutput** component, and select the **Link with a tHashOutput** check box.

**Configuring data retrieval from hash cache and data output**

**Procedure**

1. Double-click **tHashInput** to display its **Basic settings** view.
2. Select **Built-In** from the **Schema** drop-down list. Click **Edit schema** to define the data structure, which is the same as that of **tHashOutput**.

3. Select **tHashOutput_1** from the **Component list** drop down list.

4. Double-click **tFileOutputDelimited** to display its **Basic settings** view.

5. Select **Built-In** from the **Property Type** drop-down list. In the **File Name** field, enter the full path and name of the file, e.g. "E:/Allr70207V5.0/Talend-All-r70207-V5.0.0NB/workspace/out.csv".

6. Select the **Include Header** check box and click **Sync columns** to retrieve the schema from the previous component.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl+S** to save the Job.
2. Press **F6**, or click **Run** on the **Run** tab to execute the Job.

**Results**

You can find that mass entries are written and read very rapidly.
Clearing the memory before loading data to it in case an iterator exists in the same subJob

In this scenario, the usage of the Append option of tHashOutput is demonstrated as it helps remove repetitive or unwanted data in case an iterator exists in the same subJob as tHashOutput.

To build the Job, do the following:

Dropping and linking the components

Procedure
1. Drag and drop the following components from the Palette to the workspace: tLoop, tFixedFlowInput, tHashOutput, tHashInput and tLogRow.
2. Connect tLoop to tFixedFlowInput using a Row > Iterate link.
3. Connect tFixedFlowInput to tHashOutput using a Row > Main link.
4. Connect tHashInput to tLogRow using a Row > Main link.
5. Connect tLoop to tHashInput using an OnSubjobOk link.

Configuring the components

Configuring data input and hash cache

Procedure
1. Double-click the tLoop component to display its Basic settings view.

2. Select For as the loop type. Type in 1, 2, 1 in the From, To and Step fields respectively. Keep the Values are increasing check box selected.
3. Double-click the tFixedFlowInput component to display its Basic settings view.
4. Select **Built-In** from the **Schema** drop-down list.

**Note:**
You can select **Repository** from the **Schema** drop-down list to fill in the relevant fields automatically if the relevant metadata has been stored in the **Repository**. For more information about **Metadata**, see the **Talend Studio User Guide**.

5. Click **Edit schema** to define the data structure of the input flow. In this case, the input has one column: **Name**.

6. Click **OK** to close the dialog box.

7. Fill in the **Number of rows** field to specify the entries to output, for example 1.

8. Select the **Use Single Table** check box. In the **Values** table, assign a value to the **Name** field, e.g. **Marx**.

9. Double-click **tHashOutput** to display its **Basic settings** view.
10. Select Built-In from the Schema drop-down list and click Sync columns to retrieve the schema from the previous component. Select Keep all from the Keys management drop-down list and deselect the Append check box.

Configuring data retrieval from hash cache and data output

Procedure

1. Double-click tHashInput to display its Basic settings view.

2. Select Built-In from the Schema drop-down list. Click Edit schema to define the data structure, which is the same as that of tHashOutput.

3. Select tHashOutput_2 from the Component list drop-down list.

4. Double-click tLogRow to display its Basic settings view.

5. Select Built-In from the Schema drop-down list and click Sync columns to retrieve the schema from the previous component. In the Mode area, select Table (print values in cells of a table).

Saving and executing the Job

Procedure

1. Press Ctrl+S to save the Job.

2. Press F6, or click Run on the Run tab to execute the Job.

You can find that only one row was output although two rows were generated by tFixedFlowInput.
tHashOutput

Loads data to the cache memory to offer high-speed access, facilitating transactions involving a large amount of data.

It should be noted that loading data will consume a lot of memory to store records for each record has an overhead. The number of inputted entries also impacts the usage of memory.

The components of the Technical family are normally hidden from the Palette by default. For more information about how to show them on the Palette, see Talend Studio User Guide.

tHashOutput Standard properties

These properties are used to configure tHashOutput running in the Standard Job framework.

The Standard tHashOutput component belongs to the Technical family.

The component in this framework is available in all Talend products.

Basic settings

| Schema and Edit schema | A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either built-in or remotely stored in the Repository. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available: 
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• View schema: choose this option to view the schema only.</td>
</tr>
<tr>
<td></td>
<td>• Change to built-in property: choose this option to change the schema to Built-in for local changes.</td>
</tr>
<tr>
<td></td>
<td>• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.</td>
</tr>
<tr>
<td></td>
<td>Click Sync columns to retrieve the schema from the previous component connected in the Job.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Built-in</th>
<th>The schema is created and stored locally for this component only. Related topic: see the Talend Studio User Guide.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Repository</th>
<th>The schema already exists and is stored in the Repository, hence can be reused. Related topic: see the Talend Studio User Guide.</th>
</tr>
</thead>
</table>

| Link with a tHashOutput | Select this check box to connect to a tHashOutput component. |
Component list
Drop-down list of available tHashOutput components.

Data write model
Drop-down list of available data write modes.

Keys management
Drop-down list of available keys management modes.
- **Keep all**: writes all the data received to the cache memory.
- **Keep first**: writes only the first record to the cache memory if multiple records received have the same key value.

Append
Selected by default, this option is designed to append data to the memory in case an iterator exists in the same subJob. If it is unchecked, tHashOutput will clear the memory before loading data to it.

**Note:**
If Link with a tHashOutput is selected, this check box will be hidden but is always enabled.

Advanced settings

**tStatCatcher Statistics**
Select this check box to collect log data at the component level.

Global Variables

**Global Variables**

- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.
- **NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

Usage

**Usage rule**
This component writes data to the cache memory and is closely related to tHashInput. Together, these twin
components offer high-speed data access to facilitate transactions involving a massive amount of data.

Related scenarios

For related scenarios, see:

- Reading data from the cache memory for high-speed data access on page 1378.
- Clearing the memory before loading data to it in case an iterator exists in the same sublob on page 1382.
tHBaseClose

Closes an HBase connection you have established in your Job.

**tHBaseClose Standard properties**

These properties are used to configure tHBaseClose running in the Standard Job framework.

The Standard tHBaseClose component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| Component list | Select the tHBaseConnection component in the list if more than one connection are planned for the current Job. |

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Global Variables**

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

**Usage**

| Usage rule | This component is to be used along with HBase components, especially with tHBaseConnection. |

| Prerequisites | Before starting, ensure that you have met the Loopback IP prerequisites expected by your database. The Hadoop distribution must be properly installed, so as to guarantee the interaction with Talend Studio. The following list presents MapR related information for example. |
• Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native. For example, the library for Windows is \lib\native\MapRClient.dll in the MapR client jar file. For further information, see the following link from MapR: http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr.

Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path.

• Set the -Djava.library.path argument, for example, in the Job Run VM arguments area of the Run/Debug view in the Preferences dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

Related scenario

For a scenario in which thBaseClose is used, see Exchanging customer data with HBase on page 1402.
tHBaseConnection

Establishes an HBase connection to be reused by other HBase components in your Job.
tHBaseConnection opens a connection to an HBase database.

tHBaseConnection Standard properties

These properties are used to configure tHBaseConnection running in the Standard Job framework.
The Standard tHBaseConnection component belongs to the Big Data and the Databases NoSQL families.
The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

Basic settings

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-in or Repository</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>- Built-in: no property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>- Repository: select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

Distribution

Select the cluster you are using from the drop-down list. The options in the list vary depending on the component you are using. Among these options, the following ones requires specific configuration:

- If available in this Distribution drop-down list, the Microsoft HD Insight option allows you to use a Microsoft HD Insight cluster. For this purpose, you need to configure the connections to the HD Insight cluster and the Windows Azure Storage service of that cluster in the areas that are displayed. For detailed explanation about these parameters, search for configuring the connection manually on Talend Help Center (https://help.talend.com).

- If you select Amazon EMR, you can find more details about how to configure an Amazon EMR cluster in Talend Help Center (https://help.talend.com).

- The Custom option allows you to connect to a cluster different from any of the distributions given in this list, that is to say, to connect to a cluster not officially supported by Talend.

1. Select Import from existing version to import an officially supported distribution as base and then add other required jar files which the base distribution does not provide.

2. Select Import from zip to import the configuration zip for the custom distribution to be used. This zip file should contain the libraries of the different Hadoop elements and the index file of these libraries.

In Talend Exchange, members of Talend community have shared some ready-for-use configuration zip files which you can download from this Hadoop configuration list and directly use them in your
connection accordingly. However, because of the ongoing evolution of the different Hadoop-related projects, you might not be able to find the configuration zip corresponding to your distribution from this list; then it is recommended to use the **Import from existing version** option to take an existing distribution as base to add the jars required by your distribution.

Note that custom versions are not officially supported by Talend. Talend and its community provide you with the opportunity to connect to custom versions from the Studio but cannot guarantee that the configuration of whichever version you choose will be easy, due to the wide range of different Hadoop distributions and versions that are available. As such, you should only attempt to set up such a connection if you have sufficient Hadoop experience to handle any issues on your own.

**Note:**
In this dialog box, the active check box must be kept selected so as to import the jar files pertinent to the connection to be created between the custom distribution and this component.

For a step-by-step example about how to connect to a custom distribution and share this connection, see Connecting to a custom Hadoop distribution on page 1569.

<table>
<thead>
<tr>
<th><strong>HBase version</strong></th>
<th>Select the version of the Hadoop distribution you are using. The available options vary depending on the component you are using.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Hadoop version of the distribution</strong></td>
<td>This list is displayed only when you have selected Custom from the distribution list to connect to a cluster not yet officially supported by the Studio. In this situation, you need to select the Hadoop version of this custom cluster, that is to say, Hadoop 1 or Hadoop 2.</td>
</tr>
<tr>
<td><strong>Zookeeper quorum</strong></td>
<td>Type in the name or the URL of the Zookeeper service you use to coordinate the transaction between your Studio and your database. Note that when you configure the Zookeeper, you might need to explicitly set the <code>zookeeper.znode.parent</code> property to define the path to the root znode that contains all the znodes created and used by your database; then select the <strong>Set Zookeeper znode parent</strong> check box to define this property.</td>
</tr>
<tr>
<td><strong>Zookeeper client port</strong></td>
<td>Type in the number of the client listening port of the Zookeeper service you are using.</td>
</tr>
<tr>
<td><strong>Inspect the classpath for configurations</strong></td>
<td>Select this check box to allow the component to check the configuration files in the directory you have set with the <code>$HADOOP_CONF_DIR</code> variable and directly read parameters from these files in this directory. This feature allows you to easily change the Hadoop configuration for the component to switch between different environments, for example, from a test environment to a production environment. In this situation, the fields or options used to configure Hadoop connection and/or Kerberos security are hidden.</td>
</tr>
</tbody>
</table>
If you want to use certain parameters such as the Kerberos parameters but these parameters are not included in these Hadoop configuration files, you need to create a file called `talend-site.xml` and put this file into the same directory defined with `$HADOOP_CONF_DIR`. This `talend-site.xml` file should read as follows:

```xml
<configuration>
  <property>
    <name>talend.kerberos.authentication</name>
    <value>kinit</value>
    <description>Set the Kerberos authentication method to use. Valid values are: kinit or keytab.</description>
  </property>
  <property>
    <name>talend.kerberos.keytab.principal</name>
    <value>user@BIGDATA.COM</value>
    <description>Set the keytab's principal name.</description>
  </property>
  <property>
    <name>talend.kerberos.keytab.path</name>
    <value>/kdc/user.keytab</value>
    <description>Set the keytab's path.</description>
  </property>
  <property>
    <name>talend.encryption</name>
    <value>none</value>
    <description>Set the encryption method to use. Valid values are: none or ssl.</description>
  </property>
  <property>
    <name>talend.ssl.trustStore.path</name>
    <value>ssl</value>
    <description>Set SSL trust store path.</description>
  </property>
  <property>
    <name>talend.ssl.trustStore.password</name>
    <value>ssl</value>
    <description>Set SSL trust store password.</description>
  </property>
</configuration>
```
The parameters read from these configuration files override the default ones used by the Studio. When a parameter does not exist in these configuration files, the default one is used.

### Use kerberos authentication

If the database to be used is running with Kerberos security, select this check box, then, enter the principal names in the displayed fields. You should be able to find the information in the `hbase-site.xml` file of the cluster to be used.

- If this cluster is a MapR cluster of the version 5.0.0 or later, you can set the MapR ticket authentication configuration in addition or as an alternative by following the explanation in Connecting to a security-enabled MapR on page 1629.

Keep in mind that this configuration generates a new MapR security ticket for the username defined in the Job in each execution. If you need to reuse an existing ticket issued for the same username, leave both the Force MapR ticket authentication check box and the Use Kerberos authentication check box clear, and then MapR should be able to automatically find that ticket on the fly.

If you need to use a Kerberos keytab file to log in, select Use a keytab to authenticate. A keytab file contains pairs of Kerberos principals and encrypted keys. You need to enter the principal to be used in the Principal field and the access path to the keytab file itself in the Keytab field. This keytab file must be stored in the machine in which your Job actually runs, for example, on a Talend Jobserver.

Note that the user that executes a keytab-enabled Job is not necessarily the one a principal designates but must have the right to read the keytab file being used. For example, the user name you are using to execute a Job is user1 and the principal to be used is guest; in this situation, ensure that user1 has the right to read the keytab file to be used.

### Advanced settings

#### Properties

If you need to use custom configuration for your HBase, complete this table with the property or properties to be customized. Then at runtime, the customized property or properties will override those corresponding ones defined earlier for your HBase.

For example, you need to define the value of the `dfs.replication` property as 1 for the HBase configuration. Then you need to add one row to this table using the plus button and type in the name and the value of this property in this row.

### tStatCatcher Statistics

Select this check box to collect the log data at a component level.

### Global Variables

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the
Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

| Usage rule | This component is generally used with other HBase components, particularly **tHBaseClose**. |

### Prerequisites

Before starting, ensure that you have met the Loopback IP prerequisites expected by your database.

The Hadoop distribution must be properly installed, so as to guarantee the interaction with *Talend Studio*. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under `MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native`. For example, the library for Windows is `\lib\native\MapRClient.dll` in the MapR client jar file. For further information, see the following link from MapR: [http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr](http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr).

Without adding the specified library or libraries, you may encounter the following error: no `MapRClient` in `java.library.path`.

- Set the `-Djava.library.path` argument, for example, in the Job Run VM arguments area of the Run/Debug view in the Preferences dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

### Related scenario

For a scenario in which **tHBaseConnection** is used, see *Exchanging customer data with HBase* on page 1402.
**tHBaseInput**

Reads data from a given HBase database and extracts columns of selection.

HBase is a distributed, column-oriented database that hosts very large, sparsely populated tables on clusters.

**tHBaseInput** extracts columns corresponding to schema definition. Then it passes these columns to the next component via a Main row link.

**HBase filters**

This table presents the HBase filters available in *Talend Studio* and the parameters required by those filters.

<table>
<thead>
<tr>
<th>Filter type</th>
<th>Filter column</th>
<th>Filter family</th>
<th>Filter operation</th>
<th>Filter value</th>
<th>Filter comparator type</th>
<th>Objective</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single Column Value Filter</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>It compares the values of a given column against the value defined for the Filter value parameter. If the filtering condition is met, all columns of the row will be returned.</td>
</tr>
<tr>
<td>Family filter</td>
<td></td>
<td>Yes</td>
<td>Yes</td>
<td></td>
<td>Yes</td>
<td>It returns the columns of the family that meets the filtering condition.</td>
</tr>
<tr>
<td>Qualifier filter</td>
<td>Yes</td>
<td>Yes</td>
<td></td>
<td>Yes</td>
<td></td>
<td>It returns the columns whose column qualifiers match the filtering condition.</td>
</tr>
<tr>
<td>Column prefix filter</td>
<td>Yes</td>
<td>Yes</td>
<td></td>
<td></td>
<td></td>
<td>It returns all columns of which the qualifiers have the prefix defined for the Filter column parameter.</td>
</tr>
<tr>
<td>Multiple column prefix filter</td>
<td>Yes (Multiple prefixes are separated by comma, for example, id,id_1,id_2)</td>
<td>Yes</td>
<td></td>
<td></td>
<td></td>
<td>It works the same way as a Column prefix filter does but allows specifying multiple prefixes.</td>
</tr>
<tr>
<td>Column range filter</td>
<td>Yes (The ends of a range are separated by comma.)</td>
<td>Yes</td>
<td></td>
<td></td>
<td></td>
<td>It allows intra row scanning and returns all matching columns of a scanned row.</td>
</tr>
<tr>
<td>Row filter</td>
<td></td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td></td>
<td>It filters on row keys and returns all rows that matches the filtering condition.</td>
</tr>
<tr>
<td>Value filter</td>
<td></td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td></td>
<td>It returns only columns that have a specific value.</td>
</tr>
</tbody>
</table>
The use explained above of the listed HBase filters is subject to revisions made by Apache in its Apache HBase project; therefore, in order to fully understand how to use these HBase filters, we recommend reading Apache's HBase documentation.

**tHBaseInput Standard properties**

These properties are used to configure tHBaseInput running in the Standard Job framework.

The Standard tHBaseInput component belongs to the Big Data and the Databases NoSQL families. The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| Property type | Either Built-In or Repository.  
|---------------|--------------------------------|
|               | Built-In: No property data stored centrally.  
|               | Repository: Select the repository file where the properties are stored.  
| Icon          | Click this icon to open a database connection wizard and store the database connection parameters you set in the component Basic settings view.  
|               | For more information about setting up and storing database connection parameters, see Talend Studio User Guide.  
| Use an existing connection | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.  
| Distribution | Select the cluster you are using from the drop-down list. The options in the list vary depending on the component you are using. Among these options, the following ones requires specific configuration:  
|               | • If available in this Distribution drop-down list, the Microsoft HD Insight option allows you to use a Microsoft HD Insight cluster. For this purpose, you need to configure the connections to the HD Insight cluster and the Windows Azure Storage service of that cluster in the areas that are displayed. For detailed explanation about these parameters, search for configuring the connection manually on Talend Help Center (https://help.talend.com).  
|               | • If you select Amazon EMR, you can find more details about how to configure an Amazon EMR cluster in Talend Help Center (https://help.talend.com).  
|               | • The Custom option allows you to connect to a cluster different from any of the distributions given in this list, that is to say, to connect to a cluster not officially supported by Talend.  
|               | 1. Select Import from existing version to import an officially supported distribution as base and then add other required jar files which the base distribution does not provide.  
|               | 2. Select Import from zip to import the configuration zip for the custom distribution to be used. This zip file
should contain the libraries of the different Hadoop elements and the index file of these libraries.

In Talend Exchange, members of Talend community have shared some ready-for-use configuration zip files which you can download from this Hadoop configuration list and directly use them in your connection accordingly. However, because of the ongoing evolution of the different Hadoop-related projects, you might not be able to find the configuration zip corresponding to your distribution from this list; then it is recommended to use the Import from existing version option to take an existing distribution as base to add the jars required by your distribution.

Note that custom versions are not officially supported by Talend. Talend and its community provide you with the opportunity to connect to custom versions from the Studio but cannot guarantee that the configuration of whichever version you choose will be easy, due to the wide range of different Hadoop distributions and versions that are available. As such, you should only attempt to set up such a connection if you have sufficient Hadoop experience to handle any issues on your own.

**Note:**
In this dialog box, the active check box must be kept selected so as to import the jar files pertinent to the connection to be created between the custom distribution and this component.

For a step-by-step example about how to connect to a custom distribution and share this connection, see Connecting to a custom Hadoop distribution on page 1569.

<table>
<thead>
<tr>
<th>HBase version</th>
<th>Select the version of the Hadoop distribution you are using. The available options vary depending on the component you are using.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hadoop version of the distribution</td>
<td>This list is displayed only when you have selected Custom from the distribution list to connect to a cluster not yet officially supported by the Studio. In this situation, you need to select the Hadoop version of this custom cluster, that is to say, Hadoop 1 or Hadoop 2.</td>
</tr>
<tr>
<td>Zookeeper quorum</td>
<td>Type in the name or the URL of the Zookeeper service you use to coordinate the transaction between your Studio and your database. Note that when you configure the Zookeeper, you might need to explicitly set the zookeeper.znode.parent property to define the path to the root znode that contains all the znodes created and used by your database; then select the Set Zookeeper znode parent check box to define this property.</td>
</tr>
<tr>
<td>Zookeeper client port</td>
<td>Type in the number of the client listening port of the Zookeeper service you are using.</td>
</tr>
<tr>
<td>Use kerberos authentication</td>
<td>If the database to be used is running with Kerberos security, select this check box, then, enter the principal names in the</td>
</tr>
</tbody>
</table>
displayed fields. You should be able to find the information in the `hbase-site.xml` file of the cluster to be used.

- If this cluster is a MapR cluster of the version 5.0.0 or later, you can set the MapR ticket authentication configuration in addition or as an alternative by following the explanation in Connecting to a security-enabled MapR on page 1629.

  Keep in mind that this configuration generates a new MapR security ticket for the username defined in the Job in each execution. If you need to reuse an existing ticket issued for the same username, leave both the Force MapR ticket authentication check box and the Use Kerberos authentication check box clear, and then MapR should be able to automatically find that ticket on the fly.

If you need to use a Kerberos keytab file to log in, select Use a keytab to authenticate. A keytab file contains pairs of Kerberos principals and encrypted keys. You need to enter the principal to be used in the Principal field and the access path to the keytab file itself in the Keytab field. This keytab file must be stored in the machine in which your Job actually runs, for example, on a Talend Jobserver.

Note that the user that executes a keytab-enabled Job is not necessarily the one a principal designates but must have the right to read the keytab file being used. For example, the user name you are using to execute a Job is `user1` and the principal to be used is `guest`; in this situation, ensure that `user1` has the right to read the keytab file to be used.

### Schema and Edit schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

### Built-In

You create and store the schema locally for this component only.

### Repository

You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

### Set table Namespace mappings

Enter the string to be used to construct the mapping between an Apache HBase table and a MapR table.
<table>
<thead>
<tr>
<th><strong>Table name</strong></th>
<th>Type in the name of the table from which you need to extract columns.</th>
</tr>
</thead>
</table>

**Define a row selection**

Select this check box and then in the **Start row** and the **End row** fields, enter the corresponding row keys to specify the range of the rows you want the current component to extract.

Different from the filters you can set using **Is by filter** requiring the loading of all records before filtering the ones to be used, this feature allows you to directly select only the rows to be used.

**Mapping**

Complete this table to map the columns of the table to be used with the schema columns you have defined for the data flow to be processed.

**Die on error**

Select the check box to stop the execution of the Job when an error occurs.

Clear the check box to skip any rows on error and complete the process for error-free rows. When errors are skipped, you can collect the rows on error using a **Row > Reject** link.

### Advanced settings

<table>
<thead>
<tr>
<th><strong>tStatCatcher Statistics</strong></th>
<th>Select this check box to collect log data at the component level.</th>
</tr>
</thead>
</table>

**Properties**

If you need to use custom configuration for your database, complete this table with the property or properties to be customized. Then at runtime, the customized property or properties will override the corresponding ones used by the Studio.

For example, you need to define the value of the `dfs.replication` property as 1 for the database configuration. Then you need to add one row to this table using the plus button and type in the name and the value of this property in this row.

**Note:**

This table is not available when you are using an existing connection by selecting the **Using an existing connection** check box in the **Basic settings** view.

<table>
<thead>
<tr>
<th><strong>Is by filter</strong></th>
<th>Select this check box to use filters to perform fine-grained data selection from your database, such as selection of keys, or values, based on regular expressions.</th>
</tr>
</thead>
</table>

Once selecting it, the **Filter** table that is used to define filtering conditions becomes available.

This feature leverages filters provided by HBase and subject to constraints explained in Apache HBase documentation. Therefore, advanced knowledge of HBase is required to make full use of these filters.
Logical operation

Select the operator you need to use to define the logical relation between filters. This available operators are:

- **And**: every defined filtering conditions must be satisfied. It represents the relationship `FilterList.Operator.MUST_PASS_ALL`
- **Or**: at least one of the defined filtering conditions must be satisfied. It represents the relationship `FilterList.Operator.MUST_PASS_ONE`

Filter

Click the button under this table to add as many rows as required, each row representing a filter. The parameters you may need to set for a filter are:

- **Filter type**: the drop-down list presents pre-existing filter types that are already defined by HBase. Select the type of the filter you need to use.
- **Filter column**: enter the column qualifier on which you need to apply the active filter. This parameter becomes mandatory depending on the type of the filter and of the comparator you are using. For example, it is not used by the **Row Filter** type but is required by the **Single Column Value Filter** type.
- **Filter family**: enter the column family on which you need to apply the active filter. This parameter becomes mandatory depending on the type of the filter and of the comparator you are using. For example, it is not used by the **Row Filter** type but is required by the **Single Column Value Filter** type.
- **Filter operation**: select from the drop-down list the operation to be used for the active filter.
- **Filter Value**: enter the value on which you want to use the operator selected from the **Filter operation** drop-down list.
- **Filter comparator type**: select the type of the comparator to be combined with the filter you are using.

Depending on the **Filter type** you are using, some or each of the parameters become mandatory. For further information, see HBase filters on page 1396

Retrieve timestamps

Select this check box to load the timestamps of an HBase column into the data flow.

- **Retrieve from an HBase column**: select the HBase column which is tracked for changes in order to retrieve its corresponding timestamps.
- **Write to a schema column**: select the column you have defined in the schema to store the retrieved timestamps.

The type of this column must be **Long**.

Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_LINE: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer. ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the</th>
</tr>
</thead>
</table>
### Usage

#### Usage rule

This component is a start component of a Job and always needs an output link.

#### Prerequisites

Before starting, ensure that you have met the Loopback IP prerequisites expected by your database.

The Hadoop distribution must be properly installed, so as to guarantee the interaction with Talend Studio. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native. For example, the library for Windows is \lib\native\MapRClient.dll in the MapR client jar file. For further information, see the following link from MapR: http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr.

Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path.

- Set the -Djava.library.path argument, for example, in the Job Run VM arguments area of the Run/Debug view in the Preferences dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

### Exchanging customer data with HBase

This scenario applies only to Talend products with Big Data.

In this scenario, a six-component Job is used to exchange customer data with a given HBase.
The six components are:

- **tHBaseConnection**: creates a connection to your HBase database.
- **tFixedFlowInput**: creates the data to be written into your HBase. In the real use case, this component could be replaced by the other input components like **tFileInputDelimited**.
- **tHBaseOutput**: writes the data it receives from the preceding component into your HBase.
- **tHBaseInput**: extracts the columns of interest from your HBase.
- **tLogRow**: presents the execution result.
- **tHBaseClose**: closes the transaction.

To replicate this scenario, proceed as the following sections illustrate.

**Note:**
Before starting the replication, your Hbase and Zookeeper service should have been correctly installed and well configured. This scenario explains only how to use Talend solution to make data transaction with a given HBase.

**Dropping and linking the components**

**About this task**
To do this, proceed as follows:

**Procedure**

1. Drop **tHBaseConnection, tFixedFlowInput, tHBaseOutput, tHBaseInput, tLogRow** and **tHBaseClose** from Palette onto the Design workspace.
2. Right-click **tHBaseConnection** to open its contextual menu and select the **Trigger > On Subjob Ok** link from this menu to connect this component to **tFixedFlowInput**.
3. Do the same to create the OnSubjobOk link from tFixedFlowInput to tHBaseInput and then to tHBaseClose.
4. Right-click tFixedFlowInput and select the Row > Main link to connect this component to tHBaseOutput.
5. Do the same to create the Main link from tHBaseInput to tLogrow.

Results
The components to be used in this scenario are all placed and linked. Then you need continue to configure them successively.

Configuring the connection

About this task
To configure the connection to your Zookeeper service and thus to the HBase of interest, proceed as follows:

Procedure
1. On the Design workspace of your Studio, double-click the tHBaseConnection component to open its Component view.

![tHBaseConnection](image)

2. Select Hortonworks Data Platform 1.0 from the HBase version list.
3. In the Zookeeper quorum field, type in the name or the URL of the Zookeeper service you are using. In this example, the name of the service in use is hbase.
4. In the Zookeeper client port field, type in the number of client listening port. In this example, it is 2181.
5. If the Zookeeper znode parent location has been defined in the Hadoop cluster you are connecting to, you need to select the Set zookeeper znode parent check box and enter the value of this property in the field that is displayed.

Configuring the process of writing data into the HBase

About this task
To do this, proceed as follows:
Procedure

1. On the Design workspace, double-click the \texttt{tFixedFlowInput} component to open its Component view.

2. In this view, click the three-dot button next to \texttt{Edit schema} to open the schema editor.

3. Click the plus button three times to add three rows and in the Column column, rename the three rows respectively as: id, name and age.

4. In the Type column, click each of these rows and from the drop-down list, select the data type of every row. In this scenario, they are \texttt{Integer} for \texttt{id} and \texttt{age}, \texttt{String} for \texttt{name}.

5. Click OK to validate these changes and accept the propagation prompted by the pop-up dialog box.

6. In the Mode area, select the \texttt{Use Inline Content (delimited file)} to display the fields for editing.
7. In the **Content** field, type in the delimited data to be written into the HBase, separated with the semicolon ";". In this example, they are:

```
1;Albert;23
2;Alexandre;24
3;Alfred-Hubert;22
4;Andre;40
5;Didier;28
6;Anthony;35
7;Artus;32
8;Catherine;34
9;Charles;21
10;Christophe;36
11;Christian;67
12;Danni;54
13;Elisabeth;58
14;Emile;32
15;Gregory;30
```

8. Double-click **tHBaseOutput** to open its **Component** view.

   **Note:** If this component does not have the same schema of the preceding component, a warning icon appears. In this case, click the **Sync columns** button to retrieve the schema from the preceding one and once done, the warning icon disappears.

9. Select the **Use an existing connection** check box and then select the connection you have configured earlier. In this example, it is **tHBaseConnection_1**.

10. In the **Table name** field, type in the name of the table to be created in the HBase. In this example, it is **customer**.

11. In the **Action on table** field, select the action of interest from the drop-down list. In this scenario, select **Drop table if exists and create**. This way, if a table named customer exists already in the HBase, it will be disabled and deleted before creating this current table.

12. Click the **Advanced settings** tab to open the corresponding view.
13. In the Family parameters table, add two rows by clicking the plus button, rename them as family1 and family2 respectively and then leave the other columns empty. These two column families will be created in the HBase using the default family performance options.

**Note:** The Family parameters table is available only when the action you have selected in the Action on table field is to create a table in HBase. For further information about this Family parameters table, see tHBaseOutput on page 1410.

14. In the Families table of the Basic settings view, enter the family names in the Family name column, each corresponding to the column this family contains. In this example, the id and the age columns belong to family1 and the name column to family2.

**Note:** These column families should already exist in the HBase to be connected to; if not, you need to define them in the Family parameters table of the Advanced settings view for creating them at runtime.

**Configuring the process of extracting data from the HBase**

**About this task**

To do this, perform the following operations:

**Procedure**

1. Double-click `tHBaseInput` to open its Component view.
2. Select the **Use an existing connection** check box and then select the connection you have configured earlier. In this example, it is `tHBaseConnection_1`.

3. Click the three-dot button next to **Edit schema** to open the schema editor.

4. Click the plus button three times to add three rows and rename them as `id`, `name` and `age` respectively in the **Column** column. This means that you extract these three columns from the HBase.

5. Select the types for each of the three columns. In this example, `Integer` for `id` and `age`, `String` for `name`.

6. Click **OK** to validate these changes and accept the propagation prompted by the pop-up dialog box.

7. In the **Table name** field, type in the table from which you extract the columns of interest. In this scenario, the table is `customer`.

8. In the **Mapping** table, the **Column** column has been already filled automatically since the schema was defined, so simply enter the name of every family in the **Column family** column, each corresponding to the column it contains.

9. Double-click `tHBaseClose` to open its **Component** view.
In the **Component List** field, select the connection you need to close. In this example, this connection is *tHBaseConnection_1*.

### Executing the Job

To execute this Job, press **F6**.

Once done, the **Run** view is opened automatically, where you can check the execution result.

```
For input string: '30  
5|Didier|28  
14|Emile|32  
3|Alfred-Hubert|22  
9|Charles|21  
1|Albert|23  
11|Christian|67  
7|Artus|32  
10|Christophe|36  
8|Catherine|34  
13|Elisabeth|58  
14|Daniel|54  
6|Anthony|35  
2|Alexandre|24  
4|Andre|40
```

These columns of interest are extracted and you can process them according to your needs. Login to your HBase database, you can check the *customer* table this Job has created.
tHBaseOutput

Writes columns of data into a given HBase database.

tHBaseOutput receives data from its preceding component, creates a table in a given HBase database and writes the received data into this HBase table.

tHBaseOutput Standard properties

These properties are used to configure tHBaseOutput running in the Standard Job framework.
The Standard tHBaseOutput component belongs to the Big Data and the Databases NoSQL families.
The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

Basic settings

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-In or Repository. Built-In: No property data stored centrally. Repository: Select the repository file where the properties are stored.</th>
</tr>
</thead>
</table>

Click this icon to open a database connection wizard and store the database connection parameters you set in the component Basic settings view.

For more information about setting up and storing database connection parameters, see Talend Studio User Guide.

Use an existing connection

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

Distribution

Select the cluster you are using from the drop-down list. The options in the list vary depending on the component you are using. Among these options, the following ones requires specific configuration:

- If available in this Distribution drop-down list, the Microsoft HD Insight option allows you to use a Microsoft HD Insight cluster. For this purpose, you need to configure the connections to the HD Insight cluster and the Windows Azure Storage service of that cluster in the areas that are displayed. For detailed explanation about these parameters, search for configuring the connection manually on Talend Help Center (https://help.talend.com).
- If you select Amazon EMR, you can find more details about how to configure an Amazon EMR cluster in Talend Help Center (https://help.talend.com).
- The Custom option allows you to connect to a cluster different from any of the distributions given in this list, that is to say, to connect to a cluster not officially supported by Talend.

1. Select Import from existing version to import an officially supported distribution as base and then add
other required jar files which the base distribution does not provide.

2. Select **Import from zip** to import the configuration zip for the custom distribution to be used. This zip file should contain the libraries of the different Hadoop elements and the index file of these libraries.

In **Talend Exchange**, members of **Talend** community have shared some ready-for-use configuration zip files which you can download from this **Hadoop configuration list** and directly use them in your connection accordingly. However, because of the ongoing evolution of the different Hadoop-related projects, you might not be able to find the configuration zip corresponding to your distribution from this list; then it is recommended to use the **Import from existing version** option to take an existing distribution as base to add the jars required by your distribution.

Note that custom versions are not officially supported by **Talend**. **Talend** and its community provide you with the opportunity to connect to custom versions from the Studio but cannot guarantee that the configuration of whichever version you choose will be easy, due to the wide range of different Hadoop distributions and versions that are available. As such, you should only attempt to set up such a connection if you have sufficient Hadoop experience to handle any issues on your own.

**Note:**
In this dialog box, the active check box must be kept selected so as to import the jar files pertinent to the connection to be created between the custom distribution and this component.

For a step-by-step example about how to connect to a custom distribution and share this connection, see **Connecting to a custom Hadoop distribution** on page 1569.

<table>
<thead>
<tr>
<th><strong>HBase version</strong></th>
<th>Select the version of the Hadoop distribution you are using. The available options vary depending on the component you are using.</th>
</tr>
</thead>
</table>

| **Hadoop version of the distribution** | This list is displayed only when you have selected **Custom** from the distribution list to connect to a cluster not yet officially supported by the Studio. In this situation, you need to select the Hadoop version of this custom cluster, that is to say, **Hadoop 1** or **Hadoop 2**. |

<p>| <strong>Zookeeper quorum</strong> | Type in the name or the URL of the Zookeeper service you use to coordinate the transaction between your Studio and your database. Note that when you configure the Zookeeper, you might need to explicitly set the <code>zookeeper.znode.parent</code> property to define the path to the root znode that contains all the znodes created and used by your database; then select the <strong>Set Zookeeper znode parent</strong> check box to define this property. |</p>
<table>
<thead>
<tr>
<th><strong>Zookeeper client port</strong></th>
<th>Type in the number of the client listening port of the Zookeeper service you are using.</th>
</tr>
</thead>
</table>
| **Use kerberos authentication** | If the database to be used is running with Kerberos security, select this check box, then, enter the principal names in the displayed fields. You should be able to find the information in the `hbase-site.xml` file of the cluster to be used.  
  - If this cluster is a MapR cluster of the version 5.0.0 or later, you can set the MapR ticket authentication configuration in addition or as an alternative by following the explanation in Connecting to a security-enabled MapR on page 1629.  
  
  Keep in mind that this configuration generates a new MapR security ticket for the username defined in the Job in each execution. If you need to reuse an existing ticket issued for the same username, leave both the Force MapR ticket authentication check box and the Use Kerberos authentication check box clear, and then MapR should be able to automatically find that ticket on the fly.  
  
  If you need to use a Kerberos keytab file to log in, select Use a keytab to authenticate. A keytab file contains pairs of Kerberos principals and encrypted keys. You need to enter the principal to be used in the Principal field and the access path to the keytab file itself in the Keytab field. This keytab file must be stored in the machine in which your Job actually runs, for example, on a Talend Jobserver.  
  
  Note that the user that executes a keytab-enabled Job is not necessarily the one a principal designates but must have the right to read the keytab file being used. For example, the user name you are using to execute a Job is user1 and the principal to be used is guest; in this situation, ensure that user1 has the right to read the keytab file to be used. |
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.  
  
  Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
  - **View schema**: choose this option to view the schema only.  
  - **Change to built-in property**: choose this option to change the schema to Built-in for local changes.  
  - **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |
| **Built-In** | You create and store the schema locally for this component only. |
| **Repository** | You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. |
When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

<table>
<thead>
<tr>
<th>Set table Namespace mappings</th>
<th>Enter the string to be used to construct the mapping between an Apache HBase table and a MapR table. For the valid syntax you can use, see <a href="http://doc.mapr.com/display/MapR40x/Mapping+Table+Namespace+Between+Apache+HBase+Tables+and+MapR+Tables">http://doc.mapr.com/display/MapR40x/Mapping+Table+Namespace+Between+Apache+HBase+Tables+and+MapR+Tables</a>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table name</td>
<td>Type in the name of the HBase table you need create.</td>
</tr>
<tr>
<td>Action on table</td>
<td>Select the action you need to take for creating an HBase table.</td>
</tr>
<tr>
<td>Custom Row Key</td>
<td>Select this check box to use the customized row keys. Once selected, the corresponding field appears. Then type in the user-defined row key to index the rows of the HBase table being created. </tr>
</tbody>
</table>
properties will override the corresponding ones used by the Studio.

For example, you need to define the value of the \texttt{dfs.replication} property as 1 for the database configuration. Then you need to add one row to this table using the plus button and type in the name and the value of this property in this row.

\textbf{Note:}
This table is not available when you are using an existing connection by selecting the \texttt{Using an existing connection} check box in the Basic settings view.

\begin{table}[h]
\centering
\begin{tabular}{|l|l|}
\hline
\textbf{tStatCatcher Statistics} & Select this check box to collect log data at the component level. \\
\hline
\textbf{Family parameters} & Type in the names and, when needs be, the custom performance options of the column families to be created. These options are all attributes defined by the HBase data model, so for further explanation about these options, see Apache’s HBase documentation. \\
\hline
\textbf{Global Variables} & \textbf{NB_LINE}: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer. \\
& \textbf{ERROR_MESSAGE}: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the \texttt{Die on error} check box is cleared, if the component has this check box. \\
& A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. \\
& To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. \\
& For further information about variables, see \textit{Talend Studio User Guide}. \\
\hline
\end{tabular}
\end{table}

\begin{table}[h]
\centering
\begin{tabular}{|l|l|}
\hline
\textbf{Usage rule} & This component is normally an end component of a Job and always needs an input link. \\
\hline
\textbf{Prerequisites} & Before starting, ensure that you have met the Loopback IP prerequisites expected by your database. \\
& The Hadoop distribution must be properly installed, so as to guarantee the interaction with \textit{Talend Studio}. The following list presents MapR related information for example. \\
\hline
\end{tabular}
\end{table}
• Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under MAPR\INSTALL\hadoop\hadoop-VERSION\lib\native. For example, the library for Windows is \lib\native\MapRClient.dll in the MapR client jar file. For further information, see the following link from MapR: http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr.

Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path.

• Set the -Djava.library.path argument, for example, in the Job Run VM arguments area of the Run/Debug view in the Preferences dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

Related scenario

For related scenario to the Standard version of tHBaseOutput, see Exchanging customer data with HBase on page 1402.
tHCatalogInput

Reads data from an HCatalog managed Hive database and send data to the component that follows.

The tHCatalogInput component reads data from the specified HCatalog managed database and sends data in the data flow to the console or to a specified local file by connecting this component to a proper component.

tHCatalogInput Standard properties

These properties are used to configure tHCatalogInput running in the Standard Job framework. The Standard tHCatalogInput component belongs to the Big Data family. The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

Basic settings

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-in or Repository</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

Schema and Edit Schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word l.i.n.e when naming the fields.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

<table>
<thead>
<tr>
<th>Distribution</th>
<th>Built-in: The schema will be created and stored locally for this component only. Related topic: see Talend Studio User Guide.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Repository: The schema already exists and is stored in the Repository, hence can be reused in various projects and Job designs. Related topic: see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

Select the cluster you are using from the drop-down list. The options in the list vary depending on the component you are using. Among these options, the following ones require specific configuration:
• If available in this **Distribution** drop-down list, the **Microsoft HD Insight** option allows you to use a Microsoft HD Insight cluster. For this purpose, you need to configure the connections to the HD Insight cluster and the Windows Azure Storage service of that cluster in the areas that are displayed. For detailed explanation about these parameters, search for configuring the connection manually on Talend Help Center (https://help.talend.com).

• If you select **Amazon EMR**, you can find more details about how to configure an Amazon EMR cluster in Talend Help Center (https://help.talend.com).

• The **Custom** option allows you to connect to a cluster different from any of the distributions given in this list, that is to say, to connect to a cluster not officially supported by **Talend**.

1. Select **Import from existing version** to import an officially supported distribution as base and then add other required jar files which the base distribution does not provide.

2. Select **Import from zip** to import the configuration zip for the custom distribution to be used. This zip file should contain the libraries of the different Hadoop elements and the index file of these libraries.

In **Talend Exchange**, members of **Talend** community have shared some ready-for-use configuration zip files which you can download from this **Hadoop configuration** list and directly use them in your connection accordingly. However, because of the ongoing evolution of the different Hadoop-related projects, you might not be able to find the configuration zip corresponding to your distribution from this list; then it is recommended to use the **Import from existing version** option to take an existing distribution as base to add the jars required by your distribution.

Note that custom versions are not officially supported by **Talend**. **Talend** and its community provide you with the opportunity to connect to custom versions from the Studio but cannot guarantee that the configuration of whichever version you choose will be easy, due to the wide range of different Hadoop distributions and versions that are available. As such, you should only attempt to set up such a connection if you have sufficient Hadoop experience to handle any issues on your own.

**Note:**

In this dialog box, the active check box must be kept selected so as to import the jar files pertinent to the connection to be created between the custom distribution and this component.

For a step-by-step example about how to connect to a custom distribution and share this connection, see [Connecting to a custom Hadoop distribution](#) on page 1569.
<table>
<thead>
<tr>
<th><strong>HCatalog version</strong></th>
<th>Select the version of the Hadoop distribution you are using. The available options vary depending on the component you are using.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Templeton hostname</strong></td>
<td>Fill this field with the URL of Templeton Webservice.</td>
</tr>
<tr>
<td><strong>Note:</strong> Templeton is a webservice API for HCatalog. It has been renamed to WebHCat by the Apache community. This service facilitates the access to HCatalog and the related Hadoop elements such as Pig. For further information about Templeton (WebHCat), see <a href="https://cwiki.apache.org/confluence/display/Hive/WebHCat">https://cwiki.apache.org/confluence/display/Hive/WebHCat</a> +UsingWebHCat.</td>
<td></td>
</tr>
<tr>
<td><strong>Templeton port</strong></td>
<td>Fill this field with the port of URL of Templeton Webservice. By default, this value is 50111.</td>
</tr>
<tr>
<td><strong>Note:</strong> Templeton is a webservice API for HCatalog. It has been renamed to WebHCat by the Apache community. This service facilitates the access to HCatalog and the related Hadoop elements such as Pig. For further information about Templeton (WebHCat), see <a href="https://cwiki.apache.org/confluence/display/Hive/WebHCat">https://cwiki.apache.org/confluence/display/Hive/WebHCat</a> +UsingWebHCat.</td>
<td></td>
</tr>
<tr>
<td><strong>Use kerberos authentication</strong></td>
<td>If you are accessing the Hadoop cluster running with Kerberos security, select this check box, then, enter the Kerberos principal name for the NameNode in the field displayed. This enables you to use your user name to authenticate against the credentials stored in Kerberos.</td>
</tr>
<tr>
<td>• If this cluster is a MapR cluster of the version 5.0.0 or later, you can set the MapR ticket authentication configuration in addition or as an alternative by following the explanation in Connecting to a security-enabled MapR on page 1629.</td>
<td></td>
</tr>
<tr>
<td>Keep in mind that this configuration generates a new MapR security ticket for the username defined in the Job in each execution. If you need to reuse an existing ticket issued for the same username, leave both the Force MapR ticket authentication check box and the Use Kerberos authentication check box clear, and then MapR should be able to automatically find that ticket on the fly.</td>
<td></td>
</tr>
<tr>
<td>This check box is available depending on the Hadoop distribution you are connecting to.</td>
<td></td>
</tr>
<tr>
<td><strong>Use a keytab to authenticate</strong></td>
<td>Select the Use a keytab to authenticate check box to log into a Kerberos-enabled system using a given keytab file. A keytab file contains pairs of Kerberos principals and encrypted keys. You need to enter the principal to be used in the Principal field and the access path to the keytab file itself in the Keytab field. This keytab file must be stored in the machine in which your Job actually runs, for example, on a Talend Jobserver.</td>
</tr>
</tbody>
</table>
Note that the user that executes a keytab-enabled Job is not necessarily the one a principal designates but must have the right to read the keytab file being used. For example, the user name you are using to execute a Job is user1 and the principal to be used is guest; in this situation, ensure that user1 has the right to read the keytab file to be used.

<table>
<thead>
<tr>
<th>Database</th>
<th>The database in which the HCatalog managed tables are placed. By default, this database is the Hive one named default.</th>

<tbody>
<tr>
<td>Field separator</td>
<td>Enter character, string or regular expression to separate fields for the transferred data.</td>
</tr>
<tr>
<td>Custom encoding</td>
<td>Select the encoding from the list or select Custom and define it manually. This field is compulsory for database data handling. The supported encodings depend on the JVM that you are using. For more information, see <a href="https://docs.oracle.com">https://docs.oracle.com</a>.</td>
</tr>
</tbody>
</table>
| Hadoop properties| Talend Studio uses a default configuration for its engine to perform operations in a Hadoop distribution. If you need to use a custom configuration in a specific situation, complete this table with the property or properties to be customized. Then at runtime, the customized property or properties will override those default ones.  
  - Note that if you are using the centrally stored metadata from the Repository, this table automatically inherits the properties defined in that metadata and becomes uneditable unless you change the Property type from Repository to Built-in. |
For further information about the properties required by
Hadoop and its related systems such as HDFS and Hive,
see the documentation of the Hadoop distribution you are
using or see Apache’s Hadoop documentation on http://
hadoop.apache.org/docs and then select the version of the
documentation you want. For demonstration purposes, the
links to some properties are listed below:

- Typically, the HDFS-related properties can be found in
  the hdfs-default.xml file of your distribution, such as
  http://hadoop.apache.org/docs/r2.6.0/hadoop-project-
dist/hadoop-hdfs/hdfs-default.xml.
- Apache also provides a page to list the Hive-related
  properties: https://cwiki.apache.org/confluence/display/
  Hive/Configuration+Properties.

---

### Retrieve the HCatalog logs
Select this check box to retrieve log files generated during
HCatalog operations.

### Standard Output Folder
Fill this field with the path to which log files are stored.

**Note:**
This field is enabled only when you selected Retrieve the
HCatalog logs check box.

### Error Output Folder
Fill this field with the path to which error log files are
stored.

**Note:**
This field is enabled only when you selected Retrieve the
HCatalog logs check box.

### tStatCatcher Statistics
Select this check box to gather the Job processing metadata
at the Job level as well as at each component level.

---

### Global Variables

#### Global Variables

**ERROR_MESSAGE**: the error message generated by the
component when an error occurs. This is an After variable
and it returns a string. This variable functions only if the
Die on error check box is cleared, if the component has this
check box.

A Flow variable functions during the execution of a
component while an After variable functions after the
execution of the component.

To fill up a field or expression with a variable, press Ctrl +
Space to access the variable list and choose the variable to
use from it.

For further information about variables, see Talend Studio
User Guide.

---

### Usage

#### Usage rule
This component is commonly used as the starting
component in a Job.
HCatalog is built on top of the Hive metastore to provide read and write interface for Pig and MapReduce, so that the latter systems can use the metadata of Hive to easily read and write data in HDFS.

For further information, see Apache documentation about HCatalog: [https://cwiki.apache.org/confluence/display/Hive/HCatalog](https://cwiki.apache.org/confluence/display/Hive/HCatalog).

### Prerequisites

The Hadoop distribution must be properly installed, so as to guarantee the interaction with [Talend Studio](https://www.talend.com). The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR's documentation, the library or libraries of a MapR client corresponding to each OS version can be found under `MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native`. For example, the library for Windows is `\lib\native\MapRClient.dll` in the MapR client jar file. For further information, see the following link from MapR: [http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr](http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr).

Without adding the specified library or libraries, you may encounter the following error: `no MapRClient in java.library.path`.

- Set the `-Djava.library.path` argument, for example, in the Job Run VM arguments area of the Run/Debug view in the Preferences dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

### Limitation

When Use kerberos authentication is selected, the component cannot work with IBM JVM.

### Related scenario

For a related scenario, see Managing HCatalog tables on Hortonworks Data Platform on page 1435.
**tHCatalogLoad**

Reads data directly from HDFS and writes this data into an established HCatalog managed table.

**tHCatalogLoad Standard properties**

These properties are used to configure tHCatalogLoad running in the Standard Job framework.

The Standard tHCatalogLoad component belongs to the Big Data family.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-in or Repository</th>
</tr>
</thead>
<tbody>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

**Distribution**

Select the cluster you are using from the drop-down list. The options in the list vary depending on the component you are using. Among these options, the following ones requires specific configuration:

- If available in this Distribution drop-down list, the Microsoft HD Insight option allows you to use a Microsoft HD Insight cluster. For this purpose, you need to configure the connections to the HD Insight cluster and the Windows Azure Storage service of that cluster in the areas that are displayed. For detailed explanation about these parameters, search for configuring the connection manually on Talend Help Center (https://help.talend.com).

- If you select Amazon EMR, you can find more details about how to configure an Amazon EMR cluster in Talend Help Center (https://help.talend.com).

- The Custom option allows you to connect to a cluster different from any of the distributions given in this list, that is to say, to connect to a cluster not officially supported by Talend.

1. Select **Import from existing version** to import an officially supported distribution as base and then add other required jar files which the base distribution does not provide.

2. Select **Import from zip** to import the configuration zip for the custom distribution to be used. This zip file should contain the libraries of the different Hadoop elements and the index file of these libraries.

In Talend Exchange, members of Talend community have shared some ready-for-use configuration zip files which you can download from this Hadoop configuration list and directly use them in your connection accordingly. However, because of the ongoing evolution of the different Hadoop-related projects, you might not be able to find the
configuration zip corresponding to your distribution from this list; then it is recommended to use the Import from existing version option to take an existing distribution as base to add the jars required by your distribution.

Note that custom versions are not officially supported by Talend. Talend and its community provide you with the opportunity to connect to custom versions from the Studio but cannot guarantee that the configuration of whichever version you choose will be easy, due to the wide range of different Hadoop distributions and versions that are available. As such, you should only attempt to set up such a connection if you have sufficient Hadoop experience to handle any issues on your own.

**Note:**
In this dialog box, the active check box must be kept selected so as to import the jar files pertinent to the connection to be created between the custom distribution and this component.

For a step-by-step example about how to connect to a custom distribution and share this connection, see Connecting to a custom Hadoop distribution on page 1569.

<table>
<thead>

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>Description</th>
</tr>
</thead>
</table>
| **Usage rule** | This component can be used in a single-component subjob.  
HCatalog is built on top of the Hive metastore to provide read and write interface for Pig and MapReduce, so that the latter systems can use the metadata of Hive to easily read and write data in HDFS.  
For further information, see Apache documentation about HCatalog: [https://cwiki.apache.org/confluence/display/Hive/HCatalog](https://cwiki.apache.org/confluence/display/Hive/HCatalog). |
The Hadoop distribution must be properly installed, so as to guarantee the interaction with Talend Studio. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR's documentation, the library or libraries of a MapR client corresponding to each OS version can be found under MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native. For example, the library for Windows is \lib\native\MapRClient.dll in the MapR client jar file. For further information, see the following link from MapR: http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr.

Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path.

- Set the -Djava.library.path argument, for example, in the Job Run VM arguments area of the Run/Debug view in the Preferences dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

When Use kerberos authentication is selected, the component cannot work with IBM JVM.

For a related scenario, see Managing HCatalog tables on Hortonworks Data Platform on page 1435.
tHCatalogOperation

Prepares the HCatalog managed database/table/partition to be processed.

tHCatalogOperation manages the data stored in HCatalog managed Hive database/table/partition.

**tHCatalogOperation Standard properties**

These properties are used to configure tHCatalogOperation running in the Standard Job framework.

The Standard tHCatalogOperation component belongs to the Big Data family.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<tr>
<th><strong>Templeton port</strong></th>
<th>Fill this field with the port of URL of Templeton Webservice. By default, the value for this field is 50111.</th>
</tr>
</thead>
</table>

**Note:**

Templeton is a webservice API for HCatalog. It has been renamed to WebHCat by the Apache community. This service facilitates the access to HCatalog and the related Hadoop elements such as Pig. For further information about Templeton (WebHCat), see [https://cwiki.apache.org/confluence/display/Hive/WebHCat +UsingWebHCat.](#)

<table>
<thead>
<tr>
<th><strong>Use kerberos authentication</strong></th>
<th>If you are accessing the Hadoop cluster running with Kerberos security, select this check box, then, enter the</th>
</tr>
</thead>
</table>
Kerberos principal name for the NameNode in the field displayed. This enables you to use your user name to authenticate against the credentials stored in Kerberos.

- If this cluster is a MapR cluster of the version 5.0.0 or later, you can set the MapR ticket authentication configuration in addition or as an alternative by following the explanation in Connecting to a security-enabled MapR on page 1629.

Keep in mind that this configuration generates a new MapR security ticket for the username defined in the Job in each execution. If you need to reuse an existing ticket issued for the same username, leave both the **Force MapR ticket authentication** check box and the **Use Kerberos authentication** check box clear, and then MapR should be able to automatically find that ticket on the fly.

This check box is available depending on the Hadoop distribution you are connecting to.

<table>
<thead>
<tr>
<th>Use a keytab to authenticate</th>
<th>Select the <strong>Use a keytab to authenticate</strong> check box to log into a Kerberos-enabled system using a given keytab file. A keytab file contains pairs of Kerberos principals and encrypted keys. You need to enter the principal to be used in the <strong>Principal</strong> field and the access path to the keytab file itself in the <strong>Keytab</strong> field. This keytab file must be stored in the machine in which your Job actually runs, for example, on a Talend Jobserver. Note that the user that executes a keytab-enabled Job is not necessarily the one a principal designates but must have the right to read the keytab file being used. For example, the user name you are using to execute a Job is user1 and the principal to be used is guest; in this situation, ensure that user1 has the right to read the keytab file to be used.</th>
</tr>
</thead>
</table>
| Operation on | Select an object from the list for the DB operation as follows:
- **Database**: The HCatalog managed database in HDFS.
- **Table**: The HCatalog managed table in HDFS.
- **Partition**: The partition specified by the user. |
<p>| Operation | Select an action from the list for the DB operation. For further information about the DB operation in HDFS, see <a href="https://cwiki.apache.org/Hive/">https://cwiki.apache.org/Hive/</a>. |
| Create the table only it doesn’t exist already | Select this check box to avoid creating duplicate table when you create a table. |
| <strong>Note</strong>: This check box is enabled only when you have selected <strong>Table</strong> from the <strong>Operation on</strong> list. |
| Database | Fill this field with the name of the database in which the HCatalog managed tables are placed. |
| Table | Fill this field to operate on one or multiple tables in a database or on a specified HDFS location. |</p>
<table>
<thead>
<tr>
<th><strong>Note:</strong></th>
<th>This field is enabled only when you have selected Table from the Operation on list. For further information about the operation on Table, see <a href="https://cwiki.apache.org/Hive/">https://cwiki.apache.org/Hive/</a>.</th>

**Global Variables**

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the |
### Usage

#### Usage rule

This component is commonly used in a single-component subjob.

HCatalog is built on top of the Hive metastore to provide read and write interface for Pig and MapReduce, so that the latter systems can use the metadata of Hive to easily read and write data in HDFS.

For further information, see Apache documentation about HCatalog: [https://cwiki.apache.org/confluence/display/Hive/HCatalog](https://cwiki.apache.org/confluence/display/Hive/HCatalog).

#### Prerequisites

The Hadoop distribution must be properly installed, so as to guarantee the interaction with Talend Studio. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native. For example, the library for Windows is \lib\native\MapRClient.dll in the MapR client jar file. For further information, see the following link from MapR: [http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr](http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr).

Without adding the specified library or libraries, you may encounter the following error: `no MapRClient in java.library.path`.

- Set the `-Djava.library.path` argument, for example, in the Job Run VM arguments area of the Run/Debug view in the Preferences dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

#### Limitation

When **Use kerberos authentication** is selected, the component cannot work with IBM JVM.
Managing HCatalog tables on Hortonworks Data Platform

This scenario applies only to Talend products with Big Data.

This scenario describes a six-component Job that includes the common operations for the HCatalog table management on Hortonworks Data Platform. Sub-sections in this scenario covers DB operations including:

- Creating a table to the database in HDFS;
- Writing data to the HCatalog managed table;
- Writing data to the partitioned table using `tHCatalogLoad`;
- Reading data from the HCatalog managed table;
- Outputting the data read from the table in HDFS.

**Note:**
Knowledge of Hive Data Definition Language and HCatalog Data Definition Language is required. For further information about Hive Data Definition Language, see https://cwiki.apache.org/confluence/display/Hive/LanguageManual+DDL. For further information about HCatalog Data Definition Language, see https://cwiki.apache.org/confluence/display/HCATALOG/Design+Document+-+Java+APIs+for+HCatalog+DDL+Commands.

**Setting up the Job**

**Procedure**

1. Drop the following components from the Palette to the design workspace: `tHCatalogOperation`, `tHCatalogLoad`, `tHCatalogInput`, `tHCatalogOutput`, `tFixedFlowInput`, and `tFileOutputDelimited`.

2. Right-click `tHCatalogOperation` to connect it to `tFixedFlowInput` component using a `Trigger>OnSubjobOk` connection.
3. Right-click `tFixedFlowInput` to connect it to `tHCatalogOutput` using a `Row > Main` connection.
4. Right-click `tFixedFlowInput` to connect it to `tHCatalogLoad` using a `Trigger > OnSubjobOk` connection.
5. Right-click `tHCatalogLoad` to connect it to the `tHCatalogInput` component using a `Trigger > OnSubjobOk` connection.
6. Right-click `tHCatalogInput` to connect it to `tFileOutputDelimited` using a `Row > Main` connection.

**Creating a table in HDFS**

**Procedure**

1. Double-click `tHCatalogOperation` to open its Basic settings view.

![tHCatalogOperation_1](image)

2. Click Edit schema to define the schema for the table to be created.

![tHCatalogOperation_2](image)
3. Click [+] to add at least one column to the schema and click OK when you finish setting the schema. In this scenario, the columns added to the schema are: name, country and age.

4. Fill the Templeton hostname field with URL of the Templeton webservice you are using. In this scenario, fill this field with "192.168.0.131".

5. Fill the Templeton port field with the port for Templeton hostname. By default, the value for this field is "50111".

6. Select Table from the Operation on list and Drop if exist and create from the Operation list to create a table in HDFS.

7. Fill the Database field with an existing database name in HDFS. In this scenario, the database name is "talend".

8. Fill the Table field with the name of the table to be created. In this scenario, the table name is "Customer".

9. Fill the Username field with the username for the DB authentication.

10. Select the Set the user group to use check box to specify the user group. The default user group is "root", you need to specify the value for this field according to real practice.

11. Select the Set the permissions to use check box to specify the user permission. The default value for this field is "rwxrwxr-x".

12. Select the Set partitions check box to enable the partition schema.

13. Click the Edit schema button check box to define the partition schema.

14. Click [+] to add one column to the schema and click OK when you finish setting the schema. In this scenario, the column added to the partition schema is: match_age.

Writing data to the existing table

Procedure

1. Double-click tFixedFlowInput to open its Basic settings view.

2. Click Edit schema to define a same schema as the one you defined in tHCatalogOperation.

3. Fill the Number of rows field with integer 8.
4. Select **Use Inline Table** in the **Mode** area.
5. Click [+] to add new lines in the inline table.
6. Double-click **tHCatalogOutput** to open its **Basic settings** view.

![Inline Table Settings](image)

7. Click **Sync columns** to retrieve the schema defined in the preceding component.
8. Fill the **NameNode URI** field with the URI to the NameNode. If you are using WebHDFS, the location should be webhdfs://masternode:portnumber; WebHDFS with SSL is not supported yet.
9. Fill the **File name** field with the HDFS location of the file you write data to. In this scenario, the file location is "/user/hdp/Customer/Customer.csv".
10. Select **Overwrite** from the **Action** list.
11. Fill the **Templeton hostname** field with URL of the Templeton webservice you are using. In this scenario, fill this field with "192.168.0.131".
12. Fill the **Templeton port** field with the port for **Templeton hostname**. By default, the value for this field is "50111".
13. Fill the **Database** field, the **Table** field, the **Username** field with the same value you specified in **tHCatalogOperation**.
14. Fill the **Partition** field with "match_age=27".
15. Fill the **File location** field with the HDFS location to which the table will be saved. In this example, use "hdfs://192.168.0.131:8020/user/hdp/Customer".

**Writing data to the partitioned table using tHCatalogLoad**

**Procedure**

1. Double-click **tHCatalogLoad** to open its **Basic settings** view.
2. Fill the Partition field with "match_age=26".
3. Do the rest of the settings in the same way as configuring tHCatalogOperation.

Reading data from the table in HDFS

Procedure
1. Double-click tHCatalogInput to open its Basic settings view.

2. Click Edit schema to define the schema of the table to be read from the database.
3. Click [+ ] to add at least one column to the schema. In this scenario, the columns added to the schema are age and name.

4. Fill the Partition field with "match_age=26".

5. Do the rest of the settings in the same way as configuring THCatalogOperation.

Outputting the data read from the table in HDFS to the console

Procedure

1. Double-click tLogRow to open its Basic settings view.

2. Click Sync columns to retrieve the schema defined in the preceding component.

3. Select Table from the Mode area.

Job execution

Press CTRL+S to save your Job and F6 to execute it.
The data of the restricted table read from the HDFS is displayed onto the console.

Type in `http://talend-hdp:50075/browseDirectory.jsp?dir=/user/hdp/Customer&namenodeInfoPort=50070` to the address bar of your browser to view the table you created:

tHCatalogOutput

Receives data from its incoming flow and writes this data into an HCatalog managed table.

**tHCatalogOutput Standard properties**

These properties are used to configure tHCatalogOutput running in the Standard Job framework.

The Standard tHCatalogOutput component belongs to the Big Data family.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either <strong>Built-in</strong> or <strong>Repository</strong></th>

<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong>:</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

**Schema and Edit Schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Built-In**: You create and store the schema locally for this component only.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).
Select the cluster you are using from the drop-down list. The options in the list vary depending on the component you are using. Among these options, the following ones require specific configuration:

- If available in this Distribution drop-down list, the Microsoft HD Insight option allows you to use a Microsoft HD Insight cluster. For this purpose, you need to configure the connections to the HD Insight cluster and the Windows Azure Storage service of that cluster in the areas that are displayed. For detailed explanation about these parameters, search for configuring the connection manually on Talend Help Center (https://help.talend.com).
- If you select Amazon EMR, you can find more details about how to configure an Amazon EMR cluster in Talend Help Center (https://help.talend.com).
- The Custom option allows you to connect to a cluster different from any of the distributions given in this list, that is to say, to connect to a cluster not officially supported by Talend.

1. Select Import from existing version to import an officially supported distribution as base and then add other required jar files which the base distribution does not provide.
2. Select Import from zip to import the configuration zip for the custom distribution to be used. This zip file should contain the libraries of the different Hadoop elements and the index file of these libraries.

In Talend Exchange, members of Talend community have shared some ready-for-use configuration zip files which you can download from this Hadoop configuration list and directly use them in your connection accordingly. However, because of the ongoing evolution of the different Hadoop-related projects, you might not be able to find the configuration zip corresponding to your distribution from this list; then it is recommended to use the Import from existing version option to take an existing distribution as base to add the jars required by your distribution.

Note that custom versions are not officially supported by Talend. Talend and its community provide you with the opportunity to connect to custom versions from the Studio but cannot guarantee that the configuration of whichever version you choose will be easy, due to the wide range of different Hadoop distributions and versions that are available. As such, you should only attempt to set up such a connection if you have sufficient Hadoop experience to handle any issues on your own.

Note:
In this dialog box, the active check box must be kept selected so as to import the jar files pertinent to the connection to be created between the custom distribution and this component.

For a step-by-step example about how to connect to a custom distribution and share this connection, see
<table>
<thead>
<tr>
<th><strong>HCatalog version</strong></th>
<th>Select the version of the Hadoop distribution you are using. The available options vary depending on the component you are using.</th>
</tr>
</thead>
</table>
| **Use kerberos authentication** | If you are accessing the Hadoop cluster running with Kerberos security, select this check box, then, enter the Kerberos principal name for the NameNode in the field displayed. This enables you to use your user name to authenticate against the credentials stored in Kerberos.  
  - If this cluster is a MapR cluster of the version 5.0.0 or later, you can set the MapR ticket authentication configuration in addition or as an alternative by following the explanation in [Connecting to a security-enabled MapR](#) on page 1629.  
  Keep in mind that this configuration generates a new MapR security ticket for the username defined in the Job in each execution. If you need to reuse an existing ticket issued for the same username, leave both the [Force MapR ticket authentication](#) check box and the [Use Kerberos authentication](#) check box clear, and then MapR should be able to automatically find that ticket on the fly.  
  This check box is available depending on the Hadoop distribution you are connecting to. |
| **Use a keytab to authenticate** | Select the [Use a keytab to authenticate](#) check box to log into a Kerberos-enabled system using a given keytab file. A keytab file contains pairs of Kerberos principals and encrypted keys. You need to enter the principal to be used in the **Principal** field and the access path to the keytab file itself in the **Keytab** field. This keytab file must be stored in the machine in which your Job actually runs, for example, on a Talend Jobserver.  
  Note that the user that executes a keytab-enabled Job is not necessarily the one a principal designates but must have the right to read the keytab file being used. For example, the user name you are using to execute a Job is `user1` and the principal to be used is `guest`; in this situation, ensure that `user1` has the right to read the keytab file to be used. |
| **NameNode URI** | Type in the URI of the Hadoop NameNode, the master node of a Hadoop system. For example, we assume that you have chosen a machine called `masternode` as the NameNode, then the location is `hdfs://masternode:portnumber`. If you are using WebHDFS, the location should be `webhdfs://masternode:portnumber`; WebHDFS with SSL is not supported yet. |
| **File name** | Browse to, or enter the location of the file which you write data to. This file is created automatically if it does not exist. |
| **Action** | Select a DB operation in HDFS:  
  - **Create**: Creates a file with data using the file name defined in the **File Name** field.  
  - **Overwrite**: Overwrites the data in the file specified in the **File Name** field. |
**Append**: Inserts the data into the file specified in the **File Name** field. The specified file is created automatically if it does not exist.

<th>Fill this field with the port of URL of Templeton Webservice. By default, this value is 50111.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Note:</strong> Templeton is a webservice API for HCatalog. It has been renamed to WebHCat by the Apache community. This service facilitates the access to HCatalog and the related Hadoop elements such as Pig. For further information about Templeton (WebHCat), see <a href="https://cwiki.apache.org/confluence/display/Hive/WebHCat+UsingWebHCat">https://cwiki.apache.org/confluence/display/Hive/WebHCat+UsingWebHCat</a>.</td>
<td></td>
</tr>
</tbody>
</table>

| **Database** | Fill this field to specify an existing database in HDFS. |

| **Table** | Fill this field to specify an existing table in HDFS. |

<table>
<thead>
<tr>
<th><strong>Partition</strong></th>
<th>Fill this field to specify one or more partitions for the partition operation on the specified table. When you specify multiple partitions, use commas to separate every two partitions and use double quotation marks to quote the partition string. If you are reading a non-partitioned table, leave this field empty.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Note:</strong> For further information about <strong>Partition</strong>, see <a href="https://cwiki.apache.org/Hive/">https://cwiki.apache.org/Hive/</a>.</td>
<td></td>
</tr>
</tbody>
</table>

| **Username** | Fill this field with the username for the DB authentication. |

| **File location** | Fill this field with the path to which source data file is stored. |

| **Die on error** | This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows. |

**Advanced settings**

<p>| <strong>Row separator</strong> | The separator used to identify the end of a row. |</p>
<table>
<thead>
<tr>
<th><strong>Field separator</strong></th>
<th>Enter character, string or regular expression to separate fields for the transferred data.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Custom encoding</strong></td>
<td>Select the encoding from the list or select Custom and define it manually. This field is compulsory for database data handling. The supported encodings depend on the JVM that you are using. For more information, see <a href="https://docs.oracle.com">https://docs.oracle.com</a>.</td>
</tr>
</tbody>
</table>
| **Hadoop properties** | **Talend Studio** uses a default configuration for its engine to perform operations in a Hadoop distribution. If you need to use a custom configuration in a specific situation, complete this table with the property or properties to be customized. Then at runtime, the customized property or properties will override those default ones.  
- Note that if you are using the centrally stored metadata from the Repository, this table automatically inherits the properties defined in that metadata and becomes uneditable unless you change the **Property type** from Repository to Built-in.  
For further information about the properties required by Hadoop and its related systems such as HDFS and Hive, see the documentation of the Hadoop distribution you are using or see Apache’s Hadoop documentation on [http://hadoop.apache.org/docs](http://hadoop.apache.org/docs) and then select the version of the documentation you want. For demonstration purposes, the links to some properties are listed below:  
- Typically, the HDFS-related properties can be found in the `hdfs-default.xml` file of your distribution, such as [http://hadoop.apache.org/docs/r2.6.0/hadoop-project-dist/hadoop-hdfs/hdfs-default.xml](http://hadoop.apache.org/docs/r2.6.0/hadoop-project-dist/hadoop-hdfs/hdfs-default.xml).  
- Apache also provides a page to list the Hive-related properties: [https://cwiki.apache.org/confluence/display/Hive/Configuration+Properties](https://cwiki.apache.org/confluence/display/Hive/Configuration+Properties). |
| **Retrieve the HCatalog logs** | Select this check box to retrieve log files generated during HCatalog operations. |
| **Standard Output Folder** | Browse to, or enter the directory where the log files are stored.  
**Note:**  
This field is enabled only when you selected **Retrieve the HCatalog logs** check box. |
| **Error Output Folder** | Browse to, or enter the directory where the error log files are stored.  
**Note:**  
This field is enabled only when you selected **Retrieve the HCatalog logs** check box. |
| **tStatCatcher Statistics** | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |
### Global Variables

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

**Usage rule**

This component is commonly used together with an input component.

HCatalog is built on top of the Hive metastore to provide read and write interface for Pig and MapReduce, so that the latter systems can use the metadata of Hive to easily read and write data in HDFS.

For further information, see Apache documentation about HCatalog: [https://cwiki.apache.org/confluence/display/Hive/HCatalog](https://cwiki.apache.org/confluence/display/Hive/HCatalog).

### Prerequisites

The Hadoop distribution must be properly installed, so as to guarantee the interaction with *Talend Studio*. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under **MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native**. For example, the library for Windows is **\lib\native\MapRClient.dll** in the MapR client jar file. For further information, see the following link from MapR: [http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr](http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr).

  Without adding the specified library or libraries, you may encounter the following error: *no MapRClient in java.library.path*.

- Set the **-Djava.library.path** argument, for example, in the **Job Run VM arguments** area of the **Run/Debug** view in the **Preferences** dialog box in the **Window** menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the **Data viewer** to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.
Related scenario

For a related scenario, see Managing HCatalog tables on Hortonworks Data Platform on page 1435.
tHDFSCompare

Compares two files in HDFS and based on the read-only schema, generates a row flow that presents the comparison information.

tHDFSCompare helps to control the quality of the data processed.

**tHDFSCompare Standard properties**

These properties are used to configure tHDFSCompare running in the Standard Job framework.

The Standard tHDFSCompare component belongs to the Big Data and the File families.

The component in this framework is available in all *Talend products with Big Data* and in *Talend Data Fabric*.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either <strong>Built-in</strong> or <strong>Repository</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-in</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the **Component List** click the HDFS connection component from which you want to reuse the connection details already defined.

Note that when a Job contains the parent Job and the child Job, **Component List** presents only the connection components in the same Job level.

**Distribution**

Select the cluster you are using from the drop-down list. The options in the list vary depending on the component you are using. Among these options, the following ones requires specific configuration:

- If available in this **Distribution** drop-down list, the **Microsoft HD Insight** option allows you to use a Microsoft HD Insight cluster. For this purpose, you need to configure the connections to the HD Insight cluster and the Windows Azure Storage service of that cluster in the areas that are displayed. For detailed explanation about these parameters, search for configuring the connection manually on Talend Help Center (https://help.talend.com).
- If you select **Amazon EMR**, you can find more details about how to configure an Amazon EMR cluster in Talend Help Center (https://help.talend.com).
- The **Custom** option allows you to connect to a cluster different from any of the distributions given in this list, that is to say, to connect to a cluster not officially supported by Talend.

1. Select **Import from existing version** to import an officially supported distribution as base and then add other required jar files which the base distribution does not provide.
2. Select **Import from zip** to import the configuration zip for the custom distribution to be used. This zip file should contain the libraries of the different Hadoop elements and the index file of these libraries.

In **Talend Exchange**, members of **Talend** community have shared some ready-for-use configuration zip files which you can download from this Hadoop configuration list and directly use them in your connection accordingly. However, because of the ongoing evolution of the different Hadoop-related projects, you might not be able to find the configuration zip corresponding to your distribution from this list; then it is recommended to use the **Import from existing version** option to take an existing distribution as base to add the jars required by your distribution.

Note that custom versions are not officially supported by **Talend**. **Talend** and its community provide you with the opportunity to connect to custom versions from the Studio but cannot guarantee that the configuration of whichever version you choose will be easy, due to the wide range of different Hadoop distributions and versions that are available. As such, you should only attempt to set up such a connection if you have sufficient Hadoop experience to handle any issues on your own.

Note: In this dialog box, the active check box must be kept selected so as to import the jar files pertinent to the connection to be created between the custom distribution and this component.

For a step-by-step example about how to connect to a custom distribution and share this connection, see **Connecting to a custom Hadoop distribution** on page 1569.

<table>
<thead>
<tr>
<th>Version</th>
<th>Select the version of the Hadoop distribution you are using. The available options vary depending on the component you are using.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scheme</td>
<td>Select the URI scheme of the file system to be used from the <strong>Scheme</strong> drop-down list. This scheme could be</td>
</tr>
<tr>
<td></td>
<td>• HDFS</td>
</tr>
<tr>
<td></td>
<td>• WebHDFS. WebHDFS with SSL is not supported yet.</td>
</tr>
<tr>
<td></td>
<td>• ADLS</td>
</tr>
<tr>
<td></td>
<td>The schemes present on this list vary depending on the distribution you are using and only the scheme that appears on this list with a given distribution is officially supported by Talend.</td>
</tr>
<tr>
<td></td>
<td>Once a scheme is selected, the corresponding syntax such as <code>webhdfs://localhost:50070/</code> for WebHDFS is displayed in the field for the NameNode location of your cluster.</td>
</tr>
<tr>
<td></td>
<td>If you have selected <strong>ADLS</strong>, the connection parameters to be defined become:</td>
</tr>
</tbody>
</table>
• In the **Client ID** and the **Client key** fields, enter, respectively, the authentication ID and the authentication key generated upon the registration of the application that the current Job you are developing uses to access Azure Data Lake Storage.

Ensure that the application to be used has appropriate permissions to access Azure Data Lake. You can check this on the Required permissions view of this application on Azure. For further information, see Azure documentation Assign the Azure AD application to the Azure Data Lake Storage account file or folder.

• In the **Token endpoint** field, copy-paste the OAuth 2.0 token endpoint that you can obtain from the **Endpoints** list accessible on the **App registrations** page on your Azure portal.

For a video demonstration, see Configure and use Azure in a Job.

### NameNode URI

Type in the URI of the Hadoop NameNode, the master node of a Hadoop system. For example, we assume that you have chosen a machine called `masternode` as the NameNode, then the location is `hdfs://masternode:portnumber`. If you are using WebHDFS, the location should be `webhdfs://masternode:portnumber`; WebHDFS with SSL is not supported yet.

### Use kerberos authentication

If you are accessing the Hadoop cluster running with Kerberos security, select this check box, then, enter the Kerberos principal name for the NameNode in the field displayed. This enables you to use your user name to authenticate against the credentials stored in Kerberos.

- If this cluster is a MapR cluster of the version 5.0.0 or later, you can set the MapR ticket authentication configuration in addition or as an alternative by following the explanation in Connecting to a security-enabled MapR on page 1629.

Keep in mind that this configuration generates a new MapR security ticket for the username defined in the Job in each execution. If you need to reuse an existing ticket issued for the same username, leave both the **Force MapR ticket authentication** check box and the Use Kerberos authentication check box clear, and then MapR should be able to automatically find that ticket on the fly.

This check box is available depending on the Hadoop distribution you are connecting to.

### Use a keytab to authenticate

Select the **Use a keytab to authenticate** check box to log into a Kerberos-enabled system using a given keytab file. A keytab file contains pairs of Kerberos principals and encrypted keys. You need to enter the principal to be used in the **Principal** field and the access path to the keytab file itself in the **Keytab** field. This keytab file must be stored in the machine in which your Job actually runs, for example, on a Talend Jobserver.

Note that the user that executes a keytab-enabled Job is not necessarily the one a principal designates but must have the right to read the keytab file being used. For example, the user name you are using to execute a Job is `user1` and the
principal to be used is guest; in this situation, ensure that user1 has the right to read the keytab file to be used.

<table>
<thead>
<tr>
<th>User name</th>
<th>The User name field is available when you are not using Kerberos to authenticate. In the User name field, enter the login user name for your distribution. If you leave it empty, the user name of the machine hosting the Studio will be used.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Group</td>
<td>Enter the membership including the authentication user under which the HDFS instances were started. This field is available depending on the distribution you are using.</td>
</tr>
<tr>
<td>Schema and Edit schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. The schema of this component is read-only. You can click Edit schema to view the schema.</td>
</tr>
<tr>
<td>Comparison mode</td>
<td>Select the mode to be applied on the comparison.</td>

<td></td>
<td>To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td></td>
<td>For further information about variables, see <a href="https://cwiki.apache.org/confluence/display/Hive/Configuration+Properties">Talend Studio User Guide</a>.</td>
</tr>
</tbody>
</table>

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>tHDFSCcompare can be standalone component or send the information it generates to its following component.</th>
</tr>
</thead>
</table>

**Dynamic settings**

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your HDFS connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access files in different HDFS systems or different distributions, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic
settings and context variables, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>Prerequisites</th>
<th>The Hadoop distribution must be properly installed, so as to guarantee the interaction with Talend Studio. The following list presents MapR related information for example.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Prerequisites</td>
<td>• Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native. For example, the library for Windows is \lib\native\MapRClient.dll in the MapR client jar file. For further information, see the following link from MapR: <a href="http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr">http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr</a>. Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path. • Set the -Djava.library.path argument, for example, in the Job Run VM arguments area of the Run/Debug view in the Preferences dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR. For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.</td>
</tr>
</tbody>
</table>

| Limitation | JRE 1.6+ is required. |

**Related scenarios**

No scenario is available for the Standard version of this component yet.
tHDFSConnection

Connects to a given HDFS so that the other Hadoop components can reuse the connection it creates to communicate with this HDFS.

tHDFSConnection provides connection to the Hadoop distributed file system (HDFS) of interest at runtime.

**tHDFSConnection Standard properties**

These properties are used to configure tHDFSConnection running in the Standard Job framework.

The Standard tHDFSConnection component belongs to the Big Data and the File families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>

</tr>
</tbody>
</table>
check this on the Required permissions view of this application on Azure. For further information, see Azure documentation Assign the Azure AD application to the Azure Data Lake Storage account file or folder.

- In the **Token endpoint** field, copy-paste the OAuth 2.0 token endpoint that you can obtain from the **Endpoints** list accessible on the **App registrations** page on your Azure portal.

For a video demonstration, see **Configure and use Azure in a Job**.

### NameNode URI
Type in the URI of the Hadoop NameNode, the master node of a Hadoop system. For example, we assume that you have chosen a machine called `masternode` as the NameNode, then the location is `hdfs://masternode:portnumber`. If you are using WebHDFS, the location should be `webhdfs://masternode:portnumber`; WebHDFS with SSL is not supported yet.

### Inspect the classpath for configurations
Select this check box to allow the component to check the configuration files in the directory you have set with the `$HADOOP_CONF_DIR` variable and directly read parameters from these files in this directory. This feature allows you to easily change the Hadoop configuration for the component to switch between different environments, for example, from a test environment to a production environment.

In this situation, the fields or options used to configure Hadoop connection and/or Kerberos security are hidden.

If you want to use certain parameters such as the Kerberos parameters but these parameters are not included in these Hadoop configuration files, you need to create a file called `talend-site.xml` and put this file into the same directory defined with `$HADOOP_CONF_DIR`. This `talend-site.xml` file should read as follows:

```xml
<!-- Put site-specific property overrides in this file. -->
<configuration>
  <property>
    <name>talend.kerberos.authentication</name>
    <value>kinit</value>
    <description>Set the Kerberos authentication method to use. Valid values are: kinit or keytab.</description>
  </property>
  <property>
    <name>talend.kerberos.keytab.principal</name>
    <value>user@BIGDATA.COM</value>
    <description>Set the keytab’s principal name.</description>
  </property>
  <property>
    <name>talend.kerberos.keytab.path</name>
    <value>/kdc/user.keytab</value>
  </property>
</configuration>
```
<description> Set the keytab's path. </description>
</property>

<property>
  <name>talend.encryption</name>
  <value>none</value>
  <description> Set the encryption method to use. Valid values are: none or ssl. </description>
</property>

<property>
  <name>talend.ssl.trustStore.path</name>
  <value>ssl</value>
  <description> Set SSL trust store path. </description>
</property>

<property>
  <name>talend.ssl.trustStore.password</name>
  <value>ssl</value>
  <description> Set SSL trust store password. </description>
</property>

The parameters read from these configuration files override the default ones used by the Studio. When a parameter does not exist in these configuration files, the default one is used.

**Use kerberos authentication**

If you are accessing the Hadoop cluster running with Kerberos security, select this check box, then, enter the Kerberos principal name for the NameNode in the field displayed. This enables you to use your user name to authenticate against the credentials stored in Kerberos.

- If this cluster is a MapR cluster of the version 5.0.0 or later, you can set the MapR ticket authentication configuration in addition or as an alternative by following the explanation in Connecting to a security-enabled MapR on page 1629.

  Keep in mind that this configuration generates a new MapR security ticket for the username defined in the Job in each execution. If you need to reuse an existing ticket issued for the same username, leave both the Force MapR ticket authentication check box and the Use Kerberos authentication check box clear, and then MapR should be able to automatically find that ticket on the fly.

  This check box is available depending on the Hadoop distribution you are connecting to.

**Use a keytab to authenticate**

Select the Use a keytab to authenticate check box to log into a Kerberos-enabled system using a given keytab file. A keytab file contains pairs of Kerberos principals and encrypted keys. You need to enter the principal to be used in the Principal field and the access path to the keytab file.
itself in the **Keytab** field. This keytab file must be stored in the machine in which your Job actually runs, for example, on a Talend Jobserver.

Note that the user that executes a keytab-enabled Job is not necessarily the one a principal designates but must have the right to read the keytab file being used. For example, the user name you are using to execute a Job is `user1` and the principal to be used is `guest`; in this situation, ensure that `user1` has the right to read the keytab file to be used.

<table>

</table>
| Hadoop properties | *Talend Studio* uses a default configuration for its engine to perform operations in a Hadoop distribution. If you need to use a custom configuration in a specific situation, complete this table with the property or properties to be customized. Then at runtime, the customized property or properties will override those default ones.  
  • Note that if you are using the centrally stored metadata from the **Repository**, this table automatically inherits the properties defined in that metadata and becomes uneditable unless you change the **Property type** from **Repository** to **Built-in**.  
For further information about the properties required by Hadoop and its related systems such as HDFS and Hive, see the documentation of the Hadoop distribution you are using or see Apache’s Hadoop documentation on [http://hadoop.apache.org/docs](http://hadoop.apache.org/docs) and then select the version of the documentation you want. For demonstration purposes, the links to some properties are listed below:  
  • Typically, the HDFS-related properties can be found in the **hdfs-default.xml** file of your distribution, such as [http://hadoop.apache.org/docs/r2.6.0/hadoop-project-dist/hadoop-hdfs/hdfs-default.xml](http://hadoop.apache.org/docs/r2.6.0/hadoop-project-dist/hadoop-hdfs/hdfs-default.xml).  
  • Apache also provides a page to list the Hive-related properties: [https://cwiki.apache.org/confluence/display/Hive/Configuration+Properties](https://cwiki.apache.org/confluence/display/Hive/Configuration+Properties). |
| Use datanode hostname | Select the **Use datanode hostname** check box to allow the Job to access datanodes via their hostnames. This actually sets the **dfs.client.use.datanode.hostname** property to **true**. |
| Setup HDFS encryption configurations | If the HDFS transparent encryption has been enabled in your cluster, select the **Setup HDFS encryption configurations** check box and in the **HDFS encryption key provider** field that is displayed, enter the location of the KMS proxy.  
For further information about the HDFS transparent encryption and its KMS proxy, see [Transparent Encryption in HDFS](http://hadoop.apache.org/docs). |
## Advanced settings

| **tStatCatcher Statistics** | Select this check box to collect log data at the component level. |

## Global Variables

| **Global Variables** | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it. For further information about variables, see **Talend Studio User Guide**. |

## Usage

| **Usage rule** | This component is generally used with other Hadoop components. |

### Prerequisites

The Hadoop distribution must be properly installed, so as to guarantee the interaction with **Talend Studio**. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under `MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native`. For example, the library for Windows is `\lib\native\MapRClient.dll` in the MapR client jar file. For further information, see the following link from MapR: [http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr](http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr).

Without adding the specified library or libraries, you may encounter the following error: **no MapRClient in java.library.path.**

- Set the `-Djava.library.path` argument, for example, in the **Job Run VM arguments** area of the **Run/Debug** view in the **Preferences** dialog box in the **Window** menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the **Data viewer** to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.
| Limitations | JRE 1.6+ is required. |

**Related scenarios**

No scenario is available for the Standard version of this component yet.
**tHDFSCopy**

copies a source file or folder into a target directory in HDFS and removes this source if required.

**tHDFSCopy Standard properties**

These properties are used to configure tHDFSCopy running in the Standard Job framework.

The Standard tHDFSCopy component belongs to the Big Data and the File families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-in or Repository</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the Component List click the HDFS connection component from which you want to reuse the connection details already defined.

Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level.

**Distribution**

Select the cluster you are using from the drop-down list. The options in the list vary depending on the component you are using. Among these options, the following ones requires specific configuration:

- If available in this Distribution drop-down list, the Microsoft HD Insight option allows you to use a Microsoft HD Insight cluster. For this purpose, you need to configure the connections to the HD Insight cluster and the Windows Azure Storage service of that cluster in the areas that are displayed. For detailed explanation about these parameters, search for configuring the connection manually on Talend Help Center ([https://help.talend.com](https://help.talend.com)).
- If you select Amazon EMR, you can find more details about how to configure an Amazon EMR cluster in Talend Help Center ([https://help.talend.com](https://help.talend.com)).
- The Custom option allows you to connect to a cluster different from any of the distributions given in this list, that is to say, to connect to a cluster not officially supported by Talend.

1. Select Import from existing version to import an officially supported distribution as base and then add other required jar files which the base distribution does not provide.
2. Select Import from zip to import the configuration zip for the custom distribution to be used. This zip file should contain the libraries of the different Hadoop elements and the index file of these libraries.
In **Talend Exchange**, members of **Talend** community have shared some ready-for-use configuration zip files which you can download from this **Hadoop configuration** list and directly use them in your connection accordingly. However, because of the ongoing evolution of the different Hadoop-related projects, you might not be able to find the configuration zip corresponding to your distribution from this list; then it is recommended to use the **Import from existing version** option to take an existing distribution as base to add the jars required by your distribution.

Note that custom versions are not officially supported by **Talend**. **Talend** and its community provide you with the opportunity to connect to custom versions from the Studio but cannot guarantee that the configuration of whichever version you choose will be easy, due to the wide range of different Hadoop distributions and versions that are available. As such, you should only attempt to set up such a connection if you have sufficient Hadoop experience to handle any issues on your own.

**Note:**

In this dialog box, the active check box must be kept selected so as to import the jar files pertinent to the connection to be created between the custom distribution and this component.

For a step-by-step example about how to connect to a custom distribution and share this connection, see **Connecting to a custom Hadoop distribution** on page 1569.

<table>
<thead>
<tr>
<th>Version</th>
<th>Select the version of the Hadoop distribution you are using. The available options vary depending on the component you are using.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scheme</td>
<td>Select the URI scheme of the file system to be used from the Scheme drop-down list. This scheme could be ADLS&lt;HDFS WebHDFS WebHDFS with SSL is not supported yet. ADLS. The schemes present on this list vary depending on the distribution you are using and only the scheme that appears on this list with a given distribution is officially supported by Talend. Once a scheme is selected, the corresponding syntax such as <code>webhdfs://localhost:50070/</code> for WebHDFS is displayed in the field for the NameNode location of your cluster. If you have selected <strong>ADLS</strong>, the connection parameters to be defined become: • In the <strong>Client ID</strong> and the <strong>Client key</strong> fields, enter, respectively, the authentication ID and the authentication key generated upon the registration of the application that the current Job you are developing uses to access Azure Data Lake Storage.</td>
</tr>
</tbody>
</table>
Ensure that the application to be used has appropriate permissions to access Azure Data Lake. You can check this on the Required permissions view of this application on Azure. For further information, see Azure documentation Assign the Azure AD application to the Azure Data Lake Storage account file or folder.

- In the **Token endpoint** field, copy-paste the OAuth 2.0 token endpoint that you can obtain from the **Endpoints** list accessible on the **App registrations** page on your Azure portal.

For a video demonstration, see Configure and use Azure in a Job.

**NameNode URI**

Type in the URI of the Hadoop NameNode, the master node of a Hadoop system. For example, we assume that you have chosen a machine called `masternode` as the NameNode, then the location is `hdfs://masternode:portnumber`. If you are using WebHDFS, the location should be `webhdfs://masternode:portnumber`. WebHDFS with SSL is not supported yet.

**Use kerberos authentication**

If you are accessing the Hadoop cluster running with Kerberos security, select this check box, then, enter the Kerberos principal name for the NameNode in the field displayed. This enables you to use your user name to authenticate against the credentials stored in Kerberos.

- If this cluster is a MapR cluster of the version 5.0.0 or later, you can set the MapR ticket authentication configuration in addition or as an alternative by following the explanation in Connecting to a security-enabled MapR on page 1629.

Keep in mind that this configuration generates a new MapR security ticket for the username defined in the Job in each execution. If you need to reuse an existing ticket issued for the same username, leave both the Force MapR ticket authentication check box and the Use Kerberos authentication check box clear, and then MapR should be able to automatically find that ticket on the fly.

This check box is available depending on the Hadoop distribution you are connecting to.

**Use a keytab to authenticate**

Select the **Use a keytab to authenticate** check box to log into a Kerberos-enabled system using a given keytab file. A keytab file contains pairs of Kerberos principals and encrypted keys. You need to enter the principal to be used in the **Principal** field and the access path to the keytab file itself in the **Keytab** field. This keytab file must be stored in the machine in which your Job actually runs, for example, on a Talend Jobserver.

Note that the user that executes a keytab-enabled Job is not necessarily the one a principal designates but must have the right to read the keytab file being used. For example, the user name you are using to execute a Job is `user1` and the principal to be used is `guest`; in this situation, ensure that `user1` has the right to read the keytab file to be used.

**User name**

The **User name** field is available when you are not using Kerberos to authenticate. In the **User name** field, enter the login user name for your distribution. If you leave it empty,
the user name of the machine hosting the Studio will be used.

<table>
<thead>
<tr>
<th>Group</th>
<th>Enter the membership including the authentication user under which the HDFS instances were started. This field is available depending on the distribution you are using.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source file or directory</td>
<td>Browse to, or enter the path pointing to the data to be used in the file system.</td>
</tr>
<tr>
<td>Target location</td>
<td>Browse to, or enter the directory in HDFS to which you need to copy the data.</td>
</tr>
<tr>
<td>Rename</td>
<td>To rename the file or folder copied to the target location, select this check box to display the <strong>New name</strong> field, then, enter the new name.</td>
</tr>
<tr>
<td>Copy merge</td>
<td>Select this check box to merge the <em>part</em> files generated at the end of a MapReduce computation. Once selecting it, you need to enter the name of the final merged file in the <strong>Merge name</strong> field.</td>
</tr>
<tr>
<td>Remove source</td>
<td>Select this check box to remove the source file or folder once this source is copied to the target location.</td>
</tr>
<tr>
<td>Override target file (This option does not override the directory)</td>
<td>Select this check box to override the file already existing in the target location. This option does not override the folder.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| Hadoop properties | Talend Studio uses a default configuration for its engine to perform operations in a Hadoop distribution. If you need to use a custom configuration in a specific situation, complete this table with the property or properties to be customized. Then at runtime, the customized property or properties will override those default ones.  

- Note that if you are using the centrally stored metadata from the Repository, this table automatically inherits the properties defined in that metadata and becomes uneditable unless you change the **Property type** from Repository to Built-in.

For further information about the properties required by Hadoop and its related systems such as HDFS and Hive, see the documentation of the Hadoop distribution you are using or see Apache’s Hadoop documentation on [http://hadoop.apache.org/docs](http://hadoop.apache.org/docs) and then select the version of the documentation you want. For demonstration purposes, the links to some properties are listed below:

- Typically, the HDFS-related properties can be found in the `hdfs-default.xml` file of your distribution, such as [http://hadoop.apache.org/docs/r2.6.0/hadoop-project-dist/hadoop-hdfs/hdfs-default.xml](http://hadoop.apache.org/docs/r2.6.0/hadoop-project-dist/hadoop-hdfs/hdfs-default.xml).
- Apache also provides a page to list the Hive-related properties: [https://cwiki.apache.org/confluence/display/Hive/Configuration+Properties](https://cwiki.apache.org/confluence/display/Hive/Configuration+Properties).

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |
Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>DESTINATION_FILEPATH: the destination file path. This is an After variable and it returns a string.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>SOURCE_FILEPATH: the source file path. This is an After variable and it returns a string.</td>
</tr>

</table>

For further information about the properties required by Hadoop, see the Hadoop documentation.

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>DELETE_PATH</strong>: the path to the deleted file or folder. This is an After variable and it returns a string.</td>
</tr>
<tr>
<td><strong>CURRENT_STATUS</strong>: the execution result of the component. This is an After variable and it returns a string.</td>
</tr>
<tr>
<td><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
</tr>
</thead>
<tbody>
<tr>
<td>This component is used to compose a single-component Job or subjob.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Dynamic settings</th>
</tr>
</thead>
<tbody>
<tr>
<td>Click the [*] button to add a row in the table and fill the <strong>Code</strong> field with a context variable to choose your HDFS connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access files in different HDFS systems or different distributions, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of <a href="#">Talend Studio</a>.</td>
</tr>
</tbody>
</table>
The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

### Prerequisites

The Hadoop distribution must be properly installed, so as to guarantee the interaction with Talend Studio. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under `MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native`. For example, the library for Windows is `\lib\native\MapRClient.dll` in the MapR client jar file. For further information, see the following link from MapR: [http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr](http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr).

Without adding the specified library or libraries, you may encounter the following error: no MapRClient in `java.library.path`.

- Set the `-Djava.library.path` argument, for example, in the **Job Run VM arguments** area of the **Run/Debug** view in the **Preferences** dialog box in the **Window** menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the **Data viewer** to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

### Limitations

JRE 1.6+ is required.

## Related scenarios

No scenario is available for the Standard version of this component yet.
tHDFSEexist

Checks whether a file exists in a specific directory in HDFS.

**tHDFSEexist Standard properties**

These properties are used to configure tHDFSEexist running in the Standard Job framework.

The Standard tHDFSEexist component belongs to the Big Data and the File families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>

<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined.

Note that when a Job contains the parent Job and the child Job, **Component List** presents only the connection components in the same Job level.

**Distribution**

Select the cluster you are using from the drop-down list.

The options in the list vary depending on the component you are using. Among these options, the following ones requires specific configuration:

- If available in this **Distribution** drop-down list, the **Microsoft HD Insight** option allows you to use a Microsoft HD Insight cluster. For this purpose, you need to configure the connections to the HD Insight cluster and the Windows Azure Storage service of that cluster in the areas that are displayed. For detailed explanation about these parameters, search for configuring the connection manually on Talend Help Center (https://help.talend.com).
- If you select **Amazon EMR**, you can find more details about how to configure an Amazon EMR cluster in Talend Help Center (https://help.talend.com).
- The **Custom** option allows you to connect to a cluster different from any of the distributions given in this list, that is to say, to connect to a cluster not officially supported by Talend.

1. Select **Import from existing version** to import an officially supported distribution as base and then add other required jar files which the base distribution does not provide.
2. Select **Import from zip** to import the configuration zip for the custom distribution to be used. This zip file
should contain the libraries of the different Hadoop elements and the index file of these libraries.

In Talend Exchange, members of Talend community have shared some ready-for-use configuration zip files which you can download from this Hadoop configuration list and directly use them in your connection accordingly. However, because of the ongoing evolution of the different Hadoop-related projects, you might not be able to find the configuration zip corresponding to your distribution from this list; then it is recommended to use the Import from existing version option to take an existing distribution as base to add the jars required by your distribution.

Note that custom versions are not officially supported by Talend. Talend and its community provide you with the opportunity to connect to custom versions from the Studio but cannot guarantee that the configuration of whichever version you choose will be easy, due to the wide range of different Hadoop distributions and versions that are available. As such, you should only attempt to set up such a connection if you have sufficient Hadoop experience to handle any issues on your own.

For a step-by-step example about how to connect to a custom distribution and share this connection, see Connecting to a custom Hadoop distribution on page 1569.

### Version

Select the version of the Hadoop distribution you are using. The available options vary depending on the component you are using.

### Scheme

Select the URI scheme of the file system to be used from the Scheme drop-down list. This scheme could be

- HDFS
- WebHDFS. WebHDFS with SSL is not supported yet.
- ADLS

The schemes present on this list vary depending on the distribution you are using and only the scheme that appears on this list with a given distribution is officially supported by Talend.

Once a scheme is selected, the corresponding syntax such as `webhdfs://localhost:50070/` for WebHDFS is displayed in the field for the NameNode location of your cluster.

If you have selected ADLS, the connection parameters to be defined become:

- In the Client ID and the Client key fields, enter, respectively, the authentication ID and the authentication key generated upon the registration of...
the application that the current Job you are developing uses to access Azure Data Lake Storage.

Ensure that the application to be used has appropriate permissions to access Azure Data Lake. You can check this on the Required permissions view of this application on Azure. For further information, see Azure documentation Assign the Azure AD application to the Azure Data Lake Storage account file or folder.

- In the **Token endpoint** field, copy-paste the OAuth 2.0 token endpoint that you can obtain from the **Endpoints** list accessible on the **App registrations** page on your Azure portal.

For a video demonstration, see Configure and use Azure in a Job.

<table>
<thead>
<tr>
<th>NameNode URI</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type in the URI of the Hadoop NameNode, the master node of a Hadoop system. For example, we assume that you have chosen a machine called <em>masternode</em> as the NameNode, then the location is <code>hdfs://masternode:portnumber</code>. If you are using WebHDFS, the location should be <code>webhdfs://masternode:portnumber</code>; WebHDFS with SSL is not supported yet.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Use kerberos authentication</th>
</tr>
</thead>
<tbody>
<tr>
<td>If you are accessing the Hadoop cluster running with Kerberos security, select this check box, then, enter the Kerberos principal name for the NameNode in the field displayed. This enables you to use your user name to authenticate against the credentials stored in Kerberos.</td>
</tr>
</tbody>
</table>

- If this cluster is a MapR cluster of the version 5.0.0 or later, you can set the MapR ticket authentication configuration in addition or as an alternative by following the explanation in Connecting to a security-enabled MapR on page 1629.

Keep in mind that this configuration generates a new MapR security ticket for the username defined in the Job in each execution. If you need to reuse an existing ticket issued for the same username, leave both the **Force MapR ticket authentication** check box and the **Use Kerberos authentication** check box clear, and then MapR should be able to automatically find that ticket on the fly.

This check box is available depending on the Hadoop distribution you are connecting to.

<table>
<thead>
<tr>
<th>Use a keytab to authenticate</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select the <strong>Use a keytab to authenticate</strong> check box to log into a Kerberos-enabled system using a given keytab file. A keytab file contains pairs of Kerberos principals and encrypted keys. You need to enter the principal to be used in the <strong>Principal</strong> field and the access path to the keytab file itself in the <strong>Keytab</strong> field. This keytab file must be stored in the machine in which your Job actually runs, for example, on a Talend Jobserver.</td>
</tr>
</tbody>
</table>

Note that the user that executes a keytab-enabled Job is not necessarily the one a principal designates but must have the right to read the keytab file being used. For example, the user name you are using to execute a Job is *user1* and the principal to be used is *guest*; in this situation, ensure that *user1* has the right to read the keytab file to be used.
User name

The **User name** field is available when you are not using Kerberos to authenticate. In the **User name** field, enter the login user name for your distribution. If you leave it empty, the user name of the machine hosting the Studio will be used.

Group

Enter the membership including the authentication user under which the HDFS instances were started. This field is available depending on the distribution you are using.

HDFS directory

Browse to, or enter the path pointing to the data to be used in the file system.

File name or relative path

Enter the name of the file you want to check whether this file exists. Or if needs be, browse to the file or enter the path to the file, relative to the directory you entered in **HDFS directory**.

**Advanced settings**

**Hadoop properties**

*Talend Studio* uses a default configuration for its engine to perform operations in a Hadoop distribution. If you need to use a custom configuration in a specific situation, complete this table with the property or properties to be customized. Then at runtime, the customized property or properties will override those default ones.

- Note that if you are using the centrally stored metadata from the **Repository**, this table automatically inherits the properties defined in that metadata and becomes uneditable unless you change the **Property type** from **Repository** to **Built-in**.

For further information about the properties required by Hadoop and its related systems such as HDFS and Hive, see the documentation of the Hadoop distribution you are using or see Apache’s Hadoop documentation on [http://hadoop.apache.org/docs](http://hadoop.apache.org/docs) and then select the version of the documentation you want. For demonstration purposes, the links to some properties are listed below:

- Typically, the HDFS-related properties can be found in the `hdfs-default.xml` file of your distribution, such as [http://hadoop.apache.org/docs/r2.6.0/hadoop-project-dist/hadoop-hdfs/hdfs-default.xml](http://hadoop.apache.org/docs/r2.6.0/hadoop-project-dist/hadoop-hdfs/hdfs-default.xml).
- Apache also provides a page to list the Hive-related properties: [https://cwiki.apache.org/confluence/display/Hive/Configuration+Properties](https://cwiki.apache.org/confluence/display/Hive/Configuration+Properties).

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

**Global Variables**

**Global Variables**

**EXISTS**: the result of whether a specified file exists. This is a Flow variable and it returns a boolean.

**FILENAME**: the name of the file processed. This is an After variable and it returns a string.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable.
and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

---

### Usage

#### Usage rule

**tHDFSExist** is a standalone component.

---

#### Dynamic settings

Click the [*] button to add a row in the table and fill the **Code** field with a context variable to choose your HDFS connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access files in different HDFS systems or different distributions, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of [Talend Studio](#).

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see [Reading data from databases through context-based dynamic connections](#) on page 2457 and [Reading data from different MySQL databases using dynamically loaded connection parameters](#) on page 491. For more information on Dynamic settings and context variables, see [Talend Studio User Guide](#).

---

#### Prerequisites

The Hadoop distribution must be properly installed, so as to guarantee the interaction with [Talend Studio](#). The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under `MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native`. For example, the library for Windows is `\lib\native\MapRClient.dll` in the MapR client jar file. For further information, see the following link from MapR: [http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr](http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr).

Without adding the specified library or libraries, you may encounter the following error: `no MapRClient in java.library.path`.

- Set the `-Djava.library.path` argument, for example, in the **Job Run VM arguments** area of the
Checking the existence of a file in HDFS

This scenario applies only to Talend products with Big Data.

In this scenario, the two-component Job checks whether a specific file exists in HDFS and returns a message to indicate the result of the verification.

In the real-world practice, you can take further action to process the file checked according to the verification result, using the other HDFS components provided with the Studio.

Launch the Hadoop distribution in which you want to check the existence of a particular file. Then, proceed as follows:

**Linking the components**

**Procedure**

1. In the Integration perspective of Talend Studio, create an empty Job, named hdfsexist_file for example, from the Job Designs node in the Repository tree view.
   For further information about how to create a Job, see the Talend Studio User Guide.
2. Drop tHDFSExist and tMsgBox onto the workspace.
3. Connect them using the Trigger > Run if link.

**Configuring the connection to HDFS**

**Procedure**

1. Double-click tHDFSExist to open its Component view.
2. In the **Version** area, select the Hadoop distribution you are connecting to and its version.
3. In the **Connection** area, enter the values of the parameters required to connect to the HDFS.
   In the real-world practice, you may use **tHDFSConnection** to create a connection and reuse it from the current component. For further information, see **tHDFSConnection** on page 1457.
4. In the **HDFS Directory** field, browse to, or enter the path to the folder where the file to be checked is. In this example, browse to `/user/ychen/data/hdfs/out/dest`.
5. In the **File name or relative path** field, enter the name of the file you want to check the existence. For example, **output.csv**.

### Defining the message to be returned

**Procedure**

1. Double-click **tMsgBox** to open its **Component** view.

   ![Component view of tMsgBox](image)

2. In the **Title** field, enter the title to be used for the pop-up message box to be created.
3. In the **Buttons** list, select **OK**. This defines the button to be displayed on the message box.
4. In the **Icon** list, select **Icon information**.
5. In the **Message** field, enter the message you want to displayed once the file checking is done. In this example, enter "This file does not exist!".
**Defining the condition**

**Procedure**

1. Click the **If** link to open the **Basic settings** view, where you are able to define the condition for checking the existence of this file.

2. In the **Condition** box, press **Ctrl+Space** to access the variable list and select the global variable **EXISTS**. Type an exclamation mark before the variable to negate the meaning of the variable.

**Executing the Job**

**Procedure**

Press **F6** to execute this Job.

**Results**

Once done, a message box pops up to indicate that this file called *output.csv* does not exist in the directory you defined earlier.

In the HDFS we check the existence of the file, browse to this directory specified, you can see that this file does not exist.
Contents of directory `/user/ychen/data/hdfs/dest`

Goto: `/user/ychen/data/hdfs/dest` [go]

Go back to DFS home
tHDFSGet

Copies files from Hadoop distributed file system (HDFS), pastes them in a user-defined directory and if needs be, renames them.

tHDFSGet connects to Hadoop distributed file system, helping to obtain large-scale files with optimized performance.

**tHDFSGet Standard properties**

These properties are used to configure tHDFSGet running in the Standard Job framework.

The Standard tHDFSGet component belongs to the Big Data and the File families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-in or Repository</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Use an existing connection</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select this check box and in the Component List click the HDFS connection component from which you want to reuse the connection details already defined.</td>
</tr>
</tbody>
</table>

Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level.

<table>
<thead>
<tr>
<th>Distribution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select the cluster you are using from the drop-down list. The options in the list vary depending on the component you are using. Among these options, the following ones requires specific configuration:</td>
</tr>
<tr>
<td>• If available in this Distribution drop-down list, the Microsoft HD Insight option allows you to use a Microsoft HD Insight cluster. For this purpose, you need to configure the connections to the HD Insightcluster and the Windows Azure Storage service of that cluster in the areas that are displayed. For detailed explanation about these parameters, search for configuring the connection manually on Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
<tr>
<td>• If you select Amazon EMR, you can find more details about how to configure an Amazon EMR cluster in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
<tr>
<td>• The Custom option allows you to connect to a cluster different from any of the distributions given in this list, that is to say, to connect to a cluster not officially supported by Talend.</td>
</tr>
<tr>
<td>1. Select Import from existing version to import an officially supported distribution as base and then add</td>
</tr>
</tbody>
</table>
other required jar files which the base distribution does not provide.

2. Select Import from zip to import the configuration zip for the custom distribution to be used. This zip file should contain the libraries of the different Hadoop elements and the index file of these libraries.

In Talend Exchange, members of Talend community have shared some ready-for-use configuration zip files which you can download from this Hadoop configuration list and directly use them in your connection accordingly. However, because of the ongoing evolution of the different Hadoop-related projects, you might not be able to find the configuration zip corresponding to your distribution from this list; then it is recommended to use the Import from existing version option to take an existing distribution as base to add the jars required by your distribution.

Note that custom versions are not officially supported by Talend. Talend and its community provide you with the opportunity to connect to custom versions from the Studio but cannot guarantee that the configuration of whichever version you choose will be easy, due to the wide range of different Hadoop distributions and versions that are available. As such, you should only attempt to set up such a connection if you have sufficient Hadoop experience to handle any issues on your own.

Note:
In this dialog box, the active check box must be kept selected so as to import the jar files pertinent to the connection to be created between the custom distribution and this component.

For a step-by-step example about how to connect to a custom distribution and share this connection, see Connecting to a custom Hadoop distribution on page 1569.

<table>
<thead>
<tr>
<th>Version</th>
<th>Select the version of the Hadoop distribution you are using. The available options vary depending on the component you are using.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scheme</td>
<td>Select the URI scheme of the file system to be used from the Scheme drop-down list. This scheme could be:</td>
</tr>
<tr>
<td></td>
<td>• HDFS</td>
</tr>
<tr>
<td></td>
<td>• WebHDFS. WebHDFS with SSL is not supported yet.</td>
</tr>
<tr>
<td></td>
<td>• ADLS</td>
</tr>
<tr>
<td></td>
<td>The schemes present on this list vary depending on the distribution you are using and only the scheme that appears on this list with a given distribution is officially supported by Talend.</td>
</tr>
<tr>
<td></td>
<td>Once a scheme is selected, the corresponding syntax such as webhdfs://localhost:50070/ for WebHDFS is displayed in the field for the NameNode location of your cluster.</td>
</tr>
<tr>
<td></td>
<td>If you have selected ADLS, the connection parameters to be defined become:</td>
</tr>
</tbody>
</table>
• In the **Client ID** and the **Client key** fields, enter, respectively, the authentication ID and the authentication key generated upon the registration of the application that the current Job you are developing uses to access Azure Data Lake Storage.

Ensure that the application to be used has appropriate permissions to access Azure Data Lake. You can check this on the Required permissions view of this application on Azure. For further information, see Azure documentation Assign the Azure AD application to the Azure Data Lake Storage account file or folder.

• In the **Token endpoint** field, copy-paste the OAuth 2.0 token endpoint that you can obtain from the **Endpoints** list accessible on the **App registrations** page on your Azure portal.

For a video demonstration, see **Configure and use Azure in a Job**.

**NameNode URI**

Type in the URI of the Hadoop NameNode, the master node of a Hadoop system. For example, we assume that you have chosen a machine called *masternode* as the NameNode, then the location is `hdfs://masternode:portnumber`. If you are using WebHDFS, the location should be `webhdfs://masternode:portnumber`; WebHDFS with SSL is not supported yet.

**Use kerberos authentication**

If you are accessing the Hadoop cluster running with Kerberos security, select this check box, then, enter the Kerberos principal name for the NameNode in the field displayed. This enables you to use your user name to authenticate against the credentials stored in Kerberos.

• If this cluster is a MapR cluster of the version 5.0.0 or later, you can set the MapR ticket authentication configuration in addition or as an alternative by following the explanation in Connecting to a security-enabled MapR on page 1629.

Keep in mind that this configuration generates a new MapR security ticket for the username defined in the Job in each execution. If you need to reuse an existing ticket issued for the same username, leave both the **Force MapR ticket authentication** check box and the **Use Kerberos authentication** check box clear, and then MapR should be able to automatically find that ticket on the fly.

This check box is available depending on the Hadoop distribution you are connecting to.

**Use a keytab to authenticate**

Select the **Use a keytab to authenticate** check box to log into a Kerberos-enabled system using a given keytab file. A keytab file contains pairs of Kerberos principals and encrypted keys. You need to enter the principal to be used in the **Principal** field and the access path to the keytab file itself in the **Keytab** field. This keytab file must be stored in the machine in which your Job actually runs, for example, on a Talend Jobserver.

Note that the user that executes a keytab-enabled Job is not necessarily the one a principal designates but must have the right to read the keytab file being used. For example, the user name you are using to execute a Job is *user1* and the
principal to be used is *guest*; in this situation, ensure that *user1* has the right to read the keytab file to be used.

<table>
<thead>
<tr>
<th><strong>User name</strong></th>

| **Hadoop properties** | *Talend Studio* uses a default configuration for its engine to perform operations in a Hadoop distribution. If you need to use a custom configuration in a specific situation, complete this table with the property or properties to be customized. Then at runtime, the customized property or properties will override those default ones.  
- Note that if you are using the centrally stored metadata from the **Repository**, this table automatically inherits the properties defined in that metadata and becomes uneditable unless you change the **Property type** from **Repository** to **Built-in**.  
For further information about the properties required by Hadoop and its related systems such as HDFS and Hive, see the documentation of the Hadoop distribution you are using or see Apache’s Hadoop documentation on http://hadoop.apache.org/docs and then select the version of the |
For demonstration purposes, the links to some properties are listed below:

- Typically, the HDFS-related properties can be found in the `hdfs-default.xml` file of your distribution, such as [http://hadoop.apache.org/docs/r2.6.0/hadoop-project-dist/hadoop-hdfs/hdfs-default.xml](http://hadoop.apache.org/docs/r2.6.0/hadoop-project-dist/hadoop-hdfs/hdfs-default.xml).
- Apache also provides a page to list the Hive-related properties: [https://cwiki.apache.org/confluence/display/Hive/Configuration+Properties](https://cwiki.apache.org/confluence/display/Hive/Configuration%2BProperties).

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_FILE: the number of files processed. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>CURRENT_STATUS: the execution result of the component. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td></td>
<td>TRANSFER_MESSAGES: file transferred information. This is an After variable and it returns a string.</td>
</tr>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](https://docs.talend.com/).

### Usage

#### Usage rule

This component combines HDFS connection and data extraction, thus used as a single-component subjob to move data from HDFS to an user-defined local directory.

Different from the `tHDFSInput` and the `tHDFSOutput` components, it runs standalone and does not generate input or output flow for the other components.

It is often connected to the Job using `OnSubjobOk` or `OnComponentOk` link, depending on the context.

#### Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your HDFS connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access files in different HDFS systems or different distributions, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the
### Component List

Box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

### Prerequisites

The Hadoop distribution must be properly installed, so as to guarantee the interaction with **Talend Studio**. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under `MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native`. For example, the library for Windows is `\lib\native\MapRClient.dll` in the MapR client jar file. For further information, see the following link from MapR: [http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr](http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr).

  Without adding the specified library or libraries, you may encounter the following error: `no MapRClient in java.library.path`.

- Set the `-Djava.library.path` argument, for example, in the **Job Run VM arguments** area of the **Run/Debug** view in the **Preferences** dialog box in the **Window** menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the **Data viewer** to view locally in the Studio the data stored in MapR.

  For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

### Limitations

JRE 1.6+ is required.

---

**Computing data with Hadoop distributed file system**

This scenario applies only to **Talend products with Big Data**.

The following scenario describes a simple Job that creates a file in a defined directory, get it into and out of HDFS, subsequently store it to another local directory, and read it at the end of the Job.

### Setting up the Job

**Procedure**

1. Drop the following components from the **Palette** onto the design workspace: tFixedFlowInput, tFileOutputDelimited, tHDFSPut, tHDFSGet, tFileInputDelimited and tLogRow.

2. Connect **tFixedFlowInput** to **tFileOutputDelimited** using a **Row > Main** connection.
3. Connect `tFileInputDelimited` to `tLogRow` using a `Row > Main` connection.
4. Connect `tFixedFlowInput` to `tHDFSPut` using an `OnSubjobOk` connection.
5. Connect `tHDFSPut` to `tHDFSGet` using an `OnSubjobOk` connection.
6. Connect `tHDFSGet` to `tFileInputDelimited` using an `OnSubjobOk` connection.

**Configuring the input component**

**Procedure**

1. Double-click `tFixedFlowInput` to define the component in its **Basic settings** view.
2. Set the **Schema** to **Built-In** and click the three-dot [...] button next to **Edit Schema** to describe the data structure you want to create from internal variables. In this scenario, the schema contains one column: `content`. 

```
<table>
<thead>
<tr>
<th>Column</th>
<th>Key</th>
<th>Type</th>
<th>N.</th>
<th>Date Pa...</th>
<th>Le...</th>
<th>Pr...</th>
<th>D...</th>
<th>Co...</th>
</tr>
</thead>
<tbody>
<tr>
<td>content</td>
<td></td>
<td>String</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```
3. Click the plus button to add the parameter line.
4. Click **OK** to close the dialog box and accept to propagate the changes when prompted by the studio.
5. In **Basic settings**, define the corresponding value in the **Mode** area using the **Use Single Table** option. In this scenario, the value is "Hello world!".

![Basic settings configuration](image)

**Configuring the tFileOutputDelimited component**

**Procedure**

1. Double-click **tFileOutputDelimited** to define the component in its **Basic settings** view.

![](image)

2. Click the [...] button next to the **File Name** field and browse to the output file you want to write data in, `in.txt` in this example.

**Loading the data from the local file**

**Procedure**

1. Double-click **tHDFSPut** to define the component in its **Basic settings** view.
2. Select, for example, Apache 0.20.2 from the Hadoop version list.

3. In the NameNode URI, the Username and the Group fields, enter the connection parameters to the HDFS. If you are using WebHDFS, the location should be webhdfs://masternode:portnumber; WebHDFS with SSL is not supported yet.

4. Next to the Local directory field, click the three-dot [...] button to browse to the folder with the file to be loaded into the HDFS. In this scenario, the directory has been specified while configuring **tFileOutputDelimited**: C:/hadoopfiles/putFile/.

5. In the HDFS directory field, type in the intended location in HDFS to store the file to be loaded. In this example, it is /testFile.

6. Click the Overwrite file field to stretch the drop-down.

7. From the menu, select always.

8. In the Files area, click the plus button to add a row in which you define the file to be loaded.

9. In the File mask column, enter *.txt to replace newLine between quotation marks and leave the New name column as it is. This allows you to extract all the .txt files in the specified directory without changing their names. In this example, the file is in.txt.

**Getting the data from the HDFS**

**Procedure**

1. Double-click **tHDFSGet** to define the component in its Basic settings view.
2. Select, for example, Apache 0.20.2 from the Hadoop version list.

3. In the NameNode URI, the Username, the Group fields, enter the connection parameters to the HDFS. If you are using WebHDFS, the location should be webhdfs://masternode:portnumber; WebHDFS with SSL is not supported yet.

4. In the HDFS directory field, type in location storing the loaded file in HDFS. In this example, it is `/testFile`.

5. Next to the Local directory field, click the three-dot [...] button to browse to the folder intended to store the files that are extracted out of the HDFS. In this scenario, the directory is: `C:/hadoopfiles/getFile/`.

6. Click the Overwrite file field to stretch the drop-down.

7. From the menu, select always.

8. In the Files area, click the plus button to add a row in which you define the file to be extracted.

9. In the File mask column, enter `*.txt` to replace `newLine` between quotation marks and leave the New name column as it is. This allows you to extract all the .txt files from the specified directory in the HDFS without changing their names. In this example, the file is `in.txt`.

**Reading data from the HDFS and saving the data locally**

**Procedure**

1. Double-click tFileInputDelimited to define the component in its Basic settings view.
2. Set property type to **Built-In**.

3. Next to the **File Name/Stream** field, click the three-dot button to browse to the file you have obtained from the HDFS. In this scenario, the directory is `C:/hadoopfiles/getFile/in.txt`.

4. Set **Schema** to **Built-In** and click **Edit schema** to define the data to pass on to the **tLogRow** component.

5. Click the plus button to add a new column.

6. Click **OK** to close the dialog box and accept to propagate the changes when prompted by the studio.

**Executing the Job**

Save the Job and press **F6** to execute it.

The `in.txt` file is created and loaded into the HDFS.
The file is also extracted from the HDFS by `tHDFSGet` and is read by `tFileInputDelimited`.

```
Starting job feature11712_hadoop_get_put at 18:09 04/05/2010.
[statistics] connecting to socket on port 3637
[statistics] connected
hello world!
[statistics] disconnected
Job feature11712_hadoop_get_put ended at 18:09 04/05/2010.
exit code-0
```
tHDFSInput

Extracts the data in a HDFS file for other components to process it.

tHDFSInput reads a file located on a given Hadoop distributed file system (HDFS) and puts the data of interest from this file into a Talend schema. Then it passes the data to the component that follows.

**tHDFSInput Standard properties**

These properties are used to configure tHDFSInput running in the Standard Job framework.

The Standard tHDFSInput component belongs to the Big Data and the File families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| Property type | Either Built-In or Repository.  
|               | **Built-In**: No property data stored centrally.  
|               | **Repository**: Select the repository file where the properties are stored.  
| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.  
|               | Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
|               | • **View schema**: choose this option to view the schema only.  
|               | • **Change to built-in property**: choose this option to change the schema to **Built-In** for local changes.  
|               | • **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.  
|               | **Built-In**: You create and store the schema locally for this component only.  
|               | **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.  
| Use an existing connection | Select this check box and in the **Component List** click the HDFS connection component from which you want to reuse the connection details already defined.  

1496
Note that when a Job contains the parent Job and the child Job, **Component List** presents only the connection components in the same Job level.

### Distribution

Select the cluster you are using from the drop-down list. The options in the list vary depending on the component you are using. Among these options, the following ones require specific configuration:

- **If available in this Distribution drop-down list, the Microsoft HD Insight** option allows you to use a Microsoft HD Insight cluster. For this purpose, you need to configure the connections to the HD Insight cluster and the Windows Azure Storage service of that cluster in the areas that are displayed. For detailed explanation about these parameters, search for configuring the connection manually on Talend Help Center ([https://help.talend.com](https://help.talend.com)).

- **If you select Amazon EMR**, you can find more details about how to configure an Amazon EMR cluster in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

- **The Custom option allows you to connect to a cluster different from any of the distributions given in this list, that is to say, to connect to a cluster not officially supported by Talend.**

1. **Select Import from existing version** to import an officially supported distribution as base and then add other required jar files which the base distribution does not provide.

2. **Select Import from zip** to import the configuration zip for the custom distribution to be used. This zip file should contain the libraries of the different Hadoop elements and the index file of these libraries.

   In Talend Exchange, members of Talend community have shared some ready-for-use configuration zip files which you can download from this Hadoop configuration list and directly use them in your connection accordingly. However, because of the ongoing evolution of the different Hadoop-related projects, you might not be able to find the configuration zip corresponding to your distribution from this list; then it is recommended to use the **Import from existing version** option to take an existing distribution as base to add the jars required by your distribution.

   Note that custom versions are not officially supported by Talend. Talend and its community provide you with the opportunity to connect to custom versions from the Studio but cannot guarantee that the configuration of whichever version you choose will be easy, due to the wide range of different Hadoop distributions and versions that are available. As such, you should only attempt to set up such a connection if you have sufficient Hadoop experience to handle any issues on your own.
**Version**
Select the version of the Hadoop distribution you are using. The available options vary depending on the component you are using.

**Scheme**
Select the URI scheme of the file system to be used from the **Scheme** drop-down list. This scheme could be:

- HDFS
- WebHDFS. WebHDFS with SSL is not supported yet.
- ADLS

The schemes present on this list vary depending on the distribution you are using and only the scheme that appears on this list with a given distribution is officially supported by Talend.

Once a scheme is selected, the corresponding syntax such as `webhdfs://localhost:50070/` for WebHDFS is displayed in the field for the NameNode location of your cluster.

If you have selected **ADLS**, the connection parameters to be defined become:

- In the **Client ID** and the **Client key** fields, enter, respectively, the authentication ID and the authentication key generated upon the registration of the application that the current Job you are developing uses to access Azure Data Lake Storage.

  Ensure that the application to be used has appropriate permissions to access Azure Data Lake. You can check this on the Required permissions view of this application on Azure. For further information, see Azure documentation [Assign the Azure AD application to the Azure Data Lake Storage account file or folder](#).

- In the **Token endpoint** field, copy-paste the OAuth 2.0 token endpoint that you can obtain from the **Endpoints** list accessible on the **App registrations** page on your Azure portal.

  For a video demonstration, see [Configure and use Azure in a Job](#).

**NameNode URI**
Type in the URI of the Hadoop NameNode, the master node of a Hadoop system. For example, we assume that you have chosen a machine called **masternode** as the NameNode, then the location is `hdfs://masternode:portnumber`. If you are using WebHDFS, the location should be `webhdfs://masternode:portnumber`; WebHDFS with SSL is not supported yet.
| **Use kerberos authentication** | If you are accessing the Hadoop cluster running with Kerberos security, select this check box, then, enter the Kerberos principal name for the NameNode in the field displayed. This enables you to use your user name to authenticate against the credentials stored in Kerberos.  
- If this cluster is a MapR cluster of the version 5.0.0 or later, you can set the MapR ticket authentication configuration in addition or as an alternative by following the explanation in Connecting to a security-enabled MapR on page 1629.  
  Keep in mind that this configuration generates a new MapR security ticket for the username defined in the Job in each execution. If you need to reuse an existing ticket issued for the same username, leave both the **Force MapR ticket authentication** check box and the **Use Kerberos authentication** check box clear, and then MapR should be able to automatically find that ticket on the fly.  
This check box is available depending on the Hadoop distribution you are connecting to. |
| **Use a keytab to authenticate** | Select the **Use a keytab to authenticate** check box to log into a Kerberos-enabled system using a given keytab file. A keytab file contains pairs of Kerberos principals and encrypted keys. You need to enter the principal to be used in the **Principal** field and the access path to the keytab file itself in the **Keytab** field. This keytab file must be stored in the machine in which your Job actually runs, for example, on a Talend Jobserver.  
Note that the user that executes a keytab-enabled Job is not necessarily the one a principal designates but must have the right to read the keytab file being used. For example, the user name you are using to execute a Job is **user1** and the principal to be used is **guest**; in this situation, ensure that **user1** has the right to read the keytab file to be used. |
| **User name** | The **User name** field is available when you are not using Kerberos to authenticate. In the **User name** field, enter the login user name for your distribution. If you leave it empty, the user name of the machine hosting the Studio will be used. |
| **Group** | Enter the membership including the authentication user under which the HDFS instances were started. This field is available depending on the distribution you are using. |
| **File Name** | Browse to, or enter the path pointing to the data to be used in the file system.  
If the path you set points to a folder, this component will read all of the files stored in that folder. Furthermore, if sub-folders exist in that folder and you need to read files in the sub-folders, select the **Include sub-directories if path is directory** check box in the **Advanced settings** view. |
| **Type** | Select the type of the file to be processed. The type of the file may be:  
- **Text file**.  
- **Sequence file**: a Hadoop sequence file consists of binary key/value pairs and is suitable for the Map/ |

Once you select the **Sequence file** format, the **Key column** list and the **Value column** list appear to allow you to select the keys and the values of that Sequence file to be processed.

<table>
<thead>
<tr>
<th><strong>Row separator</strong></th>
<th>The separator used to identify the end of a row. This field is not available for a Sequence file.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Field separator</strong></td>
<td>Enter character, string or regular expression to separate fields for the transferred data. This field is not available for a Sequence file.</td>
</tr>
<tr>
<td><strong>Header</strong></td>
<td>Set values to ignore the header of the transferred data. For example, enter 0 to ignore no rows for the data without header and set 1 for the data with header at the first row. This field is not available for a Sequence file.</td>
</tr>
<tr>
<td><strong>Custom encoding</strong></td>
<td>You may encounter encoding issues when you process the stored data. In that situation, select this check box to display the <strong>Encoding</strong> list. Select the encoding from the list or select <strong>Custom</strong> and define it manually. This field is compulsory for database data handling. The supported encodings depend on the JVM that you are using. For more information, see <a href="https://docs.oracle.com">https://docs.oracle.com</a>. This option is not available for a Sequence file.</td>
</tr>
<tr>
<td><strong>Compression</strong></td>
<td>Select the <strong>Uncompress the data</strong> check box to uncompress the input data. Hadoop provides different compression formats that help reduce the space needed for storing files and speed up data transfer. When reading a compressed file, the Studio needs to uncompress it before being able to feed it to the input flow. This option is not available for a Sequence file.</td>
</tr>
</tbody>
</table>

### Advanced settings

| **Include sub-directories if path is directory** | Select this check box to read not only the folder you have specified in the **File name** field but also the sub-folders in that folder. |
| **Hadoop properties** | **Talend Studio** uses a default configuration for its engine to perform operations in a Hadoop distribution. If you need to use a custom configuration in a specific situation, complete this table with the property or properties to be customized. Then at runtime, the customized property or properties will override those default ones.

- Note that if you are using the centrally stored metadata from the **Repository**, this table automatically inherits the properties defined in that metadata and becomes uneditable unless you change the **Property type** from **Repository** to **Built-in**. |
For further information about the properties required by Hadoop and its related systems such as HDFS and Hive, see the documentation of the Hadoop distribution you are using or see Apache’s Hadoop documentation on http://hadoop.apache.org/docs and then select the version of the documentation you want. For demonstration purposes, the links to some properties are listed below:

- Typically, the HDFS-related properties can be found in the hdfs-default.xml file of your distribution, such as http://hadoop.apache.org/docs/r2.6.0/hadoop-project-dist/hadoop-hdfs/hdfs-default.xml.
- Apache also provides a page to list the Hive-related properties: https://cwiki.apache.org/confluence/display/Hive/Configuration+Properties.

### tStatCatcher Statistics

Select this check box to collect log data at the component level. Note that this check box is not available in the Map/Reduce version of the component.

### Global Variables

**Global Variables**

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

**Usage rule**

This component needs an output link.

**Dynamic settings**

Click the [*] button to add a row in the table and fill the **Code** field with a context variable to choose your HDFS connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access files in different HDFS systems or different distributions, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of *Talend Studio*.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see *Reading data from databases through context-based dynamic connections* on page 2457 and *Reading data from different MySQL databases using dynamically loaded connection*.
**Prerequisites**

The Hadoop distribution must be properly installed, so as to guarantee the interaction with Talend Studio. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under `MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native`. For example, the library for Windows is `\lib\native\MapRClient.dll` in the MapR client jar file. For further information, see the following link from MapR: http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr.

Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path.

- Set the `-Djava.library.path` argument, for example, in the Job Run VM arguments area of the Run/Debug view in the Preferences dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

**Limitations**

JRE 1.6+ is required.

---

### Using HDFS components to work with Azure Data Lake Storage (ADLS)

This scenario describes how to use the HDFS components to read data from and write data to Azure Data Lake Storage.

This scenario applies only to Talend products with Big Data.

- `tFixedFlowInput`: it provides sample data to the Job.
- `tHDFSOutput`: it writes sample data to Azure Data Lake Store.
- `tHDFSInput`: it reads sample data from Azure Data Lake Store.
- `tLogRow`: it displays the output of the Job on the console of the Run view of the Job.

#### Configuring your Azure Data Lake Storage

**Before you begin**

An Azure subscription is required.
Procedure

1. Create your Azure Data Lake Storage account. For more details about how to do this, see Azure
documentation: Create an Azure Data Lake Storage account.

2. Create an Azure Active Directory application on your Azure portal. For more details about how to
do this, see the “Create an Azure Active Directory application” section in Azure documentation:
Use portal to create an Azure Active Directory application.

3. Obtain the application ID and the authentication key from the portal.
   a) On the list of the registered applications, click the application you created and registered in
      the previous step to display its information blade.
   b) In the Essentials area, copy its application ID.
   c) Click All settings to display the Settings blade and click Required permissions on that blade.
   d) On the Required permissions blade, click Windows Azure Active Directory to display the
      Enable Access blade.
   e) Select the permissions to be granted to your application and click Save to close the Enable
      Access blade. You may need the consent of the administrator of your Azure portal to
      eventually validate the grant.
   f) Still on the Required permissions blade of your application, click Add and on the Add API
      access blade, click Select an API.
   g) Click Azure Data Lake and then click Select to validate your selection and automatically open
      the Enable Access blade of this API.
   h) Select the permission to be granted and click Select to close the Enable Access blade.
   i) On the Add API access blade, click Done to return to the Setting blade of your application.
   j) Click Keys to open the Keys blade.
   k) In the Password area, enter the description of you key, define its duration of validity and then
      click Save to display the value of your key.
   l) Copy the key value and keep it somewhere you think safe because you are not able to retrieve
      the key anymore once you leave this blade.

4. Back to the list of the Azure Data Lake Storage services, select the Data Lake Storage you created
   at the beginning of the procedure and then click Data Explorer.

5. On the blade that is opened, click Access to open the Access blade.

6. Click Add and on the Select User or Group blade, search for your application, select it and click the
   Select button to open the Select Permission blade.

7. Select the permission to be assigned to your application and click OK.
   In this example, select all the permissions.

8. Obtain the Azure OAUTH 2.0 token endpoint by proceeding as follows:
   a) Click Azure Active Directory and on the blade that is displayed, click App registrations.
   b) On the App registrations blade, click Endpoints and on the Endpoints blade, copy the value of
      the OAUTH 2.0 TOKEN ENDPOINT field.

Creating an HDFS Job in the Studio

Procedure

1. On the Integration perspective, drop the following components from the Palette onto the design
   workspace: tFixedFlowInput, tHDFSOutput, tHDFSInput and tLogRow.

2. Connect tFixedFlowInput to tHDFSOutput using a Row > Main link.

3. Do the same to connect tHDFSInput to tLogRow.
4. Connect **tFixedFlowInput** to **tHDFSInput** using a **Trigger > OnSubjobOk** link.

**Results**

![Diagram](image_url)

**Configuring the HDFS components to work with Azure Data Lake Storage**

**Procedure**

1. Double-click **tFixedFlowInput** to open its **Component** view to provide sample data to the Job.
   - The sample data to be used contains only one row with two column: id and name.
2. Click the [...] button next to **Edit schema** to open the schema editor.
3. Click the [+] button to add the two columns and rename them to id and name.
4. Click **OK** to close the schema editor and validate the schema.
5. In the **Mode** area, select **Use single table**.
   - The id and the name columns automatically appear in the **Value** table and you can enter the values you want within double quotation marks in the **Value** column for the two schema values.
6. Double-click **tHDFSOutput** to open its **Component** view.
7. In the Version area, select Hortonworks or Cloudera depending on the distribution you are using. In the Standard framework, only these two distributions with ADLS are supported by the HDFS components.

8. From the Scheme drop-down list, select ADLS. The ADLS related parameters appear in the Component view.

9. In the URI field, enter the NameNode service of your application. The location of this service is actually the address of your Data Lake Store.

For example, if your Data Lake Storage name is data_lake_store_name, the NameNode URI to be used is adl://data_lake_store_name.azuredatalakestore.net.

10. In the Client ID and the Client key fields, enter, respectively, the authentication ID and the authentication key generated upon the registration of the application that the current Job you are developing uses to access Azure Data Lake Storage.

Ensure that the application to be used has appropriate permissions to access Azure Data Lake. You can check this on the Required permissions view of this application on Azure. For further information, see Azure documentation Assign the Azure AD application to the Azure Data Lake Storage account file or folder.

This application must be the one to which you assigned permissions to access your Azure Data Lake Storage in the previous step.

11. In the Token endpoint field, copy-paste the OAuth 2.0 token endpoint that you can obtain from the Endpoints list accessible on the App registrations page on your Azure portal.
12. In the **File name** field, enter the directory to be used to store the sample data on Azure Data Lake Storage.

13. From the **Action** drop-down list, select **Create** if the directory to be used does not exist yet on Azure Data Lake Storage; if this folder already exists, select **Overwrite**.

14. Do the same configuration for **tHDFSInput**.

15. If you run your Job on Windows, following **this procedure** to add the winutils.exe program to your Job.

16. Press **F6** to run your Job.
tHDFSList

tHDFSList retrieves a list of files or folders based on a filemask pattern and iterates on each unity.

**tHDFSList Standard properties**

These properties are used to configure tHDFSList running in the Standard Job framework.

The Standard tHDFSList component belongs to the Big Data and the File families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either <strong>Built-in</strong> or <strong>Repository</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Built-in</strong>: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the Component List click the HDFS connection component from which you want to reuse the connection details already defined.

Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level.

**Distribution**

Select the cluster you are using from the drop-down list. The options in the list vary depending on the component you are using. Among these options, the following ones requires specific configuration:

- If available in this Distribution drop-down list, the **Microsoft HD Insight** option allows you to use a Microsoft HD Insight cluster. For this purpose, you need to configure the connections to the HD Insight cluster and the Windows Azure Storage service of that cluster in the areas that are displayed. For detailed explanation about these parameters, search for configuring the connection manually on Talend Help Center (https://help.talend.com).

- If you select **Amazon EMR**, you can find more details about how to configure an Amazon EMR cluster in Talend Help Center (https://help.talend.com).

- The **Custom** option allows you to connect to a cluster different from any of the distributions given in this list, that is to say, to connect to a cluster not officially supported by Talend.

  1. Select **Import from existing version** to import an officially supported distribution as base and then add other required jar files which the base distribution does not provide.

  2. Select **Import from zip** to import the configuration zip for the custom distribution to be used. This zip file should contain the libraries of the different Hadoop elements and the index file of these libraries.
In **Talend Exchange**, members of **Talend** community have shared some ready-for-use configuration zip files which you can download from this **Hadoop configuration** list and directly use them in your connection accordingly. However, because of the ongoing evolution of the different Hadoop-related projects, you might not be able to find the configuration zip corresponding to your distribution from this list; then it is recommended to use the **Import from existing version** option to take an existing distribution as base to add the jars required by your distribution.

Note that custom versions are not officially supported by **Talend**. **Talend** and its community provide you with the opportunity to connect to custom versions from the Studio but cannot guarantee that the configuration of whichever version you choose will be easy, due to the wide range of different Hadoop distributions and versions that are available. As such, you should only attempt to set up such a connection if you have sufficient Hadoop experience to handle any issues on your own.

**Note:**

In this dialog box, the active check box must be kept selected so as to import the jar files pertinent to the connection to be created between the custom distribution and this component.

For a step-by-step example about how to connect to a custom distribution and share this connection, see **Connecting to a custom Hadoop distribution** on page 1569.

### Version

Select the version of the Hadoop distribution you are using. The available options vary depending on the component you are using.

### Scheme

Select the URI scheme of the file system to be used from the **Scheme** drop-down list. This scheme could be:

- HDFS
- WebHDFS. WebHDFS with SSL is not supported yet.
- ADLS

The schemes present on this list vary depending on the distribution you are using and only the scheme that appears on this list with a given distribution is officially supported by Talend.

Once a scheme is selected, the corresponding syntax such as `webhdfs://localhost:50070/` for WebHDFS is displayed in the field for the NameNode location of your cluster.

If you have selected **ADLS**, the connection parameters to be defined become:

- In the **Client ID** and the **Client key** fields, enter, respectively, the authentication ID and the authentication key generated upon the registration of the application that the current Job you are developing uses to access Azure Data Lake Storage.
Ensure that the application to be used has appropriate permissions to access Azure Data Lake. You can check this on the Required permissions view of this application on Azure. For further information, see Azure documentation Assign the Azure AD application to the Azure Data Lake Storage account file or folder.

- In the **Token endpoint** field, copy-paste the OAuth 2.0 token endpoint that you can obtain from the **Endpoints** list accessible on the **App registrations** page on your Azure portal.

For a video demonstration, see Configure and use Azure in a Job.

<table>
<thead>
<tr>
<th><strong>NameNode URI</strong></th>
<th>Type in the URI of the Hadoop NameNode, the master node of a Hadoop system. For example, we assume that you have chosen a machine called <em>masternode</em> as the NameNode, then the location is <code>hdfs://masternode:portnumber</code>. If you are using WebHDFS, the location should be <code>webhdfs://masternode:portnumber</code>; WebHDFS with SSL is not supported yet.</th>
</tr>
</thead>
</table>

| **Use kerberos authentication** | If you are accessing the Hadoop cluster running with Kerberos security, select this check box, then, enter the Kerberos principal name for the NameNode in the field displayed. This enables you to use your user name to authenticate against the credentials stored in Kerberos.  
- If this cluster is a MapR cluster of the version 5.0.0 or later, you can set the MapR ticket authentication configuration in addition or as an alternative by following the explanation in Connecting to a security-enabled MapR on page 1629.  
Keep in mind that this configuration generates a new MapR security ticket for the username defined in the Job in each execution. If you need to reuse an existing ticket issued for the same username, leave both the **Force MapR ticket authentication** check box and the **Use Kerberos authentication** check box clear, and then MapR should be able to automatically find that ticket on the fly.  
This check box is available depending on the Hadoop distribution you are connecting to. |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|

| **Use a keytab to authenticate** | Select the **Use a keytab to authenticate** check box to log into a Kerberos-enabled system using a given keytab file. A keytab file contains pairs of Kerberos principals and encrypted keys. You need to enter the principal to be used in the **Principal** field and the access path to the keytab file itself in the **Keytab** field. This keytab file must be stored in the machine in which your Job actually runs, for example, on a Talend Jobserver.  
Note that the user that executes a keytab-enabled Job is not necessarily the one a principal designates but must have the right to read the keytab file being used. For example, the user name you are using to execute a Job is *user1* and the principal to be used is *guest*; in this situation, ensure that *user1* has the right to read the keytab file to be used. |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|

<p>| <strong>User name</strong> | The <strong>User name</strong> field is available when you are not using Kerberos to authenticate. In the <strong>User name</strong> field, enter the login user name for your distribution. If you leave it empty, |</p>
<table>
<thead>
<tr>
<th><strong>Group</strong></th>
<th>Enter the membership including the authentication user under which the HDFS instances were started. This field is available depending on the distribution you are using.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>HDFS Directory</strong></td>
<td>Browse to, or enter the path pointing to the data to be used in the file system.</td>
</tr>
</tbody>
</table>
| **FileList Type** | Select the type of input you want to iterate on from the list:  
- **Files** if the input is a set of files,  
- **Directories** if the input is a set of directories,  
- **Both** if the input is a set of the above two types. |
| **Include subdirectories** | Select this check box if the selected input source type includes sub-directories. |
| **Case Sensitive** | Set the case mode from the list to either create or not create case sensitive filter on filenames. |
| **Use Glob Expressions as Filemask** | This check box is selected by default. It filters the results using a Global Expression (*Glob Expressions*). |
| **Files** | Click the plus button to add as many filter lines as needed:  
- **Filemask**: in the added filter lines, type in a filename or a filemask using special characters or regular expressions. |
| **Order by** | The folders are listed first of all, then the files. You can choose to prioritise the folder and file order either:  
- **By default**: alphabetical order, by folder then file;  
- **By file name**: alphabetical order or reverse alphabetical order;  
- **By file size**: smallest to largest or largest to smallest;  
- **By modified date**: most recent to least recent or least recent to most recent. |

**Note:**
If ordering **by file name**, in the event of identical file names then **modified date** takes precedence. If ordering **by file size**, in the event of identical file sizes then **file name** takes precedence. If ordering **by modified date**, in the event of identical dates then **file name** takes precedence.

| **Order action** | Select a sort order by clicking one of the following radio buttons:  
- **ASC**: ascending order;  
- **DESC**: descending order; |

**Advanced settings**

| **Use Exclude Filemask** | Select this check box to enable **Exclude Filemask** field to exclude filtering condition based on file type: |
**Exclude Filemask**: Fill in the field with file types to be excluded from the Filemasks in the Basic settings view.

**Note**: File types in this field should be quoted with double quotation marks and separated by comma.

<table>
<thead>
<tr>

</tbody>
</table>

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>CURRENT_FILE</strong>: the current file name. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td><strong>CURRENT_FILEDIRECTORY</strong>: the current file directory. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td><strong>CURRENT_FILEEXTENSION</strong>: the extension of the current file. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td><strong>CURRENT_FILEPATH</strong>: the current file path. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td><strong>NB_FILE</strong>: the number of files iterated upon so far. This is a Flow variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>tHDFSList provides a list of files or folders from a defined HDFS directory on which it iterates.</th>
</tr>
</thead>
</table>

#### Dynamic settings

Click the [*] button to add a row in the table and fill the **Code** field with a context variable to choose your HDFS connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access files in different HDFS systems or different distributions, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of *Talend Studio*.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on **Dynamic settings** and context variables, see *Talend Studio User Guide*.

### Connections

Outgoing links (from this component to another):

- **Row**: Iterate
- **Trigger**: On Subjob Ok; On Subjob Error; Run if; On Component Ok; On Component Error.

Incoming links (from one component to this one):

- **Row**: Iterate.
- **Trigger**: Run if; On Subjob Ok; On Subjob Error; On component Ok; On Component Error; Synchronize; Parallelize.

For further information regarding connections, see *Talend Studio User Guide*.

### Prerequisites

The Hadoop distribution must be properly installed, so as to guarantee the interaction with *Talend Studio*. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under `MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native`. For example, the library for Windows is `\lib\native\MapRClient.dll` in the MapR client library directory.
t jar file. For further information, see the following link from MapR: [http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr](http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr).

Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path.

- Set the `-Djava.library.path` argument, for example, in the Job Run VM arguments area of the Run/Debug view in the Preferences dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

| Limitation | JRE 1.6+ is required. |

## Iterating on a HDFS directory

This scenario applies only to [Talend products with Big Data](https://www.talend.com/products/). This scenario uses a two-component Job to iterate on a specified directory in HDFS so as to select the files from there towards a local directory.

### Preparing the data to be used

**Procedure**

Create the files to be iterated on in the HDFS you want to use. In this scenario, two files are created in the directory: `/user/ychen/data/hdfs/out`. 
Contents of directory /user/ychen/data/hdfs/out

Goto: /user/ychen/data/hdfs/out

Go to parent directory

Go back to DFS home

Local logs

Log directory

This is Apache Hadoop release 1.0.3

You can design a Job in the Studio to create the two files. For further information, see tHDFSPut on page 1538 or tHDFSOutput on page 1518.

Linking the components

Procedure

1. In the Integration perspective of Talend Studio, create an empty Job, named HDFSList for example, from the Job Designs node in the Repository tree view.
   For further information about how to create a Job, see the Talend Studio User Guide.
2. Drop tHDFSList and tHDFSGet onto the workspace.
3. Connect them using the Row > Iterate link.

Configuring the iteration

Procedure

1. Double-click tHDFSList to open its Component view.
2. In the **Version** area, select the Hadoop distribution you are connecting to and its version.

3. In the **Connection** area, enter the values of the parameters required to connect to the HDFS.
   In the real-world practice, you may use `tHDFSConnection` to create a connection and reuse it from the current component. For further information, see `tHDFSConnection` on page 1457.

4. In the **HDFS Directory** field, enter the path to the folder where the files to be iterated on are. In this example, as presented earlier, the directory is `/user/ychen/data/hdfs/out/`.

5. In the **FileList Type** field, select **File**.

6. In the **Files** table, click **add one row and enter * between the quotation marks to iterate on any files existing.**

### Selecting the files

**Procedure**

1. Double-click `tHDFSGet` to open its **Component** view.
2. In the **Version** area, select the Hadoop distribution you are connecting to and its version.

3. In the **Connection** area, enter the values of the parameters required to connect to the HDFS.

   In the real-world practice, you may have used **thDFSConne**ction to create a connection; then you can reuse it from the current component. For further information, see **thDFSConne**ction on page 1457.

4. In the **HDFS directory** field, enter the path to the folder holding the files to be retrieved.

   To do this with the auto-completion list, place the mouse pointer in this field, then, press **Ctrl + Space** to display the list and select the **tHDFSLis**t_1_CURRENT_FILEDIRECTORY variable to reuse the directory you have defined in **tHDFSLis**t. In this variable, **tHDFSLis**t_1 is the label of the component. If you label it differently, select the variable accordingly.

   Once selecting this variable, the directory reads, for example, `((String)globalMap.get("tHDFSLis**t_1_CURRENT_FILEDIRECTORY"))` in this field.

   For further information about how to label a component, see the **Talend Studio User Guide**.

5. In the **Local directory** field, enter the path, or browse to the folder you want to place the selected files in. This folder will be created if it does not exist. In this example, it is `C:/hdfsFiles`.

6. In the **Overwrite file** field, select **always**.

7. In the **Files** table, click to add one row and enter `*` between the quotation marks in the **Filemask** column in order to get any files existing.

**Executing the Job**

**Procedure**

Press **F6** to execute this Job.
**Results**

Once done, you can check the files created in the local directory.
tHDFSOutput

Writes data flows it receives into a given Hadoop distributed file system (HDFS).

tHDFSOutput Standard properties

These properties are used to configure tHDFSOutput running in the Standard Job framework.
The Standard tHDFSOutput component belongs to the Big Data and the File families.
The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

Basic settings

| Property type | Either Built-In or Repository.  
|---------------|--------------------------------|
|               | Built-In: No property data stored centrally.  
|               | Repository: Select the repository file where the properties are stored.  

Schema and Edit Schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

Built-In: You create and store the schema locally for this component only.

Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

Use an existing connection

Select this check box and in the Component List click the HDFS connection component from which you want to reuse the connection details already defined.

Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level.

Distribution

Select the cluster you are using from the drop-down list.
The options in the list vary depending on the component.
you are using. Among these options, the following ones requires specific configuration:

- If available in this **Distribution** drop-down list, the **Microsoft HD Insight** option allows you to use a Microsoft HD Insight cluster. For this purpose, you need to configure the connections to the HD Insight cluster and the Windows Azure Storage service of that cluster in the areas that are displayed. For detailed explanation about these parameters, search for configuring the connection manually on Talend Help Center (https://help.talend.com).

- If you select **Amazon EMR**, you can find more details about how to configure an Amazon EMR cluster in Talend Help Center (https://help.talend.com).

- The **Custom** option allows you to connect to a cluster different from any of the distributions given in this list, that is to say, to connect to a cluster not officially supported by Talend.

1. Select **Import from existing version** to import an officially supported distribution as base and then add other required jar files which the base distribution does not provide.

2. Select **Import from zip** to import the configuration zip for the custom distribution to be used. This zip file should contain the libraries of the different Hadoop elements and the index file of these libraries.

In Talend Exchange, members of Talend community have shared some ready-for-use configuration zip files which you can download from this Hadoop configuration list and directly use them in your connection accordingly. However, because of the ongoing evolution of the different Hadoop-related projects, you might not be able to find the configuration zip corresponding to your distribution from this list; then it is recommended to use the **Import from existing version** option to take an existing distribution as base to add the jars required by your distribution.

Note that custom versions are not officially supported by Talend. Talend and its community provide you with the opportunity to connect to custom versions from the Studio but cannot guarantee that the configuration of whichever version you choose will be easy, due to the wide range of different Hadoop distributions and versions that are available. As such, you should only attempt to set up such a connection if you have sufficient Hadoop experience to handle any issues on your own.

Note:

In this dialog box, the active check box must be kept selected so as to import the jar files pertinent to the connection to be created between the custom distribution and this component.

For a step-by-step example about how to connect to a custom distribution and share this connection, see Connecting to a custom Hadoop distribution on page 1569.
<table>
<thead>
<tr>
<th><strong>Version</strong></th>
<th>Select the version of the Hadoop distribution you are using. The available options vary depending on the component you are using.</th>
</tr>
</thead>
</table>
| **Scheme**  | Select the URI scheme of the file system to be used from the Scheme drop-down list. This scheme could be  
|             | • HDFS  
|             | • WebHDFS. WebHDFS with SSL is not supported yet.  
|             | • ADLS  
|             | The schemes present on this list vary depending on the distribution you are using and only the scheme that appears on this list with a given distribution is officially supported by Talend.  
|             | Once a scheme is selected, the corresponding syntax such as webhdfs://localhost:50070/ for WebHDFS is displayed in the field for the NameNode location of your cluster.  
|             | If you have selected ADLS, the connection parameters to be defined become:  
|             | • In the Client ID and the Client key fields, enter, respectively, the authentication ID and the authentication key generated upon the registration of the application that the current Job you are developing uses to access Azure Data Lake Storage.  
|             | Ensure that the application to be used has appropriate permissions to access Azure Data Lake. You can check this on the Required permissions view of this application on Azure. For further information, see Azure documentation Assign the Azure AD application to the Azure Data Lake Storage account file or folder.  
|             | • In the Token endpoint field, copy-paste the OAuth 2.0 token endpoint that you can obtain from the Endpoints list accessible on the App registrations page on your Azure portal.  
|             | For a video demonstration, see Configure and use Azure in a Job. |
| **NameNode URI** | Type in the URI of the Hadoop NameNode, the master node of a Hadoop system. For example, we assume that you have chosen a machine called masternode as the NameNode, then the location is hdfs://masternode:portnumber. If you are using WebHDFS, the location should be webhdfs://masternode:portnumber; WebHDFS with SSL is not supported yet. |
| **Use kerberos authentication** | If you are accessing the Hadoop cluster running with Kerberos security, select this check box, then, enter the Kerberos principal name for the NameNode in the field displayed. This enables you to use your user name to authenticate against the credentials stored in Kerberos.  
|             | • If this cluster is a MapR cluster of the version 5.0.0 or later, you can set the MapR ticket authentication configuration in addition or as an alternative by following the explanation in Connecting to a security-enabled MapR on page 1629.  
|             | Keep in mind that this configuration generates a new MapR security ticket for the username defined in the Job in each execution. If you need to reuse an existing |
ticket issued for the same username, leave both the **Force MapR ticket authentication** check box and the **Use Kerberos authentication** check box clear, and then MapR should be able to automatically find that ticket on the fly.

This check box is available depending on the Hadoop distribution you are connecting to.

### Use a keytab to authenticate

Select the **Use a keytab to authenticate** check box to log into a Kerberos-enabled system using a given keytab file. A keytab file contains pairs of Kerberos principals and encrypted keys. You need to enter the principal to be used in the **Principal** field and the access path to the keytab file itself in the **Keytab** field. This keytab file must be stored in the machine in which your Job actually runs, for example, on a Talend Jobserver.

Note that the user that executes a keytab-enabled Job is not necessarily the one a principal designates but must have the right to read the keytab file being used. For example, the user name you are using to execute a Job is `user1` and the principal to be used is `guest`; in this situation, ensure that `user1` has the right to read the keytab file to be used.

### User name

The **User name** field is available when you are not using Kerberos to authenticate. In the **User name** field, enter the login user name for your distribution. If you leave it empty, the user name of the machine hosting the Studio will be used.

### Group

Enter the membership including the authentication user under which the HDFS instances were started. This field is available depending on the distribution you are using.

### File Name

Browse to, or enter the location of the file which you write data to. This file is created automatically if it does not exist.

### Type

Select the type of the file to be processed. The type of the file may be:

- **Text file**.
- **Sequence file**: a Hadoop sequence file consists of binary key/value pairs and is suitable for the Map/Reduce framework. For further information, see [http://wiki.apache.org/hadoop/SequenceFile](http://wiki.apache.org/hadoop/SequenceFile).

Once you select the **Sequence file** format, the **Key column** list and the **Value column** list appear to allow you to select the keys and the values of that Sequence file to be processed.

### Action

Select an operation in HDFS:

- **Create**: Creates a file with data using the file name defined in the **File Name** field.
- **Overwrite**: Overwrites the data in the file specified in the **File Name** field.
- **Append**: Inserts the data into the file specified in the **File Name** field. The specified file is created automatically if it does not exist.

### Row separator

The separator used to identify the end of a row.
<table>
<thead>
<tr>
<th>Field separator</th>
<th>Enter character, string or regular expression to separate fields for the transferred data. This field is not available for a Sequence file.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Custom encoding</td>
<td>You may encounter encoding issues when you process the stored data. In that situation, select this check box to display the <strong>Encoding</strong> list. Select the encoding from the list or select <strong>Custom</strong> and define it manually. This field is compulsory for database data handling. The supported encodings depend on the JVM that you are using. For more information, see <a href="https://docs.oracle.com">https://docs.oracle.com</a>. This option is not available for a Sequence file.</td>
</tr>
<tr>
<td>Compression</td>
<td>Select the <strong>Compress the data</strong> check box to compress the output data. Hadoop provides different compression formats that help reduce the space needed for storing files and speed up data transfer. When reading a compressed file, the Studio needs to uncompress it before being able to feed it to the input flow. Note that when the type of the file to be written is <strong>Sequence File</strong>, the compression algorithm is embedded within the container files (the <code>part-*</code> files) of this sequence file. These files can be read by a <strong>Talend</strong> component such as <strong>hDFSInput</strong> within MapReduce Jobs and other applications that understand the sequence file format. Alternatively, when the type is <strong>Text File</strong>, the output files can be accessed with standard compression utilities that understand the <code>bzip2</code> or <code>gzip</code> container files.</td>
</tr>
<tr>
<td>Include header</td>
<td>Select this check box to output the header of the data. This option is not available for a Sequence file.</td>
</tr>
</tbody>
</table>

### Advanced settings

**Hadoop properties**

*Talend Studio* uses a default configuration for its engine to perform operations in a Hadoop distribution. If you need to use a custom configuration in a specific situation, complete this table with the property or properties to be customized. Then at runtime, the customized property or properties will override those default ones.

- Note that if you are using the centrally stored metadata from the **Repository**, this table automatically inherits the properties defined in that metadata and becomes uneditable unless you change the **Property type** from **Repository** to **Built-in**.

For further information about the properties required by Hadoop and its related systems such as HDFS and Hive, see the documentation of the Hadoop distribution you are using or see Apache’s Hadoop documentation on [http://hadoop.apache.org/docs](http://hadoop.apache.org/docs) and then select the version of the documentation you want. For demonstration purposes, the links to some properties are listed below:
Typically, the HDFS-related properties can be found in the hdfs-default.xml file of your distribution, such as http://hadoop.apache.org/docs/r2.6.0/hadoop-project-dist/hadoop-hdfs/hdfs-default.xml.

Apache also provides a page to list the Hive-related properties: https://cwiki.apache.org/confluence/display/Hive/Configuration+Properties.

**Global Variables**

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

**Usage**

**Usage rule**

This component needs an input component.

**Dynamic settings**

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your HDFS connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access files in different HDFS systems or different distributions, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the **Use an existing connection** check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

**Prerequisites**

The Hadoop distribution must be properly installed, so as to guarantee the interaction with Talend Studio. The following list presents MapR related information for example.
• Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under \MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native. For example, the library for Windows is \lib\native\MapRClient.dll in the MapR client jar file. For further information, see the following link from MapR: http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr.

Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path.

• Set the -Djava.library.path argument, for example, in the Job Run VM arguments area of the Run/Debug view in the Preferences dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

**Limitations**

| JRE 1.6+ is required. |

**Related scenario**

• Related topic, see Writing data in a delimited file on page 1109.
• Related topic, see Computing data with Hadoop distributed file system on page 1489.
tHDFSOutputRaw

Transfers data of different formats such as hierarchical data in the form of a single column into a given HDFS file system.

tHDFSOutputRaw receives a single-column input flow and writes the data into HDFS.

tHDFSOutputRaw Standard properties

These properties are used to configure tHDFSOutputRaw running in the Standard Job framework.

The Standard tHDFSOutputRaw component belongs to the Big Data family.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

Basic settings

| Property type | Either **Built-In** or **Repository**.  
|               | **Built-In**: No property data stored centrally.  
|               | **Repository**: Select the repository file where the properties are stored. |

**Schema and Edit Schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

The schema of this component is read-only. You can click **Edit schema** to view the schema.

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No upon completion** and choose this schema metadata again in the **Repository Content** window.

**Use an existing connection**

Select this check box and in the **Component List** click the HDFS connection component from which you want to reuse the connection details already defined.

Note that when a Job contains the parent Job and the child Job, **Component List** presents only the connection components in the same Job level.

**Distribution**

Select the cluster you are using from the drop-down list. The options in the list vary depending on the component you are using. Among these options, the following ones requires specific configuration:

- **Microsoft HD Insight** option allows you to use a Microsoft HD Insight cluster. For this purpose, you need
to configure the connections to the HD Insight cluster and the Windows Azure Storage service of that cluster in the areas that are displayed. For detailed explanation about these parameters, search for configuring the connection manually on Talend Help Center (https://help.talend.com).

- If you select Amazon EMR, you can find more details about how to configure an Amazon EMR cluster in Talend Help Center (https://help.talend.com).
- The Custom option allows you to connect to a cluster different from any of the distributions given in this list, that is to say, to connect to a cluster not officially supported by Talend.

1. Select Import from existing version to import an officially supported distribution as base and then add other required jar files which the base distribution does not provide.

2. Select Import from zip to import the configuration zip for the custom distribution to be used. This zip file should contain the libraries of the different Hadoop elements and the index file of these libraries.

In Talend Exchange, members of Talend community have shared some ready-for-use configuration zip files which you can download from this Hadoop configuration list and directly use them in your connection accordingly. However, because of the ongoing evolution of the different Hadoop-related projects, you might not be able to find the configuration zip corresponding to your distribution from this list; then it is recommended to use the Import from existing version option to take an existing distribution as base to add the jars required by your distribution.

Note that custom versions are not officially supported by Talend. Talend and its community provide you with the opportunity to connect to custom versions from the Studio but cannot guarantee that the configuration of whichever version you choose will be easy, due to the wide range of different Hadoop distributions and versions that are available. As such, you should only attempt to set up such a connection if you have sufficient Hadoop experience to handle any issues on your own.

**Note:**

In this dialog box, the active check box must be kept selected so as to import the jar files pertinent to the connection to be created between the custom distribution and this component.

For a step-by-step example about how to connect to a custom distribution and share this connection, see Connecting to a custom Hadoop distribution on page 1569.

| Version | Select the version of the Hadoop distribution you are using. The available options vary depending on the component you are using. |
| Scheme | Select the URI scheme of the file system to be used from the **Scheme** drop-down list. This scheme could be:
- HDFS
- WebHDFS. WebHDFS with SSL is not supported yet.
- ADLS

The schemes present on this list vary depending on the distribution you are using and only the scheme that appears on this list with a given distribution is officially supported by Talend.

Once a scheme is selected, the corresponding syntax such as `webhdfs://localhost:50070/` for WebHDFS is displayed in the field for the NameNode location of your cluster.

If you have selected **ADLS**, the connection parameters to be defined become:
- In the **Client ID** and the **Client key** fields, enter, respectively, the authentication ID and the authentication key generated upon the registration of the application that the current Job you are developing uses to access Azure Data Lake Storage.
  
  Ensure that the application to be used has appropriate permissions to access Azure Data Lake. You can check this on the Required permissions view of this application on Azure. For further information, see Azure documentation [Assign the Azure AD application to the Azure Data Lake Storage account file or folder.](#)

- In the **Token endpoint** field, copy-paste the OAuth 2.0 token endpoint that you can obtain from the **Endpoints** list accessible on the **App registrations** page on your Azure portal.

For a video demonstration, see [Configure and use Azure in a Job.](#)

| NameNode URI | Type in the URI of the Hadoop NameNode, the master node of a Hadoop system. For example, we assume that you have chosen a machine called `masternode` as the NameNode, then the location is `hdfs://masternode:portnumber`. If you are using WebHDFS, the location should be `webhdfs://masternode:portnumber`; WebHDFS with SSL is not supported yet.

| Use kerberos authentication | If you are accessing the Hadoop cluster running with Kerberos security, select this check box, then, enter the Kerberos principal name for the NameNode in the field displayed. This enables you to use your user name to authenticate against the credentials stored in Kerberos.

- If this cluster is a MapR cluster of the version 5.0.0 or later, you can set the MapR ticket authentication configuration in addition or as an alternative by following the explanation in [Connecting to a security-enabled MapR](#) on page 1629.

  Keep in mind that this configuration generates a new MapR security ticket for the username defined in the Job in each execution. If you need to reuse an existing ticket issued for the same username, leave both the **Force MapR ticket authentication** check box and the **Use Kerberos authentication** check box clear, and then...
MapR should be able to automatically find that ticket on the fly.
This check box is available depending on the Hadoop distribution you are connecting to.

### Use a keytab to authenticate
Select the **Use a keytab to authenticate** check box to log into a Kerberos-enabled system using a given keytab file. A keytab file contains pairs of Kerberos principals and encrypted keys. You need to enter the principal to be used in the **Principal** field and the access path to the keytab file itself in the **Keytab** field. This keytab file must be stored in the machine in which your Job actually runs, for example, on a Talend Jobserver.

Note that the user that executes a keytab-enabled Job is not necessarily the one a principal designates but must have the right to read the keytab file being used. For example, the user name you are using to execute a Job is `user1` and the principal to be used is `guest`; in this situation, ensure that `user1` has the right to read the keytab file to be used.

### Use Datanode hostname
Select the **Use Datanode hostname** check box to allow the Job to access datanodes via their hostnames. This actually sets the `dfs.client.use.datanode.hostname` property to `true`. When connecting to a S3N filesystem, you must select this check box.

### User name
The **User name** field is available when you are not using Kerberos to authenticate. In the **User name** field, enter the login user name for your distribution. If you leave it empty, the user name of the machine hosting the Studio will be used.

### Group
Enter the membership including the authentication user under which the HDFS instances were started. This field is available depending on the distribution you are using.

### File Name
Browse to, or enter the location of the file which you write data to. This file is created automatically if it does not exist.

### Action
Select an operation in HDFS:
- **Create**: Creates a file with data using the file name defined in the **File Name** field.
- **Overwrite**: Overwrites the data in the file specified in the **File Name** field.
- **Append**: Inserts the data into the file specified in the **File Name** field. The specified file is created automatically if it does not exist.

### Custom encoding
You may encounter encoding issues when you process the stored data. In that situation, select this check box to display the **Encoding** list.

Select the encoding from the list or select **Custom** and define it manually. This field is compulsory for database data handling. The supported encodings depend on the JVM that you are using. For more information, see [https://docs.oracle.com](https://docs.oracle.com).

This option is not available for a Sequence file.
**Compression**

Select the **Compress the data** check box to compress the output data.

Hadoop provides different compression formats that help reduce the space needed for storing files and speed up data transfer. When reading a compressed file, the Studio needs to uncompress it before being able to feed it to the input flow.

Note that when the type of the file to be written is **Sequence File**, the compression algorithm is embedded within the container files (the `part-*` files) of this sequence file. These files can be read by a **Talend component** such as **tHDFSInput** within MapReduce Jobs and other applications that understand the sequence file format. Alternatively, when the type is **Text File**, the output files can be accessed with standard compression utilities that understand the `bzip2` or `gzip` container files.

**Die on error**

Select the check box to stop the execution of the Job when an error occurs.

Clear the check box to skip any rows on error and complete the process for error-free rows. When errors are skipped, you can collect the rows on error using a **Row > Reject** link.

**Advanced settings**

**Hadoop properties**

*Talend Studio* uses a default configuration for its engine to perform operations in a Hadoop distribution. If you need to use a custom configuration in a specific situation, complete this table with the property or properties to be customized. Then at runtime, the customized property or properties will override those default ones.

- Note that if you are using the centrally stored metadata from the **Repository**, this table automatically inherits the properties defined in that metadata and becomes uneditable unless you change the **Property type** from **Repository** to **Built-in**.

For further information about the properties required by Hadoop and its related systems such as HDFS and Hive, see the documentation of the Hadoop distribution you are using or see Apache's Hadoop documentation on [http://hadoop.apache.org/docs](http://hadoop.apache.org/docs) and then select the version of the documentation you want. For demonstration purposes, the links to some properties are listed below:

- Typically, the HDFS-related properties can be found in the `hdfs-default.xml` file of your distribution, such as [http://hadoop.apache.org/docs/r2.6.0/hadoop-project-dist/hadoop-hdfs/hdfs-default.xml](http://hadoop.apache.org/docs/r2.6.0/hadoop-project-dist/hadoop-hdfs/hdfs-default.xml).
- Apache also provides a page to list the Hive-related properties: [https://cwiki.apache.org/confluence/display/Hive/Configuration+Properties](https://cwiki.apache.org/confluence/display/Hive/Configuration+Properties).

**tStatCatcher Statistics**

Select this check box to collect log data at the component level.
### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>FILENAME_PATH: the path of the input file. This is an After variable and it returns a string.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td></td>
<td>For further information about variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component needs an input component that provides the data of a single column. This column must be labeled to content and its type must be Object.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>For example, you can:</td>
</tr>
<tr>
<td></td>
<td>• use tConvertType to convert a column from String to Object, or</td>
</tr>
<tr>
<td></td>
<td>• use tJavaRow to add the data to be processed into the globalMap object so that this data becomes available as a global variable for the other components such as tFixedFlowInput to construct this required single column.</td>
</tr>
<tr>
<td></td>
<td>For further information about tConvertType, see tConvertType on page 498.</td>
</tr>
<tr>
<td></td>
<td>For further information about tJavaRow, see tJavaRow on page 1827.</td>
</tr>
<tr>
<td></td>
<td>For further information about tFixedFlowInput, see tFixedFlowInput on page 1192.</td>
</tr>
<tr>
<td></td>
<td>For further information about how to use a global variable, see the section describing how to use contexts and variables in Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Dynamic settings</th>
<th>Click the [+ ] button to add a row in the table and fill the Code field with a context variable to choose your HDFS connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access files in different HDFS systems or different distributions, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.</td>
</tr>
</tbody>
</table>
For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

### Prerequisites

The Hadoop distribution must be properly installed, so as to guarantee the interaction with Talend Studio. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native. For example, the library for Windows is lib\native\MapRClient.dll in the MapR client jar file. For further information, see the following link from MapR: http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr.

  Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path.

- Set the -Djava.library.path argument, for example, in the Job Run VM arguments area of the Run/Debug view in the Preferences dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

### Related Scenario

Once you have properly configured the connection to HDFS for this component, this component works exactly the same way as tFileOutputRaw.

For further information about tFileOutputRaw, see tFileOutputRaw on page 1146.
**tHDFSProperties**

Creates a single row flow that displays the properties of a file processed in HDFS.

**tHDFSProperties Standard properties**

These properties are used to configure tHDFSProperties running in the Standard Job framework.

The Standard tHDFSProperties component belongs to the Big Data and the File families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-in or Repository</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Built-in: No property data stored centrally. Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the Component List click the HDFS connection component from which you want to reuse the connection details already defined.

Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level.

**Distribution**

Select the cluster you are using from the drop-down list. The options in the list vary depending on the component you are using. Among these options, the following ones requires specific configuration:

- If available in this Distribution drop-down list, the Microsoft HD Insight option allows you to use a Microsoft HD Insight cluster. For this purpose, you need to configure the connections to the HD Insight cluster and the Windows Azure Storage service of that cluster in the areas that are displayed. For detailed explanation about these parameters, search for configuring the connection manually on Talend Help Center (https://help.talend.com).
- If you select Amazon EMR, you can find more details about how to configure an Amazon EMR cluster in Talend Help Center (https://help.talend.com).
- The Custom option allows you to connect to a cluster different from any of the distributions given in this list, that is to say, to connect to a cluster not officially supported by Talend.

1. Select Import from existing version to import an officially supported distribution as base and then add other required jar files which the base distribution does not provide.
2. Select Import from zip to import the configuration zip for the custom distribution to be used. This zip file should contain the libraries of the different Hadoop elements and the index file of these libraries.
In Talend Exchange, members of Talend community have shared some ready-for-use configuration zip files which you can download from this Hadoop configuration list and directly use them in your connection accordingly. However, because of the ongoing evolution of the different Hadoop-related projects, you might not be able to find the configuration zip corresponding to your distribution from this list; then it is recommended to use the Import from existing version option to take an existing distribution as base to add the jars required by your distribution.

Note that custom versions are not officially supported by Talend. Talend and its community provide you with the opportunity to connect to custom versions from the Studio but cannot guarantee that the configuration of whichever version you choose will be easy, due to the wide range of different Hadoop distributions and versions that are available. As such, you should only attempt to set up such a connection if you have sufficient Hadoop experience to handle any issues on your own.

Note:
In this dialog box, the active check box must be kept selected so as to import the jar files pertinent to the connection to be created between the custom distribution and this component.

For a step-by-step example about how to connect to a custom distribution and share this connection, see Connecting to a custom Hadoop distribution on page 1569.

<table>
<thead>
<tr>
<th>Version</th>
<th>Select the version of the Hadoop distribution you are using. The available options vary depending on the component you are using.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scheme</td>
<td>Select the URI scheme of the file system to be used from the Scheme drop-down list. This scheme could be&lt;br&gt;• HDFS&lt;br&gt;• WebHDFS. WebHDFS with SSL is not supported yet.&lt;br&gt;• ADLS&lt;br&gt;The schemes present on this list vary depending on the distribution you are using and only the scheme that appears on this list with a given distribution is officially supported by Talend.&lt;br&gt;Once a scheme is selected, the corresponding syntax such as webhdfs://localhost:50070/ for WebHDFS is displayed in the field for the NameNode location of your cluster.&lt;br&gt;If you have selected ADLS, the connection parameters to be defined become:&lt;br&gt;• In the Client ID and the Client key fields, enter, respectively, the authentication ID and the authentication key generated upon the registration of the application that the current Job you are developing uses to access Azure Data Lake Storage.</td>
</tr>
</tbody>
</table>
Ensure that the application to be used has appropriate permissions to access Azure Data Lake. You can check this on the Required permissions view of this application on Azure. For further information, see Azure documentation Assign the Azure AD application to the Azure Data Lake Storage account file or folder.

- In the **Token endpoint** field, copy-paste the OAuth 2.0 token endpoint that you can obtain from the **Endpoints** list accessible on the **App registrations** page on your Azure portal.

For a video demonstration, see **Configure and use Azure in a Job**.

**NameNode URI**

Type in the URI of the Hadoop NameNode, the master node of a Hadoop system. For example, we assume that you have chosen a machine called *masternode* as the NameNode, then the location is **hdfs://masternode:portnumber**. If you are using WebHDFS, the location should be **webhdfs://masternode:portnumber**; WebHDFS with SSL is not supported yet.

**Use kerberos authentication**

If you are accessing the Hadoop cluster running with Kerberos security, select this check box, then, enter the Kerberos principal name for the NameNode in the field displayed. This enables you to use your user name to authenticate against the credentials stored in Kerberos.

- If this cluster is a MapR cluster of the version 5.0.0 or later, you can set the MapR ticket authentication configuration in addition or as an alternative by following the explanation in Connecting to a security-enabled MapR on page 1629.

  Keep in mind that this configuration generates a new MapR security ticket for the username defined in the Job in each execution. If you need to reuse an existing ticket issued for the same username, leave both the **Force MapR ticket authentication** check box and the **Use Kerberos authentication** check box clear, and then MapR should be able to automatically find that ticket on the fly.

  This check box is available depending on the Hadoop distribution you are connecting to.

**Use a keytab to authenticate**

Select the **Use a keytab to authenticate** check box to log into a Kerberos-enabled system using a given keytab file. A keytab file contains pairs of Kerberos principals and encrypted keys. You need to enter the principal to be used in the **Principal** field and the access path to the keytab file itself in the **Keytab** field. This keytab file must be stored in the machine in which your Job actually runs, for example, on a Talend Jobserver.

  Note that the user that executes a keytab-enabled Job is not necessarily the one a principal designates but must have the right to read the keytab file being used. For example, the user name you are using to execute a Job is *user1* and the principal to be used is *guest*; in this situation, ensure that *user1* has the right to read the keytab file to be used.

**User name**

The **User name** field is available when you are not using Kerberos to authenticate. In the **User name** field, enter the login user name for your distribution. If you leave it empty,
the user name of the machine hosting the Studio will be used.

<table>
<thead>
<tr>
<th>Group</th>
<th>Enter the membership including the authentication user under which the HDFS instances were started. This field is available depending on the distribution you are using.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Schema and Edit schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. The schema of this component is read-only. You can click Edit schema to view the schema.</td>
</tr>
<tr>
<td>File</td>
<td>Browse to, or enter the path pointing to the data to be used in the file system.</td>
</tr>
<tr>
<td>Get file checksum</td>
<td>Select this check box to generate and output the MD5 information of the file processed. Note that this is an HDFS only checksum and not a true MD5 hash that can be compared with the MD5 value obtained, for example, from tFileInputProperties. For further information about this component, see tFileInputProperties on page 1072.</td>
</tr>
</tbody>
</table>

### Advanced settings

| Hadoop properties | Talend Studio uses a default configuration for its engine to perform operations in a Hadoop distribution. If you need to use a custom configuration in a specific situation, complete this table with the property or properties to be customized. Then at runtime, the customized property or properties will override those default ones.  

- Note that if you are using the centrally stored metadata from the Repository, this table automatically inherits the properties defined in that metadata and becomes uneditable unless you change the Property type from Repository to Built-in.  

For further information about the properties required by Hadoop and its related systems such as HDFS and Hive, see the documentation of the Hadoop distribution you are using or see Apache’s Hadoop documentation on [http://hadoop.apache.org/docs](http://hadoop.apache.org/docs) and then select the version of the documentation you want. For demonstration purposes, the links to some properties are listed below:  

- Typically, the HDFS-related properties can be found in the hdfs-default.xml file of your distribution, such as [http://hadoop.apache.org/docs/r2.6.0/hadoop-project-dist/hadoop-hdfs/hdfs-default.xml](http://hadoop.apache.org/docs/r2.6.0/hadoop-project-dist/hadoop-hdfs/hdfs-default.xml).  

- Apache also provides a page to list the Hive-related properties: [https://cwiki.apache.org/confluence/display/Hive/Configuration+Properties](https://cwiki.apache.org/confluence/display/Hive/Configuration+Properties). |
| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |
Global Variables

**Global Variables**

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

Usage

**Usage rule**

**tHDFSProperties** can be standalone component or send the information it generates to its following component.

**Dynamic settings**

Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your HDFS connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access files in different HDFS systems or different distributions, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of **Talend Studio**.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see [Reading data from databases through context-based dynamic connections](#) on page 2457 and [Reading data from different MySQL databases using dynamically loaded connection parameters](#) on page 491. For more information on **Dynamic settings** and context variables, see [Talend Studio User Guide](#).

Prerequisites

The Hadoop distribution must be properly installed, so as to guarantee the interaction with **Talend Studio**. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under `MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native`. For example, the library for Windows is `\lib\native\MapRClient.dll` in the MapR client jar file. For further information, see the following link from MapR: [http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr](http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr).
Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path.

- Set the -Djava.library.path argument, for example, in the Job Run VM arguments area of the Run/Debug view in the Preferences dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

<table>
<thead>
<tr>
<th>Limitation</th>
<th>JRE 1.6+ is required.</th>
</tr>
</thead>
</table>

**Related scenario**

Related topic, see Procedure on page 1152

Related topic, see Iterating on a HDFS directory on page 1513
tHDFSPut

Connects to Hadoop distributed file system to load large-scale files into it with optimized performance.

tHDFSPut copies files from an user-defined directory, pastes them into a given Hadoop distributed file system (HDFS) and if needs be, renames these files.

**tHDFSPut Standard properties**

These properties are used to configure tHDFSPut running in the Standard Job framework.

The Standard tHDFSPut component belongs to the Big Data and the File families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-in or Repository</th>
</tr>
</thead>
<tbody>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the Component List click the HDFS connection component from which you want to reuse the connection details already defined.

Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level.

**Distribution**

Select the cluster you are using from the drop-down list. The options in the list vary depending on the component you are using. Among these options, the following ones requires specific configuration:

- If available in this Distribution drop-down list, the Microsoft HD Insight option allows you to use a Microsoft HD Insight cluster. For this purpose, you need to configure the connections to the HD Insight cluster and the Windows Azure Storage service of that cluster in the areas that are displayed. For detailed explanation about these parameters, search for configuring the connection manually on Talend Help Center (https://help.talend.com).
- If you select Amazon EMR, you can find more details about how to configure an Amazon EMR cluster in Talend Help Center (https://help.talend.com).
- The Custom option allows you to connect to a cluster different from any of the distributions given in this list, that is to say, to connect to a cluster not officially supported by Talend.

1. Select Import from existing version to import an officially supported distribution as base and then add
other required jar files which the base distribution does not provide.

2. Select **Import from zip** to import the configuration zip for the custom distribution to be used. This zip file should contain the libraries of the different Hadoop elements and the index file of these libraries.

   In **Talend Exchange**, members of **Talend** community have shared some ready-for-use configuration zip files which you can download from this **Hadoop configuration** list and directly use them in your connection accordingly. However, because of the ongoing evolution of the different Hadoop-related projects, you might not be able to find the configuration zip corresponding to your distribution from this list; then it is recommended to use the **Import from existing version** option to take an existing distribution as base to add the jars required by your distribution.

   Note that custom versions are not officially supported by **Talend**. **Talend** and its community provide you with the opportunity to connect to custom versions from the Studio but cannot guarantee that the configuration of whichever version you choose will be easy, due to the wide range of different Hadoop distributions and versions that are available. As such, you should only attempt to set up such a connection if you have sufficient Hadoop experience to handle any issues on your own.

   **Note:**
   In this dialog box, the active check box must be kept selected so as to import the jar files pertinent to the connection to be created between the custom distribution and this component.

   For a step-by-step example about how to connect to a custom distribution and share this connection, see **Connecting to a custom Hadoop distribution** on page 1569.

**Version**

Select the version of the Hadoop distribution you are using. The available options vary depending on the component you are using.

**Scheme**

Select the URI scheme of the file system to be used from the **Scheme** drop-down list. This scheme could be

- HDFS
- WebHDFS. WebHDFS with SSL is not supported yet.
- ADLS

The schemes present on this list vary depending on the distribution you are using and only the scheme that appears on this list with a given distribution is officially supported by Talend.

Once a scheme is selected, the corresponding syntax such as `webhdfs://localhost:50070/` for WebHDFS is displayed in the field for the NameNode location of your cluster.

If you have selected **ADLS**, the connection parameters to be defined become:
- In the **Client ID** and the **Client key** fields, enter, respectively, the authentication ID and the authentication key generated upon the registration of the application that the current Job you are developing uses to access Azure Data Lake Storage.

Ensure that the application to be used has appropriate permissions to access Azure Data Lake. You can check this on the Required permissions view of this application on Azure. For further information, see Azure documentation Assign the Azure AD application to the Azure Data Lake Storage account file or folder.

- In the **Token endpoint** field, copy-paste the OAuth 2.0 token endpoint that you can obtain from the **Endpoints** list accessible on the **App registrations** page on your Azure portal.

For a video demonstration, see Configure and use Azure in a Job.

**NameNode URI**

Type in the URI of the Hadoop NameNode, the master node of a Hadoop system. For example, we assume that you have chosen a machine called *masternode* as the NameNode, then the location is **hdfs://masternode:portnumber**. If you are using WebHDFS, the location should be **webhdfs://masternode:portnumber**; WebHDFS with SSL is not supported yet.

**Use kerberos authentication**

- If you are accessing the Hadoop cluster running with Kerberos security, select this check box, then, enter the Kerberos principal name for the NameNode in the field displayed. This enables you to use your user name to authenticate against the credentials stored in Kerberos.

  - If this cluster is a MapR cluster of the version 5.0.0 or later, you can set the MapR ticket authentication configuration in addition or as an alternative by following the explanation in Connecting to a security-enabled MapR on page 1629.

  Keep in mind that this configuration generates a new MapR security ticket for the username defined in the Job in each execution. If you need to reuse an existing ticket issued for the same username, leave both the **Force MapR ticket authentication** check box and the **Use Kerberos authentication** check box clear, and then MapR should be able to automatically find that ticket on the fly.

  This check box is available depending on the Hadoop distribution you are connecting to.

**Use a keytab to authenticate**

- Select the **Use a keytab to authenticate** check box to log into a Kerberos-enabled system using a given keytab file. A keytab file contains pairs of Kerberos principals and encrypted keys. You need to enter the principal to be used in the **Principal** field and the access path to the keytab file itself in the **Keytab** field. This keytab file must be stored in the machine in which your Job actually runs, for example, on a Talend Jobserver.

  Note that the user that executes a keytab-enabled Job is not necessarily the one a principal designates but must have the right to read the keytab file being used. For example, the user name you are using to execute a Job is **user1** and the
principal to be used is guest; in this situation, ensure that user1 has the right to read the keytab file to be used.

<table>
<thead>
<tr>
<th>User name</th>
<th>The <strong>User name</strong> field is available when you are not using Kerberos to authenticate. In the <strong>User name</strong> field, enter the login user name for your distribution. If you leave it empty, the user name of the machine hosting the Studio will be used.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Group</td>
<td>Enter the membership including the authentication user under which the HDFS instances were started. This field is available depending on the distribution you are using.</td>
</tr>
<tr>
<td>Local directory</td>
<td>Local directory where are stored the files to be loaded into HDFS.</td>
</tr>
<tr>
<td>HDFS directory</td>
<td>Browse to, or enter the path pointing to the data to be used in the file system.</td>
</tr>
<tr>
<td>Overwrite file</td>
<td>Options to overwrite or not the existing file with the new one.</td>
</tr>
</tbody>
</table>
| Use Perl5 Regex Expression as Filemask | Select this check box if you want to use Perl5 regular expressions in the **Files** field as file filters. This is useful when the name of the file to be used contains special characters such as parentheses.  
For information about Perl5 regular expression syntax, see [Perl5 Regular Expression Syntax](#). |
| Files | In the **Files** area, the fields to be completed are:
- **File mask**: type in the file name to be selected from the local directory. Regular expression is available.
- **New name**: give a new name to the loaded file. |
| Die on error | This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. |

### Advanced settings

- **tStatCatcher Statistics**
  - Select this check box to collect log data at the component level.

- **Hadoop properties**
  - **Talend Studio** uses a default configuration for its engine to perform operations in a Hadoop distribution. If you need to use a custom configuration in a specific situation, complete this table with the property or properties to be customized. Then at runtime, the customized property or properties will override those default ones.  
    - Note that if you are using the centrally stored metadata from the **Repository**, this table automatically inherits the properties defined in that metadata and becomes uneditable unless you change the **Property type** from **Repository** to **Built-in**.  
  
  For further information about the properties required by Hadoop and its related systems such as HDFS and Hive, see the documentation of the Hadoop distribution you are using or see Apache’s Hadoop documentation on [http://]
hadoop.apache.org/docs and then select the version of the documentation you want. For demonstration purposes, the links to some properties are listed below:

- Typically, the HDFS-related properties can be found in the hdfs-default.xml file of your distribution, such as http://hadoop.apache.org/docs/r2.6.0/hadoop-project-dist/hadoop-hdfs/hdfs-default.xml.
- Apache also provides a page to list the Hive-related properties: https://cwiki.apache.org/confluence/display/Hive/Configuration+Properties.

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_FILE: the number of files processed. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>TRANSFER_MESSAGES: file transferred information. This is an After variable and it returns a string.</td>
</tr>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component combines HDFS connection and data extraction, thus usually used as a single-component subjob to move data from a user-defined local directory to HDFS.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Different from the tHDFSInput and the tHDFSOutput components, it runs standalone and does not generate input or output flow for the other components.</td>
</tr>
<tr>
<td></td>
<td>It is often connected to the Job using OnSubjobOk or OnComponentOk link, depending on the context.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Dynamic settings</th>
<th>Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your HDFS connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access files in different HDFS systems or different distributions, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.</td>
</tr>
</tbody>
</table>
For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>Prerequisites</th>
<th>The Hadoop distribution must be properly installed, so as to guarantee the interaction with Talend Studio. The following list presents MapR related information for example.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR's documentation, the library or libraries of a MapR client corresponding to each OS version can be found under MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native. For example, the library for Windows is \lib\native\MapRClient.dll in the MapR client jar file. For further information, see the following link from MapR: <a href="http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr">http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr</a>.</td>
</tr>
<tr>
<td></td>
<td>Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path.</td>
</tr>
<tr>
<td></td>
<td>• Set the -Djava.library.path argument, for example, in the Job Run VM arguments area of the Run/Debug view in the Preferences dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.</td>
</tr>
<tr>
<td></td>
<td>For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.</td>
</tr>
</tbody>
</table>

| Limitations | JRE 1.6+ is required. |

**Related scenario**

For related scenario, see Computing data with Hadoop distributed file system on page 1489.
tHDFSRename

Renames the selected files or specified directory on HDFS.

**tHDFSRename Standard properties**

These properties are used to configure tHDFSRename running in the Standard Job framework.

The Standard tHDFSRename component belongs to the Big Data and the File families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>

</thead>
<tbody>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

| Use an existing connection          | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. |
|-------------------------------------| Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level. |

| Distribution                        | Select the cluster you are using from the drop-down list. The options in the list vary depending on the component you are using. Among these options, the following ones requires specific configuration: |
|-------------------------------------| - If available in this Distribution drop-down list, the Microsoft HD Insight option allows you to use a Microsoft HD Insight cluster. For this purpose, you need to configure the connections to the HD Insight cluster and the Windows Azure Storage service of that cluster in the areas that are displayed. For detailed explanation about these parameters, search for configuring the connection manually on Talend Help Center (https://help.talend.com). |
|                                      | - If you select Amazon EMR, you can find more details about how to configure an Amazon EMR cluster in Talend Help Center (https://help.talend.com). |
|                                      | - The Custom option allows you to connect to a cluster different from any of the distributions given in this list, that is to say, to connect to a cluster not officially supported by Talend. |
|                                      | 1. Select Import from existing version to import an officially supported distribution as base and then add other required jar files which the base distribution does not provide. |
|                                      | 2. Select Import from zip to import the configuration zip for the custom distribution to be used. This zip file
should contain the libraries of the different Hadoop elements and the index file of these libraries.

In Talend Exchange, members of Talend community have shared some ready-for-use configuration zip files which you can download from this Hadoop configuration list and directly use them in your connection accordingly. However, because of the ongoing evolution of the different Hadoop-related projects, you might not be able to find the configuration zip corresponding to your distribution from this list; then it is recommended to use the Import from existing version option to take an existing distribution as base to add the jars required by your distribution.

Note that custom versions are not officially supported by Talend. Talend and its community provide you with the opportunity to connect to custom versions from the Studio but cannot guarantee that the configuration of whichever version you choose will be easy, due to the wide range of different Hadoop distributions and versions that are available. As such, you should only attempt to set up such a connection if you have sufficient Hadoop experience to handle any issues on your own.

Note:
In this dialog box, the active check box must be kept selected so as to import the jar files pertinent to the connection to be created between the custom distribution and this component.

For a step-by-step example about how to connect to a custom distribution and share this connection, see Connecting to a custom Hadoop distribution on page 1569.

For demonstration purposes, the links to some properties are listed below:  
  - Typically, the HDFS-related properties can be found in the **hdfs-default.xml** file of your distribution, such as http://hadoop.apache.org/docs/r2.6.0/hadoop-project-dist/hadoop-hdfs/hdfs-default.xml.  
  - Apache also provides a page to list the Hive-related properties: https://cwiki.apache.org/confluence/display/Hive/Configuration+Properties.
Global Variables

Global Variables

| NB_FILE: the number of files processed. This is an After variable and it returns an integer. |
| CURRENT_STATUS: the execution result of the component. This is a Flow variable and it returns a string. |
| ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. |

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule

This component is used to compose a single-component Job or sublob.

Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your HDFS connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access files in different HDFS systems or different distributions, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Prerequisites

The Hadoop distribution must be properly installed, so as to guarantee the interaction with Talend Studio. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under MAPR\INSTALL\hadoop\hadoop-VERSION\lib\native. For example, the library for
Windows is `\lib\native\MapRClient.dll` in the MapR client jar file. For further information, see the following link from MapR: http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr.

Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path.

- Set the `-Djava.library.path` argument, for example, in the Job Run VM arguments area of the Run/Debug view in the Preferences dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

| Limitation | JRE 1.6+ is required. |

**Related scenario**

For related scenario, see Computing data with Hadoop distributed file system on page 1489.
**tHDFSRowCount**

Reads a file in HDFS row by row in order to determine the number of rows this file contains.

`tHDFSRowCount` counts the number of rows in a file in HDFS. If the file to be processed is a Hadoop sequence file type or a large dataset, it is recommended to use a `tAggregateRow` to count the records.

**tHDFSRowCount Standard properties**

These properties are used to configure `tHDFSRowCount` running in the Standard Job framework.

The `Standard tHDFSRowCount` component belongs to the Big Data and the File families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| Property Type | Built-In: You create and store the schema locally for this component only.  
Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.  
Use an existing connection | Select this check box and in the Component List click the HDFS connection component from which you want to reuse the connection details already defined.  
Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level.  
Distribution | Select the cluster you are using from the drop-down list. The options in the list vary depending on the component you are using. Among these options, the following ones requires specific configuration:  
- If available in this Distribution drop-down list, the Microsoft HD Insight option allows you to use a Microsoft HD Insight cluster. For this purpose, you need to configure the connections to the HD Insight cluster and the Windows Azure Storage service of that cluster in the areas that are displayed. For detailed explanation about these parameters, search for configuring the connection manually on Talend Help Center (https://help.talend.com).  
- If you select Amazon EMR, you can find more details about how to configure an Amazon EMR cluster in Talend Help Center (https://help.talend.com).  
- The Custom option allows you to connect to a cluster different from any of the distributions given in this list, that is to say, to connect to a cluster not officially supported by Talend.  
1. Select Import from existing version to import an officially supported distribution as base and then add other required jar files which the base distribution does not provide. |  
| --- | --- |
2. Select **Import from zip** to import the configuration zip for the custom distribution to be used. This zip file should contain the libraries of the different Hadoop elements and the index file of these libraries.

In **Talend Exchange**, members of **Talend** community have shared some ready-for-use configuration zip files which you can download from this **Hadoop configuration** list and directly use them in your connection accordingly. However, because of the ongoing evolution of the different Hadoop-related projects, you might not be able to find the configuration zip corresponding to your distribution from this list; then it is recommended to use the **Import from existing version** option to take an existing distribution as base to add the jars required by your distribution.

Note that custom versions are not officially supported by **Talend**. **Talend** and its community provide you with the opportunity to connect to custom versions from the Studio but cannot guarantee that the configuration of whichever version you choose will be easy, due to the wide range of different Hadoop distributions and versions that are available. As such, you should only attempt to set up such a connection if you have sufficient Hadoop experience to handle any issues on your own.

**Note:**
In this dialog box, the active check box must be kept selected so as to import the jar files pertinent to the connection to be created between the custom distribution and this component.

For a step-by-step example about how to connect to a custom distribution and share this connection, see **Connecting to a custom Hadoop distribution** on page 1569.

<table>
<thead>
<tr>
<th>Version</th>
<th>Select the version of the Hadoop distribution you are using. The available options vary depending on the component you are using.</th>

</thead>
</table>
| Scheme  | Select the URI scheme of the file system to be used from the **Scheme** drop-down list. This scheme could be
|         | • HDFS
|         | • WebHDFS. WebHDFS with SSL is not supported yet.
|         | • ADLS
|         | The schemes present on this list vary depending on the distribution you are using and only the scheme that appears on this list with a given distribution is officially supported by Talend.
|         | Once a scheme is selected, the corresponding syntax such as `webhdfs://localhost:50070/` for WebHDFS is displayed in the field for the NameNode location of your cluster.
|         | If you have selected **ADLS**, the connection parameters to be defined become: |
In the **Client ID** and the **Client key** fields, enter, respectively, the authentication ID and the authentication key generated upon the registration of the application that the current Job you are developing uses to access Azure Data Lake Storage. Ensure that the application to be used has appropriate permissions to access Azure Data Lake. You can check this on the Required permissions view of this application on Azure. For further information, see Azure documentation Assign the Azure AD application to the Azure Data Lake Storage account file or folder.

- In the **Token endpoint** field, copy-paste the OAuth 2.0 token endpoint that you can obtain from the Endpoints list accessible on the App registrations page on your Azure portal.

For a video demonstration, see Configure and use Azure in a Job.

### NameNode URI
Type in the URI of the Hadoop NameNode, the master node of a Hadoop system. For example, we assume that you have chosen a machine called *masternode* as the NameNode, then the location is `hdfs://masternode:portnumber`. If you are using WebHDFS, the location should be `webhdfs://masternode:portnumber`; WebHDFS with SSL is not supported yet.

### Use kerberos authentication
If you are accessing the Hadoop cluster running with Kerberos security, select this check box, then, enter the Kerberos principal name for the NameNode in the field displayed. This enables you to use your user name to authenticate against the credentials stored in Kerberos.

- If this cluster is a MapR cluster of the version 5.0.0 or later, you can set the MapR ticket authentication configuration in addition or as an alternative by following the explanation in Connecting to a security-enabled MapR on page 1629.

  Keep in mind that this configuration generates a new MapR security ticket for the username defined in the Job in each execution. If you need to reuse an existing ticket issued for the same username, leave both the **Force MapR ticket authentication** check box and the **Use Kerberos authentication** check box clear, and then MapR should be able to automatically find that ticket on the fly.

  This check box is available depending on the Hadoop distribution you are connecting to.

### Use a keytab to authenticate
Select the **Use a keytab to authenticate** check box to log into a Kerberos-enabled system using a given keytab file. A keytab file contains pairs of Kerberos principals and encrypted keys. You need to enter the principal to be used in the **Principal** field and the access path to the keytab file itself in the **Keytab** field. This keytab file must be stored in the machine in which your Job actually runs, for example, on a Talend Jobserver.

Note that the user that executes a keytab-enabled Job is not necessarily the one a principal designates but must have the right to read the keytab file being used. For example, the user name you are using to execute a Job is *user1* and the
principal to be used is guest; in this situation, ensure that user1 has the right to read the keytab file to be used.

### User name

- **User name** field is available when you are not using Kerberos to authenticate. In the **User name** field, enter the login user name for your distribution. If you leave it empty, the user name of the machine hosting the Studio will be used.

### Group

- Enter the membership including the authentication user under which the HDFS instances were started. This field is available depending on the distribution you are using.

### File name

- Browse to, or enter the path pointing to the data to be used in the file system.

### Row separator

- The separator used to identify the end of a row.

### Ignore empty rows

- Select this check box to skip the empty rows.

### Encoding

- Select the encoding from the list or select Custom and define it manually. This field is compulsory for database data handling. The supported encodings depend on the JVM that you are using. For more information, see https://docs.oracle.com.

### Compression

- Select the Uncompress the data check box to uncompress the input data.

- Hadoop provides different compression formats that help reduce the space needed for storing files and speed up data transfer. When reading a compressed file, the Studio needs to uncompress it before being able to feed it to the input flow.

### Advanced settings

#### Hadoop properties

- **Talend Studio** uses a default configuration for its engine to perform operations in a Hadoop distribution. If you need to use a custom configuration in a specific situation, complete this table with the property or properties to be customized. Then at runtime, the customized property or properties will override those default ones.

  - Note that if you are using the centrally stored metadata from the Repository, this table automatically inherits the properties defined in that metadata and becomes uneditable unless you change the **Property type** from Repository to Built-in.

- For further information about the properties required by Hadoop and its related systems such as HDFS and Hive, see the documentation of the Hadoop distribution you are using or see Apache's Hadoop documentation on [http://hadoop.apache.org/docs](http://hadoop.apache.org/docs) and then select the version of the documentation you want. For demonstration purposes, the links to some properties are listed below:

  - Typically, the HDFS-related properties can be found in the hdfs-default.xml file of your distribution, such as [http://hadoop.apache.org/docs/r2.6.0/hadoop-project-dist/hadoop-hdfs/hdfs-default.xml](http://hadoop.apache.org/docs/r2.6.0/hadoop-project-dist/hadoop-hdfs/hdfs-default.xml).
tHDFSRowCount

- Apache also provides a page to list the Hive-related properties: https://cwiki.apache.org/confluence/display/Hive/Configuration+Properties.

<table>
<thead>
<tr>
<th>Column</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>tStatCatcher Statistics</td>
<td>Select this check box to gather the Job processing metadata at a Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

### Global Variables

**Global Variables**

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>COUNT</td>
<td>the number of rows in a file. This is a Flow variable and it returns an integer.</td>
</tr>
<tr>
<td>ERROR_MESSAGE</td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

### Usage

**Usage rule**

thHDFSRowCount is a standalone component; it must be used with a OnSubjobOk connection to tJava in order to return the row count.

The valid code for tJava to get this count could be:

```java
System.out.print(((Integer)globalMap.get("thHDFSRowCount_1_COUNT")));
```

In this example, thHDFSRowCount_1 is the label of this component in a Job, so it may vary among different use cases; COUNT is the global variable of thHDFSRowCount, representing the integer flow of the row count.

For further information about how to label a component or how to use a global variable in a Job, see the [Talend Studio User Guide](#).

**Dynamic settings**

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your HDFS connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access files in different HDFS systems or different distributions, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the
Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

### Prerequisites

The Hadoop distribution must be properly installed, so as to guarantee the interaction with Talend Studio. The following list presents MapR related information for example:

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native. For example, the library for Windows is \lib\native\MapRClient.dll in the MapR client jar file. For further information, see the following link from MapR: http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr.

Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path.

- Set the -Djava.library.path argument, for example, in the Job Run VM arguments area of the Run/Debug view in the Preferences dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

### Limitation

JRE 1.6+ is required.

### Related scenarios

No scenario is available for the Standard version of this component yet.
tHiveClose

Closes connection to a Hive database.

tHiveClose closes an active connection to a database.

**tHiveClose Standard properties**

These properties are used to configure tHiveClose running in the Standard Job framework. The Standard tHiveClose component belongs to the Big Data and the Databases families. The component in this framework is available in all Talend products.

**Basic settings**

| Component list | If there is more than one connection used in the Job, select tHiveConnection from the list. |

**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect the log data at a component level. |

**Global Variables**

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.  
For further information about variables, see Talend Studio User Guide. |

**Usage**

| Usage rule | This component is to be used along with other Hive components, especially with tHiveConnection as tHiveConnection allows you to open a connection for the transaction which is underway. |

| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an |
environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see [Reading data from databases through context-based dynamic connections](#) on page 2457 and [Reading data from different MySQL databases using dynamically loaded connection parameters](#) on page 491. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

### Prerequisites

The Hadoop distribution must be properly installed, so as to guarantee the interaction with **Talend Studio**. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under `MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native`. For example, the library for Windows is `\lib\native\MapRClient.dll` in the MapR client jar file. For further information, see the following link from MapR: [http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr](http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr).

  Without adding the specified library or libraries, you may encounter the following error: `no MapRClient in java.library.path`.

- Set the `-Djava.library.path` argument, for example, in the **Job Run VM arguments** area of the **Run/Debug** view in the **Preferences** dialog box in the **Window** menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the **Data viewer** to view locally in the Studio the data stored in MapR.

  For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

### Related scenarios

No scenario is available for the Standard version of this component yet.
tHiveConnection

Establishes a Hive connection to be reused by other Hive components in your Job.
tHiveConnection opens a connection to a Hive database.

tHiveConnection Standard properties

These properties are used to configure tHiveConnection running in the Standard Job framework.
The Standard tHiveConnection component belongs to the Big Data, the Databases and the ELT families.
The component in this framework is available in all Talend products.

Basic settings

Connection configuration:

- When you use this component with Qubole on AWS:

  | API Token | Click the ... button next to the API Token field to enter the authentication token generated for the Qubole user account to be used. For further information about how to obtain this token, see Manage Qubole account from the Qubole documentation.
  |
  | Cluster label | Select the Cluster label check box and enter the name of the Qubole cluster to be used. If leaving this check box clear, the default cluster is used.
  |
  | Change API endpoint | Select the Change API endpoint check box and select the region to be used. If leaving this check box clear, the default region is used.

- When you use this component with Google Dataproc:

  | Project identifier | Enter the ID of your Google Cloud Platform project. If you are not certain about your project ID, check it in the Manage Resources page of your Google Cloud Platform services.
  |
  | Cluster identifier | Enter the ID of your Dataproc cluster to be used.
<table>
<thead>
<tr>
<th><strong>Region</strong></th>
<th>Leave the default value <code>global</code> as is, since this is the only region which the Studio supports for Google Cloud Platform.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Google Storage staging bucket</strong></td>
<td>As a Talend Job expects its dependent jar files for execution, specify the Google Storage directory to which these jar files are transferred so that your Job can access these files at execution. The directory to be entered must end with a slash (<code>/</code>). If not existing, the directory is created on the fly but the bucket to be used must already exist.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Fill this field with the name of the database.</td>
</tr>
<tr>
<td><strong>Provide Google Credentials in file</strong></td>
<td>Leave this check box clear, when you launch your Job from a given machine in which Google Cloud SDK has been installed and authorized to use your user account credentials to access Google Cloud Platform. In this situation, this machine is often your local machine. For further information about this Google Credentials file, see the administrator of your Google Cloud Platform or visit Google Cloud Platform Auth Guide.</td>
</tr>
</tbody>
</table>

**When you use this component with HDInsight:**

| **WebHCat configuration** | Enter the address and the authentication information of the Microsoft HD Insight cluster to be used. For example, the address could be `your_hdinsight_cluster_name.azurehdinsight.net` and the authentication information is your Azure account name: `ychen`. The Studio uses this service to submit the Job to the HD Insight cluster. In the **Job result folder** field, enter the location in which you want to store the execution result of a Job in the Azure Storage to be used. |
| **HDInsight configuration** | - The **Username** is the one defined when creating your cluster. You can find it in the **SSH + Cluster login** blade of your cluster.  
- The **Password** is defined when creating your HDInsight cluster for authentication to this cluster. |
| **Windows Azure Storage configuration** | Enter the address and the authentication information of the Azure Storage account to be used. In this configuration, you do not define where to read or write your business data but define where to deploy your Job only. Therefore always use the Azure Storage system for this configuration. In the **Container** field, enter the name of the container to be used. You can find the available containers in the **Blob** blade of the Azure Storage account to be used. In the **Deployment Blob** field, enter the location in which you want to store the current Job and its dependent libraries in this Azure Storage account. In the **Hostname** field, enter the Primary Blob Service Endpoint of your Azure Storage account without the `https://` part. You can find this endpoint in the **Properties** blade of this storage account. |
In the **Username** field, enter the name of the Azure Storage account to be used.

In the **Password** field, enter the access key of the Azure Storage account to be used. This key can be found in the **Access keys** blade of this storage account.

| Database | Fill this field with the name of the database. |

- **When you use the other distributions:**

| **Connection mode** | Select a connection mode from the list. The options vary depending on the distribution you are using. |
|**Hive server** | Select the Hive server through which you want the Job using this component to execute queries on Hive. This **Hive server** list is available only when the Hadoop distribution to be used such as **HortonWorks Data Platform V1.2.0 (Bimota)** supports HiveServer2. It allows you to select HiveServer2 (**Hive 2**), the server that better support concurrent connections of multiple clients than HiveServer (**Hive 1**).

For further information about HiveServer2, see [https://cwiki.apache.org/confluence/display/Hive/Setting+Up+HiveServer2](https://cwiki.apache.org/confluence/display/Hive/Setting+Up+HiveServer2).

|**Host** | Database server IP address. |
|**Port** | Listening port number of DB server. |
|**Database** | Fill this field with the name of the database. |

**Note:**

This field is not available when you select **Embedded** from the **Connection mode** list.

| **Username** and **Password** | DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
|**Use kerberos authentication** | If you are accessing a Hive Metastore running with Kerberos security, select this check box and then enter the relevant parameters in the fields that appear.

- If this cluster is a MapR cluster of the version 5.0.0 or later, you can set the MapR ticket authentication configuration in addition or as an alternative by following the explanation in Connecting to a security-enabled MapR on page 1629.

Keep in mind that this configuration generates a new MapR security ticket for the username defined in the Job in each execution. If you need to reuse an existing ticket issued for the same username, leave both the **Force MapR ticket authentication** check box and the **Use Kerberos authentication** check box clear, and then MapR should be able to automatically find that ticket on the fly. |
The values of the following parameters can be found in the hive-site.xml file of the Hive system to be used.

1. **Hive principal** uses the value of hive.metastore.kerberos.principal. This is the service principal of the Hive Metastore.

2. **HiveServer2 local user principal** uses the value of hive.server2.authentication.kerberos.principal.

3. **HiveServer2 local user keytab** uses the value of hive.server2.authentication.kerberos.keytab.

4. **Metastore URL** uses the value of javax.jdo.option.ConnectionURL. This is the JDBC connection string to the Hive Metastore.

5. **Driver class** uses the value of javax.jdo.option.ConnectionDriverName. This is the name of the driver for the JDBC connection.

6. **Username** uses the value of javax.jdo.option.ConnectionUserName. This, as well as the Password parameter, is the user credential for connecting to the Hive Metastore.

7. **Password** uses the value of javax.jdo.option.ConnectionPassword.

For the other parameters that are displayed, please consult the Hadoop configuration files they belong to. For example, the **Namenode principal** can be found in the hdfs-site.xml file or the hdfs-default.xml file of the distribution you are using.

This check box is available depending on the Hadoop distribution you are connecting to.

---

### Use a keytab to authenticate

Select the **Use a keytab to authenticate** check box to log into a Kerberos-enabled system using a given keytab file. A keytab file contains pairs of Kerberos principals and encrypted keys. You need to enter the principal to be used in the **Principal** field and the access path to the keytab file itself in the **Keytab** field. This keytab file must be stored in the machine in which your Job actually runs, for example, on a Talend Jobserver.

Note that the user that executes a keytab-enabled Job is not necessarily the one a principal designates but must have the right to read the keytab file being used. For example, the user name you are using to execute a Job is `user1` and the principal to be used is `guest`; in this situation, ensure that `user1` has the right to read the keytab file to be used.

---

### Use SSL encryption

Select this check box to enable the SSL or TLS encrypted connection.

Then in the fields that are displayed, provide the authentication information:

- In the **Trust store path** field, enter the path, or browse to the TrustStore file to be used. By default, the supported TrustStore types are **JKS** and **PKCS 12**.
- To enter the password, click the `[...]` button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

This feature is available only to the HiveServer2 in the **Standalone** mode of the following distributions:
### Set Resource Manager

Select this check box and in the displayed field, enter the location of the ResourceManager of your distribution. For example, `tal-qall4.talend.lan:8050`.

Then you can continue to set the following parameters depending on the configuration of the Hadoop cluster to be used (if you leave the check box of a parameter clear, then at runtime, the configuration about this parameter in the Hadoop cluster to be used will be ignored):

1. Select the **Set resourcemanager scheduler address** check box and enter the Scheduler address in the field that appears.
2. Select the **Set jobhistory address** check box and enter the location of the JobHistory server of the Hadoop cluster to be used. This allows the metrics information of the current Job to be stored in that JobHistory server.
3. Select the **Set staging directory** check box and enter this directory defined in your Hadoop cluster for temporary files created by running programs. Typically, this directory can be found under the `yarn.app.mapreduce.am.staging-dir` property in the configuration files such as `yarn-site.xml` or `mapred-site.xml` of your distribution.
4. Allocate proper memory volumes to the **Map** and the **Reduce** computations and the **ApplicationMaster** of YARN by selecting the **Set memory** check box in the Advanced settings view.
5. Select the **Set Hadoop user** check box and enter the user name under which you want to execute the Job. Since a file or a directory in Hadoop has its specific owner with appropriate read or write rights, this field allows you to execute the Job directly under the user name that has the appropriate rights to access the file or directory to be processed.
6. Select the **Use datanode hostname** check box to allow the Job to access datanodes via their hostnames. This actually sets the `dfs.client.use.datanode.hostname` property to `true`. When connecting to a S3N filesystem, you must select this check box.

For further information about these parameters, see the documentation or contact the administrator of the Hadoop cluster to be used.

### Set NameNode URI

Select this check box and in the displayed field, enter the URI of the Hadoop NameNode, the master node of a Hadoop system. For example, assuming that you have chosen a machine called `masternode` as the NameNode, then the location is `hdfs://masternode:portnumber`. If you are using WebHDFS, the...
location should be webhdfs://masternode:portnumber; WebHDFS with SSL is not supported yet.

For further information about the Hadoop Map/Reduce framework, see the Map/Reduce tutorial in Apache’s Hadoop documentation on http://hadoop.apache.org.

The other properties:

| Property type | Either Built-In or Repository.  
|               | **Built-In:** No property data stored centrally.  
|               | **Repository:** Select the repository file where the properties are stored.  

| Distribution | Select the cluster you are using from the drop-down list. The options in the list vary depending on the component you are using. Among these options, the following ones requires specific configuration:  
|              | • If available in this Distribution drop-down list, the **Microsoft HD Insight** option allows you to use a Microsoft HD Insight cluster. For this purpose, you need to configure the connections to the HD Insight cluster and the Windows Azure Storage service of that cluster in the areas that are displayed. For detailed explanation about these parameters, search for configuring the connection manually on Talend Help Center (https://help.talend.com).  
|              | • If you select **Amazon EMR**, you can find more details about how to configure an Amazon EMR cluster in Talend Help Center (https://help.talend.com).  
|              | • The **Custom** option allows you to connect to a cluster different from any of the distributions given in this list, that is to say, to connect to a cluster not officially supported by Talend.  
|              | 1. Select **Import from existing version** to import an officially supported distribution as base and then add other required jar files which the base distribution does not provide.  
|              | 2. Select **Import from zip** to import the configuration zip for the custom distribution to be used. This zip file should contain the libraries of the different Hadoop elements and the index file of these libraries.  
|              | In Talend Exchange, members of Talend community have shared some ready-for-use configuration zip files which you can download from this Hadoop configuration list and directly use them in your connection accordingly. However, because of the ongoing evolution of the different Hadoop-related projects, you might not be able to find the configuration zip corresponding to your distribution from this list; then it is recommended to use the **Import from existing version** option to take an existing distribution as base to add the jars required by your distribution.  
|              | Note that custom versions are not officially supported by Talend. Talend and its community provide you with the opportunity to connect to custom versions from the Studio but cannot guarantee that the configuration of whichever version you choose will be easy, due to the wide range of different Hadoop...
distributions and versions that are available. As such, you should only attempt to set up such a connection if you have sufficient Hadoop experience to handle any issues on your own.

**Note:**
In this dialog box, the active check box must be kept selected so as to import the jar files pertinent to the connection to be created between the custom distribution and this component.

For a step-by-step example about how to connect to a custom distribution and share this connection, see [Connecting to a custom Hadoop distribution](#) on page 1569.

<table>
<thead>
<tr>
<th><strong>Hive version</strong></th>
<th>Select the version of the Hadoop distribution you are using. The available options vary depending on the component you are using.</th>
</tr>
</thead>
</table>

**Inspect the classpath for configurations**

Select this check box to allow the component to check the configuration files in the directory you have set with the `$HADOOP_CONF_DIR` variable and directly read parameters from these files in this directory. This feature allows you to easily change the Hadoop configuration for the component to switch between different environments, for example, from a test environment to a production environment.

In this situation, the fields or options used to configure Hadoop connection and/or Kerberos security are hidden.

If you want to use certain parameters such as the Kerberos parameters but these parameters are not included in these Hadoop configuration files, you need to create a file called `talend-site.xml` and put this file into the same directory defined with `$HADOOP_CONF_DIR`. This `talend-site.xml` file should read as follows:

```xml
<configuration>
  <property>
    <name>talend.kerberos.authentication</name>
    <value>kinit</value>
    <description>Set the Kerberos authentication method to use. Valid values are: kinit or keytab.</description>
  </property>
  <property>
    <name>talend.kerberos.keytab.principal</name>
    <value>user@BIGDATA.COM</value>
    <description>Set the keytab’s principal name.</description>
  </property>
  <property>
    <name>talend.kerberos.keytab.path</name>
```
<value>/kdc/user.keytab</value>
<description>Set the keytab's path.</description>

<property>
  <name>talend.encryption</name>
  <value>none</value>
  <description>Set the encryption method to use. Valid values are: none or ssl.</description>
</property>

<property>
  <name>talend.ssl.trustStore.path</name>
  <value>ssl</value>
  <description>Set SSL trust store path.</description>
</property>

<property>
  <name>talend.ssl.trustStore.password</name>
  <value>ssl</value>
  <description>Set SSL trust store password.</description>
</property>

The parameters read from these configuration files override the default ones used by the Studio. When a parameter does not exist in these configuration files, the default one is used.

Note that this option is available only in Hive Standalone mode with Hive 2.

Use or register a shared DB Connection

Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the Shared DB Connection Name field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child.

This option is incompatible with the Use dynamic job and Use an independent process to run subjob options of the tRunJob component. Using a shared connection together with a tRunJob component with either of these two options enabled will cause your Job to fail.

Execution engine

Select this check box and from the drop-down list, select the framework you need to use to run the Job.

This list is available only when you are using the Embedded mode for the Hive connection and the distribution you are working with is:

- Custom: this option allows you to connect to a distribution supporting Tez but not officially supported by Talend.
Before using Tez, ensure that the Hadoop cluster you are using supports Tez. You will need to configure the access to the relevant Tez libraries via the **Advanced settings** view of this component.

For further information about Hive on Tez, see Apache’s related documentation in [https://cwiki.apache.org/confluence/display/Hive/Hive+on+Tez](https://cwiki.apache.org/confluence/display/Hive/Hive+on+Tez). Some examples are presented there to show how Tez can be used to gain performance over MapReduce.

| Store by HBase | Select this check box to display the parameters to be set to allow the Hive components to access HBase tables:  
| | • Once this access is configured, you will be able to use, in `tHiveRow` and `tHiveInput`, the Hive QL statements to read and write data in HBase.  
| | • If you are using the Kerberos authentication, you need to define the HBase related principals in the corresponding fields that are displayed.  
| | For further information about this access involving Hive and HBase, see Apache’s Hive documentation about Hive/HBase integration. |

| Zookeeper quorum | Type in the name or the URL of the Zookeeper service you use to coordinate the transaction between your Studio and your database. Note that when you configure the Zookeeper, you might need to explicitly set the `zookeeper.znode.parent` property to define the path to the root znode that contains all the znodes created and used by your database; then select the **Set Zookeeper znode parent** check box to define this property. |

| Zookeeper client port | Type in the number of the client listening port of the Zookeeper service you are using. |

| Define the jars to register for HBase | Select this check box to display the **Register jar for HBase** table, in which you can register any missing jar file required by HBase, for example, the Hive Storage Handler, by default, registered along with your Hive installation. |

| Register jar for HBase | Click the [+ ] button to add rows to this table, then, in the **Jar name** column, select the jar file(s) to be registered and in the **Jar path** column, enter the path(s) pointing to that or those jar file(s). |

**Advanced settings**

| Tez Lib | Select how the Tez libraries are accessed:  
| | • **Auto install:** at runtime, the Job uploads and deploys the Tez libraries provided by the Studio into the directory you specified in the **Install folder in HDFS** field, for example, `/tmp/usr/tez`.  
| | If you have set the `tez.lib.uris` property in the properties table, this directory overrides the value of that property at runtime. But the other properties set in the properties table are still effective.  
| | • **Use exist:** the Job accesses the Tez libraries already deployed in the Hadoop cluster to be used. You need |
to enter the path pointing to those libraries in the **Lib path (folder or file)** field.

- **Lib jar**: this table appears when you have selected **Auto install** from the **Tez lib** list and the distribution you are using is **Custom**. In this table, you need to add the Tez libraries to be uploaded.

### Hadoop properties

*Talend Studio* uses a default configuration for its engine to perform operations in a Hadoop distribution. If you need to use a custom configuration in a specific situation, complete this table with the property or properties to be customized. Then at runtime, the customized property or properties will override those default ones.

- Note that if you are using the centrally stored metadata from the **Repository**, this table automatically inherits the properties defined in that metadata and becomes uneditable unless you change the **Property type** from **Repository** to **Built-in**.

For further information about the properties required by Hadoop and its related systems such as HDFS and Hive, see the documentation of the Hadoop distribution you are using or see Apache’s Hadoop documentation on [http://hadoop.apache.org/docs](http://hadoop.apache.org/docs) and then select the version of the documentation you want. For demonstration purposes, the links to some properties are listed below:

- Typically, the HDFS-related properties can be found in the `hdfs-default.xml` file of your distribution, such as [http://hadoop.apache.org/docs/r2.6.0/hadoop-project-dist/hadoop-hdfs/hdfs-default.xml](http://hadoop.apache.org/docs/r2.6.0/hadoop-project-dist/hadoop-hdfs/hdfs-default.xml).
- Apache also provides a page to list the Hive-related properties: [https://cwiki.apache.org/confluence/display/Hive/Configuration+Properties](https://cwiki.apache.org/confluence/display/Hive/Configuration+Properties).

### Hive properties

*Talend Studio* uses a default configuration for its engine to perform operations in a Hive database. If you need to use a custom configuration in a specific situation, complete this table with the property or properties to be customized. Then at runtime, the customized property or properties will override those default ones. For further information for Hive dedicated properties, see [https://cwiki.apache.org/confluence/display/Hive/AdminManual+Configuration](https://cwiki.apache.org/confluence/display/Hive/AdminManual+Configuration).

- If you need to use Tez to run your Hive Job, add `hive.execution.engine` to the **Properties** column and `Tez` to the **Value** column, enclosing both of these strings in double quotation marks.
- Note that if you are using the centrally stored metadata from the **Repository**, this table automatically inherits the properties defined in that metadata and becomes uneditable unless you change the **Property type** from **Repository** to **Built-in**.

### Mapred job map memory mb and Mapred job reduce memory mb

You can tune the map and reduce computations by selecting the **Set memory** check box to set proper memory allocations for the computations to be performed by the Hadoop system.

In that situation, you need to enter the values you need in the **Mapred job map memory mb** and the **Mapred job reduce memory mb** fields, respectively. By default, the values are both 1000 which are normally appropriate for running the computations.
Path separator in server

Leave the default value of the Path separator in server as it is, unless you have changed the separator used by your Hadoop distribution’s host machine for its PATH variable or in other words, that separator is not a colon (:). In that situation, you must change this value to the one you are using in that host.

Global Variables

Global Variables

ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule

This component is generally used with other Hive components, particularly tHiveClose.

If the Studio used to connect to a Hive database is operated on Windows, you must manually create a folder called tmp in the root of the disk where this Studio is installed.

Prerequisites

The Hadoop distribution must be properly installed, so as to guarantee the interaction with Talend Studio. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native. For example, the library for Windows is \lib\native\MapRClient.dll in the MapR client jar file. For further information, see the following link from MapR: http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr.

Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path.

- Set the -Djava.library.path argument, for example, in the Job Run VM arguments area of the Run/Debug view in the Preferences dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This
Connecting to a custom Hadoop distribution

As explained in the properties table, when you select the Custom option from the Distribution drop-down list, you are connecting to a Hadoop distribution different from any of the Hadoop distributions provided on that Distribution list in the Studio.

After selecting this Custom option, click the button to display the Import custom definition dialog box and proceed as follows:

Procedure

1. Depending on your situation, select Import from existing version or Import from zip to configure the custom Hadoop distribution to be connected to.
   - If you have the zip file of the custom Hadoop distribution you need to connect to, select Import from zip. Talend community provides this kind of zip files that you can download from http://www.talendforge.org/exchange/index.php.
   - Otherwise, select Import from existing version to import an officially supported Hadoop distribution as base so as to customize it by following the wizard.

Note that the check boxes in the wizard allow you to select the Hadoop element(s) you need to import. All the check boxes are not always displayed in your wizard depending on the context in which you are creating the connection. For example, if you are creating this connection for a Hive component, then only the Hive check box appears.
2. Whether you have selected **Import from existing version** or **Import from zip**, verify that each check box next to the Hadoop element you need to import has been selected.

3. Click **OK** and then in the pop-up warning, click **Yes** to accept overwriting any custom setup of jar files previously implemented.

   Once done, the **Custom Hadoop version definition** dialog box becomes active.

![Custom Hadoop Version Definition](image)

   This dialog box lists the Hadoop elements and their jar files you are importing.

4. If you have selected **Import from zip**, click **OK** to validate the imported configuration.

   If you have selected **Import from existing version** as base, you should still need to add more jar files to customize that version. Then from the tab of the Hadoop element you need to customize, for example, the **HDFS/HCatalog/Oozie** tab, click the [+ ] button to open the **Select libraries** dialog box.

5. Select the **External libraries** option to open its view.

6. Browse to and select any jar file you need to import.

7. Click **OK** to validate the changes and to close the **Select libraries** dialog box.

   Once done, the selected jar file appears on the list in the tab of the Hadoop element being configured.

   Note that if you need to share the custom Hadoop setup with another Studio, you can export this custom connection from the **Custom Hadoop version definition** window using the **button.
8. In the **Custom Hadoop version definition** dialog box, click **OK** to validate the customized configuration. This brings you back to the **Distribution** list in the **Basic settings** view of the component.

**Results**

Now that the configuration of the custom Hadoop version has been set up and you are back to the **Distribution** list, you are able to continue to enter other parameters required by the connection.

If the custom Hadoop version you need to connect to contains YARN and you want to use it, select the **Use YARN** check box next to the **Distribution** list.

A video is available in the following link to demonstrate, by taking HDFS as example, how to set up the connection to a custom Hadoop cluster, also referred to as an unsupported Hadoop distribution: [How to add an unsupported Hadoop distribution to the Studio](#).

**Creating a partitioned Hive table**

This scenario illustrates how to use **tHiveConnection**, **tHiveCreateTable** and **tHiveLoad** to create a partitioned Hive table and write data in it.

Note that **tHiveCreateTable** and **tHiveLoad** are available only when you are using one of the **Talend** solutions with Big Data.

The sample data to be used in this scenario is employee information of a company, reading as follows:

1;Lyndon;Fillmore;21-05-2008;US
2;Ronald;McKinley;15-08-2008
3;Ulysses;Roosevelt;05-10-2008
4;Harry;Harrison;23-11-2007
5;Lyndon;Garfield;19-07-2007
6;James;Quincy;15-07-2008
7;Chester;Jackson;26-02-2008
8;Dwight;McKinley;16-07-2008
9;Jimmy;Johnson;23-12-2007
10;Herbert;Fillmore;03-04-2008
The information contains some employees' names and the dates when they are registered in a HR system. Since these employees work for the US subsidiary of the company, you will create a US partition for this sample data.

Before starting to replicate this scenario, ensure that you have appropriate rights and permissions to access the Hive database to be used.

Note that if you are using the Windows operating system, you have to create a tmp folder at the root of the disk where the Studio is installed.

Then proceed as follows:

**Linking the components**

**Procedure**

1. In the **Integration** perspective of the Studio, create an empty Job from the **Job Designs** node in the **Repository** tree view.
   
   For further information about how to create a Job, see the chapter describing how to designing a Job in *Talend Studio User Guide*.

2. Drop **tHiveConnection**, **tHiveCreateTable** and **tHiveLoad** onto the workspace.

3. Connect them using the **Trigger > On Subjob OK** link.

**Configuring the connection to Hive**

**About this task**

Configuring **tHiveConnection**

**Procedure**

1. Double-click **tHiveConnection** to open its **Component** view.
2. From the Property type list, select Built-in. If you have created the connection to be used in Repository, then select Repository, click the button to open the Repository content dialog box and select that connection. This way, the Studio will reuse that set of connection information for this Job.

For further information about how to create a Hadoop connection in Repository, see the chapter describing the Hadoop cluster node of the Talend Open Studio for Big Data Getting Started Guide.

3. In the Version area, select the Hadoop distribution to be used and its version. If you cannot find from the list the distribution corresponding to yours, select Custom so as to connect to a Hadoop distribution not officially supported in the Studio.

For a step-by-step example about how to use this Custom option, see Connecting to a custom Hadoop distribution on page 1569.

4. In the Connection area, enter the connection parameters to the Hive database to be used.

5. In the Name node field, enter the location of the master node, the NameNode, of the distribution to be used. For example, talend-hdp-all:50300. If you are using WebHDFS, the location should be webhdfs://masternode:portnumber; WebHDFS with SSL is not supported yet.

6. In the Job tracker field, enter the location of the JobTracker of your distribution. For example, hdfs://talend-hdp-all:8020.

Note that the notion Job in this term JobTracker designates the MR or the MapReduce jobs described in Apache’s documentation on http://hadoop.apache.org/.

Configuring tHiveConnection

Procedure

1. Double-click tHiveConnection to open its Component view.
2. From the Property type list, select **Built-in**. If you have created the connection to be used in **Repository**, then select **Repository**, click the button to open the **Repository content** dialog box and select that connection. This way, the Studio will reuse that set of connection information for this Job.

For further information about how to create a Hadoop connection in Repository, see the chapter describing the **Hadoop cluster** node of the *Talend Open Studio for Big Data Getting Started Guide*.

3. In the **Version** area, select the Hadoop distribution to be used and its version. If you cannot find from the list the distribution corresponding to yours, select **Custom** so as to connect to a Hadoop distribution not officially supported in the Studio.

For a step-by-step example about how to use this **Custom** option, see Connecting to a custom Hadoop distribution on page 1569.

4. In the **Connection** area, enter the connection parameters to the Hive database to be used.

5. In the **Name node** field, enter the location of the master node, the NameNode, of the distribution to be used. For example, `talend-hdp-all:50300`. If you are using WebHDFS, the location should be `webhdfs://masternode:portnumber`; WebHDFS with SSL is not supported yet.

6. In the **Job tracker** field, enter the location of the JobTracker of your distribution. For example, `hdfs://talend-hdp-all:8020`.

Note that the notion Job in this term JobTracker designates the MR or the MapReduce jobs described in Apache’s documentation on [http://hadoop.apache.org/](http://hadoop.apache.org/).
Creating the Hive table

Defining the schema

Procedure

1. Double-click `tHiveCreateTable` to open its Component view.

2. Select the Use an existing connection check box and from Component list, select the connection configured in the `tHiveConnection` component you are using for this Job.

3. Click the button next to Edit schema to open the schema editor.

4. Click the button four times to add four rows and in the Column column, rename them to `Id`, `FirstName`, `LastName` and `Reg_date`, respectively.
Note that you cannot use the Hive reserved keywords to name the columns, such as location or date.

5. In the Type column, select the type of the data in each column. In this scenario, Id is of the Integer type, Reg_date is of the Date type and the others are of the String type.

6. In the DB type column, select the Hive type of each column corresponding to their data types you have defined. For example, Id is of INT and Reg_date is of TIMESTAMP.

7. In the Data pattern column, define the pattern corresponding to that of the raw data. In this example, use the default one.

8. Click OK to validate these changes.

Defining the table settings

Procedure

1. In Table name field, enter the name of the Hive table to be created. In this scenario, it is employees.

2. From the Action on table list, select Create table if not exists.

3. From the Format list, select the data format that this Hive table in question is created for. In this scenario, it is TEXTFILE.

4. Select the Set partitions check box to add the US partition as explained at the beginning of this scenario. To define this partition, click the button next to Edit schema that appears.

5. Leave the Set file location check box clear to use the default path for Hive table.

6. Select the Set Delimited row format check box to display the available options of row format.

7. Select the Field check box and enter a semicolon (;) as field separator in the field that appears.

8. Select the Line check box and leave the default value as line separator.

Writing data to the table

About this task
Configuring tHiveLoad

Procedure

1. Double-click tHiveLoad to open its Component view.
2. Select the **Use an existing connection** check box and from **Component list**, select the connection configured in the **tHiveConnection** component you are using for this Job.

3. From the **Load action** field, select **LOAD** to write data from the file holding the sample data that is presented at the beginning of this scenario.

4. In the **File path** field, enter the directory where the sample data is stored. In this example, the data is stored in the HDFS system to be used.

   In the real-world practice, you can use **tHDFSOutput** to write data into the HDFS system and you need to ensure that the Hive application has the appropriate rights and permissions to read or even move the data.

   For further information about **tHDFSOutput**, see **tHDFSOutput** on page 1518.

   For further information about the related rights and permissions, see the documentation or contact the administrator of the Hadoop cluster to be used.

   Note if you need to read data from a local file system other than the HDFS system, ensure that the data to be read is stored in the local file system of the machine in which the Job is run and then select the **Local** check box in this **Basic settings** view. For example, when the connection mode to Hive is **Standalone**, the Job is run in the machine where the Hive application is installed and thus the data should be stored in that machine.

5. In the **Table name** field, enter the name of the target table you need to load data in. In this scenario, it is **employees**.

6. From the **Action on file** list, select **APPEND**.

7. Select the **Set partitions** check box and in the field that appears, enter the partition you need to add data to. In this scenario, this partition is **country='US'**.

### Configuring tHiveLoad

**Procedure**

1. Double-click **tHiveLoad** to open its **Component** view.

   ![Component view](image)

   2. Select the **Use an existing connection** check box and from **Component list**, select the connection configured in the **tHiveConnection** component you are using for this Job.

   3. From the **Load action** field, select **LOAD** to write data from the file holding the sample data that is presented at the beginning of this scenario.
4. In the **File path** field, enter the directory where the sample data is stored. In this example, the data is stored in the HDFS system to be used. In the real-world practice, you can use `hdfsOutput` to write data into the HDFS system and you need to ensure that the Hive application has the appropriate rights and permissions to read or even move the data.

For further information about the related rights and permissions, see the documentation or contact the administrator of the Hadoop cluster to be used.

Note if you need to read data from a local file system other than the HDFS system, ensure that the data to be read is stored in the local file system of the machine in which the Job is run and then select the **Local** check box in this **Basic settings** view. For example, when the connection mode to Hive is **Standalone**, the Job is run in the machine where the Hive application is installed and thus the data should be stored in that machine.

5. In the **Table name** field, enter the name of the target table you need to load data in. In this scenario, it is `employees`.

6. From the **Action on file** list, select **APPEND**.

7. Select the **Set partitions** check box and in the field that appears, enter the partition you need to add data to. In this scenario, this partition is `country='US'`.

### Executing the Job

Then you can press **F6** to run this Job.

Once done, the **Run** view is opened automatically, where you can check the execution process.

You can as well verify the results in the web console of the Hadoop distribution used.

**File: /apps/hive/warehouse/employees/country=US/employee.csv**

If you need to obtain more details about the Job, it is recommended to use the web console of the Jobtracker provided by the Hadoop distribution you are using.
tHiveCreateTable

Creates Hive tables that fit a wide range of Hive data formats.

A proper Hive data format such as RC or ORC allows you to obtain a better performance in processing data with Hive.

tHiveCreateTable connects to the Hive database to be used and creates a Hive table that is dedicated to data of the format you specify.

**tHiveCreateTable Standard properties**

These properties are used to configure tHiveCreateTable running in the Standard Job framework.

The Standard tHiveCreateTable component belongs to the Big Data and the Databases families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

Connection configuration:

- When you use this component with Qubole on AWS:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>API Token</td>
<td>Click the ... button next to the <strong>API Token</strong> field to enter the authentication token generated for the Qubole user account to be used. For further information about how to obtain this token, see Manage Qubole account from the Qubole documentation. This token allows you to specify the user account you want to use to access Qubole. Your Job automatically uses the rights and permissions granted to this user account in Qubole.</td>
</tr>
<tr>
<td>Cluster label</td>
<td>Select the <strong>Cluster label</strong> check box and enter the name of the Qubole cluster to be used. If leaving this check box clear, the default cluster is used. If you need details about your default cluster, ask the administrator of your Qubole service. You can also read this article from the Qubole documentation to find more information about configuring a default Qubole cluster.</td>
</tr>
<tr>
<td>Change API endpoint</td>
<td>Select the <strong>Change API endpoint</strong> check box and select the region to be used. If leaving this check box clear, the default region is used. For further information about the Qubole Endpoints supported on QDS-on-AWS, see Supported Qubole Endpoints on Different Cloud Providers.</td>
</tr>
</tbody>
</table>

- When you use this component with Google Dataproc:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Project identifier</td>
<td>Enter the ID of your Google Cloud Platform project. If you are not certain about your project ID, check it in the Manage Resources page of your Google Cloud Platform services.</td>
</tr>
<tr>
<td>Cluster identifier</td>
<td>Enter the ID of your Dataproc cluster to be used.</td>
</tr>
<tr>
<td>--------------------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td>Region</td>
<td>Leave the default value <code>global</code> as is, since this is the only region which the Studio supports for Google Cloud Platform.</td>
</tr>
<tr>
<td>Google Storage staging bucket</td>
<td>As a Talend Job expects its dependent jar files for execution, specify the Google Storage directory to which these jar files are transferred so that your Job can access these files at execution. The directory to be entered must end with a slash <code>/</code>. If not existing, the directory is created on the fly but the bucket to be used must already exist.</td>
</tr>
<tr>
<td>Database</td>
<td>Fill this field with the name of the database.</td>
</tr>
<tr>
<td>Provide Google Credentials in file</td>
<td>Leave this check box clear, when you launch your Job from a given machine in which Google Cloud SDK has been installed and authorized to use your user account credentials to access Google Cloud Platform. In this situation, this machine is often your local machine. For further information about this Google Credentials file, see the administrator of your Google Cloud Platform or visit Google Cloud Platform Auth Guide.</td>
</tr>
</tbody>
</table>

• When you use this component with HDInsight:

<table>
<thead>
<tr>
<th>WebHCat configuration</th>
<th>Enter the address and the authentication information of the Microsoft HD Insight cluster to be used. For example, the address could be <code>your_hdinsight_cluster_name.azuredhdinsight.net</code> and the authentication information is your Azure account name: <code>ychen</code>. The Studio uses this service to submit the Job to the HD Insight cluster. In the <code>Job result folder</code> field, enter the location in which you want to store the execution result of a Job in the Azure Storage to be used.</th>
</tr>
</thead>
</table>
| HDInsight configuration | • The `Username` is the one defined when creating your cluster. You can find it in the `SSH + Cluster login` blade of your cluster.  
  • The `Password` is defined when creating your HDInsight cluster for authentication to this cluster. |
| Windows Azure Storage configuration | Enter the address and the authentication information of the Azure Storage account to be used. In this configuration, you do not define where to read or write your business data but define where to deploy your Job only. Therefore always use the Azure Storage system for this configuration. In the `Container` field, enter the name of the container to be used. You can find the available containers in the `Blob` blade of the Azure Storage account to be used. In the `Deployment Blob` field, enter the location in which you want to store the current Job and its dependent libraries in this Azure Storage account. In the `Hostname` field, enter the Primary Blob Service Endpoint of your Azure Storage account without the... |
https:// part. You can find this endpoint in the Properties blade of this storage account.

In the **Username** field, enter the name of the Azure Storage account to be used.

In the **Password** field, enter the access key of the Azure Storage account to be used. This key can be found in the **Access keys** blade of this storage account.

### Database

Fill this field with the name of the database.

- **Connection mode**
  
  Select a connection mode from the list. The options vary depending on the distribution you are using.

- **Hive server**
  
  Select the Hive server through which you want the Job using this component to execute queries on Hive.

  This **Hive server** list is available only when the Hadoop distribution to be used such as [HortonWorks Data Platform V1.2.0 (Bimota)](https://cwiki.apache.org/confluence/display/Hive/Setting+Up+HiveServer2) supports HiveServer2. It allows you to select HiveServer2 (**Hive 2**), the server that better support concurrent connections of multiple clients than HiveServer (**Hive 1**).

  For further information about HiveServer2, see [https://cwiki.apache.org/confluence/display/Hive/Setting+Up+HiveServer2](https://cwiki.apache.org/confluence/display/Hive/Setting+Up+HiveServer2).

- **Host**
  
  Database server IP address.

- **Port**
  
  Listening port number of DB server.

- **Database**
  
  Fill this field with the name of the database.

  **Note:**
  This field is not available when you select **Embedded** from the **Connection mode** list.

- **Username and Password**
  
  DB user authentication data.

  To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

- **Use kerberos authentication**
  
  If you are accessing a Hive Metastore running with Kerberos security, select this check box and then enter the relevant parameters in the fields that appear.

  - If this cluster is a MapR cluster of the version 5.0.0 or later, you can set the MapR ticket authentication configuration in addition or as an alternative by following the explanation in [Connecting to a security-enabled MapR](#) on page 1629.

    Keep in mind that this configuration generates a new MapR security ticket for the username defined in the Job in each execution. If you need to reuse an existing ticket issued for the same username, leave both the **Force MapR ticket authentication** check box and the **Use Kerberos authentication** check box clear,
and then MapR should be able to automatically find that ticket on the fly.

The values of the following parameters can be found in the `hive-site.xml` file of the Hive system to be used.

1. **Hive principal** uses the value of `hive.metastore.kerberos.principal`. This is the service principal of the Hive Metastore.
2. **HiveServer2 local user principal** uses the value of `hive.server2.authentication.kerberos.principal`.
3. **HiveServer2 local user keytab** uses the value of `hive.server2.authentication.kerberos.keytab`.
4. **Metastore URL** uses the value of `javax.jdo.option.ConnectionURL`. This is the JDBC connection string to the Hive Metastore.
5. **Driver class** uses the value of `javax.jdo.option.ConnectionDriverName`. This is the name of the driver for the JDBC connection.
6. **Username** uses the value of `javax.jdo.option.ConnectionUserName`. This, as well as the Password parameter, is the user credential for connecting to the Hive Metastore.
7. **Password** uses the value of `javax.jdo.option.ConnectionPassword`.

For the other parameters that are displayed, please consult the Hadoop configuration files they belong to. For example, the **Namenode principal** can be found in the `hdfs-site.xml` file or the `hdfs-default.xml` file of the distribution you are using.

This check box is available depending on the Hadoop distribution you are connecting to.

### Use a keytab to authenticate

Select the **Use a keytab to authenticate** check box to log into a Kerberos-enabled system using a given keytab file. A keytab file contains pairs of Kerberos principals and encrypted keys. You need to enter the principal to be used in the **Principal** field and the access path to the keytab file itself in the **Keytab** field. This keytab file must be stored in the machine in which your Job actually runs, for example, on a Talend Jobserver.

Note that the user that executes a keytab-enabled Job is not necessarily the one a principal designates but must have the right to read the keytab file being used. For example, the user name you are using to execute a Job is `user1` and the principal to be used is `guest`; in this situation, ensure that `user1` has the right to read the keytab file to be used.

### Use SSL encryption

Select this check box to enable the SSL or TLS encrypted connection.

Then in the fields that are displayed, provide the authentication information:

- In the **Trust store path** field, enter the path, or browse to the TrustStore file to be used. By default, the supported TrustStore types are **JKS** and **PKCS 12**.
- To enter the password, click the `[...]` button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.
This feature is available only to the HiveServer2 in the **Standalone** mode of the following distributions:

- Hortonworks Data Platform 2.0 +
- Cloudera CDH4 +
- Pivotal HD 2.0 +
- Amazon EMR 4.0.0 +

### Set Resource Manager

Select this check box and in the displayed field, enter the location of the ResourceManager of your distribution. For example, `tal-qall14.talend.lan:8050`.

Then you can continue to set the following parameters depending on the configuration of the Hadoop cluster to be used (if you leave the check box of a parameter clear, then at runtime, the configuration about this parameter in the Hadoop cluster to be used will be ignored):

1. Select the **Set resourcemanager scheduler address** check box and enter the Scheduler address in the field that appears.
2. Select the **Set jobhistory address** check box and enter the location of the JobHistory server of the Hadoop cluster to be used. This allows the metrics information of the current Job to be stored in that JobHistory server.
3. Select the **Set staging directory** check box and enter this directory defined in your Hadoop cluster for temporary files created by running programs. Typically, this directory can be found under the `yarn.app.mapreduce.am.staging-dir` property in the configuration files such as `yarn-site.xml` or `mapred-site.xml` of your distribution.
4. Allocate proper memory volumes to the **Map** and the **Reduce** computations and the **ApplicationMaster** of YARN by selecting the **Set memory** check box in the **Advanced settings** view.
5. Select the **Set Hadoop user** check box and enter the user name under which you want to execute the Job. Since a file or a directory in Hadoop has its specific owner with appropriate read or write rights, this field allows you to execute the Job directly under the user name that has the appropriate rights to access the file or directory to be processed.
6. Select the **Use datanode hostname** check box to allow the Job to access datanodes via their hostnames. This actually sets the `dfs.client.use.datanode.hostname` property to `true`. When connecting to a S3N filesystem, you must select this check box.

For further information about these parameters, see the documentation or contact the administrator of the Hadoop cluster to be used.

### Set NameNode URI

Select this check box and in the displayed field, enter the URI of the Hadoop NameNode, the master node of a Hadoop system. For example, assuming that you have chosen a machine called `masternode` as the NameNode, then the location is `hdfs://masternode:8020`.

HiveCreateTable

If you are using WebHDFS, the location should be webhdfs://masternode:portnumber; WebHDFS with SSL is not supported yet.

For further information about the Hadoop Map/Reduce framework, see the Map/Reduce tutorial in Apache’s Hadoop documentation on http://hadoop.apache.org.

The other properties:

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-in or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

Use an existing connection

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

Distribution

Select the cluster you are using from the drop-down list. The options in the list vary depending on the component you are using. Among these options, the following ones requires specific configuration:

- If available in this Distribution drop-down list, the Microsoft HD Insight option allows you to use a Microsoft HD Insight cluster. For this purpose, you need to configure the connections to the HD Insight cluster and the Windows Azure Storage service of that cluster in the areas that are displayed. For detailed explanation about these parameters, search for configuring the connection manually on Talend Help Center (https://help.talend.com).
- If you select Amazon EMR, you can find more details about how to configure an Amazon EMR cluster in Talend Help Center (https://help.talend.com).
- The Custom option allows you to connect to a cluster different from any of the distributions given in this list, that is to say, to connect to a cluster not officially supported by Talend.

1. Select Import from existing version to import an officially supported distribution as base and then add
other required jar files which the base distribution does not provide.

2. Select **Import from zip** to import the configuration zip for the custom distribution to be used. This zip file should contain the libraries of the different Hadoop elements and the index file of these libraries.

In Talend Exchange, members of Talend community have shared some ready-for-use configuration zip files which you can download from this Hadoop configuration list and directly use them in your connection accordingly. However, because of the ongoing evolution of the different Hadoop-related projects, you might not be able to find the configuration zip corresponding to your distribution from this list; then it is recommended to use the **Import from existing version** option to take an existing distribution as base to add the jars required by your distribution.

Note that custom versions are not officially supported by Talend. Talend and its community provide you with the opportunity to connect to custom versions from the Studio but cannot guarantee that the configuration of whichever version you choose will be easy, due to the wide range of different Hadoop distributions and versions that are available. As such, you should only attempt to set up such a connection if you have sufficient Hadoop experience to handle any issues on your own.

Note:
In this dialog box, the active check box must be kept selected so as to import the jar files pertinent to the connection to be created between the custom distribution and this component.

For a step-by-step example about how to connect to a custom distribution and share this connection, see **Connecting to a custom Hadoop distribution** on page 1569.

### Hive version

Select the version of the Hadoop distribution you are using. The available options vary depending on the component you are using.

### Schema and Edit Schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No upon**
<table>
<thead>
<tr>
<th><strong>Table Name</strong></th>
<th>Name of the table to be created.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Action on table</strong></td>
<td>Select the action to be carried out for creating a table.</td>
</tr>
<tr>
<td><strong>Format</strong></td>
<td>Select the data format to which the table to be created is dedicated.</td>
</tr>
<tr>
<td></td>
<td>The available data formats vary depending on the version of the Hadoop distribution you are using.</td>
</tr>
<tr>
<td></td>
<td>Note that when the file format to be used is PARQUET, you might be prompted to find the specific PARQUET jar file and install it into the Studio.</td>
</tr>
<tr>
<td></td>
<td>• When the connection mode to Hive is Embedded, the Job is run in your local machine and calls this jar installed in the Studio.</td>
</tr>
<tr>
<td></td>
<td>• When the connection mode to Hive is Standalone, the Job is run in the server hosting Hive and this jar file is sent to the HDFS system of the cluster you are connecting to. Therefore, ensure that you have properly defined the NameNode URI in the corresponding field of the Basic settings view.</td>
</tr>
<tr>
<td></td>
<td>This jar file can be downloaded from Apache’s site. You can find more details about how to install external modules in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
<tr>
<td><strong>Inputformat class and Outputformat class</strong></td>
<td>These fields appear only when you have selected INPUTFORMAT and OUTPUTFORMAT from the Format list.</td>
</tr>
<tr>
<td></td>
<td>These fields allow you to enter the name of the jar files to be used for the data formats not available in the Format list.</td>
</tr>
<tr>
<td><strong>Storage class</strong></td>
<td>Enter the name of the storage handler to be used for creating a non-native table (Hive table stored and managed in other systems than Hive, for example, Cassandra or MongoDB).</td>
</tr>
<tr>
<td></td>
<td>This field is available only when you have selected STORAGE from the Format list.</td>
</tr>
<tr>
<td></td>
<td>For further information about a storage handler, see <a href="https://cwiki.apache.org/confluence/display/Hive/StorageHandlers">https://cwiki.apache.org/confluence/display/Hive/StorageHandlers</a>.</td>
</tr>
</tbody>
</table>

Built-In: You create and store the schema locally for this component only.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).
<table>
<thead>
<tr>
<th><strong>Set partitions</strong></th>
<th>Select this check box to add partition columns to the table to be created. Once selecting it, you need to define the schema of the partition columns you need to add.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Set file location</strong></td>
<td>If you want to create a Hive table in a directory other than the default one, select this check box and enter the directory in HDFS you want to use to hold the table content. This is typical useful when you need to create an external Hive table by selecting the Create an external table check box in the Advanced settings tab.</td>
</tr>
</tbody>
</table>
| **Use S3 endpoint** | The Use S3 endpoint check box is displayed when you have selected the Set file location check box to create an external Hive table. Once this Use S3 endpoint check box is selected, you need to enter the following parameters in the fields that appear:  
• **S3 bucket**: enter the name of the bucket in which you need to create the table.  
• **Bucket name**: enter the name of the bucket in which you want to store the dependencies of your Job. This bucket must already exist on S3.  
• **Temporary resource folder**: enter the directory in which you want to store the dependencies of your Job. For example, enter temp_resources to write the dependencies in the /temp_resources folder in the bucket.  
If this folder already exists at runtime, its contents are overwritten by the upcoming dependencies; otherwise, this folder is automatically created.  
• **Access key** and **Secret key**: enter the authentication information required to connect to the Amazon S3 bucket to be used.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.  
Note that the format of the S3 file is S3N (S3 Native Filesystem).  
Since a Hive table created in S3 is actually an external table, this Use S3 endpoint check box must be used with the Create an external table case being selected. |

**Advanced settings**

| **Like table** | Select this check box and enter the name of the Hive table you want to copy. This allows you to copy the definition of an existing table without copying its data.  
For further information about the Like parameter, see Apache's information about Hive's Data Definition Language. |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| **Create an external table** | Select this check box to make the table to be created an external Hive table. This kind of Hive table leaves the raw data where it is if the data is in HDFS.  
An external table is usually the better choice for accessing shared data existing in a file system. |
For further information about an external Hive table, see Apache’s documentation about Hive.

<table>
<thead>
<tr>
<th>Table comment</th>
<th>Enter the description you want to use for the table to be created.</th>
</tr>
</thead>
<tbody>
<tr>
<td>As select</td>
<td>Select this check box and enter the As select statement for creating a Hive table that is based on a Select statement.</td>
</tr>
<tr>
<td>Set clustered_by or skewed_by statement</td>
<td>Enter the Clustered by statement to cluster the data of a table or a partition into buckets, or/and enter the Skewed by statement to allow Hive to extract the heavily skewed data and put it into separate files. This is typically used for obtaining better performance during queries.</td>
</tr>
<tr>
<td>SerDe properties</td>
<td>If you are using the SerDe row format, you can add any custom SerDe properties to override the default ones used by the Hadoop engine of the Studio.</td>
</tr>
<tr>
<td>Table properties</td>
<td>Add any custom Hive table properties you want to override the default ones used by the Hadoop engine of the Studio.</td>
</tr>
<tr>
<td>Temporary path</td>
<td>If you do not want to set the Jobtracker and the NameNode when you execute the query select * from your_table_name, you need to set this temporary path. For example, /C:/select_all in Windows.</td>
</tr>
<tr>
<td>Hadoop properties</td>
<td>Talend Studio uses a default configuration for its engine to perform operations in a Hadoop distribution. If you need to use a custom configuration in a specific situation, complete this table with the property or properties to be customized. Then at runtime, the customized property or properties will override those default ones. • Note that if you are using the centrally stored metadata from the Repository, this table automatically inherits the properties defined in that metadata and becomes uneditable unless you change the Property type from Repository to Built-in. For further information about the properties required by Hadoop and its related systems such as HDFS and Hive, see the documentation of the Hadoop distribution you are using or see Apache’s Hadoop documentation on <a href="http://hadoop.apache.org/docs">http://hadoop.apache.org/docs</a> and then select the version of the documentation you want. For demonstration purposes, the links to some properties are listed below: • Typically, the HDFS-related properties can be found in the hdfs-default.xml file of your distribution, such as <a href="http://hadoop.apache.org/docs/r2.6.0/hadoop-project-dist/hadoop-hdfs/hdfs-default.xml">http://hadoop.apache.org/docs/r2.6.0/hadoop-project-dist/hadoop-hdfs/hdfs-default.xml</a>. • Apache also provides a page to list the Hive-related properties: <a href="https://cwiki.apache.org/confluence/display/Hive/Configuration+Properties">https://cwiki.apache.org/confluence/display/Hive/Configuration+Properties</a>.</td>
</tr>
<tr>
<td>Hive properties</td>
<td>Talend Studio uses a default configuration for its engine to perform operations in a Hive database. If you need to use a custom configuration in a specific situation, complete this table with the property or properties to be customized. Then at runtime, the customized property or properties will override those default ones. For further information for</td>
</tr>
</tbody>
</table>
Hive dedicated properties, see https://cwiki.apache.org/confluence/display/Hive/AdminManual+Configuration.

- If you need to use Tez to run your Hive Job, add `hive.execution.engine` to the Properties column and `Tez` to the Value column, enclosing both of these strings in double quotation marks.
- Note that if you are using the centrally stored metadata from the Repository, this table automatically inherits the properties defined in that metadata and becomes uneditable unless you change the Property type from Repository to Built-in.

<table>
<thead>
<tr>
<th>Mapred job map memory mb and Mapred job reduce memory mb</th>
<th>You can tune the map and reduce computations by selecting the Set memory check box to set proper memory allocations for the computations to be performed by the Hadoop system. In that situation, you need to enter the values you need in the Mapred job map memory mb and the Mapred job reduce memory mb fields, respectively. By default, the values are both 1000 which are normally appropriate for running the computations. The memory parameters to be set are Map (in Mb), Reduce (in Mb) and ApplicationMaster (in Mb). These fields allow you to dynamically allocate memory to the map and the reduce computations and the ApplicationMaster of YARN.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Path separator in server</td>
<td>Leave the default value of the Path separator in server as it is, unless you have changed the separator used by your Hadoop distribution's host machine for its PATH variable or in other words, that separator is not a colon (:). In that situation, you must change this value to the one you are using in that host.</td>
</tr>
<tr>
<td>tStatCatcher Statistics</td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>QUERY: the query statement being processed. This is a Flow variable and it returns a string. ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide.</th>
</tr>
</thead>
</table>
## Usage

### Usage rule

<table>
<thead>
<tr>
<th>Component</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>This component works standalone.</td>
<td></td>
</tr>
<tr>
<td>If the Studio used to connect to a Hive database is operated on Windows, you must manually create a folder called <code>tmp</code> in the root of the disk where this Studio is installed.</td>
<td></td>
</tr>
</tbody>
</table>

### Row format

- Set Delimited row format
- Set SerDe row format

### Dynamic settings

Click the `+` button to add a row in the table and fill the `Code` field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the `Use an existing connection` check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see *Reading data from databases through context-based dynamic connections* on page 2457 and *Reading data from different MySQL databases using dynamically loaded connection parameters* on page 491. For more information on **Dynamic settings** and context variables, see *Talend Studio User Guide*.

### Prerequisites

The Hadoop distribution must be properly installed, so as to guarantee the interaction with *Talend Studio*. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under `MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native`. For example, the library for Windows is `\lib\native\MapRClient.dll` in the MapR client jar file. For further information, see the following link from MapR: [http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr](http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr).

Without adding the specified library or libraries, you may encounter the following error: `no MapRClient in java.library.path`.

- Set the `-Djava.library.path` argument, for example, in the **Job Run VM arguments** area of the **Run/Debug** view in the **Preferences** dialog box in the **Window** menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of...
the Data viewer to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

Related scenario

For a related scenario, see Creating a partitioned Hive table on page 1571.
**tHiveInput**

Extracts data from Hive and sends the data to the component that follows.

**tHiveInput** is the dedicated component to the Hive database (the Hive data warehouse system). It can execute a given HiveQL query in order to extract the data from Hive.

When ACID is enabled on the Hive side, a Spark Job cannot delete or update a table and unless data is compacted, this Job cannot correctly read aggregated data from a Hive table, either. This is a known limitation described in the Spark bug tracking system: https://issues.apache.org/jira/browse/SPARK-15348.

**tHiveInput Standard properties**

These properties are used to configure tHiveInput running in the Standard Job framework.

The Standard tHiveInput component belongs to the Big Data and the Databases families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

Connection configuration:

- When you use this component with Qubole on AWS:

  | API Token | Click the ... button next to the API Token field to enter the authentication token generated for the Qubole user account to be used. For further information about how to obtain this token, see Manage Qubole account from the Qubole documentation. This token allows you to specify the user account you want to use to access Qubole. Your Job automatically uses the rights and permissions granted to this user account in Qubole. |
  | Cluster label | Select the Cluster label check box and enter the name of the Qubole cluster to be used. If leaving this check box clear, the default cluster is used. If you need details about your default cluster, ask the administrator of your Qubole service. You can also read this article from the Qubole documentation to find more information about configuring a default Qubole cluster. |
  | Change API endpoint | Select the Change API endpoint check box and select the region to be used. If leaving this check box clear, the default region is used. For further information about the Qubole Endpoints supported on QDS-on-AWS, see Supported Qubole Endpoints on Different Cloud Providers. |

- When you use this component with Google Dataproc:

  | Project identifier | Enter the ID of your Google Cloud Platform project. |
If you are not certain about your project ID, check it in the Manage Resources page of your Google Cloud Platform services.

<table>
<thead>
<tr>
<th><strong>Cluster identifier</strong></th>
<th>Enter the ID of your Dataproc cluster to be used.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Region</strong></td>
<td>Leave the default value <code>global</code> as is, since this is the only region which the Studio supports for Google Cloud Platform.</td>
</tr>
<tr>
<td><strong>Google Storage staging bucket</strong></td>
<td>As a Talend Job expects its dependent jar files for execution, specify the Google Storage directory to which these jar files are transferred so that your Job can access these files at execution. The directory to be entered must end with a slash <code>/</code>. If not existing, the directory is created on the fly but the bucket to be used must already exist.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Fill this field with the name of the database.</td>
</tr>
<tr>
<td><strong>Access Key and Secret Key</strong></td>
<td>Enter the authentication information obtained from Google for tHiveInput to read temporary data from Google Storage. These keys can be consulted on the Interoperable Access tab view under the Google Cloud Storage tab of the project from the Google APIs Console. To enter the secret key, click the <code>[...]</code> button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. For more information about the access key and secret key, go to <a href="https://developers.google.com/storage/docs/v1/getting-startedv1?hl=en/">https://developers.google.com/storage/docs/v1/getting-startedv1?hl=en/</a> and see the description about developer keys.</td>
</tr>
<tr>
<td><strong>Provide Google Credentials in file</strong></td>
<td>Leave this check box clear, when you launch your Job from a given machine in which Google Cloud SDK has been installed and authorized to use your user account credentials to access Google Cloud Platform. In this situation, this machine is often your local machine. For further information about this Google Credentials file, see the administrator of your Google Cloud Platform or visit Google Cloud Platform Auth Guide.</td>
</tr>
</tbody>
</table>

- When you use this component with HDInsight:

<table>
<thead>
<tr>
<th><strong>WebHCat configuration</strong></th>
<th>Enter the address and the authentication information of the Microsoft HD Insight cluster to be used. For example, the address could be <code>your_hdinsight_cluster_name.azuredhinsight.net</code> and the authentication information is your Azure account name: <code>ychen</code>. The Studio uses this service to submit the Job to the HD Insight cluster. In the Job result folder field, enter the location in which you want to store the execution result of a Job in the Azure Storage to be used.</th>
</tr>
</thead>
</table>
### HDInsight configuration
- The **Username** is the one defined when creating your cluster. You can find it in the **SSH + Cluster login** blade of your cluster.
- The **Password** is defined when creating your HDInsight cluster for authentication to this cluster.

### Windows Azure Storage configuration
Enter the address and the authentication information of the Azure Storage account to be used. In this configuration, you do not define where to read or write your business data but define where to deploy your Job only. Therefore always use the Azure Storage system for this configuration.

In the **Container** field, enter the name of the container to be used. You can find the available containers in the **Blob** blade of the Azure Storage account to be used.

In the **Deployment Blob** field, enter the location in which you want to store the current Job and its dependent libraries in this Azure Storage account.

In the **Hostname** field, enter the Primary Blob Service Endpoint of your Azure Storage account without the https:// part. You can find this endpoint in the **Properties** blade of this storage account.

In the **Username** field, enter the name of the Azure Storage account to be used.

In the **Password** field, enter the access key of the Azure Storage account to be used. This key can be found in the **Access keys** blade of this storage account.

### Database
Fill this field with the name of the database.

- **Note:**
  - This field is not available when you select **Embedded** from the **Connection mode** list.

### When you use the other distributions:

#### Connection mode
Select a connection mode from the list. The options vary depending on the distribution you are using.

#### Hive server
Select the Hive server through which you want the Job using this component to execute queries on Hive.

This **Hive server** list is available only when the Hadoop distribution to be used such as **HortonWorks Data Platform V1.2.0 (Bimota)** supports HiveServer2. It allows you to select HiveServer2 (**Hive 2**), the server that better support concurrent connections of multiple clients than HiveServer (**Hive 1**).

For further information about HiveServer2, see https://cwiki.apache.org/confluence/display/Hive/Setting+Up+HiveServer2.
### Username and Password

DB user authentication data.

To enter the password, click the [..] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

### Use kerberos authentication

If you are accessing a Hive Metastore running with Kerberos security, select this check box and then enter the relevant parameters in the fields that appear.

- If this cluster is a MapR cluster of the version 5.0.0 or later, you can set the MapR ticket authentication configuration in addition or as an alternative by following the explanation in Connecting to a security-enabled MapR on page 1629.

Keep in mind that this configuration generates a new MapR security ticket for the username defined in the Job in each execution. If you need to reuse an existing ticket issued for the same username, leave both the **Force MapR ticket authentication** check box and the **Use Kerberos authentication** check box clear, and then MapR should be able to automatically find that ticket on the fly.

The values of the following parameters can be found in the `hive-site.xml` file of the Hive system to be used.

1. **Hive principal** uses the value of `hive.metastore.kerberos.principal`. This is the service principal of the Hive Metastore.
2. **HiveServer2 local user principal** uses the value of `hive.server2.authentication.kerberos.principal`.
3. **HiveServer2 local user keytab** uses the value of `hive.server2.authentication.kerberos.keytab`.
4. **Metastore URL** uses the value of `javax.jdo.option.ConnectionURL`. This is the JDBC connection string to the Hive Metastore.
5. **Driver class** uses the value of `javax.jdo.option.ConnectionDriverName`. This is the name of the driver for the JDBC connection.
6. **Username** uses the value of `javax.jdo.option.ConnectionUserName`. This, as well as the **Password** parameter, is the user credential for connecting to the Hive Metastore.
7. **Password** uses the value of `javax.jdo.option.ConnectionPassword`.

For the other parameters that are displayed, please consult the Hadoop configuration files they belong to. For example, the **Namenode principal** can be found in the `hdfs-site.xml` file or the `hdfs-default.xml` file of the distribution you are using.

This check box is available depending on the Hadoop distribution you are connecting to.

### Use a keytab to authenticate

Select the **Use a keytab to authenticate** check box to log into a Kerberos-enabled system using a given keytab file. A keytab file contains pairs of Kerberos principals and encrypted keys. You need to enter the principal to be used in the **Principal** field and the access path to the keytab file itself in the **Keytab** field. This keytab file must
be stored in the machine in which your Job actually runs, for example, on a Talend Jobserver.

Note that the user that executes a keytab-enabled Job is not necessarily the one a principal designates but must have the right to read the keytab file being used. For example, the user name you are using to execute a Job is user1 and the principal to be used is guest; in this situation, ensure that user1 has the right to read the keytab file to be used.

**Use SSL encryption**

Select this check box to enable the SSL or TLS encrypted connection.

Then in the fields that are displayed, provide the authentication information:

- In the **Trust store path** field, enter the path, or browse to the TrustStore file to be used. By default, the supported TrustStore types are JKS and PKCS 12.
- To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

This feature is available only to the HiveServer2 in the **Standalone** mode of the following distributions:

- Hortonworks Data Platform 2.0 +
- Cloudera CDH4 +
- Pivotal HD 2.0 +
- Amazon EMR 4.0.0 +

**Set Resource Manager**

Select this check box and in the displayed field, enter the location of the ResourceManager of your distribution. For example, `tal-qa114.talend.lan:8050`.

Then you can continue to set the following parameters depending on the configuration of the Hadoop cluster to be used (if you leave the check box of a parameter clear, then at runtime, the configuration about this parameter in the Hadoop cluster to be used will be ignored):

1. Select the **Set resourcemanager scheduler address** check box and enter the Scheduler address in the field that appears.
2. Select the **Set jobhistory address** check box and enter the location of the JobHistory server of the Hadoop cluster to be used. This allows the metrics information of the current Job to be stored in that JobHistory server.
3. Select the **Set staging directory** check box and enter this directory defined in your Hadoop cluster for temporary files created by running programs. Typically, this directory can be found under the `yarn.app.mapreduce.am.staging-dir` property in the configuration files such as `yarn-site.xml` or `mapred-site.xml` of your distribution.
4. Allocate proper memory volumes to the **Map** and the **Reduce** computations and the **ApplicationMaster** of YARN by selecting the **Set memory** check box in the **Advanced settings** view.
5. Select the **Set Hadoop user** check box and enter the user name under which you want to execute the Job. Since a file or a directory in Hadoop has its specific owner with appropriate read or write rights, this field...
allows you to execute the Job directly under the user name that has the appropriate rights to access the file or directory to be processed.

6. Select the **Use datanode hostname** check box to allow the Job to access datanodes via their hostnames. This actually sets the `dfs.client.use.datanode.hostname` property to `true`. When connecting to a S3N filesystem, you must select this check box.

For further information about these parameters, see the documentation or contact the administrator of the Hadoop cluster to be used.

| Set NameNode URI | Select this check box and in the displayed field, enter the URI of the Hadoop NameNode, the master node of a Hadoop system. For example, assuming that you have chosen a machine called `masternode` as the NameNode, then the location is `hdfs://masternode:portnumber`. If you are using WebHDFS, the location should be `webhdfs://masternode:portnumber`; WebHDFS with SSL is not supported yet. For further information about the Hadoop Map/Reduce framework, see the Map/Reduce tutorial in Apache’s Hadoop documentation on [http://hadoop.apache.org](http://hadoop.apache.org). |

The other properties:

| Property type | Either **Built-In** or **Repository**.  
**Built-In**: No property data stored centrally.  
**Repository**: Select the repository file where the properties are stored. |
| --- | --- |

| Use an existing connection | Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined.  
**Note**: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:  
1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.  
2. In the child level, use a dedicated connection component to read that registered database connection.  
For an example about how to share a database connection across Job levels, see **Talend Studio User Guide**. |
| --- | --- |

| Distribution | Select the cluster you are using from the drop-down list. The options in the list vary depending on the component you are using. Among these options, the following ones requires specific configuration: |
If available in this Distribution drop-down list, the Microsoft HD Insight option allows you to use a Microsoft HD Insight cluster. For this purpose, you need to configure the connections to the HD Insight cluster and the Windows Azure Storage service of that cluster in the areas that are displayed. For detailed explanation about these parameters, search for configuring the connection manually on Talend Help Center (https://help.talend.com).

If you select Amazon EMR, you can find more details about how to configure an Amazon EMR cluster in Talend Help Center (https://help.talend.com).

The Custom option allows you to connect to a cluster different from any of the distributions given in this list, that is to say, to connect to a cluster not officially supported by Talend.

1. Select Import from existing version to import an officially supported distribution as base and then add other required jar files which the base distribution does not provide.

2. Select Import from zip to import the configuration zip for the custom distribution to be used. This zip file should contain the libraries of the different Hadoop elements and the index file of these libraries.

In Talend Exchange, members of Talend community have shared some ready-for-use configuration zip files which you can download from this Hadoop configuration list and directly use them in your connection accordingly. However, because of the ongoing evolution of the different Hadoop-related projects, you might not be able to find the configuration zip corresponding to your distribution from this list; then it is recommended to use the Import from existing version option to take an existing distribution as base to add the jars required by your distribution.

Note that custom versions are not officially supported by Talend. Talend and its community provide you with the opportunity to connect to custom versions from the Studio but cannot guarantee that the configuration of whichever version you choose will be easy, due to the wide range of different Hadoop distributions and versions that are available. As such, you should only attempt to set up such a connection if you have sufficient Hadoop experience to handle any issues on your own.

Note:

In this dialog box, the active check box must be kept selected so as to import the jar files pertinent to the connection to be created between the custom distribution and this component.

For a step-by-step example about how to connect to a custom distribution and share this connection, see Connecting to a custom Hadoop distribution on page 1569.
<table>
<thead>
<tr>
<th><strong>Hive version</strong></th>
<th>Select the version of the Hadoop distribution you are using. The available options vary depending on the component you are using.</th>
</tr>
</thead>
</table>
| **Schema and **Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word **line** when naming the fields. Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
  - **View schema**: choose this option to view the schema only.  
  - **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
  - **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window. |
| **Built-in**: | The schema is created and stored locally for this component only. Related topic: see *Talend Studio User Guide*. |
| **Repository**: | The schema already exists and is stored in the Repository, hence can be reused. Related topic: see *Talend Studio User Guide*. |
| **Table Name** | Name of the table to be processed. |
| **Query type** | Either **Built-in** or **Repository**. |
| **Built-in**: | Fill in manually the query statement or build it graphically using SQLBuilder. |
| **Repository**: | Select the relevant query stored in the Repository. The Query field gets accordingly filled in. |
| **Guess Query** | Click the **Guess Query** button to generate the query which corresponds to your table schema in the Query field. |
| **Guess schema** | Click this button to retrieve the schema from the table. |
| **This query uses Parquet objects** | When available, select this check box to indicate that the table to be handled uses the PARQUET format and thus make the component to call the required jar file. Note that when the file format to be used is **PARQUET**, you might be prompted to find the specific PARQUET jar file and install it into the Studio.  
  - When the connection mode to Hive is **Embedded**, the Job is run in your local machine and calls this jar installed in the Studio.  
  - When the connection mode to Hive is **Standalone**, the Job is run in the server hosting Hive and this jar file is sent to the HDFS system of the cluster you are connecting to. Therefore, ensure that you have properly
defined the NameNode URI in the corresponding field of the **Basic settings** view.

This jar file can be downloaded from Apache’s site. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

**Query**

Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.

For further information about the Hive query language, see https://cwiki.apache.org/confluence/display/Hive/LanguageManual.

**Note:** Compressed data in the form of Gzip or Bzip2 can be processed through the query statements. For details, see https://cwiki.apache.org/confluence/display/Hive/CompressedStorage.

Hadoop provides different compression formats that help reduce the space needed for storing files and speed up data transfer. When reading a compressed file, the Studio needs to uncompress it before being able to feed it to the input flow.

**Execution engine**

Select this check box and from the drop-down list, select the framework you need to use to run the Job.

This list is available only when you are using the **Embedded** mode for the Hive connection and the distribution you are working with is:

- Custom: this option allows you connect to a distribution supporting Tez but not officially supported by Talend .

Before using Tez, ensure that the Hadoop cluster you are using supports Tez. You will need to configure the access to the relevant Tez libraries via the **Advanced settings** view of this component.

For further information about Hive on Tez, see Apache’s related documentation in https://cwiki.apache.org/confluence/display/Hive/Hive+on+Tez. Some examples are presented there to show how Tez can be used to gain performance over MapReduce.

**Advanced settings**

**Tez lib**

Select how the Tez libraries are accessed:

- **Auto install:** at runtime, the Job uploads and deploys the Tez libraries provided by the Studio into the directory you specified in the **Install folder in HDFS** field, for example, /tmp/usr/tez.

  If you have set the `tez.lib.uris` property in the properties table, this directory overrides the value of that property at runtime. But the other properties set in the properties table are still effective.

- **Use exist:** the Job accesses the Tez libraries already deployed in the Hadoop cluster to be used. You need to enter the path pointing to those libraries in the **Lib path (folder or file)** field.
<table>
<thead>
<tr>
<th>Lib jar</th>
<th>this table appears when you have selected <strong>Auto install</strong> from the <strong>Tez lib</strong> list and the distribution you are using is <strong>Custom</strong>. In this table, you need to add the Tez libraries to be uploaded.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Temporary path</td>
<td>If you do not want to set the Jobtracker and the NameNode when you execute the query <code>select * from your_table_name</code>, you need to set this temporary path. For example, <code>/C:/select_all</code> in Windows.</td>
</tr>
<tr>
<td>Trim all the String/Char columns</td>
<td>Select this check box to remove leading and trailing whitespace from all the String/Char columns.</td>
</tr>
<tr>
<td>Trim column</td>
<td>Remove leading and trailing whitespace from defined columns. <strong>Note:</strong> Clear the <strong>Trim all the String/Char columns</strong> check box to enable <strong>Trim column</strong> in this field.</td>
</tr>
<tr>
<td>Hadoop properties</td>
<td><strong>Talend Studio</strong> uses a default configuration for its engine to perform operations in a Hadoop distribution. If you need to use a custom configuration in a specific situation, complete this table with the property or properties to be customized. Then at runtime, the customized property or properties will override those default ones.</td>
</tr>
<tr>
<td></td>
<td>• Note that if you are using the centrally stored metadata from the <strong>Repository</strong>, this table automatically inherits the properties defined in that metadata and becomes uneditable unless you change the <strong>Property type</strong> from <strong>Repository</strong> to <strong>Built-in</strong>.</td>
</tr>
<tr>
<td></td>
<td>For further information about the properties required by Hadoop and its related systems such as HDFS and Hive, see the documentation of the Hadoop distribution you are using or see Apache’s Hadoop documentation on <a href="http://hadoop.apache.org/docs">http://hadoop.apache.org/docs</a> and then select the version of the documentation you want. For demonstration purposes, the links to some properties are listed below:</td>
</tr>
<tr>
<td></td>
<td>• Typically, the HDFS-related properties can be found in the <code>hdfs-default.xml</code> file of your distribution, such as <a href="http://hadoop.apache.org/docs/r2.6.0/hadoop-project-dist/hadoop-hdfs/hdfs-default.xml">http://hadoop.apache.org/docs/r2.6.0/hadoop-project-dist/hadoop-hdfs/hdfs-default.xml</a>.</td>
</tr>
<tr>
<td></td>
<td>• Apache also provides a page to list the Hive-related properties: <a href="https://cwiki.apache.org/confluence/display/Hive/Configuration+Properties">https://cwiki.apache.org/confluence/display/Hive/Configuration+Properties</a>.</td>
</tr>
<tr>
<td>Hive properties</td>
<td><strong>Talend Studio</strong> uses a default configuration for its engine to perform operations in a Hive database. If you need to use a custom configuration in a specific situation, complete this table with the property or properties to be customized. Then at runtime, the customized property or properties will override those default ones. For further information for Hive dedicated properties, see <a href="https://cwiki.apache.org/confluence/display/Hive/Configuration+Properties">https://cwiki.apache.org/confluence/display/Hive/Configuration+Properties</a>.</td>
</tr>
<tr>
<td></td>
<td>• If you need to use Tez to run your Hive Job, add <code>hive.execution.engine</code> to the <strong>Properties</strong> column and <code>Tez</code> to the <strong>Value</strong> column, enclosing both of these strings in double quotation marks.</td>
</tr>
</tbody>
</table>
- Note that if you are using the centrally stored metadata from the Repository, this table automatically inherits the properties defined in that metadata and becomes uneditable unless you change the Property type from Repository to Built-in.

<table>

### Global Variables

| Global Variables | **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer. |
|------------------| **QUERY**: the query statement being processed. This is a Flow variable and it returns a string. |
|                  | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. |
|                  | A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. |
|                  | To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. |
|                  | For further information about variables, see [Talend Studio User Guide](#). |

### Usage

| Usage rule | This component offers the benefit of flexible DB queries and covers all possible Hive QL queries. |
If the Studio used to connect to a Hive database is operated on Windows, you must manually create a folder called tmp in the root of the disk where this Studio is installed.

**HBase Configuration**

**Store by HBase**

**Note:**
Available only when the **Use an existing connection** check box is clear

**Dynamic settings**

Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

**Prerequisites**

The Hadoop distribution must be properly installed, so as to guarantee the interaction with **Talend Studio**. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under `MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native`. For example, the library for Windows is `\lib\native\MapRClient.dll` in the MapR client jar file. For further information, see the following link from MapR: [http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr](http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr).

Without adding the specified library or libraries, you may encounter the following error: `no MapRClient in java.library.path`. 

Zookeeper quorum

Zookeeper client port

Define the jars to register for HBase

Register jar for HBase
Related scenarios

For a scenario about how an input component is used in a Job, see Writing columns from a MySQL database to an output file using tMysqlInput on page 2451.

You need to keep in mind the parameters required by Hadoop, such as NameNode and Jobtracker, when configuring this component since the component needs to connect to a Hadoop distribution.
tHiveLoad

Writes data of different formats into a given Hive table or to export data from a Hive table to a directory.

tHiveLoad connects to a given Hive database and copies or moves data into an existing Hive table or a directory you specify.

**tHiveLoad Standard properties**

These properties are used to configure tHiveLoad running in the Standard Job framework.

The Standard tHiveLoad component belongs to the Big Data and the Databases families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

Connection configuration:

- When you use this component with Qubole on AWS:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>API Token</td>
<td>Click the ... button next to the API Token field to enter the authentication token generated for the Qubole user account to be used. For further information about how to obtain this token, see Manage Qubole account from the Qubole documentation. This token allows you to specify the user account you want to use to access Qubole. Your Job automatically uses the rights and permissions granted to this user account in Qubole.</td>
</tr>
<tr>
<td>Cluster label</td>
<td>Select the Cluster label check box and enter the name of the Qubole cluster to be used. If leaving this check box clear, the default cluster is used. If you need details about your default cluster, ask the administrator of your Qubole service. You can also read this article from the Qubole documentation to find more information about configuring a default Qubole cluster.</td>
</tr>
<tr>
<td>Change API endpoint</td>
<td>Select the Change API endpoint check box and select the region to be used. If leaving this check box clear, the default region is used. For further information about the Qubole Endpoints supported on QDS-on-AWS, see Supported Qubole Endpoints on Different Cloud Providers.</td>
</tr>
</tbody>
</table>

- When you use this component with Google Dataproc:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Project identifier</td>
<td>Enter the ID of your Google Cloud Platform project. If you are not certain about your project ID, check it in the Manage Resources page of your Google Cloud Platform services.</td>
</tr>
<tr>
<td>Cluster identifier</td>
<td>Enter the ID of your Dataproc cluster to be used.</td>
</tr>
<tr>
<td><strong>Region</strong></td>
<td>Leave the default value <code>global</code> as is, since this is the only region which the Studio supports for Google Cloud Platform.</td>
</tr>
<tr>
<td><strong>Google Storage staging bucket</strong></td>
<td>As a Talend Job expects its dependent jar files for execution, specify the Google Storage directory to which these jar files are transferred so that your Job can access these files at execution. The directory to be entered must end with a slash (<code>/</code>). If not existing, the directory is created on the fly but the bucket to be used must already exist.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Fill this field with the name of the database.</td>
</tr>
<tr>
<td><strong>Provide Google Credentials in file</strong></td>
<td>Leave this check box clear, when you launch your Job from a given machine in which Google Cloud SDK has been installed and authorized to use your user account credentials to access Google Cloud Platform. In this situation, this machine is often your local machine. For further information about this Google Credentials file, see the administrator of your Google Cloud Platform or visit Google Cloud Platform Auth Guide.</td>
</tr>
</tbody>
</table>

- When you use this component with HDInsight:

| **WebHCat configuration** | Enter the address and the authentication information of the Microsoft HD Insight cluster to be used. For example, the address could be `your_hdinsight_cluster_name.azurehdinsight.net` and the authentication information is your Azure account name: `ychen`. The Studio uses this service to submit the Job to the HD Insight cluster. In the `Job result folder` field, enter the location in which you want to store the execution result of a Job in the Azure Storage to be used. |
| **HDInsight configuration** | - The **Username** is the one defined when creating your cluster. You can find it in the **SSH + Cluster login** blade of your cluster.  
- The **Password** is defined when creating your HDInsight cluster for authentication to this cluster. |
| **Windows Azure Storage configuration** | Enter the address and the authentication information of the Azure Storage account to be used. In this configuration, you do not define where to read or write your business data but define where to deploy your Job only. Therefore always use the Azure Storage system for this configuration. In the `Container` field, enter the name of the container to be used. You can find the available containers in the **Blob** blade of the Azure Storage account to be used. In the `Deployment Blob` field, enter the location in which you want to store the current Job and its dependent libraries in this Azure Storage account. In the `Hostname` field, enter the Primary Blob Service Endpoint of your Azure Storage account without the `https://` part. You can find this endpoint in the **Properties** blade of this storage account. |
In the **Username** field, enter the name of the Azure Storage account to be used.

In the **Password** field, enter the access key of the Azure Storage account to be used. This key can be found in the **Access keys** blade of this storage account.

| Database | Fill this field with the name of the database. |

- **Connection mode**
  - Select a connection mode from the list. The options vary depending on the distribution you are using.

- **Hive server**
  - Select the Hive server through which you want the Job using this component to execute queries on Hive.
  - This **Hive server** list is available only when the Hadoop distribution to be used such as **HortonWorks Data Platform V1.2.0 (Bimota)** supports HiveServer2. It allows you to select HiveServer2 (**Hive 2**), the server that better support concurrent connections of multiple clients than HiveServer (**Hive 1**).
  - For further information about HiveServer2, see [https://cwiki.apache.org/confluence/display/Hive/Setting+Up+HiveServer2](https://cwiki.apache.org/confluence/display/Hive/Setting+Up+HiveServer2).

- **Host**
  - Database server IP address.

- **Port**
  - Listening port number of DB server.

- **Database**
  - Fill this field with the name of the database.

  **Note:**
  This field is not available when you select **Embedded** from the **Connection mode** list.

- **Username and Password**
  - DB user authentication data.
  - To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

- **Use kerberos authentication**
  - If you are accessing a Hive Metastore running with Kerberos security, select this check box and then enter the relevant parameters in the fields that appear.
  - If this cluster is a MapR cluster of the version 5.0.0 or later, you can set the MapR ticket authentication configuration in addition or as an alternative by following the explanation in **Connecting to a security-enabled MapR** on page 1629.
  - Keep in mind that this configuration generates a new MapR security ticket for the username defined in the Job in each execution. If you need to reuse an existing ticket issued for the same username, leave both the **Force MapR ticket authentication** check box and the **Use Kerberos authentication** check box clear, and then MapR should be able to automatically find that ticket on the fly.
The values of the following parameters can be found in the `hive-site.xml` file of the Hive system to be used.

1. **Hive principal** uses the value of `hive.metastore.kerberos.principal`. This is the service principal of the Hive Metastore.

2. **HiveServer2 local user principal** uses the value of `hive.server2.authentication.kerberos.principal`.

3. **HiveServer2 local user keytab** uses the value of `hive.server2.authentication.kerberos.keytab`.

4. **Metastore URL** uses the value of `javax.jdo.option.ConnectionURL`. This is the JDBC connection string to the Hive Metastore.

5. **Driver class** uses the value of `javax.jdo.option.ConnectionDriverName`. This is the name of the driver for the JDBC connection.

6. **Username** uses the value of `javax.jdo.option.ConnectionUserName`. This, as well as the `Password` parameter, is the user credential for connecting to the Hive Metastore.

7. **Password** uses the value of `javax.jdo.option.ConnectionPassword`.

For the other parameters that are displayed, please consult the Hadoop configuration files they belong to. For example, the **Namenode principal** can be found in the `hdfs-site.xml` file or the `hdfs-default.xml` file of the distribution you are using.

This check box is available depending on the Hadoop distribution you are connecting to.

| Use a keytab to authenticate | Select the **Use a keytab to authenticate** check box to log into a Kerberos-enabled system using a given keytab file. A keytab file contains pairs of Kerberos principals and encrypted keys. You need to enter the principal to be used in the **Principal** field and the access path to the keytab file itself in the **Keytab** field. This keytab file must be stored in the machine in which your Job actually runs, for example, on a Talend Jobserver.

Note that the user that executes a keytab-enabled Job is not necessarily the one a principal designates but must have the right to read the keytab file being used. For example, the user name you are using to execute a Job is **user1** and the principal to be used is **guest**; in this situation, ensure that **user1** has the right to read the keytab file to be used. |

| Use SSL encryption | Select this check box to enable the SSL or TLS encrypted connection.

Then in the fields that are displayed, provide the authentication information:

- **Trust store path**
  - In the **Trust store path** field, enter the path, or browse to the TrustStore file to be used. By default, the supported TrustStore types are **JKS** and **PKCS 12**.
  - To enter the password, click the `[...]` button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

This feature is available only to the HiveServer2 in the **Standalone** mode of the following distributions: |
- Hortonworks Data Platform 2.0 +
- Cloudera CDH4 +
- Pivotal HD 2.0 +
- Amazon EMR 4.0.0 +

### Set Resource Manager

Select this check box and in the displayed field, enter the location of the ResourceManager of your distribution. For example, `tal-qall14.talend.lan:8050`.

Then you can continue to set the following parameters depending on the configuration of the Hadoop cluster to be used (if you leave the check box of a parameter clear, then at runtime, the configuration about this parameter in the Hadoop cluster to be used will be ignored):

1. Select the **Set resourcemanager scheduler address** check box and enter the Scheduler address in the field that appears.
2. Select the **Set jobhistory address** check box and enter the location of the JobHistory server of the Hadoop cluster to be used. This allows the metrics information of the current Job to be stored in that JobHistory server.
3. Select the **Set staging directory** check box and enter this directory defined in your Hadoop cluster for temporary files created by running programs. Typically, this directory can be found under the `yarn.app.mapreduce.am.staging-dir` property in the configuration files such as `yarn-site.xml` or `mapred-site.xml` of your distribution.
4. Allocate proper memory volumes to the **Map** and the **Reduce** computations and the **ApplicationMaster** of YARN by selecting the **Set memory** check box in the Advanced settings view.
5. Select the **Set Hadoop user** check box and enter the user name under which you want to execute the Job. Since a file or a directory in Hadoop has its specific owner with appropriate read or write rights, this field allows you to execute the Job directly under the user name that has the appropriate rights to access the file or directory to be processed.
6. Select the **Use datanode hostname** check box to allow the Job to access datanodes via their hostnames. This actually sets the `dfs.client.use.datanode.hostname` property to **true**. When connecting to a S3N filesystem, you must select this check box.

For further information about these parameters, see the documentation or contact the administrator of the Hadoop cluster to be used.

### Set NameNode URI

Select this check box and in the displayed field, enter the URI of the Hadoop NameNode, the master node of a Hadoop system. For example, assuming that you have chosen a machine called `masternode` as the NameNode, then the location is `hdfs://masternode:portnumber`. If you are using WebHDFS, the
The other properties:

| Property type | Either Built-In or Repository.  
|               | Built-In: No property data stored centrally.  
|               | Repository: Select the repository file where the properties are stored.  |

| Use an existing connection | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.  

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:  
1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.  
2. In the child level, use a dedicated connection component to read that registered database connection.  

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.  |

| Distribution | Select the cluster you are using from the drop-down list. The options in the list vary depending on the component you are using. Among these options, the following ones requires specific configuration:  
|              | • If available in this Distribution drop-down list, the Microsoft HD Insight option allows you to use a Microsoft HD Insight cluster. For this purpose, you need to configure the connections to the HD Insight cluster and the Windows Azure Storage service of that cluster in the areas that are displayed. For detailed explanation about these parameters, search for configuring the connection manually on Talend Help Center (https://help.talend.com).  
|              | • If you select Amazon EMR, you can find more details about how to configure an Amazon EMR cluster in Talend Help Center (https://help.talend.com).  
|              | • The Custom option allows you to connect to a cluster different from any of the distributions given in this list, that is to say, to connect to a cluster not officially supported by Talend.  
|              | 1. Select Import from existing version to import an officially supported distribution as base and then add other required jar files which the base distribution does not provide. |
2. Select **Import from zip** to import the configuration zip for the custom distribution to be used. This zip file should contain the libraries of the different Hadoop elements and the index file of these libraries.

In **Talend Exchange**, members of **Talend** community have shared some ready-for-use configuration zip files which you can download from this **Hadoop configuration list** and directly use them in your connection accordingly. However, because of the ongoing evolution of the different Hadoop-related projects, you might not be able to find the configuration zip corresponding to your distribution from this list; then it is recommended to use the **Import from existing version** option to take an existing distribution as base to add the jars required by your distribution.

Note that custom versions are not officially supported by **Talend**. **Talend** and its community provide you with the opportunity to connect to custom versions from the Studio but cannot guarantee that the configuration of whichever version you choose will be easy, due to the wide range of different Hadoop distributions and versions that are available. As such, you should only attempt to set up such a connection if you have sufficient Hadoop experience to handle any issues on your own.

**Note:**

In this dialog box, the active check box must be kept selected so as to import the jar files pertinent to the connection to be created between the custom distribution and this component.

For a step-by-step example about how to connect to a custom distribution and share this connection, see **Connecting to a custom Hadoop distribution** on page 1569.

<table>
<thead>
<tr>
<th><strong>Hive version</strong></th>
<th>Select the version of the Hadoop distribution you are using. The available options vary depending on the component you are using.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Load action</strong></td>
<td>Select the action you need to carry for writing data into the specified destination.</td>
</tr>
<tr>
<td></td>
<td>• When you select <strong>LOAD</strong>, you are moving or copying data from a directory you specify.</td>
</tr>
<tr>
<td></td>
<td>• When you select <strong>INSERT</strong>, you are moving or copying data based on queries.</td>
</tr>
<tr>
<td><strong>Execution engine</strong></td>
<td>Select this check box and from the drop-down list, select the framework you need to use to perform the <strong>INSERT</strong> action.</td>
</tr>
<tr>
<td></td>
<td>This list is available only when you are using the <strong>Embedded</strong> mode for the Hive connection and the distribution you are working with is:</td>
</tr>
<tr>
<td></td>
<td>• Custom: this option allows you connect to a distribution supporting Tez but not officially supported by <strong>Talend</strong>.</td>
</tr>
</tbody>
</table>
Before using Tez, ensure that the Hadoop cluster you are using supports Tez. You will need to configure the access to the relevant Tez libraries via the **Advanced settings** view of this component.

For further information about Hive on Tez, see Apache’s related documentation in [https://cwiki.apache.org/confluence/display/Hive/Hive+on+Tez](https://cwiki.apache.org/confluence/display/Hive/Hive+on+Tez). Some examples are presented there to show how Tez can be used to gain performance over MapReduce.

| Target type | This drop-down list appears only when you have selected **INSERT** from the **Load action** list. Select from this list the type of the location you need to write data in.  
- If you select **Table** as destination, you can still choose to append data to or overwrite the contents in the specified table.  
- If you select **Directory** as destination, you are overwriting the contents in the specified directory. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Table name</td>
<td>Enter the name of the Hive table you need to write data in. Note that with the <strong>INSERT</strong> action, this field is available only when you have selected <strong>Table</strong> from the <strong>Target type</strong> list.</td>
</tr>
</tbody>
</table>
| File path | Enter the directory you need to read data from or write data in, depending on the action you have selected from the **Load action** list.  
- If you have selected **LOAD**: this is the path to the data you want to copy or move into the specified Hive table.  
- If you have selected **INSERT**: this is the directory to which you want to export data from a Hive table. With this action, the **File path** field is available only when you have selected **Directory** from the **Target type** list. |
| The target table uses the Parquet format | If the table in which you need to write data is a PARQUET table, select this check box. Note that when the file format to be used is **PARQUET**, you might be prompted to find the specific PARQUET jar file and install it into the Studio.  
- When the connection mode to Hive is **Embedded**, the Job is run in your local machine and calls this jar installed in the Studio.  
- When the connection mode to Hive is **Standalone**, the Job is run in the server hosting Hive and this jar file is sent to the HDFS system of the cluster you are connecting to. Therefore, ensure that you have properly defined the NameNode URI in the corresponding field of the **Basic settings** view.  
This jar file can be downloaded from Apache’s site. You can find more details about how to install external modules in Talend Help Center ([https://help.talend.com](https://help.talend.com)). Then from the **Compression** list that appears, select the compression mode you need to use to handle the PARQUET file. The default mode is **Uncompressed**. |
| Action on file | Select the action to be carried out for writing data. |
This list is available only when the target is a Hive table; if the target is a directory, the action to be used is automatically **OVERWRITE**.

**Query**

This field appears when you have selected **INSERT** from the **Load action** list.

Enter the appropriate query for selecting the data to be exported to the specified Hive table or directory.

**Local**

Select this check box to use the Hive **LOCAL** statement for accessing a local directory. Note that this local directory is actually in the machine in which the Job is run. Therefore, when the connection mode to Hive is **Standalone**, the Job is run in the machine where the Hive application is installed and thus this local directory is in that machine.

This statement is used along with the directory you have defined in the **File path** field. Therefore, this **Local** check box is available only when the **File path** field is available.

- If you are using the **LOAD** action, **tHiveLoad** copies the local data to the target table.
- If you are using the **INSERT** action, **tHiveLoad** copies data to a local directory.
- If you leave this **Local** check box clear, the directory defined in the **File path** field is assumed to be in the HDFS system to be used and data will be moved to the target location.

For further information about this **LOCAL** statement, see Apache’s documentation about Hive’s Language.

**Set partitions**

Select this check box to use the Hive **Partition** clause in loading or inserting data in a Hive table. You need to enter the partition keys and their values to be used in the field that appears.

For example, enter `country='US', state='CA'`. This makes a partition clause reading `Partition (country='US', state='CA')`, that is to say, a **US and CA** partition.

Also, it is recommended to select the **Create partition if not exist** check box that appears to ensure that you will not create a duplicate partition.

**Die on error**

Select this check box to kill the Job when an error occurs.

### Advanced settings

**Tez lib**

Select how the Tez libraries are accessed:

- **Auto install**: at runtime, the Job uploads and deploys the Tez libraries provided by the Studio into the directory you specified in the **Install folder in HDFS** field, for example, `/tmp/usr/tez`.

  If you have set the `tez.lib.uris` property in the properties table, this directory overrides the value of that property at runtime. But the other properties set in the properties table are still effective.

- **Use exist**: the Job accesses the Tez libraries already deployed in the Hadoop cluster to be used. You need to enter the path pointing to those libraries in the **Lib path (folder or file)** field.
<table>
<thead>
<tr>
<th>HiveLoad</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Lib jar</strong>: this table appears when you have selected <strong>Auto install</strong> from the <strong>Tez lib</strong> list and the distribution you are using is <strong>Custom</strong>. In this table, you need to add the Tez libraries to be uploaded.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Temporary path</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>If you do not want to set the Jobtracker and the NameNode when you execute the query <code>select * from your_table_name</code>, you need to set this temporary path. For example, <code>/C/select_all</code> in Windows.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Hadoop properties</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><em>Talend Studio</em> uses a default configuration for its engine to perform operations in a Hadoop distribution. If you need to use a custom configuration in a specific situation, complete this table with the property or properties to be customized. Then at runtime, the customized property or properties will override those default ones.</td>
</tr>
<tr>
<td>• Note that if you are using the centrally stored metadata from the <strong>Repository</strong>, this table automatically inherits the properties defined in that metadata and becomes uneditable unless you change the <strong>Property type</strong> from <strong>Repository</strong> to <strong>Built-in</strong>.</td>
</tr>
<tr>
<td>For further information about the properties required by Hadoop and its related systems such as HDFS and Hive, see the documentation of the Hadoop distribution you are using or see Apache's Hadoop documentation on <a href="http://hadoop.apache.org/docs">http://hadoop.apache.org/docs</a> and then select the version of the documentation you want. For demonstration purposes, the links to some properties are listed below:</td>
</tr>
<tr>
<td>• Typically, the HDFS-related properties can be found in the <code>hdfs-default.xml</code> file of your distribution, such as <a href="http://hadoop.apache.org/docs/r2.6.0/hadoop-project-dist/hadoop-hdfs/hdfs-default.xml">http://hadoop.apache.org/docs/r2.6.0/hadoop-project-dist/hadoop-hdfs/hdfs-default.xml</a>.</td>
</tr>
<tr>
<td>• Apache also provides a page to list the Hive-related properties: <a href="https://cwiki.apache.org/confluence/display/Hive/Configuration+Properties">https://cwiki.apache.org/confluence/display/Hive/Configuration+Properties</a>.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Hive properties</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><em>Talend Studio</em> uses a default configuration for its engine to perform operations in a Hive database. If you need to use a custom configuration in a specific situation, complete this table with the property or properties to be customized. Then at runtime, the customized property or properties will override those default ones. For further information for Hive dedicated properties, see <a href="https://cwiki.apache.org/confluence/display/Hive/AdminManual+Configuration">https://cwiki.apache.org/confluence/display/Hive/AdminManual+Configuration</a>.</td>
</tr>
<tr>
<td>• If you need to use Tez to run your Hive Job, add <strong>hive.execution.engine</strong> to the <strong>Properties</strong> column and <strong>Tez</strong> to the <strong>Value</strong> column, enclosing both of these strings in double quotation marks.</td>
</tr>
<tr>
<td>• Note that if you are using the centrally stored metadata from the <strong>Repository</strong>, this table automatically inherits the properties defined in that metadata and becomes uneditable unless you change the <strong>Property type</strong> from <strong>Repository</strong> to <strong>Built-in</strong>.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Mapred job map memory mb</strong> and <strong>Mapred job reduce memory mb</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>You can tune the map and reduce computations by selecting the <strong>Set memory</strong> check box to set proper memory allocations for the computations to be performed by the Hadoop system.</td>
</tr>
<tr>
<td>In that situation, you need to enter the values you need in the <strong>Mapred job map memory mb</strong> and the <strong>Mapred job reduce memory mb</strong>.</td>
</tr>
</tbody>
</table>
memory mb fields, respectively. By default, the values are both 1000 which are normally appropriate for running the computations.

The memory parameters to be set are **Map (in Mb)**, **Reduce (in Mb)** and **ApplicationMaster (in Mb)**. These fields allow you to dynamically allocate memory to the map and the reduce computations and the ApplicationMaster of YARN.

**Path separator in server**
Leave the default value of the **Path separator in server** as it is, unless you have changed the separator used by your Hadoop distribution’s host machine for its PATH variable or in other words, that separator is not a colon (:). In that situation, you must change this value to the one you are using in that host.

**tStatCatcher Statistics**
Select this check box to collect log data at the component level.

### Global Variables

**Global Variables**

<table>
<thead>
<tr>
<th><strong>QUERY</strong></th>
<th>The query statement being processed. This is a Flow variable and it returns a string.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>ERROR`MESSAGE</strong></td>
<td>The error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

**Usage rule**
This component works standalone and supports writing a wide range of data formats such as RC, ORC or AVRO.

If the Studio used to connect to a Hive database is operated on Windows, you must manually create a folder called *tmp* in the root of the disk where this Studio is installed.

**Dynamic settings**
Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the
Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Prerequisites

The Hadoop distribution must be properly installed, so as to guarantee the interaction with Talend Studio. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native. For example, the library for Windows is \lib\native\MapRClient.dll in the MapR client jar file. For further information, see the following link from MapR: http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr.

  Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path.

- Set the -Djava.library.path argument, for example, in the Job Run VM arguments area of the Run/Debug view in the Preferences dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

Related scenario

For a related scenario, see Creating a partitioned Hive table on page 1571
tHiveRow

Acts on the actual DB structure or on the data without handling data itself, depending on the nature of the query and the database.

tHiveRow executes the HiveQL query stated in the specified database. The row suffix means the component implements a flow in the Job design although it does not provide output.

The SQLBuilder tool helps you write your HiveQL statements easily.

This component can also perform queries in a HBase database once the Store by HBase check box is available and you have selected this check box.

tHiveRow Standard properties

These properties are used to configure tHiveRow running in the Standard Job framework.
The Standard tHiveRow component belongs to the Big Data and the Databases families.
The component in this framework is available in all Talend products.

Basic settings

Connection configuration:

- When you use this component with Qubole on AWS:

  | API Token | Click the ... button next to the API Token field to enter the authentication token generated for the Qubole user account to be used. For further information about how to obtain this token, see Manage Qubole account from the Qubole documentation. This token allows you to specify the user account you want to use to access Qubole. Your Job automatically uses the rights and permissions granted to this user account in Qubole. |
  | Cluster label | Select the Cluster label check box and enter the name of the Qubole cluster to be used. If leaving this check box clear, the default cluster is used. If you need details about your default cluster, ask the administrator of your Qubole service. You can also read this article from the Qubole documentation to find more information about configuring a default Qubole cluster. |
  | Change API endpoint | Select the Change API endpoint check box and select the region to be used. If leaving this check box clear, the default region is used. For further information about the Qubole Endpoints supported on QDS-on-AWS, see Supported Qubole Endpoints on Different Cloud Providers. |

- When you use this component with Google Dataproc:

  | Project identifier | Enter the ID of your Google Cloud Platform project. |
If you are not certain about your project ID, check it in the Manage Resources page of your Google Cloud Platform services.

<table>
<thead>
<tr>
<th><strong>Cluster identifier</strong></th>
<th>Enter the ID of your Dataproc cluster to be used.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Region</strong></td>
<td>Leave the default value <code>global</code> as is, since this is the only region which the Studio supports for Google Cloud Platform.</td>
</tr>
<tr>
<td><strong>Google Storage staging bucket</strong></td>
<td>As a Talend Job expects its dependent jar files for execution, specify the Google Storage directory to which these jar files are transferred so that your Job can access these files at execution. The directory to be entered must end with a slash <code>/</code>. If not existing, the directory is created on the fly but the bucket to be used must already exist.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Fill this field with the name of the database.</td>
</tr>
</tbody>
</table>

Provide Google Credentials in file

Leave this check box clear, when you launch your Job from a given machine in which Google Cloud SDK has been installed and authorized to use your user account credentials to access Google Cloud Platform. In this situation, this machine is often your local machine.

For further information about this Google Credentials file, see the administrator of your Google Cloud Platform or visit Google Cloud Platform Auth Guide.

- When you use this component with HDInsight:

  **WebHCat configuration**

  Enter the address and the authentication information of the Microsoft HD Insight cluster to be used. For example, the address could be `your_hdinsight_cluster_name.azurehdinsight.net` and the authentication information is your Azure account name: `ychen`. The Studio uses this service to submit the Job to the HD Insight cluster.

  In the **Job result folder** field, enter the location in which you want to store the execution result of a Job in the Azure Storage to be used.

  **HDInsight configuration**

  - The **Username** is the one defined when creating your cluster. You can find it in the **SSH + Cluster login** blade of your cluster.
  - The **Password** is defined when creating your HDInsight cluster for authentication to this cluster.

  **Windows Azure Storage configuration**

  Enter the address and the authentication information of the Azure Storage account to be used. In this configuration, you do not define where to read or write your business data but define where to deploy your Job only. Therefore always use the Azure Storage system for this configuration.

  In the **Container** field, enter the name of the container to be used. You can find the available containers in the **Blob** blade of the Azure Storage account to be used.
In the **Deployment Blob** field, enter the location in which you want to store the current Job and its dependent libraries in this Azure Storage account.

In the **Hostname** field, enter the Primary Blob Service Endpoint of your Azure Storage account without the https:// part. You can find this endpoint in the **Properties** blade of this storage account.

In the **Username** field, enter the name of the Azure Storage account to be used.

In the **Password** field, enter the access key of the Azure Storage account to be used. This key can be found in the **Access keys** blade of this storage account.

**Database**

- Fill this field with the name of the database.

**Connection mode**

Select a connection mode from the list. The options vary depending on the distribution you are using.

**Hive server**

Select the Hive server through which you want the Job using this component to execute queries on Hive.

This **Hive server** list is available only when the Hadoop distribution to be used such as HortonWorks Data Platform V1.2.0 (Bimota) supports HiveServer2. It allows you to select HiveServer2 (**Hive 2**), the server that better support concurrent connections of multiple clients than HiveServer (**Hive 1**).

For further information about HiveServer2, see [https://cwiki.apache.org/confluence/display/Hive/Setting+Up+HiveServer2](https://cwiki.apache.org/confluence/display/Hive/Setting+Up+HiveServer2).

**Host**

Database server IP address.

**Port**

Listening port number of DB server.

**Database**

- Fill this field with the name of the database.

**Username and Password**

DB user authentication data.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

**Use kerberos authentication**

If you are accessing a Hive Metastore running with Kerberos security, select this check box and then enter the relevant parameters in the fields that appear.

- If this cluster is a MapR cluster of the version 5.0.0 or later, you can set the MapR ticket authentication configuration in addition or as an alternative by following the explanation in [Connecting to a security-enabled MapR](#) on page 1629.
Keep in mind that this configuration generates a new MapR security ticket for the username defined in the Job in each execution. If you need to reuse an existing ticket issued for the same username, leave both the **Force MapR ticket authentication** check box and the **Use Kerberos authentication** check box clear, and then MapR should be able to automatically find that ticket on the fly.

The values of the following parameters can be found in the `hive-site.xml` file of the Hive system to be used.

1. **Hive principal** uses the value of `hive.metastore.kerberos.principal`. This is the service principal of the Hive Metastore.
2. **HiveServer2 local user principal** uses the value of `hive.server2.authentication.kerberos.principal`.
3. **HiveServer2 local user keytab** uses the value of `hive.server2.authentication.kerberos.keytab`.
4. **Metastore URL** uses the value of `javax.jdo.option.ConnectionURL`. This is the JDBC connection string to the Hive Metastore.
5. **Driver class** uses the value of `javax.jdo.option.ConnectionDriverName`. This is the name of the driver for the JDBC connection.
6. **Username** uses the value of `javax.jdo.option.ConnectionUserName`. This, as well as the **Password** parameter, is the user credential for connecting to the Hive Metastore.
7. **Password** uses the value of `javax.jdo.option.ConnectionPassword`.

For the other parameters that are displayed, please consult the Hadoop configuration files they belong to. For example, the **Namenode principal** can be found in the `hdfs-site.xml` file or the `hdfs-default.xml` file of the distribution you are using.

This check box is available depending on the Hadoop distribution you are connecting to.

**Use a keytab to authenticate**

Select the **Use a keytab to authenticate** check box to log into a Kerberos-enabled system using a given keytab file. A keytab file contains pairs of Kerberos principals and encrypted keys. You need to enter the principal to be used in the **Principal** field and the access path to the keytab file itself in the **Keytab** field. This keytab file must be stored in the machine in which your Job actually runs, for example, on a Talend Jobserver.

Note that the user that executes a keytab-enabled Job is not necessarily the one a principal designates but must have the right to read the keytab file being used. For example, the user name you are using to execute a Job is `user1` and the principal to be used is `guest`; in this situation, ensure that `user1` has the right to read the keytab file to be used.

**Use SSL encryption**

Select this check box to enable the SSL or TLS encrypted connection.

Then in the fields that are displayed, provide the authentication information:
| Set Resource Manager | Select this check box and in the displayed field, enter the location of the ResourceManager of your distribution. For example, t.a1-qall14.talend.lan:8050. Then you can continue to set the following parameters depending on the configuration of the Hadoop cluster to be used (if you leave the check box of a parameter clear, then at runtime, the configuration about this parameter in the Hadoop cluster to be used will be ignored):

1. Select the **Set resourcemanager scheduler address** check box and enter the Scheduler address in the field that appears.
2. Select the **Set jobhistory address** check box and enter the location of the JobHistory server of the Hadoop cluster to be used. This allows the metrics information of the current Job to be stored in that JobHistory server.
3. Select the **Set staging directory** check box and enter this directory defined in your Hadoop cluster for temporary files created by running programs. Typically, this directory can be found under the `yarn.app.mapreduce.am.staging-dir` property in the configuration files such as `yarn-site.xml` or `mapred-site.xml` of your distribution.
4. Allocate proper memory volumes to the **Map** and the **Reduce** computations and the **ApplicationMaster** of YARN by selecting the **Set memory** check box in the **Advanced settings** view.
5. Select the **Set Hadoop user** check box and enter the user name under which you want to execute the Job. Since a file or a directory in Hadoop has its specific owner with appropriate read or write rights, this field allows you to execute the Job directly under the user name that has the appropriate rights to access the file or directory to be processed.
6. Select the **Use datanode hostname** check box to allow the Job to access datanodes via their hostnames. This actually sets the `dfs.client.use.datanode.hostname` property to `true`. When connecting to a S3N filesystem, you must select this check box.

For further information about these parameters, see the documentation or contact the administrator of the Hadoop cluster to be used. |

- In the **Trust store path** field, enter the path, or browse to the TrustStore file to be used. By default, the supported TrustStore types are **JKS** and **PKCS 12**.
- To enter the password, click the `[...]` button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

This feature is available only to the HiveServer2 in the **Standalone** mode of the following distributions:

- Hortonworks Data Platform 2.0 +
- Cloudera CDH4 +
- Pivotal HD 2.0 +
- Amazon EMR 4.0.0 +

### Set NameNode URI

Select this check box and in the displayed field, enter the URI of the Hadoop NameNode, the master node of a Hadoop system. For example, assuming that you have chosen a machine called `masternode` as the NameNode, then the location is `hdfs://masternode:portnumber`. If you are using WebHDFS, the location should be `webhdfs://masternode:portnumber`; WebHDFS with SSL is not supported yet.

The other properties:

### Property type

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-In or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Built-In</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file where the properties are stored.</td>
</tr>
</tbody>
</table>

### Use an existing connection

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see [Talend Studio User Guide](https://help.talend.com).

### Distribution

Select the cluster you are using from the drop-down list. The options in the list vary depending on the component you are using. Among these options, the following ones requires specific configuration:

- If available in this Distribution drop-down list, the **Microsoft HD Insight** option allows you to use a Microsoft HD Insight cluster. For this purpose, you need to configure the connections to the HD Insight cluster and the Windows Azure Storage service of that cluster in the areas that are displayed. For detailed explanation about these parameters, search for configuring the connection manually on [Talend Help Center](https://help.talend.com).
• If you select Amazon EMR, you can find more details about how to configure an Amazon EMR cluster in Talend Help Center (https://help.talend.com).

• The Custom option allows you to connect to a cluster different from any of the distributions given in this list, that is to say, to connect to a cluster not officially supported by Talend.

1. Select Import from existing version to import an officially supported distribution as base and then add other required jar files which the base distribution does not provide.

2. Select Import from zip to import the configuration zip for the custom distribution to be used. This zip file should contain the libraries of the different Hadoop elements and the index file of these libraries.

In Talend Exchange, members of Talend community have shared some ready-for-use configuration zip files which you can download from this Hadoop configuration list and directly use them in your connection accordingly. However, because of the ongoing evolution of the different Hadoop-related projects, you might not be able to find the configuration zip corresponding to your distribution from this list; then it is recommended to use the Import from existing version option to take an existing distribution as base to add the jars required by your distribution.

Note that custom versions are not officially supported by Talend. Talend and its community provide you with the opportunity to connect to custom versions from the Studio but cannot guarantee that the configuration of whichever version you choose will be easy, due to the wide range of different Hadoop distributions and versions that are available. As such, you should only attempt to set up such a connection if you have sufficient Hadoop experience to handle any issues on your own.

Note:
In this dialog box, the active check box must be kept selected so as to import the jar files pertinent to the connection to be created between the custom distribution and this component.

For a step-by-step example about how to connect to a custom distribution and share this connection, see Connecting to a custom Hadoop distribution on page 1569.

Hive version
Select the version of the Hadoop distribution you are using. The available options vary depending on the component you are using.

Execution engine
Select this check box and from the drop-down list, select the framework you need to use to run the Job.
This list is available only when you are using the Embedded mode for the Hive connection and the distribution you are working with is:
Talend HiveRow

- **Custom:** this option allows you to connect to a distribution supporting Tez but not officially supported by Talend.

Before using Tez, ensure that the Hadoop cluster you are using supports Tez. You will need to configure the access to the relevant Tez libraries via the **Advanced settings** view of this component.

For further information about Hive on Tez, see Apache’s related documentation in [https://cwiki.apache.org/confluence/display/Hive/Hive+on+Tez](https://cwiki.apache.org/confluence/display/Hive/Hive+on+Tez). Some examples are presented there to show how Tez can be used to gain performance over MapReduce.

**Schema and Edit Schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `LINE` when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema:** choose this option to view the schema only.
- **Change to built-in property:** choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection:** choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Table Name**

Name of the table to be processed.

**Query type**

Either **Built-in** or **Repository**.

- **Built-in:** Fill in manually the query statement or build it graphically using SQLBuilder.
- **Repository:** Select the relevant query stored in the Repository. The Query field gets accordingly filled in.

**Guess Query**

Click the **Guess Query** button to generate the query which corresponds to your table schema in the Query field.

**This query uses Parquet objects**

When available, select this check box to indicate that the table to be handled uses the PARQUET format and thus make the component to call the required jar file.

Note that when the file format to be used is **PARQUET**, you might be prompted to find the specific PARQUET jar file and install it into the Studio.
- When the connection mode to Hive is **Embedded**, the Job is run in your local machine and calls this jar installed in the Studio.
- When the connection mode to Hive is **Standalone**, the Job is run in the server hosting Hive and this jar file is sent to the HDFS system of the cluster you are connecting to. Therefore, ensure that you have properly defined the NameNode URI in the corresponding field of the **Basic settings** view.

This jar file can be downloaded from Apache's site. You can find more details about how to install external modules in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

#### Query

Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.

**Note:** Compressed data in the form of Gzip or Bzip2 can be processed through the query statements. For details, see [https://cwiki.apache.org/confluence/display/Hive/CompressedStorage](https://cwiki.apache.org/confluence/display/Hive/CompressedStorage).

Hadoop provides different compression formats that help reduce the space needed for storing files and speed up data transfer. When reading a compressed file, the Studio needs to uncompress it before being able to feed it to the input flow.

#### Die on error

This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a **Row > Rejects** link.

#### Store by HBase

Select this check box to display the parameters to be set to allow the Hive components to access HBase tables:

- Once this access is configured, you will be able to use, in **tHiveRow** and **tHiveInput**, the Hive QL statements to read and write data in HBase.
- If you are using the Kerberos authentication, you need to define the HBase related principals in the corresponding fields that are displayed.

For further information about this access involving Hive and HBase, see Apache's Hive documentation about Hive/HBase integration.

#### Zookeeper quorum

Type in the name or the URL of the Zookeeper service you use to coordinate the transaction between your Studio and your database. Note that when you configure the Zookeeper, you might need to explicitly set the `zookeeper.znode.parent` property to define the path to the root znode that contains all the znodes created and used by your database; then select the **Set Zookeeper znode parent** check box to define this property.

#### Zookeeper client port

Type in the number of the client listening port of the Zookeeper service you are using.
Define the jars to register for HBase

Select this check box to display the Register jar for HBase table, in which you can register any missing jar file required by HBase, for example, the Hive Storage Handler, by default, registered along with your Hive installation.

Register jar for HBase

Click the [+ ] button to add rows to this table, then, in the Jar name column, select the jar file(s) to be registered and in the Jar path column, enter the path(s) pointing to that or those jar file(s).

Advanced settings

Tez lib

Select how the Tez libraries are accessed:

- **Auto install**: at runtime, the Job uploads and deploys the Tez libraries provided by the Studio into the directory you specified in the Install folder in HDFS field, for example, /tmp/usr/tez.
  
  If you have set the tez.lib.uris property in the properties table, this directory overrides the value of that property at runtime. But the other properties set in the properties table are still effective.

- **Use exist**: the Job accesses the Tez libraries already deployed in the Hadoop cluster to be used. You need to enter the path pointing to those libraries in the Lib path (folder or file) field.

- **Lib jar**: this table appears when you have selected Auto install from the Tez lib list and the distribution you are using is Custom. In this table, you need to add the Tez libraries to be uploaded.

Temporary path

If you do not want to set the Jobtracker and the NameNode when you execute the query `select * from your_table_name`, you need to set this temporary path. For example, /C:/select_all in Windows.

Propagate QUERY’s recordset

Select this check box to insert the result of the query into a COLUMN of the current flow. Select this column from the use column list.

**Note:**

This option allows the component to have a different schema from that of the preceding component. Moreover, the column that holds the QUERY’s recordset should be set to the type of Object and this component is usually followed by tParseRecordSet.

Hadoop properties

Talend Studio uses a default configuration for its engine to perform operations in a Hadoop distribution. If you need to use a custom configuration in a specific situation, complete this table with the property or properties to be customized. Then at runtime, the customized property or properties will override those default ones.

- **Note** that if you are using the centrally stored metadata from the Repository, this table automatically inherits the properties defined in that metadata and becomes uneditable unless you change the Property type from Repository to Built-in.
For further information about the properties required by Hadoop and its related systems such as HDFS and Hive, see the documentation of the Hadoop distribution you are using or see Apache’s Hadoop documentation on http://hadoop.apache.org/docs and then select the version of the documentation you want. For demonstration purposes, the links to some properties are listed below:

- Typically, the HDFS-related properties can be found in the hdfs-default.xml file of your distribution, such as http://hadoop.apache.org/docs/r2.6.0/hadoop-project-dist/hadoop-hdfs/hdfs-default.xml.
- Apache also provides a page to list the Hive-related properties: https://cwiki.apache.org/confluence/display/Hive/Configuration+Properties.

**Hive properties**

Talend Studio uses a default configuration for its engine to perform operations in a Hive database. If you need to use a custom configuration in a specific situation, complete this table with the property or properties to be customized. Then at runtime, the customized property or properties will override those default ones. For further information for Hive dedicated properties, see https://cwiki.apache.org/confluence/display/Hive/AdminManual+Configuration.

- If you need to use Tez to run your Hive Job, add hive.execution.engine to the Properties column and Tez to the Value column, enclosing both of these strings in double quotation marks.
- Note that if you are using the centrally stored metadata from the Repository, this table automatically inherits the properties defined in that metadata and becomes uneditable unless you change the Property type from Repository to Built-in.

**Mapred job map memory mb and Mapred job reduce memory mb**

You can tune the map and reduce computations by selecting the Set memory check box to set proper memory allocations for the computations to be performed by the Hadoop system.

In that situation, you need to enter the values you need in the Mapred job map memory mb and the Mapred job reduce memory mb fields, respectively. By default, the values are both 1000 which are normally appropriate for running the computations.

**Path separator in server**

Leave the default value of the Path separator in server as it is, unless you have changed the separator used by your Hadoop distribution’s host machine for its PATH variable or in other words, that separator is not a colon (:). In that situation, you must change this value to the one you are using in that host.

**tStatCatcher Statistics**

Select this check box to collect log data at the component level.

**Global Variables**

**Global Variables**

- **QUERY**: the query statement being processed. This is a Flow variable and it returns a string.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable.
and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

---

### Usage

#### Usage rule

This component offers the benefit of flexible DB queries and covers all possible Hive QL queries.

**thiveRow** can capture the Application_ID values and write them in the Job logs once you have activated Log4j and set the Log4j output level to **Info** for your Job involving **thiveRow**.

- For further information about how to define the Log4j output level at an individual Job level, search for customizing log4j output level at runtime on Talend Help Center (https://help.talend.com).
- For further information about how to configure Log4j at the Studio level so as to apply the configuration to all Jobs, search for configuring Log4j on Talend Help Center (https://help.talend.com).

If the Studio used to connect to a Hive database is operated on Windows, you must manually create a folder called **tmp** in the root of the disk where this Studio is installed.

---

#### Dynamic settings

Click the [+ ] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

---

#### Prerequisites

The Hadoop distribution must be properly installed, so as to guarantee the interaction with *Talend Studio*. The following list presents MapR related information for example.
• Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under `MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native`. For example, the library for Windows is `\lib\native\MapRClient.dll` in the MapR client jar file. For further information, see the following link from MapR: `http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr`.

Without adding the specified library or libraries, you may encounter the following error: `no MapRClient in java.library.path`.

• Set the `-Djava.library.path` argument, for example, in the `Job Run VM arguments` area of the `Run/Debug` view in the `Preferences` dialog box in the `Window` menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the `Data viewer` to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

---

**Connecting to a security-enabled MapR**

When designing a Job, set up the authentication configuration in the component you are using depending on how your MapR cluster is secured.

MapR supports the two following methods of authenticating a user and generating a MapR security ticket for this user: a username/password pair and Kerberos.

For further information about the MapR security mechanism, see [MapR security architecture](http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr).

For a scenario about how to secure a MapR cluster, see [Getting started with MapR security](http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr).

The different security scenarios you may face with your MapR cluster:

• When your MapR cluster is secured with Kerberos only, you only need to set up the typical Hadoop Kerberos configuration for your Job in the Studio.

• When your MapR cluster is secured with both the Kerberos mechanism and the MapR ticket security mechanism, you need to accordingly set up the configuration for both of them in your Job in the Studio.

  For details about how to configure the MapR ticket security mechanism in the Studio, see [Setting up the MapR ticket authentication](http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr) on page 1630.

• When your MapR cluster is secured with the MapR ticket security mechanism only, proceed as explained in [Setting up the MapR ticket authentication](http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr) on page 1630 to set up the MapR authentication configuration for your Job in the Studio.

You can also find an example of how to configure Kerberos authentication for a Talend Job in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

Although this example uses Cloudera for demonstration, the operations it describes are generic and thus applicable to MapR as well.
Setting up the MapR ticket authentication

Before you begin

- The MapR distribution you are using is from version 4.0.1 onwards and you have selected it as the cluster to connect to in the component to be configured.
- The MapR cluster has been properly installed and is running.
- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native. For example, the library for Windows is lib\native\MapRClient.dll in the MapR client jar file. For further information, see the following link from MapR: http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr.

Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path.
- This section explains only the authentication parameters to be used to connect to MapR. You still need to define the other parameters required by your Job.

For further information, see the documentation about each component you are using.

About this task

In a Standard Job, you need to set up this configuration in the Basic settings tab of a Hadoop-related component to be used by your Job.

In the tab, you need to proceed as follows:

Procedure

1. Select the Force MapR ticket authentication check box to display the related parameters to be defined.
2. In the Username field, enter the username to be authenticated and in the Password field, specify the password used by this user.
   
   To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

   A MapR security ticket is generated for this user by MapR and stored in the machine where the Job you are configuring is executed.
3. If the Group field is available in this tab, you need to enter the name of the group to which the user to be authenticated belongs.
4. In the Cluster name field, enter the name of the MapR cluster you want to use this username to connect to.
   
   This cluster name can be found in the mapr-clusters.conf file located in /opt/mapr/conf of the cluster.
5. In the Ticket duration field, enter the length of time (in seconds) during which the ticket is valid.

Setting the environment variable for a custom MapR ticket location (optional)

If the default MapR ticket location, /tmp/maprticket_<uid>, has been changed, set MAPR_TICKETFILE_LOCATION environment variable accordingly in the machine in which your Job is executed.
As MapR does not provide any API to specify a MapR ticket, setting the environment variable is the only way to use a custom MapR ticket location in your Job. For further information about this issue, see this post from the MapR forum.

This procedure is necessary only when you are storing the MapR tickets in a custom location. If you use the default MapR ticket location, skip this procedure.

**Setting the environment variable for a custom MapR ticket location on Mac (optional)**

**About this task**
This procedure is relevant only when you are storing the MapR tickets in a custom location and you are using Mac to run your Studio.

**Procedure**
1. In the machine in which your Job is executed, add these lines to `~/.bashrc`:

   ```
   export MAPR_TICKETFILE_LOCATION=/Users/$USER/maprticket_$UID
   launchctl setenv MAPR_TICKETFILE_LOCATION /Users/$USER/maprticket_$UID
   ```

2. Shutdown your Studio if it is open and each and every time you boot your Mac workstation, open a terminal session before starting the Studio.

**Setting the environment variable for a custom MapR ticket location on other operating systems (optional)**

**About this task**
This procedure is relevant only when you are storing the MapR tickets in a custom location and you are not using Mac to run your Studio. If you use the default MapR ticket location, skip this procedure.

**Procedure**
1. In the machine in which your Job is executed, run the following command in a commandline terminal to set the `MAPR_TICKETFILE_LOCATION` variable in memory.

   ```
   set MAPR_TICKETFILE_LOCATION=<your_custom_location>
   ```

2. Shutdown your Studio if it is open and use the same terminal to restart your Studio. If you use a Talend JobServer to run your Job, use the same terminal to restart this JobServer.

   This way, your Job retrieves this custom location from memory.

**Using a custom MapR security configuration in the `mapr.login.conf` file (optional)**

If the default security configuration of your MapR cluster has been changed, you need to configure the Job to be executed to take this custom security configuration into account.

MapR specifies its security configuration in the `mapr.login.conf` file located in `/opt/mapr/conf` of the cluster. For further information about this configuration file and the Java service it uses behind, see `mapr.login.conf` and JAAS.

If no change has been made in the `mapr.login.conf` file, skip this procedure.
About this task

To configure your Job, you need to define the related parameters in the **Basic settings** tab and the **Advanced settings** tab of the **Component** view of the component you want your Job to use to connect to MapR.

Proceed as follows to do the configuration:

**Procedure**

1. **Verify what has been changed about this `mapr.login.conf` file.**
   
   You should be able to obtain the related information from the administrator or the developer of your MapR cluster.

2. **If the location of the MapR configuration files has been changed to somewhere else in the cluster, that is to say, the MapR Home directory has been changed, select the Set the MapR Home directory check box and enter the new Home directory.** Otherwise, leave this check box clear and the default Home directory is used.

3. **If the login module to be used in the `mapr.login.conf` file has been changed, select the Specify the Hadoop login configuration check box and enter the module to be called from the `mapr.login.conf` file.** Otherwise, leave this check box clear and the default login module is used.

   For example, enter `kerberos` to call the `hadoop_kerberos` module or `hybrid` to call the `hadoop_hybrid` module.

**Related scenarios**

For related topics, see:

- **Combining two flows for selective output** on page 2514.
- **Procedure** on page 625.
- **Removing and regenerating a MySQL table index** on page 2508.

You need to keep in mind the parameters required by Hadoop, such as NameNode and Jobtracker, when configuring this component since the component needs to connect to a Hadoop distribution.
tHSQLDbInput

Executes a DB query with a strictly defined order which must correspond to the schema definition and then it passes on the field list to the next component via a Main row link.

T H S Q L D b I n p u t reads a database and extracts fields based on a query.

**tHSQLDbInput Standard properties**

These properties are used to configure tHSQLDbInput running in the Standard Job framework.

The Standard tHSQLDbInput component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-in or Repository .</th>
</tr>
</thead>
<tbody>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

Click this icon to open a database connection wizard and store the database connection parameters you set in the component Basic settings view.

For more information about setting up and storing database connection parameters, see Talend Studio User Guide.

**Running Mode**

Select on the list the Server Mode corresponding to your DB setup among the four propositions: HSQLDb Server, HSQLDb WebServer, HSQLDb In Process Persistent, HSQLDb In Memory.

**Use TLS/SSL sockets**

Select this check box to enable the secured mode if required.

**Host**

Database server IP address.

**Port**

Listening port number of DB server.

**Database Alias**

Alias name of the database.

**Username and Password**

DB user authentication data.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

**DB path**

Specify the directory to the database you want to connect to. This field is available only to the HSQLDb In Process Persistent running mode.
**Note:**
By default, if the database you specify in this field does not exist, it will be created automatically. If you want to change this default setting, modify the connection parameter set in the Additional JDBC parameter field in the Advanced settings view.

<table>
<thead>
<tr>
<th>Db name</th>
<th>Enter the database name that you want to connect to. This field is available only to the HSQLDb In Process Persistent running mode and the HSQLDb In Memory running mode.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Schema and Edit schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <code>line</code> when naming the fields.</td>
</tr>

For further information regarding connections, see [Talend Studio User Guide](#).

### Limitation

<table>
<thead>
<tr>
<th>Limitation</th>
<th>Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</th>
</tr>
</thead>
</table>

### Related scenarios

For related topics, see:
tHSQLDbOutput

Executes the action defined on the table and/or on the data contained in the table, based on the flow incoming from the preceding component in the Job.

tHSQLDbOutput writes, updates, makes changes or suppresses entries in a database.

**tHSQLDbOutput Standard properties**

These properties are used to configure tHSQLDbOutput running in the Standard Job framework.
The Standard tHSQLDbOutput component belongs to the Databases family.
The component in this framework is available in all Talend products.

### Basic settings

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either <strong>Built-in</strong> or <strong>Repository</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Built-in</strong>: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

Click this icon to open a database connection wizard and store the database connection parameters you set in the component **Basic settings** view.
For more information about setting up and storing database connection parameters, see **Talend Studio User Guide**.

**Running Mode**
Select on the list the Server Mode corresponding to your DB setup among the four propositions: **HSQLDb Server**, **HSQLDb WebServer**, **HSQLDb In Process Persistent**, **HSQLDb In Memory**.

**Use TLS/SSL sockets**
Select this check box to enable the secured mode if required.

**Host**
Database server IP address

**Port**
Listening port number of DB server.

**Database**
Name of the database

**Username and Password**
DB user authentication data.
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

**DB path**
Specify the directory to the database you want to connect to. This field is available only to the **HSQLDb In Process Persistent** running mode.
**Note:**

By default, if the database you specify in this field does not exist, it will be created automatically. If you want to change this default setting, modify the connection parameter set in the **Additional JDBC parameter** field in the **Advanced settings** view.

<table>
<thead>
<tr>
<th><strong>Db name</strong></th>
<th>Enter the database name that you want to connect to. This field is available only to the <strong>HSQLDb In Process Persistent</strong> running mode and the <strong>HSQLDb In Memory</strong> running mode.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Table</strong></td>
<td>Name of the table to be written. Note that only one table can be written at a time.</td>
</tr>
</tbody>
</table>

**Action on table**

On the table defined, you can perform one of the following operations:

- **None**: No operation is carried out.
- **Drop and create a table**: The table is removed and created again.
- **Create a table**: The table does not exist and gets created.
- **Create a table if not exists**: The table is created if it does not exist.
- **Drop a table if exists and create**: The table is removed if it already exists and created again.
- **Clear a table**: The table content is deleted.

**Action on data**

On the data of the table defined, you can perform:

- **Insert**: Add new entries to the table. If duplicates are found, Job stops.
- **Update**: Make changes to existing entries
- **Insert or update**: Insert a new record. If the record with the given reference already exists, an update would be made.
- **Update or insert**: Update the record with the given reference. If the record does not exist, a new record would be inserted.
- **Delete**: Remove entries corresponding to the input flow.

**Warning:**

It is necessary to specify at least one column as a primary key on which the **Update** and **Delete** operations are based. You can do that by clicking **Edit Schema** and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the **Advanced settings** view where you can simultaneously define primary keys for the **Update** and **Delete** operations. To do that: Select the **Use field options** check box and then in the **Key in update column**, select the check boxes next to the column names you want to use as a base for the **Update** operation. Do the same in the **Key in delete column** for the **Delete** operation.

**Schema and Edit schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next...
component. When you create a Spark Job, avoid the reserved word line when naming the fields.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

<table>
<thead>
<tr>
<th>Built-In: You create and store the schema locally for this component only.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
</tr>
</tbody>
</table>

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

| Die on error: This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a Row > Rejects link. |

### Advanced settings

**Additional JDBC parameters**

Specify additional connection properties for the DB connection you are creating. When the running mode is HSQLDb In Process Persistent, you can set the connection property ifexists=true to allow connection to an existing database only and avoid creating a new database.

**Note:**

You can press Ctrl+Space to access a list of predefined global variables.

**Commit every**

Enter the number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and, above all, better performance at execution.

**Additional Columns**

This option is not offered if you create (with or without drop) the DB table. This option allows you to call SQL functions to perform actions on columns, which are not
<table>
<thead>
<tr>
<th><strong>tHSQLDbOutput</strong></th>
<th>insert, nor update or delete actions, or action that require particular preprocessing.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Name</strong></td>
<td>Type in the name of the schema column to be altered or inserted as new column.</td>
</tr>
<tr>
<td><strong>SQL expression</strong></td>
<td>Type in the SQL statement to be executed in order to alter or insert the relevant column data.</td>
</tr>
<tr>
<td><strong>Position</strong></td>
<td>Select <strong>Before</strong>, <strong>Replace</strong> or <strong>After</strong> following the action to be performed on the reference column.</td>
</tr>
<tr>
<td><strong>Reference column</strong></td>
<td>Type in a column of reference that the <strong>tDBOutput</strong> can use to place or replace the new or altered column.</td>
</tr>
</tbody>
</table>

**Use field options**
Select this check box to customize a request, especially when there is double action on data.

**Enable debug mode**
Select this check box to display each step during processing entries in a database.

**tStat Catcher Statistics**
Select this check box to collect log data at the component level.

### Global Variables

**Global Variables**

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE</strong></td>
<td>the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_UPDATED</strong></td>
<td>the number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_INSERTED</strong></td>
<td>the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_DELETED</strong></td>
<td>the number of rows deleted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_REJECTED</strong></td>
<td>the number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>QUERY</strong></td>
<td>the query statement processed. This is an After variable and it returns a string.</td>
</tr>
</tbody>
</table>

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

### Usage

**Usage rule**
This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible.

This component must be used as an output component. It allows you to carry out actions on a table or on the data of
a table in a MySQL database. It also allows you to create a reject flow using a **Row > Rejects** link to filter data in error. For an example of **tMysqlOutput** in use, see [Retrieving data in error with a Reject link](#) on page 2485.

### Connections

<table>
<thead>
<tr>
<th></th>
<th>Outgoing links (from this component to another):</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Row</strong></td>
<td>Main; Reject</td>
</tr>
<tr>
<td><strong>Trigger</strong></td>
<td>Run if; On Component Ok; On Component Error; On Subjob Ok; On Subjob Error.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th></th>
<th>Incoming links (from one component to this one):</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Row</strong></td>
<td>Main;</td>
</tr>
<tr>
<td><strong>Trigger</strong></td>
<td>Run if; On Component Ok; On Component Error; On Subjob Ok; On Subjob Error.</td>
</tr>
</tbody>
</table>

For further information regarding connections, see [Talend Studio User Guide](#).

### Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

### Related scenarios

For related topics, see

- [Inserting a column and altering data using tMysqlOutput](#) on page 2477.
**tHSQLDbRow**

Acts on the actual DB structure or on the data (although without handling data), depending on the nature of the query and the database.
The SQLBuilder tool helps you write easily your SQL statements.

tHSQLDbRow is the specific component for this database query. It executes the SQL query stated onto the specified database. The row suffix means the component implements a flow in the job design although it doesn’t provide output.

**tHSQLDbRow Standard properties**

These properties are used to configure tHSQLDbRow running in the Standard Job framework.
The Standard tHSQLDbRow component belongs to the Databases family.
The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-in or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Running Mode</td>
<td>Select on the list the Server Mode corresponding to your DB setup among the four propositions: HSQLDb Server, HSQLDb WebServer, HSQLDb In Process Persistent, HSQLDb In Memory.</td>
</tr>
<tr>
<td>Use TLS/SSL sockets</td>
<td>Select this check box to enable the secured mode if required.</td>
</tr>
<tr>
<td>Host</td>
<td>Database server IP address</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database Alias</td>
<td>Name of the database</td>
</tr>
</tbody>
</table>
| Username and Password| DB user authentication data.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings. |
| DB path            | Specify the directory to the database you want to connect to. This field is available only to the HSQLDb In Process Persistent running mode. |
Database

Enter the database name that you want to connect to. This field is available only to the **HSQLDb In Process Persistent** running mode and the **HSQLDb In Memory** running mode.

### Note:
By default, if the database you specify in this field does not exist, it will be created automatically. If you want to change this default setting, modify the connection parameter set in the Additional JDBC parameter field in the Advanced settings view.

### Schema and Edit Schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

**Built-in:** The schema is created and stored locally for this component only. Related topic: see [*Talend Studio User Guide*](#).

**Repository:** The schema already exists and is stored in the Repository, hence can be reused. Related topic: see [*Talend Studio User Guide*](#).

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema:** choose this option to view the schema only.
- **Change to built-in property:** choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection:** choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the Repository Content window.

### Query type

Either **Built-in** or **Repository**.

**Built-in:** Fill in manually the query statement or build it graphically using SQLBuilder.

**Repository:** Select the relevant query stored in the Repository. The Query field gets accordingly filled in.

### Query

Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.

### Die on error

This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a **Row > Rejects** link.
### Advanced settings

| **Additional JDBC parameters** | Specify additional connection properties for the DB connection you are creating. When the running mode is **HSQLDb In Process Persistent**, you can set the connection property `ifexists=true` to allow connection to an existing database only and avoid creating a new database. |
| **Propagate QUERY’s recordset** | Select this check box to insert the result of the query into a **COLUMN** of the current flow. Select this column from the **use column** list. |
| **Commit every** | Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions. |
| **tStat Catcher Statistics** | Select this check box to collect log data at the component level. |

### Global Variables

| **Global Variables** | **QUERY**: Indicates the query to be processed. This is a Flow variable and it returns a string.  
For further information about variables, see *Talend Studio User Guide.*  
**Note:**  
A Flow variable means it functions during the execution of a component while an After variable means it functions after the execution of a component. |

### Usage

| **Usage rule** | This component offers the flexibility of the DB query and covers all possible SQL queries. |
| **Connections** | Outgoing links (from this component to another):  
**Row**: Main; Reject; Iterate  
**Trigger**: Run if; On Component Ok; On Component Error; On Subjob Ok; On Subjob Error.  
Incoming links (from one component to this one):  
**Row**: Main; Iterate  
**Trigger**: Run if; On Component Ok; On Component Error; On Subjob Ok; On Subjob Error.  
For further information regarding connections, see *Talend Studio User Guide.* |
| **Limitation** | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can |
find more details about how to install external modules in Talend Help Center (https://help.talend.com).

Related scenarios

For related topics, see:

- Procedure on page 625.
- Removing and regenerating a MySQL table index on page 2508.
tHttpRequest

Sends an HTTP request to the server and outputs the response information locally.

The Standard tHttpRequest component belongs to the Internet family.

The component in this framework is available in all Talend products.

Basic settings

| Schema and Edit Schema | A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either Built-in or stored remotely in the Repository.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- View schema: choose this option to view the schema only.
- Change to built-in property: choose this option to change the schema to Built-in for local changes.
- Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |

| Built-in | You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide. |
| Repository | You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide. |

| Sync columns | Click this button to retrieve the schema from the preceding component. |

| URI | Type in the Uniform Resource Identifier (URI) that identifies the data resource on the server. A URI is similar to a URL, but more general. |

<p>| Method | Select an HTTP method to define the action to be performed: |
| Post | Sends data (for example HTML form data) to the server end. |</p>
<table>
<thead>
<tr>
<th><strong>Get</strong></th>
<th>Retrieves data from the server end.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Post parameters from file</strong></td>
<td>Browse to, or enter the path to the file that is used to provide parameters (request body) to the POST method.</td>
</tr>
<tr>
<td><strong>Write response content to file</strong></td>
<td>Select this check box to save the HTTP response to a local file. You can either type in the file path in the input field or click the three-dot button to browse to the file path.</td>
</tr>
<tr>
<td><strong>Create directory if not exists</strong></td>
<td>Select this check box to create the directory defined in the Write response content to file field if it does not exist. This check box appears only when the Write response content to file check box is selected and is cleared by default.</td>
</tr>
<tr>
<td><strong>Headers</strong></td>
<td>Type in the name-value pair(s) for HTTP headers to define the parameters of the requested HTTP operation. <strong>Key</strong>: Fill in the name of the header field of an HTTP header. <strong>Value</strong>: Fill in the content of the header field of an HTTP header. For more information about definition of HTTP headers, please refer to: en.wikipedia.org/wiki/List_of_HTTP_headers.</td>
</tr>
<tr>
<td><strong>Need authentication</strong></td>
<td>Select this check box to fill in a user name and a password in the corresponding fields if authentication is needed: <strong>user</strong>: Fill in the user name for the authentication. <strong>password</strong>: Fill in the password for the authentication. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Die on error</strong></td>
<td>Select the check box to stop the execution of the Job when an error occurs. Clear the check box to skip any rows on error and complete the process for error-free rows.</td>
</tr>
</tbody>
</table>
| **Advanced settings** | Select this check box to specify the connect and read timeout values in the following two fields:  
  - **Connect timeout(s)**: Enter the connect timeout value in seconds. An exception will occur if the timeout expires before the connection can be established. The value of 0 indicates an infinite time out. By default, the connect timeout value is 30.  
  - **Read timeout(s)**: Enter the read timeout value in seconds. An exception will occur if the timeout expires before there is data available for read. By default, the read timeout value is 0, which indicates an infinite time out. |
| **tStatCatcher Statistics** | Select this check box to gather the Job processing metadata at a Job level and at each component level. |
Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>CONNECTED: the result of whether a connection to the server established. This is an After variable and it returns a boolean.</td>
</tr>
<tr>
<td></td>
<td>RESPONSE_CODE: the response code returned by the remote HTTP server. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td></td>
<td>For further information about variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

Usage

| Usage rule | This component can be used in sending HTTP requests to server and saving the response information. This component can be used as a standalone component. |

Sending a HTTP request to the server and saving the response information to a local file

This scenario describes a two-component Job that uses the GET method to retrieve information from the server end and writes the response to a local file as well as to the console.

Linking the components

Procedure

1. In the Integration perspective of the Studio, create a Job from the Job Designs node in the Repository tree view.
   For further information about how to create a Job, see the Talend Studio User Guide.
2. Drop the following components from the Palette onto the design workspace: tHttpRequest and tLogRow.
3. Connect the tHttpRequest component to the tLogRow component using a Row > Main connection.
Configuring the GET request

Procedure

1. Double-click the **HttpRequest** component to open its **Basic settings** view and define the component properties.

   ![HttpRequest Component](image)

   - **Property**
   - **URI**
   - **Method**
   - **Write response content to file**
   - **Headers**
   - **Need authentication**

2. Fill in the **URI** field with "http://192.168.0.63:8081/testHttpRequest/build.xml". Note that this URI is for demonstration purposes only and it is not a live address.

3. From the **Method** list, select **GET**.

4. Select the **Write response content to file** check box and fill in the input field on the right with the file path by manual entry, D:/test.txt for this use case.

5. Select the **Need authentication** check box and fill in the user and password, both **tomcat** in this use case.

Executing the Job

About this task

Then you can run this Job.

The **tLogRow** component is used to present the execution result of the Job.

Procedure

1. If you want to configure how the result is presented by **tLogRow**, double-click the component to open its **Component** view and in the **Mode** area, select the **Table (print values in cells of a table)** check box.

2. Press **F6** to run this Job.

Results

Once done, the response information from the server is saved and displayed.
Sending a POST request from a local JSON file

In this scenario, a four-component Job is used to read parameters from a given JSON file and send it in a POST request to a web site.

The JSON file to be used reads as follows:

```json
{"echo": [ "data":"e=hello" ]}
```

From that file, `tFileInputJSON` reads the `e` parameter and its value `hello` and `tHttpRequest` sends the pair to `http://echo.itcuties.com/`, an URL provided for demonstration by an online programming community, `www.itcuties.com`.

Note that the `e` parameter is required by `http://echo.itcuties.com/`.

Linking the components

Procedure

1. In the Integration perspective of the Studio, create an empty Job, named `httpRequestPostDemo` for example, from the Job Designs node in the Repository tree view.
   
   For further information about how to create a Job, see the Talend Studio User Guide.

2. Drop `tFileInputJSON`, `tFileOutputDelimited`, `tHttpRequest` and `tLogRow` onto the workspace.

3. Connect `tFileInputJSON` to `tHttpRequest` using the Trigger > On Subjob Ok link.

4. Connect the other components using the Row > Main link.
Reading the JSON file

Procedure

1. Double-click tFileInputJSON to open its Component view.

2. Select JsonPath without loop from the Read By drop-down list.

3. Click the [...] button next to Edit schema to open the schema editor.

4. Click the [+] button to add one row and name it, for example, to data.

5. Click OK to validate these changes and accept the propagation prompted by the pop-up dialog box.

6. In the Filename field, browse, or enter the path to the source JSON file in which the parameter to be sent is stored.

7. In the Mapping table, the data column you defined in the previous step in the component schema has been automatically added. In the JSONPath query column of this table, enter the JSON path, in double quotation marks, to extract the parameter to be sent. In this scenario, the path is echo[0].data.

Writing the parameter to a flat file

Procedure

1. Double-click tFileOutputDelimited to open its Component view.
2. In the **File name** field, browse, or enter the path to the flat file in which you want to write the extracted parameter. This file will be created if it does not exist. In this example, it is `C:/tmp/postParamsFile.txt`.

**Posting the parameter**

**Procedure**

1. Double-click **tHttpRequest** to open its **Component** view.

2. In the **URI** field, enter the server address to which the parameter is to be sent. In this scenario, it is `http://echo.itcuties.com/`.

3. From the **Method** list, select **POST**.

4. In the **Post parameters from file** field, browse, or enter the path to the flat file that contains the parameter to be used. As defined earlier with the **tFileOutputDelimited** component, this path is `C:/tmp/postParamsFile.txt`.

**Executing the Job**

Press **F6** to run this Job.

The **tLogRow** component is used to present the execution result of the Job.

Once done, the **Run** view is opened automatically, where you can check the execution result.
You can read that the site receiving the parameter returns answers.
**tImpalaClose**

Closes connection to an Impala database.

tImpalaClose closes an active connection to a given Impala database.

**tImpalaClose Standard properties**

These properties are used to configure tImpalaClose running in the Standard Job framework.

The Standard tImpalaClose component belongs to the Big Data family.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| Component list | If there is more than one connection used in the Job, select tImpalaConnection from the list. |

**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect the log data at a component level. |

**Global Variables**

**Global Variables**

| ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

**Usage**

**Usage rule**

This component is to be used along with the other Impala components, especially with tImpalaConnection as tImpalaConnection allows you to open a connection for the transaction which is underway.

**Dynamic settings**

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in
different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Prerequisites

The Hadoop distribution must be properly installed, so as to guarantee the interaction with Talend Studio. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native. For example, the library for Windows is \lib\native\MapRClient.dll in the MapR client jar file. For further information, see the following link from MapR: http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr.

Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path.

- Set the -Djava.library.path argument, for example, in the Job Run VM arguments area of the Run/Debug view in the Preferences dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

Related scenarios

No scenario is available for the Standard version of this component yet.
tImpalaConnection

Establishes an Impala connection to be reused by other Impala components in your Job.
tImpalaConnection opens a connection to an Impala database.

**tImpalaConnection Standard properties**

These properties are used to configure tImpalaConnection running in the Standard Job framework.
The Standard tImpalaConnection component belongs to the Big Data family.
The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-in or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

**Distribution**

Select the cluster you are using from the drop-down list. The options in the list vary depending on the component you are using. Among these options, the following ones requires specific configuration:

- If available in this Distribution drop-down list, the Microsoft HD Insight option allows you to use a Microsoft HD Insight cluster. For this purpose, you need to configure the connections to the HD Insight cluster and the Windows Azure Storage service of that cluster in the areas that are displayed. For detailed explanation about these parameters, search for configuring the connection manually on Talend Help Center (https://help.talend.com).
- If you select Amazon EMR, you can find more details about how to configure an Amazon EMR cluster in Talend Help Center (https://help.talend.com).
- The Custom option allows you to connect to a cluster different from any of the distributions given in this list, that is to say, to connect to a cluster not officially supported by Talend.

1. Select Import from existing version to import an officially supported distribution as base and then add other required jar files which the base distribution does not provide.
2. Select Import from zip to import the configuration zip for the custom distribution to be used. This zip file should contain the libraries of the different Hadoop elements and the index file of these libraries.

In Talend Exchange, members of Talend community have shared some ready-for-use configuration zip files which you can download from this Hadoop configuration list and directly use them in your
connection accordingly. However, because of the ongoing evolution of the different Hadoop-related projects, you might not be able to find the configuration zip corresponding to your distribution from this list; then it is recommended to use the **Import from existing version** option to take an existing distribution as base to add the jars required by your distribution.

Note that custom versions are not officially supported by **Talend**. **Talend** and its community provide you with the opportunity to connect to custom versions from the Studio but cannot guarantee that the configuration of whichever version you choose will be easy, due to the wide range of different Hadoop distributions and versions that are available. As such, you should only attempt to set up such a connection if you have sufficient Hadoop experience to handle any issues on your own.

**Note:**
In this dialog box, the active check box must be kept selected so as to import the jar files pertinent to the connection to be created between the custom distribution and this component.

For a step-by-step example about how to connect to a custom distribution and share this connection, see **Connecting to a custom Hadoop distribution** on page 1569.

<table>
<thead>
<tr>
<th><strong>Impala version</strong></th>
<th>Select the version of the Hadoop distribution you are using. The available options vary depending on the component you are using.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Host</strong></td>
<td>Database server IP address.</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>DB server listening port.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Fill this field with the name of the database.</td>
</tr>
<tr>
<td><strong>Username</strong></td>
<td>DB user authentication data.</td>
</tr>
</tbody>
</table>

**Use kerberos authentication**
If you are accessing an Impala system running with Kerberos security, select this check box and then enter the Kerberos principal of this Impala system.

- If this cluster is a MapR cluster of the version 5.0.0 or later, you can set the MapR ticket authentication configuration in addition or as an alternative by following the explanation in **Connecting to a security-enabled MapR** on page 1629.

Keep in mind that this configuration generates a new MapR security ticket for the username defined in the Job in each execution. If you need to reuse an existing ticket issued for the same username, leave both the **Force MapR ticket authentication** check box and the **Use Kerberos authentication** check box clear, and then MapR should be able to automatically find that ticket on the fly.
### Advanced settings

| **tStatCatcher Statistics** | Select this check box to collect the log data at a component level. |

### Global Variables

**Global Variables**

- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

**Usage rule**

This component is generally used with other Impala components, particularly **tImpalaClose**.

**Prerequisites**

The Hadoop distribution must be properly installed, so as to guarantee the interaction with *Talend Studio*. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under `MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native`. For example, the library for Windows is `\lib\native\MapRClient.dll` in the MapR client jar file. For further information, see the following link from MapR: [http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr](http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr).

Without adding the specified library or libraries, you may encounter the following error: `no MapRClient in java.library.path`.

- Set the `-Djava.library.path` argument, for example, in the Job Run VM arguments area of the Run/Debug view in the Preferences dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.
For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

**Related scenario**

This component is used in the similar way as a `HiveConnection` component is. For further information, see *Creating a partitioned Hive table* on page 1571.
tImpalaCreateTable

Creates Impala tables that fit a wide range of Impala data formats.

tImpalaCreateTable connects to the Impala database to be used and creates an Impala table that is dedicated to data of the format you specify.

**tImpalaCreateTable Standard properties**

These properties are used to configure tImpalaCreateTable running in the Standard Job framework.

The Standard tImpalaCreateTable component belongs to the Big Data family.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-in or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

**Distribution**

Select the cluster you are using from the drop-down list. The options in the list vary depending on the component you are using. Among these options, the following ones requires specific configuration:

- If available in this Distribution drop-down list, the Microsoft HD Insight option allows you to use a Microsoft HD Insight cluster. For this purpose, you need to configure the connections to the HD Insight cluster and the Windows Azure Storage service of that cluster in the areas that are displayed. For detailed explanation about these parameters, search for...
configuring the connection manually on Talend Help Center (https://help.talend.com).

- If you select Amazon EMR, you can find more details about how to configure an Amazon EMR cluster in Talend Help Center (https://help.talend.com).
- The Custom option allows you to connect to a cluster different from any of the distributions given in this list, that is to say, to connect to a cluster not officially supported by Talend.

1. Select Import from existing version to import an officially supported distribution as base and then add other required jar files which the base distribution does not provide.

2. Select Import from zip to import the configuration zip for the custom distribution to be used. This zip file should contain the libraries of the different Hadoop elements and the index file of these libraries.

In Talend Exchange, members of Talend community have shared some ready-for-use configuration zip files which you can download from this Hadoop configuration list and directly use them in your connection accordingly. However, because of the ongoing evolution of the different Hadoop-related projects, you might not be able to find the configuration zip corresponding to your distribution from this list; then it is recommended to use the Import from existing version option to take an existing distribution as base to add the jars required by your distribution.

Note that custom versions are not officially supported by Talend. Talend and its community provide you with the opportunity to connect to custom versions from the Studio but cannot guarantee that the configuration of whichever version you choose will be easy, due to the wide range of different Hadoop distributions and versions that are available. As such, you should only attempt to set up such a connection if you have sufficient Hadoop experience to handle any issues on your own.

Note:
In this dialog box, the active check box must be kept selected so as to import the jar files pertinent to the connection to be created between the custom distribution and this component.

For a step-by-step example about how to connect to a custom distribution and share this connection, see Connecting to a custom Hadoop distribution on page 1569.

<table>
<thead>
<tr>
<th>Impala version</th>
<th>Select the version of the Hadoop distribution you are using. The available options vary depending on the component you are using.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>Database server IP address.</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Fill this field with the name of the database.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data.</td>
</tr>
</tbody>
</table>
| **Use kerberos authentication** | If you are accessing an Impala system running with Kerberos security, select this check box and then enter the Kerberos principal of this Impala system.  
- If this cluster is a MapR cluster of the version 5.0.0 or later, you can set the MapR ticket authentication configuration in addition or as an alternative by following the explanation in Connecting to a security-enabled MapR on page 1629.  
  Keep in mind that this configuration generates a new MapR security ticket for the username defined in the Job in each execution. If you need to reuse an existing ticket issued for the same username, leave both the Force MapR ticket authentication check box and the Use Kerberos authentication check box clear, and then MapR should be able to automatically find that ticket on the fly.  
  This check box is available depending on the Hadoop distribution you are connecting to. |
| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.  
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
- **View schema**: choose this option to view the schema only.  
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.  
- **Built-In**: You create and store the schema locally for this component only.  
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.  
  When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.  
  You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)). |
<p>| <strong>Table Name</strong> | Name of the table to be created. |</p>
<table>
<thead>
<tr>
<th>Action on table</th>
<th>Select the action to be carried out for creating a table.</th>
</tr>
</thead>
</table>
| Format          | Select the data format to which the table to be created is dedicated.  
The available data formats vary depending on the version of the Hadoop distribution you are using.  
Note that when the file format to be used is PARQUET, you might be prompted to find the specific PARQUET jar file and install it into the Studio.  
• When the connection mode to Hive is Embedded, the Job is run in your local machine and calls this jar installed in the Studio.  
• When the connection mode to Hive is Standalone, the Job is run in the server hosting Hive and this jar file is sent to the HDFS system of the cluster you are connecting to. Therefore, ensure that you have properly defined the NameNode URI in the corresponding field of the Basic settings view.  
This jar file can be downloaded from Apache’s site. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |
| Set partitions   | Select this check box to add partition columns to the table to be created. Once selecting it, you need to define the schema of the partition columns you need to add. |
| Set file location| If you want to create an Impala table in a directory other than the default one, select this check box and enter the directory in HDFS you want to use to hold the table content.  
This is typical useful when you need to create an external Impala table by selecting the Create an external table check box in the Advanced settings tab. |
| Use S3 endpoint  | The Use S3 endpoint check box is displayed when you have selected the Set file location check box to create an external Impala table.  
Once this Use S3 endpoint check box is selected, you need to enter the following parameters in the fields that appear:  
• **S3 bucket**: enter the name of the bucket in which you need to create the table.  
• **Bucket name**: enter the name of the bucket in which you want to store the dependencies of your Job. This bucket must already exist on S3.  
• **Temporary resource folder**: enter the directory in which you want to store the dependencies of your Job. For example, enter temp_resources to write the dependencies in the /temp_resources folder in the bucket.  
If this folder already exists at runtime, its contents are overwritten by the upcoming dependencies; otherwise, this folder is automatically created.  
• **Access key** and **Secret key**: enter the authentication information required to connect to the Amazon S3 bucket to be used.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box.
enter the password between double quotes and click OK to save the settings.

Note that the format of the S3 file is S3N (S3 Native Filesystem).

Since an Impala table created in S3 is actually an external table, this **Use S3 endpoint** check box must be used with the [Create an external table](#) case being selected.

### Advanced settings

#### Like table
Select this check box and enter the name of the Impala table you want to copy. This allows you to copy the definition of an existing table without copying its data.

For further information about the Like parameter, see Cloudera’s information about Impala’s Data Definition Language.

#### Create an external table
Select this check box to make the table to be created an external Impala table. This kind of Impala table leaves the raw data where it is if the data is in HDFS.

An external table is usually the better choice for accessing shared data existing in a file system.

For further information about an external Impala table, see Cloudera’s documentation about Impala.

#### Table comment
Enter the description you want to use for the table to be created.

#### As select
Select this check box and enter the **As select** statement for creating an Impala table that is based on a **Select** statement.

#### Table properties
Add any custom Impala table properties you want to override the default ones used by the Hadoop engine of the Studio.

#### tStatCatcher Statistics
Select this check box to collect log data at the component level.

### Global Variables

**Global Variables**

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).
### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component works standalone.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Row format</td>
<td>Set Delimited row format</td>
</tr>
<tr>
<td>Die on error</td>
<td></td>
</tr>
</tbody>
</table>

#### Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

#### Prerequisites

The Hadoop distribution must be properly installed, so as to guarantee the interaction with Talend Studio. The following list presents MapR related information for example:

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR's documentation, the library or libraries of a MapR client corresponding to each OS version can be found under MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native. For example, the library for Windows is \lib\native\MapRClient.dll in the MapR client jar file. For further information, see the following link from MapR: http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr.

Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path.

- Set the -Djava.library.path argument, for example, in the Job Run VM arguments area of the Run/Debug view in the Preferences dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.
Related scenario

This component is used in the similar way as a **HiveCreateTable** component is. For further information, see Creating a partitioned Hive table on page 1571.
**tlmpalaInput**

Executes the select queries to extract the corresponding data and sends the data to the component that follows.

tImpalaInput is the dedicated component to the Impala database (the Impala data warehouse system). It executes the given Impala SQL query in order to extract the data of interest from Impala. It provides the SQLBuilder tool to help you write your Impala SQL statements easily.

**tlmpalaInput Standard properties**

These properties are used to configure tImpalaInput running in the Standard Job framework.

The Standard tImpalaInput component belongs to the Big Data family.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either <strong>Built-in</strong> or <strong>Repository</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Built-in</strong>: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined.

**Note**: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

**Distribution**

Select the cluster you are using from the drop-down list. The options in the list vary depending on the component you are using. Among these options, the following ones requires specific configuration:

- If available in this **Distribution** drop-down list, the **Microsoft HD Insight** option allows you to use a Microsoft HD Insight cluster. For this purpose, you need to configure the connections to the HD Insight cluster.
and the Windows Azure Storage service of that cluster in the areas that are displayed. For detailed explanation about these parameters, search for configuring the connection manually on Talend Help Center (https://help.talend.com).

- If you select Amazon EMR, you can find more details about how to configure an Amazon EMR cluster in Talend Help Center (https://help.talend.com).
- The Custom option allows you to connect to a cluster different from any of the distributions given in this list, that is to say, to connect to a cluster not officially supported by Talend.

1. Select Import from existing version to import an officially supported distribution as base and then add other required jar files which the base distribution does not provide.

2. Select Import from zip to import the configuration zip for the custom distribution to be used. This zip file should contain the libraries of the different Hadoop elements and the index file of these libraries.

In Talend Exchange, members of Talend community have shared some ready-for-use configuration zip files which you can download from this Hadoop configuration list and directly use them in your connection accordingly. However, because of the ongoing evolution of the different Hadoop-related projects, you might not be able to find the configuration zip corresponding to your distribution from this list; then it is recommended to use the Import from existing version option to take an existing distribution as base to add the jars required by your distribution.

Note that custom versions are not officially supported by Talend. Talend and its community provide you with the opportunity to connect to custom versions from the Studio but cannot guarantee that the configuration of whichever version you choose will be easy, due to the wide range of different Hadoop distributions and versions that are available. As such, you should only attempt to set up such a connection if you have sufficient Hadoop experience to handle any issues on your own.

**Note:**
In this dialog box, the active check box must be kept selected so as to import the jar files pertinent to the connection to be created between the custom distribution and this component.

For a step-by-step example about how to connect to a custom distribution and share this connection, see Connecting to a custom Hadoop distribution on page 1569.

<table>
<thead>
<tr>
<th><strong>Impala version</strong></th>
<th>Select the version of the Hadoop distribution you are using. The available options vary depending on the component you are using.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Host</strong></td>
<td>Database server IP address.</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>----------</td>
<td>-----------------------------------</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Fill this field with the name of the database.</td>
</tr>
<tr>
<td><strong>Username</strong></td>
<td>DB user authentication data.</td>
</tr>
</tbody>
</table>
| **Use kerberos authentication** | If you are accessing an Impala system running with Kerberos security, select this check box and then enter the Kerberos principal of this Impala system.  
- If this cluster is a MapR cluster of the version 5.0.0 or later, you can set the MapR ticket authentication configuration in addition or as an alternative by following the explanation in Connecting to a security-enabled MapR on page 1629.  
Keep in mind that this configuration generates a new MapR security ticket for the username defined in the Job in each execution. If you need to reuse an existing ticket issued for the same username, leave both the Force MapR ticket authentication check box and the Use Kerberos authentication check box clear, and then MapR should be able to automatically find that ticket on the fly.  
This check box is available depending on the Hadoop distribution you are connecting to. |
| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.  
Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
- **View schema**: choose this option to view the schema only.  
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.  
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.  
**Built-in**: The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide.  
**Repository**: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide.  
**Table Name** | Name of the table to be processed.  
**Query type** | Either Built-in or Repository.  
**Built-in**: Fill in manually the query statement or build it graphically using SQLBuilder |
**Repository:** Select the relevant query stored in the Repository. The Query field gets accordingly filled in.

<table>

</tr>
</tbody>
</table>
environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

### Prerequisites

The Hadoop distribution must be properly installed, so as to guarantee the interaction with **Talend Studio**. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under `MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native`. For example, the library for Windows is `\lib\native\MapRClient.dll` in the MapR client jar file. For further information, see the following link from MapR: [http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr](http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr).

  Without adding the specified library or libraries, you may encounter the following error: `no MapRClient in java.library.path`.

- Set the `-Djava.library.path` argument, for example, in the **Job Run VM arguments** area of the **Run/Debug** view in the **Preferences** dialog box in the **Window** menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the **Data viewer** to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

### Related scenarios

For a scenario about how an input component is used in a Job, see Writing columns from a MySQL database to an output file using **tMysqlInput** on page 2451.
**tImpalaLoad**

Writes data of different formats into a given Impala table or to export data from an Impala table to a directory.

tImpalaLoad connects to a given Impala database and copies or moves data into an existing Impala table or a directory you specify.

**tImpalaLoad Standard properties**

These properties are used to configure tImpalaLoad running in the Standard Job framework.

The Standard tImpalaLoad component belongs to the Big Data family.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-in or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined.

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see **Talend Studio User Guide**.

**Distribution**

Select the cluster you are using from the drop-down list. The options in the list vary depending on the component you are using. Among these options, the following ones requires specific configuration:

- If available in this **Distribution** drop-down list, the **Microsoft HD Insight** option allows you to use a Microsoft HD Insight cluster. For this purpose, you need to configure the connections to the HD Insight cluster and the Windows Azure Storage service of that
cluster in the areas that are displayed. For detailed explanation about these parameters, search for configuring the connection manually on Talend Help Center (https://help.talend.com).

- If you select Amazon EMR, you can find more details about how to configure an Amazon EMR cluster in Talend Help Center (https://help.talend.com).
- The Custom option allows you to connect to a cluster different from any of the distributions given in this list, that is to say, to connect to a cluster not officially supported by Talend.

1. Select Import from existing version to import an officially supported distribution as base and then add other required jar files which the base distribution does not provide.

2. Select Import from zip to import the configuration zip for the custom distribution to be used. This zip file should contain the libraries of the different Hadoop elements and the index file of these libraries.

In Talend Exchange, members of Talend community have shared some ready-for-use configuration zip files which you can download from this Hadoop configuration list and directly use them in your connection accordingly. However, because of the ongoing evolution of the different Hadoop-related projects, you might not be able to find the configuration zip corresponding to your distribution from this list; then it is recommended to use the Import from existing version option to take an existing distribution as base to add the jars required by your distribution.

Note that custom versions are not officially supported by Talend. Talend and its community provide you with the opportunity to connect to custom versions from the Studio but cannot guarantee that the configuration of whichever version you choose will be easy, due to the wide range of different Hadoop distributions and versions that are available. As such, you should only attempt to set up such a connection if you have sufficient Hadoop experience to handle any issues on your own.

**Note:**

In this dialog box, the active check box must be kept selected so as to import the jar files pertinent to the connection to be created between the custom distribution and this component.

For a step-by-step example about how to connect to a custom distribution and share this connection, see Connecting to a custom Hadoop distribution on page 1569.

<table>
<thead>
<tr>
<th>Impala version</th>
<th>Select the version of the Hadoop distribution you are using. The available options vary depending on the component you are using.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>Database server IP address.</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Fill this field with the name of the database.</td>
</tr>
<tr>
<td>----------</td>
<td>-----------------------------------------------</td>
</tr>
<tr>
<td>Username</td>
<td>DB user authentication data.</td>
</tr>
</tbody>
</table>
| Use kerberos authentication | If you are accessing an Impala system running with Kerberos security, select this check box and then enter the Kerberos principal of this Impala system.  
- If this cluster is a MapR cluster of the version 5.0.0 or later, you can set the MapR ticket authentication configuration in addition or as an alternative by following the explanation in Connecting to a security-enabled MapR on page 1629.  
Keep in mind that this configuration generates a new MapR security ticket for the username defined in the Job in each execution. If you need to reuse an existing ticket issued for the same username, leave both the Force MapR ticket authentication check box and the Use Kerberos authentication check box clear, and then MapR should be able to automatically find that ticket on the fly.  
This check box is available depending on the Hadoop distribution you are connecting to. |
| Load action | Select the action you need to carry for writing data into the specified destination.  
- When you select LOAD, you are moving or copying data from a directory you specify.  
- When you select INSERT, you are moving or copying data based on queries. |
| Target type | This drop-down list appears only when you have selected INSERT from the Load action list.  
Select from this list the type of the location you need to write data in.  
- If you select Table as destination, you can still choose to append data to or overwrite the contents in the specified table. This is the only option in the current release. |
| Action | Select whether you want to OVERWRITE the old data already existing in the destination or only APPEND the new data to the existing one. |
| Table name | Enter the name of the Hive table you need to write data in.  
Note that with the INSERT action, this field is available only when you have selected Table from the Target type list. |
| File path | Enter the directory you need to read data from. |
| Query | This field appears when you have selected INSERT from the Load action list.  
Enter the appropriate query for selecting the data to be exported to the specified Impala table or directory. |
| Set partitions | Select this check box to use the Impala Partition clause in loading or inserting data in a Impala table. You need to enter the partition keys and their values to be used in the field that appears. |
For example, enter `country='US', state='CA'`. This makes a partition clause reading `Partition (country='US', state='CA')`, that is to say, a US and CA partition.

Also, it is recommended to select the **Create partition if not exist** check box that appears to ensure that you will not create a duplicate partition.

<table>

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th><strong>QUERY</strong>: the query statement being processed. This is a Flow variable and it returns a string. <strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see <em>Talend Studio User Guide</em>.</th>
</tr>
</thead>
</table>

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component works standalone.</th>
</tr>
</thead>
</table>

### Dynamic settings

Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see *Reading data from databases through context-based dynamic connections* on page 2457 and *Reading data from different MySQL databases using dynamically loaded connection parameters* on page 491. For more information on **Dynamic**
settings and context variables, see Talend Studio User Guide.

**Prerequisites**

The Hadoop distribution must be properly installed, so as to guarantee the interaction with Talend Studio. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native. For example, the library for Windows is \lib\native\MapRClient.dll in the MapR client jar file. For further information, see the following link from MapR: [http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr](http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr).

Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path.

- Set the -Djava.library.path argument, for example, in the Job Run VM arguments area of the Run/Debug view in the Preferences dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

**Related scenario**

This component is used in the similar way as a tHiveLoad component is. For further information, see Creating a partitioned Hive table on page 1571.
tImpalaOutput

Executes the action defined on the data contained in the table, based on the flow incoming from the preceding component in the Job.

tImpalaOutput connects to an Impala database (the Impala data warehouse system) and writes data in an Impala table.

**tImpalaOutput Standard properties**

These properties are used to configure tImpalaOutput running in the Standard Job framework.

The Standard tImpalaOutput component belongs to the Big Data family.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-in or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

**Use an existing connection**  
Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

**Distribution**  
Select the cluster you are using from the drop-down list. The options in the list vary depending on the component you are using. Among these options, the following ones requires specific configuration:

- If available in this Distribution drop-down list, the Microsoft HD Insight option allows you to use a Microsoft HD Insight cluster. For this purpose, you need to configure the connections to the HD Insight cluster and the Windows Azure Storage service of that
cluster in the areas that are displayed. For detailed explanation about these parameters, search for configuring the connection manually on Talend Help Center (https://help.talend.com).

- If you select Amazon EMR, you can find more details about how to configure an Amazon EMR cluster in Talend Help Center (https://help.talend.com).
- The Custom option allows you to connect to a cluster different from any of the distributions given in this list, that is to say, to connect to a cluster not officially supported by Talend.

1. Select Import from existing version to import an officially supported distribution as base and then add other required jar files which the base distribution does not provide.

2. Select Import from zip to import the configuration zip for the custom distribution to be used. This zip file should contain the libraries of the different Hadoop elements and the index file of these libraries.

In Talend Exchange, members of Talend community have shared some ready-for-use configuration zip files which you can download from this Hadoop configuration list and directly use them in your connection accordingly. However, because of the ongoing evolution of the different Hadoop-related projects, you might not be able to find the configuration zip corresponding to your distribution from this list; then it is recommended to use the Import from existing version option to take an existing distribution as base to add the jars required by your distribution.

Note that custom versions are not officially supported by Talend. Talend and its community provide you with the opportunity to connect to custom versions from the Studio but cannot guarantee that the configuration of whichever version you choose will be easy, due to the wide range of different Hadoop distributions and versions that are available. As such, you should only attempt to set up such a connection if you have sufficient Hadoop experience to handle any issues on your own.

Note: In this dialog box, the active check box must be kept selected so as to import the jar files pertinent to the connection to be created between the custom distribution and this component.

For a step-by-step example about how to connect to a custom distribution and share this connection, see Connecting to a custom Hadoop distribution on page 1569.

<table>
<thead>
<tr>
<th>Impala version</th>
<th>Select the version of the Hadoop distribution you are using. The available options vary depending on the component you are using.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>Database server IP address.</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Fill this field with the name of the database.</td>
</tr>
<tr>
<td><strong>Username</strong></td>
<td>DB user authentication data.</td>
</tr>
</tbody>
</table>
| **Use kerberos authentication** | If you are accessing an Impala system running with Kerberos security, select this check box and then enter the Kerberos principal of this Impala system.  
- If this cluster is a MapR cluster of the version 5.0.0 or later, you can set the MapR ticket authentication configuration in addition or as an alternative by following the explanation in Connecting to a security-enabled MapR on page 1629.  
Keep in mind that this configuration generates a new MapR security ticket for the username defined in the Job in each execution. If you need to reuse an existing ticket issued for the same username, leave both the Force MapR ticket authentication check box and the Use Kerberos authentication check box clear, and then MapR should be able to automatically find that ticket on the fly.  
This check box is available depending on the Hadoop distribution you are connecting to. |
| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.  
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
- **View schema**: choose this option to view the schema only.  
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window. |
| **Built-in** | The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide. |
| **Repository** | The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide. |
| **Table Name** | Name of the table you need to write data in. |
| **Action** | Select whether you want to **OVERWRITE** the old data already existing in the destination or only **APPEND** the new data to the existing one. |
Extended insert

Select this check box to combine multiple rows of data into one single INSERT action. This can speed up the insert operation.

Advanced settings

tStatCatcher Statistics

Select this check box to collect log data at the component level.

Global Variables

Global Variables

ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule

This component offers the benefit of flexible DB queries and covers all possible Impala SQL queries.

Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Prerequisites

The Hadoop distribution must be properly installed, so as to guarantee the interaction with Talend Studio. The following list presents MapR related information for example.
• Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native. For example, the library for Windows is \lib\native\MapRClient.dll in the MapR client jar file. For further information, see the following link from MapR: http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr.

Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path.

• Set the -Djava.library.path argument, for example, in the Job Run VM arguments area of the Run/Debug view in the Preferences dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

**Related scenarios**

For a scenario about how an output component is used in a Job, see Inserting a column and altering data using tMysqlOutput on page 2477.
tImpalaRow

Acts on the actual DB structure or on the data (although without handling data).

The SQLBuilder tool helps you write your Impala SQL statements easily. tImpalaRow is the dedicated component for this database. It executes the Impala SQL query stated in the specified database. The Row suffix means the component implements a flow in the Job design although it does not provide output.

tImpalaRow Standard properties

These properties are used to configure tImpalaRow running in the Standard Job framework.

The Standard tImpalaRow component belongs to the Big Data family.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

Basic settings

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-in or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

Distribution | Select the cluster you are using from the drop-down list. The options in the list vary depending on the component you are using. Among these options, the following ones requires specific configuration:

- If available in this Distribution drop-down list, the Microsoft HD Insight option allows you to use a Microsoft HD Insight cluster. For this purpose, you need to configure the connections to the HD Insight cluster.
and the Windows Azure Storage service of that cluster in the areas that are displayed. For detailed explanation about these parameters, search for configuring the connection manually on Talend Help Center (https://help.talend.com).

- If you select Amazon EMR, you can find more details about how to configure an Amazon EMR cluster in Talend Help Center (https://help.talend.com).
- The Custom option allows you to connect to a cluster different from any of the distributions given in this list, that is to say, to connect to a cluster not officially supported by Talend.

For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Prerequisites

The Hadoop distribution must be properly installed, so as to guarantee the interaction with Talend Studio. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native. For example, the library for Windows is \lib\native\MapRClient.dll in the MapR client jar file. For further information, see the following link from MapR: http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr.

Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path.

- Set the -Djava.library.path argument, for example, in the Job Run VM arguments area of the Run/Debug view in the Preferences dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

Related scenarios

For related topics, see:

- Combining two flows for selective output on page 2514.
• Procedure on page 625.
• Removing and regenerating a MySQL table index on page 2508.
### tInfiniteLoop

Executes a task or a Job automatically, based on a loop.

**tInfiniteLoop runs an infinite loop on a task.**

### tInfiniteLoop Standard properties

These properties are used to configure tInfiniteLoop running in the Standard Job framework.

The Standard tInfiniteLoop component belongs to the Orchestration family.

The component in this framework is available in all Talend products.

#### Basic settings

<table>
<thead>
<tr>
<th>Wait at each iteration (in milliseconds)</th>
<th>Enter the time delay between iterations.</th>
</tr>
</thead>
</table>

#### Advanced settings

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
<th>Select this check box to collect the log data at a component level.</th>
</tr>
</thead>
</table>

#### Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  
|                 | CURRENT_ITERATION: the sequence number of the current iteration. This is a Flow variable and it returns an integer.  
|                 | A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
|                 | To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.  
|                 | For further information about variables, see Talend Studio User Guide. |

#### Usage

**Usage rule**

**tInfiniteLoop** is an input component and requires an Iterate link to connect it to the following component.

**Connections**

Outgoing links (from this component to another):

- **Row**: Iterate

**Trigger**: On Subjob Ok; On Subjob Error; Run if; On Component Ok; On Component Error.

Incoming links (from one component to this one):
Related scenario

For an example of the kind of scenario in which \texttt{tInfiniteLoop} might be used, see Procedure on page 1959, regarding the \texttt{tLoop} component.
tInformixBulkExec

Executes Insert operations in Informix databases.

tInformixOutputBulk and tInformixBulkExec are generally used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tInformixOutputBulkExec component. The advantage of using two components is that data can be transformed before it is loaded in the database.

**tInformixBulkExec Standard properties**

These properties are used to configure tInformixBulkExec running in the Standard Job framework.

The Standard tInformixBulkExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Execution Platform</td>
<td>Select the operating system you are using.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see  *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th><strong>Host</strong></th>
<th>Database server IP address.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Port</strong></td>
<td>DB server listening port.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database.</td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>Name of the schema.</td>
</tr>
</tbody>
</table>
| **Username and Password** | DB user authentication data.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings. |
| **Instance** | Name of the Informix instance to be used. This information can generally be found in the *SQL hosts* file. |
| **Table** | Name of the table to be written. Note that only one table can be written at a time. |
| **Action on table** | On the table defined, you can perform one of the following operations:  
- **None**: No operation is carried out.  
- **Drop and create a table**: The table is removed and created again.  
- **Create a table**: The table does not exist and gets created.  
- **Create a table if not exists**: The table is created if it does not exist.  
- **Drop a table if exists and create**: The table is removed if it already exists and created again.  
- **Clear a table**: The table content is deleted. |
| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word **line** when naming the fields.  
- **Built-In**: You create and store the schema locally for this component only. |
**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Informix Directory**

Informix installation directory, e.g. "C:\Program Files\IBM\IBM Informix Dynamic Server\11.50".

**Data file**

Name of the file to be loaded.

**Action on data**

On the data of the table defined, you can perform the following operations:

- **Insert**: Add new data to the table. If duplicates are found, the job stops.
- **Update**: Update the existing table data.
- **Insert or update**: Insert a new record. If the record with the given reference already exists, an update would be made.
- **Update or insert**: Update the record with the given reference. If the record does not exist, a new record would be inserted.
- **Delete**: Delete the entry data which corresponds to the input flow.

**Warning:**

You must specify at least one key upon which the Update and Delete operations are to be based. It is possible to define the columns which should be used as the key from the schema, from both the **Basic Settings** and the **Advanced Settings**, to optimise these operations.

**Advanced settings**

**Additional JDBC parameters**

Specify additional connection properties for the DB connection you are creating. This option is not available if...
you have selected the **Use an existing connection** check box in the **Basic settings**.

<table>
<thead>
<tr>
<th>Field terminated by</th>
<th>Character, string or regular expression which separates the fields.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Set DBMONEY</strong></td>
<td>Select this check box to define the decimal separator in the <strong>Decimal separator</strong> field.</td>
</tr>
<tr>
<td><strong>Set DBDATE</strong></td>
<td>Select the date format that you want to apply.</td>
</tr>
<tr>
<td><strong>Rows Before Commit</strong></td>
<td>Enter the number of rows to be processed before the commit.</td>
</tr>
<tr>
<td><strong>Bad Rows Before Abort</strong></td>
<td>Enter the number of rows in error at which point the Job should stop.</td>
</tr>
<tr>
<td><strong>tStat Catcher Statistics</strong></td>
<td>Select this check box to collect the log data at component level.</td>
</tr>
<tr>
<td><strong>Output</strong></td>
<td>Where the output should go.</td>
</tr>
</tbody>
</table>

Global Variables

- **NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.
- **NB_LINE_UPDATED**: the number of rows updated. This is an After variable and it returns an integer.
- **NB_LINE_INSERTED**: the number of rows inserted. This is an After variable and it returns an integer.
- **NB_LINE_DELETED**: the number of rows deleted. This is an After variable and it returns an integer.
- **QUERY**: the query statement processed. This is an After variable and it returns a string.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

Usage

- **Usage rule**: This component offers database query flexibility and covers all possible DB2 queries which may be required.

- **Dynamic settings**: Click the [+ ] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned.
in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

| Limitation | The database server/client must be installed on the same machine where the Studio is installed or where the Job using tInformixBulkExec is deployed, so that the component functions properly. This component requires installation of its related jar files. |

**Related scenario**

For a scenario in which tInformixBulkExec might be used, see:

- Inserting transformed data in MySQL database on page 2493.
- Truncating and inserting file data into an Oracle database on page 2700.
tInformixClose

Closes connection to Informix databases.
tInformixClose closes an active connection to a database.

tInformixClose Standard properties

These properties are used to configure tInformixClose running in the Standard Job framework.
The Standard tInformixClose component belongs to the Databases family.
The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related
to database settings vary depending on your database type selection. For more information about
dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>If there is more than one connection used in the Job, select tInformixConnection from the list.</td>
</tr>
</tbody>
</table>

Advanced settings

| tStatCatcher Statistics | Select this check box to collect the log data at a component level. |

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is generally used as an input component. It requires an output component.</th>
</tr>
</thead>
</table>
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |
Related scenario

This component is for use with `tInformixConnection` and `tInformixRollback`. They are generally used along with `tInformixConnection` as the latter allows you to open a connection for the transaction which is underway.

To see a scenario in which `tInformixClose` might be used, see `tMysqlConnection` on page 2436.
tInformixCommit

Makes a global commit just once instead of committing every row or batch of rows separately. This component improves performance and is closely related to tInformixConnection and tInformixRollback. They are generally used to execute transactions together.

tInformixCommit validates data processed in a job from a connected database.

**tInformixCommit Standard properties**

These properties are used to configure tInformixCommit running in the Standard Job framework.

The Standard tInformixCommit component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>If there is more than one connection in the Job, select tInformixConnection from the list.</td>
</tr>
<tr>
<td>Close connection</td>
<td>This check box is selected by default. It means that the database connection will be closed once the commit has been made. Clear the check box to continue using the connection once the component has completed its task.</td>
</tr>
</tbody>
</table>

**Warning:** If you are using a Row > Main type connection to link tInformixCommit to your Job, your data will be committed row by row. If this is the case, do not select this check box otherwise the connection will be closed before the commit of your first row is finalized.

**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect the log data at a component level. |

**Usage**

**Usage rule**

This component is generally used along with Informix components, particularly tInformixConnection and tInformixRollback.

**Dynamic settings**

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database.
InformixCommit

connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

### Related Scenario

This component is for use with tInformixConnection and tInformixRollback. They are generally used along with tInformixConnection as the latter allows you to open a connection for the transaction which is underway.

To see a scenario in which tInformixCommit might be used, see Inserting data in mother/daughter tables on page 2437.
tInformixConnection

Opens a connection to the specified database that can then be reused in the subsequent subjob or subjobs.

tInformixConnection is closely related to tInformixCommit and tInformixRollback. They are generally used along with tInformixConnection, with tInformixConnection opening the connection for the transaction.

**tInformixConnection Standard properties**

These properties are used to configure tInformixConnection running in the Standard Job framework. The Standard tInformixConnection component belongs to the Databases family.
The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Host</td>
<td>Database server IP address.</td>
</tr>
<tr>
<td>Port</td>
<td>DB server listening port.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database.</td>
</tr>
<tr>
<td>Schema</td>
<td>Name of the schema</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td>Instance</td>
<td>Name of the Informix instance to be used. This information can generally be found in the SQL hosts file.</td>
</tr>
<tr>
<td>Additional JDBC parameters</td>
<td>Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the <strong>Use an existing connection</strong> check box in the <strong>Basic settings</strong>.</td>
</tr>
</tbody>
</table>
### Use or register a shared DB Connection

Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the **Shared DB Connection Name** field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child.

This option is incompatible with the **Use dynamic job** and **Use an independent process to run subjob** options of the `tRunJob` component. Using a shared connection together with a `tRunJob` component with either of these two options enabled will cause your Job to fail.

### Advanced settings

#### Use Transaction

Clear this check box when the database is configured in **NO LOG** mode. If the check box is selected, you can choose whether to activate the Auto Commit option.

#### Auto Commit

Select this check box to commit any changes to the database automatically upon the transaction.

With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component.

Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component.

#### tStatCatcher Statistics

Select this check box to collect the log data at a component level.

### Usage

#### Usage rule

This component is generally used with other Informix components, particularly `tInformixCommit` and `tInformixRollback`.

#### Database Family

Databases/Informix

#### Limitation

This component requires installation of its related jar files.

### Related scenario

For a scenario in which the `tInformixConnection` might be used, see Inserting data in mother/daughter tables on page 2437.
**tInformixInput**

Reads a database and extracts fields based on a query.

`tInformixInput` executes a DB query with a strictly defined order which must correspond to the schema definition. Then it passes on the field list to the next component via a Main row link.

**tInformixInput Standard properties**

These properties are used to configure `tInformixInput` running in the Standard Job framework.

The Standard `tInformixInput` component belongs to the Databases family.

The component in this framework is available in all *Talend products*.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <em>Apply</em>.</th>
</tr>
</thead>
<tbody>
<tr>

<tr>
<td>Schema and Edit schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next</td>
</tr>
</tbody>
</table>
component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

| Built-In: You create and store the schema locally for this component only. |
| Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. |

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:
- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Query type** and **Query**
Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE</strong>: the number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>QUERY</strong>: the query statement being processed. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

### Usage

| Usage rule | This component covers all possible SQL queries for DB2 databases. |
| Dynamic settings | Click the **[+]** button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned |
in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>Limitation</th>
<th>This component requires installation of its related jar files.</th>
</tr>
</thead>
</table>

**Related scenarios**

For related topics, see:

See also scenario for **tContextLoad**: Reading data from different MySQL databases using dynamically loaded connection parameters on page 491.
**tInformixOutput**

Executes the action defined on the table and/or on the data contained in the table, based on the flow incoming from the preceding component in the Job.

tInformixOutput writes, updates, makes changes or suppresses entries in a database.

**tInformixOutput Standard properties**

These properties are used to configure tInformixOutput running in the Standard Job framework.

The Standard tInformixOutput component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>![Icon]</td>
<td>Click this icon to open a database connection wizard and store the database connection parameters you set in the component Basic settings view. For more information about setting up and storing database connection parameters, see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th>Host</th>
<th>Database server IP address</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database</td>
</tr>
<tr>
<td>DB server</td>
<td>Name of the database server</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td><strong>Table</strong></td>
<td>Name of the table to be written. Note that only one table can be written at a time</td>
</tr>
</tbody>
</table>
| **Action on table** | On the table defined, you can perform one of the following operations:  

- **None**: No operation is carried out.  
- **Drop and create a table**: The table is removed and created again.  
- **Create a table**: The table does not exist and gets created.  
- **Create a table if not exists**: The table is created if it does not exist.  
- **Drop a table if exists and create**: The table is removed if it already exists and created again.  
- **Clear a table**: The table content is deleted.  
- **Truncate table**: Truncate the table.  

**Warning:**  
A commit operation will be carried out after the table is truncated. |
| **Action on data** | On the data of the table defined, you can perform:  

- **Insert**: Add new entries to the table. If duplicates are found, Job stops.  
- **Update**: Make changes to existing entries |
**Insert or update**: Insert a new record. If the record with the given reference already exists, an update would be made.

**Update or insert**: Update the record with the given reference. If the record does not exist, a new record would be inserted.

**Delete**: Remove entries corresponding to the input flow.

**Warning:**
It is necessary to specify at least one column as a primary key on which the Update and Delete operations are based. You can do that by clicking **Edit Schema** and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the **Advanced settings** view where you can simultaneously define primary keys for the Update and Delete operations. To do that: Select the **Use field options** check box and then in the **Key in update column**, select the check boxes next to the column names you want to use as a base for the Update operation. Do the same in the **Key in delete column** for the Delete operation.

---

**Schema and Edit schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

**Built-In**: You create and store the schema locally for this component only.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Die on error**

This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-
free rows. If needed, you can retrieve the rows on error via a Row > Rejects link.

### Advanced settings

<table>
<thead>
<tr>
<th><strong>Additional JDBC parameters</strong></th>
<th>Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the <strong>Use an existing connection</strong> check box in the Basic settings.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Note:</strong></td>

<td><strong>Position:</strong></td>
<td>Select <strong>Before</strong>, <strong>Replace</strong> or <strong>After</strong> following the action to be performed on the reference column.</td>
</tr>
<tr>
<td><strong>Reference column:</strong></td>
<td>Type in a column of reference that the tDBOutput can use to place or replace the new or altered column.</td>
</tr>
<tr>
<td><strong>Use field options</strong></td>
<td>Select this check box to customize a request, especially when there is double action on data.</td>
</tr>
<tr>
<td><strong>Enable debug mode</strong></td>
<td>Select this check box to display each step during processing entries in a database.</td>
</tr>
<tr>
<td><strong>Use Batch</strong></td>
<td>Select this check box to activate the batch mode for data processing.</td>
</tr>
<tr>
<td><strong>Batch Size</strong></td>
<td>Specify the number of records to be processed in each batch. This field appears only when the <strong>Use batch mode</strong> check box is selected.</td>
</tr>
<tr>
<td><strong>Optimize the batch insertion</strong></td>
<td>Ensure the check box is selected, to optimize the insertion of batches of data.</td>
</tr>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>
## Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE</strong>: the number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_UPDATED</strong>: the number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_INSERTED</strong>: the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_DELETED</strong>: the number of rows deleted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_REJECTED</strong>: the number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>QUERY</strong>: the query statement processed. This is an After variable and it returns a string.</td>
</tr>
<tr>
<td><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

## Usage

### Usage rule

This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible.

This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in an Informix database. It also allows you to create a reject flow using a **Row > Rejects** link to filter data in error. For an example of **tMySqlOutput** in use, see *Retrieving data in error with a Reject link* on page 2485.

### Dynamic settings

Click the **[+]** button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see *Reading data from databases through context-based dynamic connections* on page 2457 and *Reading data from different*
InformixOutput

MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>Limitation</th>
<th>This component requires installation of its related jar files.</th>
</tr>
</thead>
</table>

**Related scenarios**

For **InformixOutput** related topics, see:

- Inserting a column and altering data using **MysqlOutput** on page 2477.
tInformixOutputBulk

Prepares the file to be used as a parameter in the INSERT query used to feed Informix databases.

tInformixOutputBulk and tInformixBulkExec are generally used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tInformixOutputBulkExec component. The advantage of using two components is that data can be transformed before it is loaded in the database.

 Writes a file composed of columns, based on a defined delimiter and on Informix standards.

**tInformixOutputBulk Standard properties**

These properties are used to configure tInformixOutputBulk running in the Standard Job framework. The Standard tInformixOutputBulk component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>File Name</td>
<td>Name of the file to be generated.</td>
</tr>
<tr>
<td>Append</td>
<td>Select this check box to append new rows to the end of the file.</td>
</tr>
<tr>
<td>Schema and Edit schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td>Built-In</td>
<td>You create and store the schema locally for this component only.</td>
</tr>
<tr>
<td>Repository</td>
<td>You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
</tr>
<tr>
<td>When the schema to be reused has default values that are integers or functions, ensure that these default values are</td>
<td></td>
</tr>
</tbody>
</table>
not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

### Advanced settings

<table>

You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</th>
</tr>
</thead>
</table>

### Related scenario

For a scenario in which tInformixOutputBulk might be used, see:

- Inserting transformed data in MySQL database on page 2493.
- Inserting data in bulk in MySQL database on page 2500.
tInformixOutputBulkExec

Carries out Insert operations in Informix databases using the data provided.

$tInformixOutputBulk$ and $tInformixBulkExec$ are generally used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tInformixOutputBulkExec component.

**tInformixOutputBulkExec Standard properties**

These properties are used to configure tInformixOutputBulkExec running in the Standard Job framework.

The Standard tInformixOutputBulkExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property Type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td>Execution platform</td>
<td>Select the operating system you are using.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
<table>
<thead>
<tr>
<th><strong>Host</strong></th>
<th>Database server IP address.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Port</strong></td>
<td>DB server listening port.</td>

<tr>
<td><strong>Database</strong></td>
<td>Name of the database.</td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>Name of the schema.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Instance</strong></td>
<td>Name of the Informix instance to be used. This information can generally be found in the SQL hosts file.</td>
</tr>
<tr>
<td><strong>Table</strong></td>
<td>Name of the table to be written. Note that only one table can be written at a time and the table must already exist for the insert operation to be authorised.</td>
</tr>
</tbody>
</table>
| **Action on table** | On the table defined, you can perform one of the following operations:  
  - **None**: No operation is carried out.  
  - **Drop and create a table**: The table is removed and created again.  
  - **Create a table**: The table does not exist and gets created.  
  - **Create a table if not exists**: The table is created if it does not exist.  
  - **Drop a table if exists and create**: The table is removed if it already exists and created again.  
  - **Clear a table**: The table content is deleted. |
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. 
  
  **Built-In**: You create and store the schema locally for this component only.  
  
  **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. 
  
  When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually. 
  
  You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com). |
| **Click Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available: |
- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

<table>

</tr>
</tbody>
</table>
### Encoding
Select the encoding from the list or select Custom and define it manually. This field is compulsory for DB data handling.

### tStatCatcher Statistics
Select this check box to collect the log data at a component level.

### Output
Where the output should go.

---

**Usage**

### Usage rule
This component is generally used when no particular transformation is required on the data to be inserted in the database.

### Dynamic settings
Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

### Limitation
The database server/client must be installed on the same machine where the Studio is installed or where the Job using tInformixOutputBulkExec is deployed, so that the component functions properly.

---

**Related scenario**

For a scenario in which tInformixOutputBulkExec might be used, see:

- Inserting transformed data in MySQL database on page 2493.
- Inserting data in bulk in MySQL database on page 2500.
tInformixRollback

Prevents involuntary transaction commits by canceling transactions in connected databases.

tInformixRollback is closely related to tInformixCommit and tInformixConnection. They are generally used together to execute transactions.

**tInformixRollback Standard properties**

These properties are used to configure tInformixRollback running in the Standard Job framework.

The Standard tInformixRollback component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Dynamic settings**

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.
For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

**Related Scenario**

For a scenario in which **tInformixRollback** might be used, see Rollback from inserting data in mother/daughter tables on page 2440.
**tInformixRow**

Acts on the actual DB structure or on the data (although without handling data) thanks to the SQLBuilder that helps you write easily your SQL statements.

`tInformixRow` executes the SQL query stated onto the specified database. The Row suffix means the component implements a flow in the job design although it doesn’t provide output.

**tInformixRow Standard properties**

These properties are used to configure `tInformixRow` running in the Standard Job framework.

The Standard `tInformixRow` component belongs to the Databases family.

The component in this framework is available in all *Talend products*.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see *Dynamic database components* on page 598.

**Basic settings**

</tr>
</tbody>
</table>

**Advanced settings**

| **Additional JDBC parameters** | Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the **Use an existing connection** check box in the **Basic settings**. |
| Propagate QUERY's recordset | Select this check box to insert the result of the query into a COLUMN of the current flow. Select this column from the use column list.

**Note:**
This option allows the component to have a different schema from that of the preceding component. Moreover, the column that holds the QUERY's recordset should be set to the type of Object and this component is usually followed by tParseRecordSet. |

| Use PreparedStatement | Select this check box if you want to query the database using a PreparedStatement. In the Set PreparedStatement Parameter table, define the parameters represented by '?' in the SQL instruction of the Query field in the Basic Settings tab.

**Parameter Index:** Enter the parameter position in the SQL instruction.

**Parameter Type:** Enter the parameter type.

**Parameter Value:** Enter the parameter value.

**Note:**
This option is very useful if you need to execute the same query several times. Performance levels are increased |

| Commit every | Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions. |

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

## Global Variables

| Global Variables | **QUERY**: the query statement being processed. This is a Flow variable and it returns a string.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#). |
## Usage

<table>

<td>Name of the schema.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>User authentication information. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td><strong>Instance</strong></td>
<td>Name of the Informix instance to be used. This information can generally be found in the SQL hosts file.</td>
</tr>
<tr>
<td><strong>Table</strong></td>
<td>Name of the table to be created</td>
</tr>
</tbody>
</table>
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word **line** when naming the fields. Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
  - **View schema**: choose this option to view the schema only.  
  - **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
  - **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window. |
| **Built-in**: The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide. |
| **Repository**: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide. |
| **SCD Editor** | The SCD editor helps to build and configure the data flow for slowly changing dimension outputs. For more information, see SCD management methodology on page 2522. |
| **Use memory saving Mode** | Select this check box to improve system performance. |
| **Source keys include Null** | Select this check box to allow the source key columns to have Null values.  
**Warning:** Special attention should be paid to the uniqueness of the source key(s) values when this option is selected.
### Advanced settings

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Use Transaction</strong></td>
<td>Select this check box when the database is configured in NO_LOG mode.</td>
</tr>
<tr>
<td><strong>Die on error</strong></td>
<td>This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.</td>
</tr>
<tr>
<td><strong>End date time details</strong></td>
<td>Specify the time value of the SCD end date time setting in the format of HH:mm:ss. The default value for this field is 12:00:00. This field appears only when SCD Type 2 is used and Fixed year value is selected for creating the SCD end date.</td>
</tr>
<tr>
<td><strong>Debug mode</strong></td>
<td>Select this check box to display each step of the process by which data is written in the database.</td>
</tr>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to collect the log data at a component level.</td>
</tr>
</tbody>
</table>

### Global Variables

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Global Variables</strong></td>
<td></td>
</tr>
<tr>
<td><strong>NB_LINE_UPDATED</strong></td>
<td>the number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_INSERTED</strong></td>
<td>the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_REJECTED</strong></td>
<td>the number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>ERROR_MESSAGE</strong></td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

### Usage

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Usage rule</strong></td>
<td>This component is an output component. Consequently, it requires an input component and a connection of the Row &gt; Main type.</td>
</tr>
<tr>
<td><strong>Dynamic settings</strong></td>
<td>Click the [*] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an</td>
</tr>
</tbody>
</table>
InformixSCD

environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the Component List box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

**Limitation**

| Limitation | This component does not support using SCD type 0 together with other SCD types. |

**Related scenario**

For a scenario in which **tInformixSCD** might be used, see **tMysqlSCD** on page 2519.
tInformixSP

Centralises and calls multiple and complex queries in a database.
tInformixSP calls procedures stored in a database.

**tInformixSP Standard properties**

These properties are used to configure tInformixSP running in the Standard Job framework.
The Standard tInformixSP component belongs to the Databases family.
The component in this framework is available in all Talend products.

*Note:* This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td><strong>Property type</strong></td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in</strong></td>
<td>No properties stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><strong>Use an existing connection</strong></td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

*Note:* When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

**Host** | Database server IP address.  
**Port** | Listening port number of DB server.  
**Database** | Name of the database.
<table>
<thead>
<tr>
<th><strong>Schema</strong></th>
<th>Name of the schema.</th>

<td>Select this check box to collect log data at a component level.</td>
</tr>
</tbody>
</table>

**Usage**

<table>
<thead>
<tr>
<th><strong>Usage rule</strong></th>
<th>This is an intermediary component. It can also be used as an entry component. In this case, only the entry parameters are authorized.</th>
</tr>
</thead>
</table>

**Dynamic settings**

| **Dynamic settings** | Click the [+ ] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.  

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.  

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide. |
|---------------------|-------------------------------------------------------------------------------------------------------------------------|

**Limitation**

| **Limitation** | The stored procedure syntax must correspond to that of the database.  

This component requires installation of its related jar files. |

**Related scenarios**

For related scenarios, see:
• Retrieving personal information using a stored procedure on page 2415.
• Using tMysqlSP to find a State Label using a stored procedure on page 2539.
• Checking number format using a stored procedure on page 2754.
• Executing a stored procedure using tMDMSP on page 2159.

Also, see Inserting data in mother/daughter tables on page 2437 if you want to analyse a set of records in a table or SQL query.
**tIngresBulkExec**

Inserts data in bulk to a table in the Ingres DBMS for performance gain.

tIngresOutputBulk and tIngresBulkExec are generally used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tIngresOutputBulkExec component. The advantage of using two components is that data can be transformed before it is loaded in the database.

**tIngresBulkExec Standard properties**

These properties are used to configure tIngresBulkExec running in the Standard Job framework.

The Standard tIngresBulkExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td><strong>Property type</strong></td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-in:</strong> No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository:</strong> Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><strong>Table</strong></td>
<td>Name of the table to be filled.</td>
</tr>
<tr>
<td><strong>VNode</strong></td>
<td>Name of the virtual node.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database.</td>
</tr>
<tr>
<td><strong>Action on table</strong></td>
<td>Actions that can be taken on the table defined:</td>
</tr>
<tr>
<td></td>
<td><strong>None:</strong> No operation made to the table.</td>
</tr>
<tr>
<td></td>
<td><strong>Truncate:</strong> Delete all the rows in the table and release the file space back to the operating system.</td>
</tr>
<tr>
<td><strong>File name</strong></td>
<td>Name of the file to be loaded.</td>
</tr>
<tr>
<td></td>
<td><strong>Warning:</strong> This file should be located on the same machine as the database server.</td>
</tr>
<tr>
<td><strong>Schema</strong> and <strong>Edit Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next</td>
</tr>
</tbody>
</table>
component. When you create a Spark Job, avoid the reserved word line when naming the fields.

| **Built-In** | You create and store the schema locally for this component only. |
| **Repository** | You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually. You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)). |

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Delete Working Files After Use**

Select this check box to delete the files that are created during the execution.

### Advanced settings

| **Field Separator** | Character, string or regular expression to separate fields. |
| **Row Separator** | String (ex: "\n" on Unix) to separate rows |
| **Null Indicator** | Value of the null indicator. |
| **Session User** | User of the defined session (the connection to the database). |
| **Rollback** | Enable or disable rollback. |
| **On Error** | Policy of error handling:  
- **Continue**: Continue the execution.  
- **Terminate**: Terminate the execution. |
| **Reject Row File** | Path and name of the file that holds the rejected rows. Available when **Continue** is selected from the **On Error** list. |
| **Error Count** | Number of errors to trigger the termination of the execution. |
Table of Features

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Allocation</td>
<td>Number of pages initially allocated to the table or index.</td>
</tr>
<tr>
<td>Extend</td>
<td>Number of pages by which a table or index grows.</td>
</tr>
<tr>
<td>Fill Factor</td>
<td>Specify the percentage (from 1 to 100) of each primary data page that must be filled with rows, under ideal conditions. For example, if you specify a fillfactor of 40, the DBMS Server fills 40% of each of the primary data pages in the restructured table with rows.</td>
</tr>
<tr>
<td>Min Pages/Max Pages</td>
<td>Specify the minimum/maximum number of primary pages a hash table must have. The Min. pages and Max. pages must be at least 1.</td>
</tr>
<tr>
<td>Leaf Fill</td>
<td>A bulk copy from can specify a leaffill value. This clause specifies the percentage (from 1 to 100) of each B-tree leaf page that must be filled with rows during the copy. This clause can be used only on tables with a B-tree storage structure.</td>
</tr>
<tr>
<td>Non Leaf Fill</td>
<td>A bulk copy from can specify a nonleaffill value. This clause specifies the percentage (from 1 to 100) of each B-tree non-leaf index page that must be filled with rows during the copy. This clause can be used only on tables with a B-tree storage structure.</td>
</tr>
<tr>
<td>Row Estimate</td>
<td>Specify the estimated number of rows to be copied from a file to a table during a bulk copy operation.</td>
</tr>
<tr>
<td>Trailing WhiteSpace</td>
<td>Selected by default, this check box is designed to trim the trailing white spaces and applies only to such data types as VARCHAR, NVARCHAR and TEXT.</td>
</tr>
<tr>
<td>Encoding</td>
<td>List of the encoding schemes.</td>
</tr>
<tr>
<td>Output</td>
<td>Where to output the error message:</td>
</tr>
<tr>

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE_DATA</strong></td>
<td>the number of rows read. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_BAD</strong></td>
<td>the number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>ERROR_MESSAGE</strong></td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
</tbody>
</table>
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>Deployed along with <code>tIngresOutputBulk</code>, <code>tIngresBulkExec</code> feeds the given data in bulk to the Ingres database for performance gain.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limitation</td>
<td>The database server/client must be installed on the same machine where the Studio is installed or where the Job using <code>tIngresBulkExec</code> is deployed, so that the component functions properly. Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
</tbody>
</table>

### Related scenarios

For related topics, see:

- Loading data to a table in the Ingres DBMS on page 1754
tIngresClose

Closes the transaction committed in the connected Ingres database.

**tIngresClose Standard properties**

These properties are used to configure `tIngresClose` running in the Standard Job framework.

The Standard `tIngresClose` component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the <code>tIngresConnection</code> component in the list if more than one connection are planned for the current Job.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is to be used along with Ingres components, especially with `tIngresConnection` and `tIngresCommit`. |
| Dynamic settings | Click the **[+]** button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide. |

Related scenarios

No scenario is available for the Standard version of this component yet.
**tIngresCommit**

Commits in one go, using a unique connection, a global transaction instead of doing that on every row or every batch and thus provides gain in performance.

`tIngresCommit` validates the data processed through the Job into the connected database.

**tIngresCommit Standard properties**

These properties are used to configure `tIngresCommit` running in the Standard Job framework. The Standard `tIngresCommit` component belongs to the Databases family. The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the <code>tIngresConnection</code> component in the list if more than one connection are planned for the current Job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Warning:** If you want to use a Row > Main connection to link `tIngresCommit` to your Job, your data will be committed row by row. In this case, do not select the Close connection check box or your connection will be closed before the end of your first row commit.

### Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

### Usage

| Usage rule | This component is more commonly used with other tIngres* components, especially with the `tIngresConnection` and `tIngresRollback` components. |
| Dynamic settings | Click the [+ ] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to acces |
s database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenario

For tIngresCommit related scenario, see Inserting data in mother/daughter tables on page 2437.
tIngresConnection

Opens a connection to the specified database that can then be reused in the subsequent subjob or subjobs.

tIngresConnection opens a connection to the database for a current transaction.

**tIngresConnection Standard properties**

These properties are used to configure tIngresConnection running in the Standard Job framework.

The Standard tIngresConnection component belongs to the Databases and the ELT families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-in:</strong> No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository:</strong> Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Server</td>
<td>Database server IP address.</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td>Use or register a shared DB Connection</td>
<td>Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the <strong>Shared DB Connection Name</strong> field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child.</td>
</tr>
<tr>
<td></td>
<td>This option is incompatible with the <strong>Use dynamic job</strong> and <strong>Use an independent process to run subjob</strong> options of the tRunJob component. Using a shared connection together...</td>
</tr>
</tbody>
</table>
with a **tRunJob** component with either of these two options enabled will cause your Job to fail.

### Advanced settings

| **Auto Commit** | Select this check box to commit any changes to the database automatically upon the transaction. 
With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component. 
Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. 
For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component. |
| **tStatCatcher Statistics** | Select this check box to gather the job processing metadata at a Job level as well as at each component level. |

### Usage

| **Usage rule** | This component is more commonly used with other tIngres* components, especially with the **tIngresCommit** and **tIngresRollback** components. |
| **Limitation** | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |

### Related scenarios

For **tIngresConnection** related scenario, see **Loading data to a table in the Ingres DBMS** on page 1754.
**tIngresInput**

Reads an Ingres database and extracts fields based on a query.

tIngresInput executes a DB query with a strictly defined order which must correspond to the schema definition. Then it passes on the field list to the next component via a Main row link.

**tIngresInput Standard properties**

These properties are used to configure tIngresInput running in the Standard Job framework.

The Standard tIngresInput component belongs to the Databases family.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th><strong>Database</strong></th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Property type</strong></td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td><strong>Built-in</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><img src="image" alt="Icon" /></td>
<td>Click this icon to open a database connection wizard and store the database connection parameters you set in the component Basic settings view. For more information about setting up and storing database connection parameters, see Talend Studio User Guide.</td>
</tr>
<tr>
<td><strong>Use an existing connection</strong></td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>Server</th>
<th>Database server IP address</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-In</strong>: You create and store the schema locally for this component only.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
</tr>
<tr>
<td>Query type and Query</td>
<td>Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.</td>
</tr>
</tbody>
</table>
|         | Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
  • **View schema**: choose this option to view the schema only.  
  • **Change to built-in property**: choose this option to change the schema to Built-in for local changes.  
  • **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |
Advanced settings

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Trim all the String/Char columns</td>
<td>Select this check box to remove leading and trailing whitespace from all the String/Char columns.</td>
</tr>
<tr>
<td>Trim column</td>
<td>Remove leading and trailing whitespace from defined columns.</td>
</tr>
<tr>
<td>tStat Catcher Statistics</td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NB_LINE</td>
<td>the number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>QUERY</td>
<td>the query statement being processed. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td>ERROR_MESSAGE</td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>This component covers all possible SQL queries for Ingres databases.</td>
<td></td>
</tr>
</tbody>
</table>

Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

Related scenarios

For related topics, see:

See also the scenario for tContextLoad: Reading data from different MySQL databases using dynamically loaded connection parameters on page 491.
**tIngresOutput**

Executes the action defined on the table and/or on the data contained in the table, based on the flow incoming from the preceding component in the Job.

tIngresOutput writes, updates, makes changes or suppresses entries in a database.

**tIngresOutput Standard properties**

These properties are used to configure tIngresOutput running in the Standard Job framework.

The Standard tIngresOutput component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

[Icon] Click this icon to open a database connection wizard and store the database connection parameters you set in the component Basic settings view.

For more information about setting up and storing database connection parameters, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
</table>
When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>Host</th>
<th>Database server IP address</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Table</td>
<td>Name of the table to be written. Note that only one table can be written at a time</td>
</tr>
<tr>
<td>Action on table</td>
<td>On the table defined, you can perform one of the following operations: None: No operation is carried out. Drop and create a table: The table is removed and created again. Create a table: The table does not exist and gets created. Create a table if not exists: The table is created if it does not exist. Drop a table if exists and create: The table is removed if it already exists and created again. Clear a table: The table content is deleted.</td>
</tr>
<tr>
<td>Action on data</td>
<td>On the data of the table defined, you can perform: Insert: Add new entries to the table. If duplicates are found, Job stops. Update: Make changes to existing entries Insert or update: Insert a new record. If the record with the given reference already exists, an update would be made. Update or insert: Update the record with the given reference. If the record does not exist, a new record would be inserted. Delete: Remove entries corresponding to the input flow.</td>
</tr>
</tbody>
</table>
### Warning:

It is necessary to specify at least one column as a primary key on which the **Update** and **Delete** operations are based. You can do that by clicking **Edit Schema** and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the **Advanced settings** view where you can simultaneously define primary keys for the **Update** and **Delete** operations. To do that:

- Select the **Use field options** check box and then in the **Key in update column**, select the check boxes next to the column names you want to use as a base for the **Update** operation. Do the same in the **Key in delete column** for the **Delete** operation.

### Schema and Edit Schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

**Built-In**: You create and store the schema locally for this component only.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

### Die on error

This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a **Row > Rejects** link.

### Advanced settings

**Commit every**

Enter the number of rows to be completed before committing batches of rows together into the DB. This
The option ensures transaction quality (but not rollback) and, above all, better performance at execution.

### Additional Columns

This option is not offered if you create (with or without drop) the DB table. This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing.

**Name:** Type in the name of the schema column to be altered or inserted as new column

**SQL expression:** Type in the SQL statement to be executed in order to alter or insert the relevant column data.

**Position:** Select Before, Replace or After following the action to be performed on the reference column.

**Reference column:** Type in a column of reference that the `tDBOutput` can use to place or replace the new or altered column.

### Use field options

Select this check box to customize a request, especially when there is double action on data.

### Enable debug mode

Select this check box to display each step during processing entries in a database.

### Use Batch

Select this check box to activate the batch mode for data processing.

**Note:**
This check box is available only when you have selected the Insert, Update, or Delete option in the Action on data option.

### Batch Size

Specify the number of records to be processed in each batch.
This field appears only when the Use batch mode check box is selected.

### tStat Catcher Statistics

Select this check box to collect log data at the component level.

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_LINE: the number of rows processed. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>NB_LINE_UPDATED: the number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>NB_LINE_INSERTED: the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>NB_LINE_DELETED: the number of rows deleted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>NB_LINE_REJECTED: the number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
</tbody>
</table>
**QUERY:** the query statement processed. This is an After variable and it returns a string.

**ERROR_MESSAGE:** the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

---

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
</tr>
</thead>
<tbody>
<tr>
<td>This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible. This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in an Ingres database. It also allows you to create a reject flow using a Row &gt; Rejects link to filter data in error. For an example of <em>tMySqlOutput</em> in use, see Retrieving data in error with a Reject link on page 2485.</td>
</tr>
</tbody>
</table>

**Related scenarios**

For related topics, see:

- Inserting a column and altering data using *tMysqlOutput* on page 2477.
tIngresOutputBulk

Prepares the file whose data is inserted in bulk to the Ingres DBMS for performance gain.

tIngresOutputBulk and tIngresBulkExec are generally used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tIngresOutputBulkExec component.

tIngresOutputBulk prepares a file with the schema defined and the data coming from the preceding component.

**tIngresOutputBulk Standard properties**

These properties are used to configure tIngresOutputBulk running in the Standard Job framework.
The Standard tIngresOutputBulk component belongs to the Databases family.
The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

### Schema and Edit Schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

- **Built-In**: You create and store the schema locally for this component only.
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

### Delete Working Files After Use

Select this check box to delete the files that are created during the execution.

**Usage**

**Usage rule** Usually deployed along with **tingresConnection** or **tingresRow**, **tingresOutputBulkExec** prepares an output file and feeds its data in bulk to the Ingres DBMS for performance gain.
Loading data to a table in the Ingres DBMS

In this scenario, a `tIngresOutputBulkExec` component is deployed to prepare an output file with the employee data from a .csv file and then use that output file to feed a table in an Ingres database.

Dragging and dropping components

**Procedure**

1. Drop `tIngresConnection`, `tFileInputDelimited` and `tIngresOutputBulkExec` from the Palette onto the workspace.
2. Rename `tIngresOutputBulkExec` as `save_a_copy_and_load_to_DB`.
3. Link `tIngresConnection` to `tFileInputDelimited` using an OnSubjobOk trigger.
4. Link `tFileInputDelimited` to `tIngresOutputBulkExec` using a Row > Main connection.

Configuring the components

**Procedure**

1. Double-click `tIngresConnection` to open its Basic settings view in the Component tab.

   ![tIngresConnection_1](image)

   **Basic settings**
   - **Server**: Enter the address of the server where the Ingres DBMS resides, for example, "localhost".
   - **Username**: Enter the username for the Ingres DBMS.
   - **Password**: Enter the password for the Ingres DBMS.
   - **Use or register a shared DB Connection**: Select this option if using a shared connection.

2. In the **Server** field, enter the address of the server where the Ingres DBMS resides, for example, "localhost".
Keep the default settings of the Port field.

3. In the Database field, enter the name of the Ingres database, for example ‘research’.

4. In the Username and Password fields, enter the authentication credentials.
   A context variable is used for the password here. For more information on context variables, see Talend Studio User Guide.

5. Double-click tFileInputDelimited to open its Basic settings view in the Component tab.

6. Select the source file by clicking the [...] button next to the File name/Stream field.

7. Click the [...] button next to the Edit schema field to open the schema editor.

8. Click the [+ ] button to add four columns, for example name, age, job and dept, with the data type as string, Integer, string and string respectively.
   Click OK to close the schema editor.
   Click Yes on the pop-up window that asks whether to propagate the changes to the subsequent component.
   Leave other default settings unchanged.

9. Double-click tIngresOutputBulkExec to open its Basic settings view in the Component tab.
In the **Table** field, enter the name of the table for data insertion.

11. In the **VNode** and **Database** fields, enter the names of the VNode and the database.

12. In the **File Name** field, enter the full path of the file that will hold the data of the source file.

**Executing the Job**

**Procedure**

1. Press **Ctrl+S** to save the Job.
2. Press **F6** to run the Job.

As shown above, the employee data is written to the table `employee` in the database `research` on the node `talendbj`. Meanwhile, the output file `employee_research.csv` has been generated at `C:/Users/talend/Desktop`.

**Related scenarios**

For related topics, see:

- Inserting a column and altering data using `tMysqlOutput` on page 2477.
tIngresRollback

Avoids to commit part of a transaction involuntarily by canceling the transaction committed in the connected database.

**tIngresRollback Standard properties**

These properties are used to configure tIngresRollback running in the Standard Job framework.

The Standard tIngresRollback component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tIngresConnection component in the list if more than one connection are planned for the current Job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is more commonly used with other tIngres* components, especially with the tIngresConnection and tIngresCommit components. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection |
Related scenarios

For `tingresRollback` related scenario, see Rollback from inserting data in mother/daughter tables on page 2440.
**tIngresRow**

Acts on the actual DB structure or on the data (although without handling data) using the SQLBuilder tool to write easily your SQL statements.

*tIngresRow* executes the SQL query stated onto the specified database. The Row suffix means the component implements a flow in the job design although it doesn’t provide output.

**tIngresRow Standard properties**

These properties are used to configure *tIngresRow* running in the Standard Job framework.

The Standard *tIngresRow* component belongs to the Databases family.

The component in this framework is available in all Talend products.

*Note:* This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
<tr>
<td><strong>Property type</strong></td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td><strong>Built-in</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><strong>Use an existing connection</strong></td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td><strong>Note:</strong></td>
<td>When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:</td>
</tr>
<tr>
<td><strong>1.</strong></td>
<td>In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.</td>
</tr>
<tr>
<td><strong>2.</strong></td>
<td>In the child level, use a dedicated connection component to read that registered database connection.</td>
</tr>
<tr>
<td><strong>Note:</strong></td>
<td>For an example about how to share a database connection across Job levels, see Talend Studio User Guide.</td>
</tr>
<tr>
<td><strong>Host</strong></td>
<td>Database server IP address.</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database</td>
</tr>
<tr>
<td>---</td>
<td>---</td>
</tr>
</tbody>
</table>
| **Username and Password** | DB user authentication data.  
To enter the password, click the [ ] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. |
| **Built-In** | You create and store the schema locally for this component only. |
| **Repository** | You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. |
| **Query type** | Either Built-in or Repository. |
| **Built-in** | Fill in manually the query statement or build it graphically using SQLBuilder |
| **Repository** | Select the relevant query stored in the Repository. The Query field gets accordingly filled in. |
| **Query** | Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition. |
| **Die on error** | This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a Row > Rejects link. |

**Advanced Settings**

| **Propagate QUERY’s recordset** | Select this check box to insert the result of the query into a COLUMN of the current flow. Select this column from the use column list. |
Use PreparedStatement

Select this check box if you want to query the database using a PreparedStatement. In the Set PreparedStatement Parameter table, define the parameters represented by "?" in the SQL instruction of the Query field in the Basic Settings tab.

Parameter Index: Enter the parameter position in the SQL instruction.

Parameter Type: Enter the parameter type.

Parameter Value: Enter the parameter value.

Note:
This option is very useful if you need to execute the same query several times. Performance levels are increased.

Commit every

Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions.

tStat Catcher Statistics

Select this check box to collect log data at the component level.

Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>QUERY: the query statement being processed. This is a Flow variable and it returns a string.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td></td>
<td>For further information about variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component offers the flexibility of the DB query and covers all possible SQL queries.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limitation</td>
<td>Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
</tbody>
</table>
Related scenarios

For related topics, see:

• Procedure on page 625.
• Removing and regenerating a MySQL table index on page 2508.
**tIngresSCD**

Reflects and tracks changes in a dedicated Ingres SCD table. 

**tIngresSCD** addresses Slowly Changing Dimension needs, reading regularly a source of data and logging the changes into a dedicated SCD table.

**tIngresSCD Standard properties**

These properties are used to configure **tIngresSCD** running in the Standard Job framework. 

The Standard **tIngresSCD** component belongs to the Business Intelligence and the Databases families. 

The component in this framework is available in all **Talend products**.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.

2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either <strong>Built-in</strong> or <strong>Repository</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-in</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the Repository file where properties are stored. The fields to follow are pre-filled in using fetched data.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Server</th>
<th>Database server IP address.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td><strong>Table</strong></td>
<td>Name of the table to be written. Note that only one table can be written at a time.</td>
</tr>
</tbody>
</table>
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word **line** when naming the fields. Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
  • **View schema**: choose this option to view the schema only.  
  • **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
  • **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window. |
| **SCD Editor** | The SCD editor helps to build and configure the data flow for slowly changing dimension outputs. For more information, see **SCD management methodology** on page 2522. |
| **Use memory saving Mode** | Select this check box to maximize system performance. |
| **Source keys include Null** | Select this check box to allow the source key columns to have Null values.  
  **Warning**: Special attention should be paid to the uniqueness of the source key(s) values when this option is selected. |
| **Die on error** | This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows. |
## Advanced settings

<table>
<thead>
<tr>
<th><strong>End date time details</strong></th>
<th>Specify the time value of the SCD end date time setting in the format of HH:mm:ss. The default value for this field is 12:00:00. This field appears only when SCD Type 2 is used and <strong>Fixed year value</strong> is selected for creating the SCD end date.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Debug mode</strong></td>
<td>Select this check box to display each step during processing entries in a database.</td>

<tr>
<td><strong>Limitation</strong></td>
<td>This component does not support using SCD type 0 together with other SCD types.</td>
</tr>
</tbody>
</table>

## Related scenario

For related scenarios, see [tMysqlSCD on page 2519](#).
tInterbaseClose

Closes the transaction committed in the connected Interbase database.

**tInterbaseClose Standard properties**

These properties are used to configure tInterbaseClose running in the Standard Job framework.

The Standard tInterbaseClose component belongs to the Databases family.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tInterbaseConnection component in the list if more than one connection are planned for the current Job.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is to be used along with Interbase components, especially with tInterbaseConnection and tInterbaseCommit. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |
Related scenarios

No scenario is available for the Standard version of this component yet.
**tInterbaseCommit**

Commits in one go a global transaction instead of doing that on every row or every batch and thus provides gain in performance.

*tInterbaseCommit* validates the data processed through the Job into the connected DB.

**tInterbaseCommit Standard properties**

These properties are used to configure *tInterbaseCommit* running in the Standard Job framework.

The *Standard tInterbaseCommit* component belongs to the Databases family.

The component in this framework is available in all *Talend products*.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the <em>tInterbaseConnection</em> component in the list if more than one connection are planned for the current Job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Warning:**

*If you want to use a Row > Main connection to link *tInterbaseCommit* to your Job, your data will be committed row by row. In this case, do not select the Close connection check box or your connection will be closed before the end of your first row commit.*

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is more commonly used with other tInterbase” components, especially with the *tInterbaseConnection* and *tInterbaseRollback* components. |
| Dynamic settings | Click the [*] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an... |
environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

---

**Related scenario**

For **tlInterbaseCommit** related scenario, see Inserting data in mother/daughter tables on page 2437.
**tInterbaseConnection**

Opens a connection to the specified database that can then be reused in the subsequent subjob or subjobs.

*tInterbaseConnection* opens a connection to the database for a current transaction.

**tInterbaseConnection Standard properties**

These properties are used to configure *tInterbaseConnection* running in the Standard Job framework.

The Standard *tInterbaseConnection* component belongs to the Databases and the ELT families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

| Host name | Database server IP address. |
| Database | Name of the database. |

| Username and Password | DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |

| Use or register a shared DB Connection | Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the Shared DB Connection Name field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child. This option is incompatible with the Use dynamic job and Use an independent process to run subjob options of the tRunJob component. Using a shared connection together with a tRunJob component with either of these two options enabled will cause your Job to fail. |
## Advanced settings

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Auto Commit</strong></td>
<td>Select this check box to commit any changes to the database automatically upon the transaction. With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component. Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component.</td>
</tr>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to gather the job processing metadata at a Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

## Usage

<table>

Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th>Host</th>
<th>Database server IP address</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Name of the database</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td>Table</td>
<td>Name of the table to be written. Note that only one table can be written at a time</td>
</tr>
<tr>
<td><strong>Action on table</strong></td>
<td>On the table defined, you can perform one of the following operations:</td>
</tr>
<tr>
<td></td>
<td><strong>None</strong>: No operation is carried out.</td>
</tr>
<tr>
<td></td>
<td><strong>Drop and create a table</strong>: The table is removed and created again.</td>
</tr>
<tr>
<td></td>
<td><strong>Create a table</strong>: The table does not exist and gets created.</td>
</tr>
<tr>
<td></td>
<td><strong>Create a table if not exists</strong>: The table is created if it does not exist.</td>
</tr>
<tr>
<td></td>
<td><strong>Drop table if exists and create</strong>: The table is removed if it already exists and created again.</td>
</tr>
<tr>
<td></td>
<td><strong>Clear a table</strong>: The table content is deleted.</td>
</tr>
<tr>
<td><strong>Action on data</strong></td>
<td>On the data of the table defined, you can perform:</td>
</tr>
<tr>
<td></td>
<td><strong>Insert</strong>: Add new entries to the table. If duplicates are found, Job stops.</td>
</tr>
<tr>
<td></td>
<td><strong>Update</strong>: Make changes to existing entries</td>
</tr>
<tr>
<td></td>
<td><strong>Insert or update</strong>: Insert a new record. If the record with the given reference already exists, an update would be made.</td>
</tr>
<tr>
<td></td>
<td><strong>Update or insert</strong>: Update the record with the given reference. If the record does not exist, a new record would be inserted.</td>
</tr>
<tr>
<td></td>
<td><strong>Delete</strong>: Remove entries corresponding to the input flow.</td>
</tr>
</tbody>
</table>
**Warning:**

It is necessary to specify at least one column as a primary key on which the *Update* and *Delete* operations are based. You can do that by clicking *Edit Schema* and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the *Advanced settings* view where you can simultaneously define primary keys for the *Update* and *Delete* operations. To do that:

1. Select the *Use field options* check box and then in the *Key in update column*, select the check boxes next to the column names you want to use as a base for the *Update* operation. Do the same in the *Key in delete column* for the *Delete* operation.

</table>

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE</strong></td>
<td>the number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_UPDATED</strong></td>
<td>the number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_INSERTED</strong></td>
<td>the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
</tbody>
</table>
**NB_LINE_DELETED**: the number of rows deleted. This is an After variable and it returns an integer.

**NB_LINE_REJECTED**: the number of rows rejected. This is an After variable and it returns an integer.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

---

## Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
</tr>
</thead>
<tbody>
<tr>
<td>This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible. This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in an Interbase database. It also allows you to create a reject flow using a <strong>Row &gt; Rejects</strong> link to filter data in error. For an example of <strong>tMySqlOutput</strong> in use, see <em>Retrieving data in error with a Reject link</em> on page 2485.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Dynamic settings</th>
</tr>
</thead>
<tbody>
<tr>
<td>Click the [*] button to add a row in the table and fill the <strong>Code</strong> field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.</td>
</tr>
</tbody>
</table>

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see *Reading data from databases through context-based dynamic connections* on page 2457 and *Reading data from different MySQL databases using dynamically loaded connection parameters* on page 491. For more information on **Dynamic settings** and context variables, see *Talend Studio User Guide*. |

## Limitation

This component requires installation of its related jar files.
Related scenarios

For related topics, see

- Inserting a column and altering data using tMysqlOutput on page 2477.
**tlInterbaseRollback**

Avoids to commit part of a transaction involuntarily by canceling the transaction committed in the connected Interbase database.

**tlInterbaseRollback Standard properties**

These properties are used to configure tlInterbaseRollback running in the Standard Job framework.

The Standard tlInterbaseRollback component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tlInterbaseConnection component in the list if more than one connection are planned for the current Job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is more commonly used with other tlInterbase* components, especially with the tlInterbaseConnection and tlInterbaseCommit components. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection. |
**Related scenarios**

For **tInterbaseRollback** related scenario, see *Rollback from inserting data in mother/daughter tables* on page 2440.
**tInterbaseRow**

Acts on the actual database structure or on the data (although without handling data) using the SQLBuilder tool to write easily your SQL statements.

tInterbaseRow executes the SQL query stated onto the specified database. The Row suffix means the component implements a flow in the job design although it does not provide output.

**tInterbaseRow Standard properties**

These properties are used to configure tInterbaseRow running in the Standard Job framework.

The Standard tInterbaseRow component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-in:</strong> No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository:</strong> Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>Database server IP address</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database</td>
</tr>
</tbody>
</table>
**Username and Password**

DB user authentication data.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

---

**Schema and Edit Schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

**Built-in**: The schema is created and stored locally for this component only. Related topic: see *Talend Studio User Guide*.

**Repository**: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see *Talend Studio User Guide*.

---

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

---

**Query type**

Either **Built-in** or **Repository**.

**Built-in**: Fill in manually the query statement or build it graphically using SQLBuilder.

**Repository**: Select the relevant query stored in the Repository. The **Query** field gets accordingly filled in.

---

**Query**

Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.

---

**Die on error**

This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a **Row > Rejects** link.

---

**Advanced settings**

**Propagate QUERY’s recordset**

Select this check box to insert the result of the query into a **COLUMN** of the current flow. Select this column from the **use column** list.
**Use PreparedStatement**

Select this check box if you want to query the database using a PreparedStatement. In the Set PreparedStatement Parameter table, define the parameters represented by "?" in the SQL instruction of the Query field in the Basic Settings tab.

**Parameter Index**: Enter the parameter position in the SQL instruction.

**Parameter Type**: Enter the parameter type.

**Parameter Value**: Enter the parameter value.

**Note**: This option is very useful if you need to execute the same query several times. Performance levels are increased.

**Commit every**

Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions.

**tStat Catcher Statistics**

Select this check box to collect log data at the component level.

**Global Variables**

**Global Variables**

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>QUERY</td>
<td>the query statement being processed. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td>ERROR_MESSAGE</td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

**Usage**

**Usage rule**

This component offers the flexibility of the DB query and covers all possible SQL queries.
Dynamic settings

Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see **Reading data from databases through context-based dynamic connections** on page 2457 and **Reading data from different MySQL databases using dynamically loaded connection parameters** on page 491. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

**Limitation**

This component requires installation of its related jar files.

---

**Related scenarios**

For related scenarios, see:

- **Combining two flows for selective output** on page 2514
- For **tDBSQLRow** related scenario: see **Procedure** on page 625
- For **tMySQLRow** related scenario: see **Removing and regenerating a MySQL table index** on page 2508.
**tIntervalMatch**

Returns a value based on a Join relation.

tIntervalMatch receives a main flow and aggregates it based on join to a lookup flow. Then it matches a specified value to a range of values and returns related information.

**tIntervalMatch Standard properties**

These properties are used to configure tIntervalMatch running in the Standard Job framework.

The Standard tIntervalMatch component belongs to the Data Quality family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th><strong>Schema and Edit schema</strong></th>
<th>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-in</strong></td>
<td>The schema will be created and stored locally for this component only. Related topic: see Talend Studio User Guide.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>The schema already exists and is stored in the Repository, hence can be reused in various projects and job flowcharts. Related topic: see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Search Column**

Select the main flow column containing the values to be matched with a range of values.

**Column (LOOKUP)**

Select the lookup flow column containing the values to be returned when the Join is ok.

**Lookup Column (min) / Include the bound (min)**

Select the column containing the minimum value of the range. Select the check box to include the minimum value of the range in the match.
**Lookup Column (max) / Include the bound (max)**

Select the column containing the maximum value of the range. Select the check box to include the maximum value of the range in the match.

---

**Advanced settings**

**tStat Catcher Statistics**

Select this check box to collect log data at the component level.

---

**Global Variables**

**Global Variables**

**NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see **Talend Studio User Guide**.

---

**Usage**

**Usage rule**

This component handles flow of data therefore it requires input and output, hence is defined as an intermediary step.

---

**Identifying server locations based on their IP addresses**

This scenario describes a four-component Job that checks the server IP addresses listed in the main input file against a list of IP ranges given in a lookup file to identify the hosting country for each server.
Setting up the Job

About this task

The Job requires two `tFileInputDelimited` components, a `tIntervalMatch` component and a `tLogRow` component.

Procedure

1. Drop the components onto the design workspace.
2. Connect the components using **Row > Main** connection.
   
   Note that the connection from the second `tFileInputDelimited` component to the `tIntervalMatch` component will appear as a Lookup connection.

Configuring the components

Procedure

1. Double-click the first `tFileInputDelimited` component to open its **Basic settings** view.

   ![tFileInputDelimited_1](image)

   - **Property Type**: Built-In
   - **File name/Stream**: `D:/Talend/Input/servers.txt`
   - **Row Separator**: `\n`
   - **Header**: 1
   - **Schema**: Built-In
   - **Skip empty rows**: checked
   - **Uncompress as zip file**: unchecked
   - **Die on error**: unchecked

2. Browse to the file to be used as the main input, which provides a list of servers and their IP addresses:

<table>
<thead>
<tr>
<th>Server</th>
<th>IP</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server1</td>
<td>057.010.010.010</td>
</tr>
<tr>
<td>Server2</td>
<td>001.010.010.100</td>
</tr>
<tr>
<td>Server3</td>
<td>057.030.030.030</td>
</tr>
<tr>
<td>Server4</td>
<td>053.010.010.100</td>
</tr>
</tbody>
</table>

3. Click the `[...]` button next to **Edit schema** to open the **Schema** dialog box and define the input schema. According to the input file structure, the schema is made of two columns, respectively **Server** and **IP**, both of type **String**. Then click **OK** to close the dialog box.
4. Define the number of header rows to be skipped, and keep the other settings as they are.
5. Define the properties of the second `tFileInputDelimited` component similarly.

The file to be used as the input to the lookup flow in this example lists some IP address ranges and the corresponding countries:

<table>
<thead>
<tr>
<th>StartIP;EndIP;Country</th>
</tr>
</thead>
<tbody>
<tr>
<td>001.000.000.000;001.255.255.255;USA</td>
</tr>
<tr>
<td>002.006.190.056;002.006.190.063;UK</td>
</tr>
<tr>
<td>011.000.000.000;011.255.255.255;USA</td>
</tr>
<tr>
<td>057.000.000.000;057.255.255.255;France</td>
</tr>
<tr>
<td>012.063.178.060;012.063.178.063;Canada</td>
</tr>
<tr>
<td>053.000.000.000;053.255.255.255;Germany</td>
</tr>
</tbody>
</table>

Accordingly, the schema of the lookup flow should have the following structure:
6. Double-click the **tIntervalMatch** component to open its **Basic settings** view.

7. From the **Search Column** list, select the main flow column containing the values to be matched with the range values. In this example, we want to match the servers' IP addresses with the range values from the lookup flow.

8. From the **Column (LOOKUP)** list, select the lookup column that holds the values to be returned. In this example, we want to get the names of countries where the servers are hosted.

9. Set the min and max lookup columns corresponding to the range bounds defined in the lookup schema, **StartIP** and **EndIP** respectively in this example.

### Executing the Job

**Procedure**

Press **Ctrl+S** to save your Job and press **F6** to run it.

The name of the country where each server is hosted is displayed next to the IP address.

```plaintext
[statistics] connecting to socket on port 3452
[statistics] connected
Server1 057.010.010.010 | France
Server2 091.010.010.100 | USA
Server3 057.030.030.030 | France
Server4 053.010.010.100 | Germany
[statistics] disconnected
```
**tlIterateToFlo**

Transforms non processable data into a processable flow. tlIterateToFlo transforms a list into a data flow that can be processed.

**tlIterateToFlo Standard properties**

These properties are used to configure tlIterateToFlo running in the Standard Job framework.

The Standard tlIterateToFlo component belongs to the Orchestration family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Schema and Edit Schema</th>
<th>A schema is a row description, it defines the number of fields that will be processed and passed on to the next component. The schema is either Built-in or remote in the Repository. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available: • View schema: choose this option to view the schema only. • Change to built-in property: choose this option to change the schema to Built-in for local changes. • Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Built-in</td>
<td>The schema will be created and stored locally for this component only. Related topic: see Talend Studio User Guide.</td>
</tr>
<tr>

<td>The schema already exists and is stored in the Repository, hence can be reused in various projects and Job designs. Related topic: see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Mapping</td>
<td>Column: Enter a name for the column to be created Value: Press Ctrl+Space to access all of the available variables, be they global or user-defined.</td>
</tr>
</tbody>
</table>

**Advanced Settings**

| tStatCatcher Statistics | Select this check box to collect the log data at a component level. |
Global Variables

**Global Variables**

- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

  - A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

  - To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

  - For further information about variables, see [Talend Studio User Guide](#).

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is not startable (green background) and it requires an output component.</th>
</tr>
</thead>
</table>

Connections

- Outgoing links (from this component to another):
  - **Row**: Main.
  - **Trigger**: Run if; On Component Ok; On Component Error.

- Incoming links (from one component to this one):
  - **Row**: Iterate;

- For further information regarding connections, see [Talend Studio User Guide](#).

Transforming a list of files as data flow

The following scenario describes a Job that iterates on a list of files, picks up the filename and current date and transforms this into a flow, that gets displayed on the console.

- Drop the following components: **tFileList**, **tIterateToFlow** and **tLogRow** from the Palette to the design workspace.

- Connect the **tFileList** to the **tIterateToFlow** using an iterate link and connect the Job to the **tLogRow** using a Row main connection.

- In the **tFileList Component** view, set the directory where the list of files is stored.
In this example, the files are three simple .txt files held in one directory: Countries.

No need to care about the case, hence clear the Case sensitive check box.

Leave the Include Subdirectories check box unchecked.

Then select the tIterateToFlow component and click Edit Schema to set the new schema.

Add two new columns: Filename of String type and Date of date type. Make sure you define the correct pattern in Java.

Click OK to validate.

Notice that the newly created schema shows on the Mapping table.

In each cell of the Value field, press Ctrl+Space bar to access the list of global and user-specific variables.

For the Filename column, use the global variable: tFileList_1_CURRENT_FILEPATH. It retrieves the current filepath in order to catch the name of each file, the Job iterates on.

For the Date column, use the Talend routine: Talend Date.getCurrentDate() (in Java)

Then on the tLogRow component view, select the Print values in cells of a table check box.

Save your Job and press F6 to execute it.
Starting job tIterateToFlow at 10:28 10/03/2010.

[statistics] disconnected
Job tIterateToFlow ended at 10:28 10/03/2010. [exit code=0]

The filepath displays on the *Filename* column and the current date displays on the *Date* column.
**tJasperOutput**

Creates a report in rich formats using Jaspersoft’s iReport.

This component is closely related to Jaspersoft’s report designer -- iReport. It reads and processes data from an input flow to create a report against a .jrxml report template defined via iReport. tJasperOutput reads and processes data from an input flow to create a report against a .jrxml report template defined via iReport.

**tJasperOutput Standard properties**

These properties are used to configure tJasperOutput running in the Standard Job framework.

The Standard tJasperOutput component belongs to the Business Intelligence family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Temp path</td>
<td>Path of temporary files.</td>
</tr>
<tr>
<td>Destination path</td>
<td>Path of the final report file.</td>
</tr>
<tr>
<td>File name/Stream</td>
<td>Name of the final report.</td>
</tr>
<tr>
<td>Report type</td>
<td>File type of the final report.</td>
</tr>
</tbody>
</table>

**Schema and Edit schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `LINE` when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Built-in</td>
<td>The schema is created and stored locally for this component only. Related topic: see the Talend Studio User Guide.</td>
</tr>
<tr>
<td>Repository</td>
<td>The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>
### Sync columns

Click to synchronize the output file schema with the input file schema. The Sync function only displays once the Row connection is linked with the output component.

### iReport

Edit the command to provide the path of iReport's execution file, e.g. replacing __IREPORT_PATH__ with E:\Program Files\Jaspersoft\iReport-4.1.1\bin\, or giving the full path of the execution file such as 'E:\Program Files\Jaspersoft\iReport-4.1.1\bin\Report.exe'.

### Launch

Click to run iReport.

### Advanced settings

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

| Specify Locale | Select this check box to choose a locale from the Report Locale list. |

**Note:**
The first line of the Report Locale list is empty. You can click it to customize a locale.

| Encoding | Select an encoding mode from this list. You can select Custom from the list to enter an encoding method in the field that appears. |

### Global Variables

| Global Variables | **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.  

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.  

For further information about variables, see Talend Studio User Guide. |

### Usage

| Usage rule | This component is closely related to Jaspersoft's report designer -- iReport. It reads and processes data from an input flow to create a report against a .jrxml report template defined via iReport. |
Generating a report against a .jrxml template

The following Job reads data from a .csv file and creates a .pdf report based on an existing .jrxml report template. Note that the template file should be created via Jaspersoft's iReport based on a file that shares the same schema with the source .csv file of this job.

Setting up the Job

Procedure

1. Drag and drop the following components from the Palette to the workspace: tFileInputDelimited and tJasperOutput.
2. Connect tFileInputDelimited and tJasperOutput using a Row link.

Configuring the input component

Procedure

1. Double-click the tFileInputDelimited component to display its Basic settings view.
2. Select Built-In from the Property Type drop-down list.

Note:

You can select Repository from the Property Type drop-down list to fill in the relevant fields automatically if the relevant metadata has been stored locally in the Repository. For more information about Metadata, see the Talend Studio User Guide.

3. Fill in the File name/Stream field to give the path and name of the source file, e.g. "C:/Documents and Settings/Andy ZHANG/nom.csv".
4. Keep the default settings for the Row Separator and Field Separator fields. You can also change them as needed.
5. Set 1 in the **Header** field and 0 in the **Footer** field. Leave the **Limit** field empty. You can also change them as needed.

6. Select **Built-In** from the **Schema** drop-down list and click **Edit schema** to define the data structure of the input file. In this case, the input file has 2 columns: *Nom* and *Prenom*.

![Schema ofFieldInputDelimited_1](image)

### Configuring the output component

**Procedure**

1. Double-click **tJasperOutput** to display its **Basic settings** view.

![tJasperOutput_1](image)

2. Enter the full path of the report template file created via Jaspersoft's iReport in the **Jrxml file** field. You can click the three-dot button to browse.

**Note:**

The schema of the file, which is used to create a .jrxml template file via iReport, should be the same as that of the source file that is used to create the report.

3. Enter the path for the temporary files generated during the job execution in the **Temp path** field. You can click the three-dot button to browse.

4. Enter the path for the final report file generated during the job execution in the **Destination path** field. You can click the three-dot button to browse.

5. Enter the name for the final report file generated during the job execution in the **File name/Stream** field.

6. Select the format for the final report file generated during the job execution in the **Report type** field.

7. Click **Sync columns** to retrieve the schema from the previous component.
8. Enter the path of execution file of Jaspersoft’s iReport in the iReport field, e.g. replacing __IREPORT_PATH__ with E:\Program Files\Jaspersoft\iReport-4.1.1\bin\ You can click the Launch button to run iReport.

Note:
This step is not mandatory. Yet, this helps you conveniently access the iReport software for relevant operations, e.g. creating a report template, etc.

Job execution

Procedure
1. Press CTRL+S to save your Job.
2. Press F6 to execute it.
   You can find the file out.pdf in the folder specified in the Destination path field.
**tJasperOutputExec**

Creates a report in rich formats using Jaspersoft’s iReport and offers a performance gain as it functions as a combination of an input component and a tJasperOutput component.

This component is closely related to Jaspersoft’s report designer -- iReport. It reads and processes data from a source file to create a report against a .jrxml report template defined via iReport. tJasperOutputExec is used as a combination of an input component and a tJasperOutput component. The advantage of using two separate components is that data can be transformed before being used to generate a report and the input sources can be various and rich.

Reads and processes data from a source file to create a report against a .jrxml report template defined via iReport.

**tJasperOutputExec Standard properties**

These properties are used to configure tJasperOutputExec running in the Standard Job framework.

The Standard tJasperOutputExec component belongs to the Business Intelligence family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>

Related Scenario

For related scenarios, see Generating a report against a .jrxml template on page 1799.
tJava

Extends the functionalities of a Talend Job using custom Java commands.

tJava enables you to enter personalized code in order to integrate it in Talend program. You can execute this code only once.

**tJava Standard properties**

These properties are used to configure tJava running in the Standard Job framework.
The Standard tJava component belongs to the Custom Code family.
The component in this framework is available in all Talend products.

**Basic settings**

| Code | Type in the Java code you want to execute according to the task you need to perform. For further information about Java functions syntax specific to Talend, see Talend Studio Help Contents (Help > Developer Guide > API Reference). For a complete Java reference, check http://docs.oracle.com/javaee/6/api/ |

---

**Advanced settings**

| Import | Enter the Java code to import, if necessary, external libraries used in the Code field of the Basic settings view. |

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

**Global Variables**

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. |

Note: If your custom Java code references org.talend.transform.runtime.api.ExecutionStatus, change it to org.talend.transform.runtime.common.MapExecutionStatus.
Printing out a variable content

The following scenario is a simple demo of the extended application of the `tJava` component. The Job aims at printing out the number of lines being processed using a Java command and the global variable provided in `Talend Studio`.

Setting up the Job

Procedure

1. Select and drop the following components from the Palette onto the design workspace: `tFileInputDelimited`, `tFileOutputExcel`, `tJava`.
2. Connect the `tFileInputDelimited` to the `tFileOutputExcel` using a Row Main connection. The content from a delimited txt file will be passed on through the connection to an xls-type of file without further transformation.
3. Then connect the `tFileInputDelimited` component to the `tJava` component using a Trigger > On Subjob Ok link. This link sets a sequence ordering `tJava` to be executed at the end of the main process.

Configuring the input component

Procedure

1. Set the Basic settings of the `tFileInputDelimited` component.
2. Define the path to the input file in the **File name** field.
   The input file used in this example is a simple text file made of two columns: *Names* and their respective *Emails*.

3. Click the **Edit Schema** button, and set the two-column schema. Then click **OK** to close the dialog box.

4. When prompted, click **OK** to accept the propagation, so that the *tFileOutputExcel* component gets automatically set with the input schema.

**Configuring the output component**

Set the output file to receive the input content without changes. If the file does not exist already, it will get created.
In this example, the Sheet name is *Email* and the Include Header box is selected.

**Configuring the tJava component**

**Procedure**

1. Then select the tJava component to set the Java command to execute.

```java
String var = "Nb of line processed: ";
var = var + globalMap.get("tFileInputDelimited_1_NB_LINE");
System.out.println(var);
```

2. In the Code area, type in the following command:

```java
String var = "Nb of line processed: ";
var = var + globalMap.get("tFileInputDelimited_1_NB_LINE");
System.out.println(var);
```

In this use case, we use the *NB Line* variable. To access the global variable list, press Ctrl + Space bar on your keyboard and select the relevant global parameter.

**Executing the Job**

**Procedure**

1. Press Ctrl+S to save your Job.
2. Press F6 to execute it.
Results

Nb of line processed: 4
Job JavaDb ended at 13:53 20/08/2007. [exit code=0]

The content gets passed on to the Excel file defined and the Number of lines processed are displayed on the Run console.
tJavaDBInput

Reads a database and extracts fields based on a query

tJavaDBInput executes a DB query with a strictly defined order which must correspond to the schema definition. Then it passes on the field list to the next component via a Main row link.

**tJavaDBInput Standard properties**

These properties are used to configure tJavaDBInput running in the Standard Job framework.
The Standard tJavaDBInput component belongs to the Databases family.
The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-in or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><img src="image" alt="Open Database Connection Wizard" /></td>
<td>Click this icon to open a database connection wizard and store the database connection parameters you set in the component Basic settings view. For more information about setting up and storing database connection parameters, see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Framework</td>
<td>Select your Java database framework on the list</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database</td>
</tr>
<tr>
<td>DB root path</td>
<td>Browse to your database root.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Schema and Edit schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td></td>
<td>Built-in: The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide.</td>
</tr>
<tr>
<td></td>
<td>Repository: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Query type** and **Query**

Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.

### Advanced settings

| Trim all the String/Char columns | Select this check box to remove leading and trailing whitespace from all the String/Char columns. |
| Trim column | Remove leading and trailing whitespace from defined columns. |
| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

### Global Variables

**Global Variables**

- **NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.
- **QUERY**: the query statement being processed. This is a Flow variable and it returns a string.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

**Usage rule**

This component covers all possible SQL database queries.
Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

**Related scenarios**

For related topics, see:

See also the related topic in **tContextLoad**: Reading data from different MySQL databases using dynamically loaded connection parameters on page 491.
tJavaDBOutput

Executes the action defined on the table and/or on the data contained in the table, based on the flow incoming from the preceding component in the Job.

tJavaDBOutput writes, updates, makes changes or suppresses entries in a database.

**tJavaDBOutput Standard properties**

These properties are used to configure tJavaDBOutput running in the Standard Job framework.
The Standard tJavaDBOutput component belongs to the Databases family.
The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-in or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><img src="image" alt="icon" /></td>
<td>Click this icon to open a database connection wizard and store the database connection parameters you set in the component Basic settings view.</td>
</tr>
<tr>
<td>Framework</td>
<td>Select your Java database framework on the list</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database</td>
</tr>
<tr>
<td>DB root path</td>
<td>Browse to your database root.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Table</td>
<td>Name of the table to be written. Note that only one table can be written at a time</td>
</tr>
<tr>
<td>Action on table</td>
<td>On the table defined, you can perform one of the following operations:</td>
</tr>
<tr>
<td></td>
<td><strong>None</strong>: No operation is carried out.</td>
</tr>
<tr>
<td></td>
<td><strong>Drop and create a table</strong>: The table is removed and created again.</td>
</tr>
<tr>
<td></td>
<td><strong>Create a table</strong>: The table does not exist and gets created.</td>
</tr>
<tr>
<td></td>
<td><strong>Create a table if not exists</strong>: The table is created if it does not exist.</td>
</tr>
</tbody>
</table>
Drop table if exists and create: The table is removed if it already exists and created again.

Clear a table: The table content is deleted.

**Action on data**

On the data of the table defined, you can perform:

**Insert**: Add new entries to the table. If duplicates are found, Job stops.

**Update**: Make changes to existing entries.

**Insert or update**: Insert a new record. If the record with the given reference already exists, an update would be made.

**Update or insert**: Update the record with the given reference. If the record does not exist, a new record would be inserted.

**Delete**: Remove entries corresponding to the input flow.

**Warning:**

It is necessary to specify at least one column as a primary key on which the **Update** and **Delete** operations are based. You can do that by clicking **Edit Schema** and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the **Advanced settings** view where you can simultaneously define primary keys for the **Update** and **Delete** operations. To do that:

- Select the **Use field options** check box and then in the **Key in update column**, select the check boxes next to the column names you want to use as a base for the **Update** operation.
- Do the same in the **Key in delete column** for the **Delete** operation.

**Schema and Edit schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

**Built-In**: You create and store the schema locally for this component only.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
### Update repository connection
Choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

### Die on error
This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a **Row > Rejects** link.

### Advanced settings

<table>
<thead>
<tr>
<th>Commit every</th>
<th>Enter the number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and, above all, better performance at execution.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Additional Columns</strong></td>
<td>This option is not offered if you create (with or without drop) the DB table. This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing.</td>
</tr>
<tr>
<td><strong>Name:</strong></td>
<td>Type in the name of the schema column to be altered or inserted as new column</td>
</tr>
<tr>
<td><strong>SQL expression:</strong></td>
<td>Type in the SQL statement to be executed in order to alter or insert the relevant column data.</td>
</tr>
<tr>
<td><strong>Position:</strong></td>
<td>Select <strong>Before</strong>, <strong>Replace</strong> or <strong>After</strong> following the action to be performed on the reference column.</td>
</tr>
<tr>
<td><strong>Reference column:</strong></td>
<td>Type in a column of reference that the <strong>tDBOutput</strong> can use to place or replace the new or altered column.</td>
</tr>
<tr>
<td><strong>Use field options</strong></td>
<td>Select this check box to customize a request, especially when there is double action on data.</td>
</tr>
<tr>
<td><strong>Enable debug mode</strong></td>
<td>Select this check box to display each step during processing entries in a database.</td>
</tr>
<tr>
<td><strong>tStat Catcher Statistics</strong></td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th><strong>NB_LINE:</strong> the number of rows processed. This is an After variable and it returns an integer.</th>

</tr>
<tr>
<td></td>
<td><strong>NB_LINE_INSERTED:</strong> the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td><strong>NB_LINE_DELETED:</strong> the number of rows deleted. This is an After variable and it returns an integer.</td>
</tr>
</tbody>
</table>
**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in a Java database. It also allows you to create a reject flow using a Row &gt; Rejects link to filter data in error. For an example of tMysqlOutput in use, see Retrieving data in error with a Reject link on page 2485.</td>
</tr>
</tbody>
</table>

| Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |

**Related scenarios**

For related topics, see:

- Inserting a column and altering data using tMysqlOutput on page 2477.
**tJavaDBRow**

Acts on the actual database structure or on the data (although without handling data) using the SQLBuilder tool to write easily your SQL statements.

tJavaDBRow executes the SQL query stated onto the specified database. The Row suffix means the component implements a flow in the job design although it doesn’t provide output.

**tJavaDBRow Standard properties**

These properties are used to configure tJavaDBRow running in the Standard Job framework.

The Standard tJavaDBRow component belongs to the Databases family.

The component in this framework is available in all Talend products.

### Basic settings

<table>
<thead>
<tr>
<th>Property type</th>

<tr>
<td></td>
<td><strong>Repository</strong>: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><strong>Framework</strong></td>
<td>Select your Java database framework on the list</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database</td>
</tr>
<tr>
<td><strong>DB root path</strong></td>
<td>Browse to your database root.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td><strong>Schema and Edit Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-in</strong>: The schema is created and stored locally for this component only. Related topic: see <a href="#">Talend Studio User Guide</a>.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see <a href="#">Talend Studio User Guide</a>.</td>
</tr>
<tr>
<td></td>
<td>Click <strong>Edit schema</strong> to make changes to the schema. If the current schema is of the <strong>Repository</strong> type, three options are available:</td>
</tr>
<tr>
<td></td>
<td>• <strong>View schema</strong>: choose this option to view the schema only.</td>
</tr>
</tbody>
</table>
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

<table>
<thead>
<tr>
<th>Query type</th>
<th>Either <strong>Built-in</strong> or <strong>Repository</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-in</strong>: Fill in manually the query statement or build it graphically using SQLBuilder.</td>
<td></td>
</tr>
<tr>
<td><strong>Repository</strong>: Select the relevant query stored in the Repository. The Query field gets accordingly filled in.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Query</th>
<th>Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Die on error</td>
<td>This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a <strong>Row &gt; Rejects</strong> link.</td>
</tr>
</tbody>
</table>

### Advanced settings

<table>
<thead>
<tr>
<th>Propagate QUERY's recordset</th>
<th>Select this check box to insert the result of the query into a COLUMN of the current flow. Select this column from the use column list.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Use PreparedStatement</th>
<th>Select this check box if you want to query the database using a PreparedStatement. In the <strong>Set PreparedStatement Parameter</strong> table, define the parameters represented by &quot;?&quot; in the SQL instruction of the <strong>Query</strong> field in the Basic Settings tab.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Parameter Index</strong>: Enter the parameter position in the SQL instruction.</td>
<td></td>
</tr>
<tr>
<td><strong>Parameter Type</strong>: Enter the parameter type.</td>
<td></td>
</tr>
<tr>
<td><strong>Parameter Value</strong>: Enter the parameter value.</td>
<td></td>
</tr>
</tbody>
</table>

**Note:**
This option is very useful if you need to execute the same query several times. Performance levels are increased.

<table>
<thead>
<tr>
<th>Commit every</th>
<th>Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>tStat Catcher Statistics</th>
<th>Select this check box to collect log data at the component level.</th>
</tr>
</thead>
</table>
Global Variables

| Global Variables | QUERY: the query statement being processed. This is a Flow variable and it returns a string. ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | This component offers the flexibility of the DB query and covers all possible SQL queries. |
| Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |

Related scenarios

For related topics, see:

- Procedure on page 625.
- Removing and regenerating a MySQL table index on page 2508.
**tJavaFlex**

Provides a Java code editor that lets you enter personalized code in order to integrate it in Talend program.

`tJavaFlex` enables you to add Java code to the Start/Main/End code sections of this component itself. With `tJavaFlex`, you can enter the three java-code parts (start, main and end) that constitute a kind of component dedicated to do a desired operation.

**tJavaFlex Standard properties**

These properties are used to configure `tJavaFlex` running in the Standard Job framework.
The Standard `tJavaFlex` component belongs to the Custom Code family.
The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th><strong>Schema and Edit Schema</strong></th>
<th>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <code>line</code> when naming the fields. Click <strong>Sync columns</strong> to retrieve the schema from the previous component in the Job.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-In</strong></td>
<td><strong>Built-In</strong>: You create and store the schema locally for this component only.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td><strong>Repository</strong>: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually. You can find more details about how to verify default values in retrieved schema in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
</tbody>
</table>
| **Edit schema**            | Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
  - **View schema**: choose this option to view the schema only.  
  - **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
  - **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window. |
Data Auto Propagate

Select this check box to automatically propagate the data to the component that follows.

Start code

Enter the Java code that will be called during the initialization phase.

Main code

Enter the Java code to be applied for each line in the data flow.

End code

Enter the Java code that will be called during the closing phase.

Advanced settings

Import

Enter the Java code that helps to import, if necessary, external libraries used in the Main code box of the Basic settings view.

tStatCatcher Statistics

Select this check box to gather the Job processing metadata at a job level as well as at each component level.

Global Variables

Global Variables

ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule

You can use this component as a start, intermediate or output component. You can as well use it as a one-component subjob.

Limitation

You should know the Java language.

Generating data flow

This scenario describes a two-components Job that generates a three-line data flow describing different personal titles (Miss, Mrs, and Mr) and displaying them on the console.
Setting up the Job

Procedure
1. Drop tJavaFlex and tLogRow from the Palette onto the design workspace.
2. Connect the components together using a Row > Main link.

Configuring the tJavaFlex component

Procedure
1. Double-click tJavaFlex to display its Basic settings view and define its properties.
2. Click the three-dot button next to Edit schema to open the corresponding dialog box where you can define the data structure to pass to the component that follows.
3. Click the [+] button to add two columns: key and value and then set their types to Integer and String respectively.
4. Click OK to validate your changes and close the dialog box.
5. In the **Basic settings** view of **tJavaFlex**, select the **Data Auto Propagate** check box to automatically propagate data to the component that follows.

In this example, we do not want to do any transformation on the retrieved data.

6. In the **Start code** field, enter the code to be executed in the initialization phase.

In this example, the code indicates the initialization of **tJavaFlex** by displaying the START message and sets up the loop and the variables to be used afterwards in the Java code:

   ```java
   System.out.println("## START\n#");
   String[] valueArray = ("Miss", "Mrs", "Mr");
   for (int i=0;i<valueArray.length;i++) {
   ```

7. In the **Main code** field, enter the code you want to apply on each of the data rows.

In this example, we want to display each key with its value:

   ```java
   row1.key = i;
   row1.value = valueArray[i];
   ```

8. In the **End code** field, enter the code that will be executed in the closing phase.

In this example, the brace (curly bracket) closes the loop and the code indicates the end of the execution of **tJavaFlex** by displaying the END message:

   ```java
   }
   System.out.println("## END");
   ```

9. If needed, double-click **tLogRow** and in its **Basic settings** view, click the [...] button next to **Edit schema** to make sure that the schema has been correctly propagated.
Saving and executing the Job

Procedure

1. Save your Job by pressing **Ctrl+S**.
2. Execute the Job by pressing **F6** or clicking **Run** on the **Run** tab.

```java
Starting job tJavaFlex_scenario1 at 14:49 02/09/2009.

## START
#
0|Miss
1|Mrs
2|Mr
#
## END
Job tJavaFlex_scenario1 ended at 14:49 02/09/2009. [exit code=0]
```

The three personal titles are displayed on the console along with their corresponding keys.

Processing rows of data with **tJavaFlex**

This scenario describes a two-component Job that generates random data and then collects that data and does some transformation on it line by line using Java code through the **tJavaFlex** component.

Setting up the Job

Procedure

1. Drop **tRowGenerator** and **tJavaFlex** from the **Palette** onto the design workspace.
2. Connect the components together using a **Row Main** link.

Configuring the input component

Procedure

1. Double-click **tRowGenerator** to display its **Basic settings** view and the **RowGenerator Editor** dialog box where you can define the component properties.
2. Click the plus button to add four columns: number, txt, date and flag.

3. Define the schema and set the parameters to the four columns according to the above capture.

4. In the Functions column, select the three-dot function [...] for each of the defined columns.

5. In the Parameters column, enter 10 different parameters for each of the defined columns. These 10 parameters corresponds to the data that will be randomly generated when executing tRowGenerator.

6. Click OK to validate your changes and close the editor.

**Configuring the tJavaFlex component**

**Procedure**

1. Double-click tJavaFlex to display its Basic settings view and define the components properties.

2. Click Sync columns to retrieve the schema from the preceding component.

3. In the Start code field, enter the code to be executed in the initialization phase.

   In this example, the code indicates the initialization of the tJavaFlex component by displaying the START message and defining the variable to be used afterwards in the Java code:

   ```java
   System.out.println("## START\n");
   int i = 0;
   ```

4. In the Main code field, enter the code to be applied on each line of data.
In this example, we want to show the number of each line starting from 0 and then the number and the random text transformed to upper case and finally the random date set in the editor of tRowGenerator. Then, we create a condition to show if the status is true or false and we increment the number of the line:

```java
System.out.print(" row" + i + ":");
System.out.print("# number:" + row1.number);
System.out.print(" | txt:" + row1.txt.toUpperCase());
System.out.print(" | date:" + row1.date);
if(row1.flag) System.out.println(" | flag: true");
else System.out.println(" | flag: false");
i++;
```

**Main code**

```java
System.out.print(" row" + i + ":");
System.out.print("# number:" + row1.number);
System.out.print(" | txt:" + row1.txt.toUpperCase());
System.out.print(" | date:" + row1.date);
if(row1.flag) System.out.println(" | flag: true");
else System.out.println(" | flag: false");
i++;
```

**Warning:**

*In the Main code field, “row1” corresponds to the name of the link that connects to tJavaFlex. If you rename this link, you have to modify the code.*

5. In the **End code** field, enter the code that will be executed in the closing phase.

In this example, the code indicates the end of the execution of tJavaFlex by displaying the END message:

```java
System.out.println("#
## END");
```

**End code**

```java
System.out.println("#
## END");
```

**Saving and executing the Job**

**Procedure**

1. Save your Job by pressing **Ctrl+S**.
2. Execute the Job by pressing **F6** or clicking **Run** on the **Run** tab.
Starting job tJavaFlex_scenario2 at 18.35 02/09/2009.

## START
#
row0:# number:10 | txt: TEXT5 | date:2006-05-25 | flag: false
row1:# number:7  | txt: TEXT7 | date:2006-06-26 | flag: true 
row2:# number:5  | txt: TEXT2 | date:2006-05-25 | flag: false
row3:# number:6  | txt: TEXT1 | date:2005-08-28 | flag: true 
row4:# number:8  | txt: TEXT9 | date:2006-05-25 | flag: false
row5:# number:9  | txt: TEXT1 | date:2007-01-21 | flag: false
row6:# number:7  | txt: TEXT5 | date:2004-11-21 | flag: true 
row7:# number:9  | txt: TEXT4 | date:2005-08-29 | flag: true 
row8:# number:4  | txt: TEXT6 | date:2006-06-26 | flag: false
row9:# number:3  | txt: TEXT10 | date:2006-05-25 | flag: false
#
## END

Job tJavaFlex_scenario2 ended at 18.35 02/09/2009. (exit code=0)

The console displays the randomly generated data that was modified by the java command set through tJavaFlex.
tJavaRow

Provides a code editor that lets you enter the Java code to be applied to each row of the flow. tJavaRow allows you to enter customized code which you can integrate in a Talend program.

**tJavaRow Standard properties**

These properties are used to configure tJavaRow running in the Standard Job framework. The Standard tJavaRow component belongs to the Custom Code family. The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Schema and Edit Schema</th>
<th>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <code>line</code> when naming the fields.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-In:</strong></td>
<td>You create and store the schema locally for this component only.</td>
</tr>
<tr>
<td><strong>Repository:</strong></td>
<td>You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually. You can find more details about how to verify default values in retrieved schema in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
<tr>
<td>Click <code>Edit schema</code> to make changes to the schema. If the current schema is of the <strong>Repository</strong> type, three options are available:</td>
<td></td>
</tr>
<tr>
<td>• <strong>View schema:</strong> choose this option to view the schema only.</td>
<td></td>
</tr>
<tr>
<td>• <strong>Change to built-in property:</strong> choose this option to change the schema to <strong>Built-In</strong> for local changes.</td>
<td></td>
</tr>
<tr>
<td>• <strong>Update repository connection:</strong> choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select <strong>No</strong> upon completion and choose this schema metadata again in the <strong>Repository Content</strong> window.</td>
<td></td>
</tr>
<tr>
<td>Click <strong>Sync columns</strong> to retrieve the schema from the previous component connected in the Job.</td>
<td></td>
</tr>
</tbody>
</table>

| Generate code | Click this button to automatically generate the code in the **Code** field to map the columns of the input schema with those of the output schema. This generation does not change anything in your schema. |
The principle of this mapping is to relate the columns that have the same column name. Then you can adapt the generated code depending on the actual map you need.

<table>
<thead>
<tr>

</tbody>
</table>
Transforming data line by line using tJavaRow

In this scenario, the information of a few cities read from an input delimited file is transformed using Java code through the tJavaRow component and printed on the console.

Setting up the Job

Procedure

1. Drop a tFileInputDelimited component and a tJavaRow component from the Palette onto the design workspace, and label them to better identify their roles in the Job.
2. Connect the two components using a Row > Main connection.

Configuring the components

Procedure

1. Double-click the tFileInputDelimited component to display its Basic settings view in the Component tab.

   ![Component settings](image)

   - In the File name/Stream field, type in the path to the input file in double quotation marks, or browse to the path by clicking the [...] button, and define the first line of the file as the header.
   - Click the [...] button next to Edit schema to open the Schema dialog box, and define the data structure of the input file. Then, click OK to validate the schema setting and close the dialog box.

   ```
   City;Population;LandArea;PopDensity
   Beijing;10233000;1418;7620
   Moscow;10452000;1081;9644
   Seoul;10422000;605;17215
   Tokyo;8731000;617;14151
   New York;8310000;789;10452
   ```

2. In the File name/Stream field, type in the path to the input file in double quotation marks, or browse to the path by clicking the [...] button, and define the first line of the file as the header.

   In this example, the input file has the following content:

   ```
   City;Population;LandArea;PopDensity
   Beijing;10233000;1418;7620
   Moscow;10452000;1081;9644
   Seoul;10422000;605;17215
   Tokyo;8731000;617;14151
   New York;8310000;789;10452
   ```
tJavaRow

4. Double-click the tJavaRow component to display its Basic settings view in the Component tab.

5. Click Sync columns to make sure that the schema is correctly retrieved from the preceding
component.
6. In the Code field, enter the code to be applied on each line of data based on the defined schema
columns.
In this example, we want to transform the city names to upper case, group digits of numbers
larger than 1000 using the thousands separator for ease of reading, and print the data on the
console:
System.out.print("\n" + input_row.City.toUpperCase() + ":");
System.out.print("\n - Population: "
+ FormatterUtils.format_Number(String.valueOf(input_row.Population), ',', '.') + "
people");
System.out.print("\n - Land area: "
+ FormatterUtils.format_Number(String.valueOf(input_row.LandArea), ',', '.')
+ " km2");
System.out.print("\n - Population density: "
+ FormatterUtils.format_Number(String.valueOf(input_row.PopDensity), ',', '.') + "
people/km2\n");

Note:
In the Code field, input_row refers to the link that connects to tJavaRow.

1830


Saving and executing the Job

Procedure

1. Press Ctrl+S to save your Job.
2. Press F6 or click Run on the Run tab to execute the Job.

The city information is transformed by the Java code set through tJavaRow and displayed on the console.

BEIJING:
- Population: 10,233,000 people
- Land area: 1,419 km²
- Population density: 7,620 people/km²

MCSEOU:
- Population: 10,452,000 people
- Land area: 1,081 km²
- Population density: 9,644 people/km²

SEOUL:
- Population: 10,422,000 people
- Land area: 605 km²
- Population density: 17,215 people/km²

TOKYO:
- Population: 8,731,000 people
- Land area: 617 km²
- Population density: 14,151 people/km²

NEW YORK:
- Population: 8,310,000 people
- Land area: 789 km²
- Population density: 10,452 people/km²

Job dmu_tJavaRow_s1 ended at 17:40 12/04/2012.
tJDBCClose

Closes an active JDBC connection to release the occupied resources.

**tJDBCClose Standard properties**

These properties are used to configure tJDBCClose running in the Standard Job framework.

The Standard tJDBCClose component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connection Component</td>
<td>Select the component that opens the connection you need to close from the drop-down list.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global Variables**

| ERROR_MESSAGE | The error message generated by the component when an error occurs. This is an After variable and it returns a string. |

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is to be used along with JDBC components, especially with tJDBCConnection and tJDBCCommit.</th>
</tr>
</thead>
</table>

**Dynamic settings**

Click the [+ ] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic
Related scenarios

No scenario is available for the Standard version of this component yet.
**tJDBCColumnList**

Lists all column names of a given JDBC table.

tJDBCColumnList iterates on all columns of a given table through a defined JDBC connection.

**tJDBCColumnList Standard properties**

These properties are used to configure tJDBCColumnList running in the Standard Job framework. The Standard tJDBCColumnList component belongs to the Databases family. The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Database Type</th>
<th>Select the type of the database to be accessed.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tJDBCConnection component in the list if more than one connection are planned for the current Job.</td>
</tr>
<tr>
<td>Table name</td>
<td>Enter the name of the table.</td>
</tr>
<tr>
<td>Die on error</td>
<td>Select the check box to stop the execution of the Job when an error occurs. Clear the check box to skip any rows on error and complete the process for error-free rows. When errors are skipped, you can collect the rows on error using a Row &gt; Reject link.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>CURRENT_COLUMN: the name of the column currently iterated upon. This is a Flow variable and it returns a string.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>CURRENT_COLUMN_TYPE: the ID of the type of the column currently iterated upon. This is a Flow variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>CURRENT_COLUMN_TYPE_NAME: the name of the type of the column currently iterated upon. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td></td>
<td>CURRENT_COLUMN_PRECISION: the precision of the column currently iterated upon. This is a Flow variable, and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>CURRENT_COLUMN_SCALE: the scale of the column currently iterated upon. This is a Flow variable, and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>NB_COLUMN: the number of columns iterated upon so far. This is an After variable and it returns an integer.</td>
</tr>
</tbody>
</table>
**tJDBCColumnList**

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

---

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is to be used along with JDBC components, especially with <strong>tJDBCConnection</strong>.</th>
</tr>
</thead>
</table>

### Related scenario

For **tJDBCColumnList** related scenario, see *Iterating on a DB table and listing its column names* on page 2430.
tJDBCCommit

Commits in one go a global transaction instead of doing that on every row or every batch and thus provides gain in performance.

tJDBCCommit validates the data processed through the Job into the connected DB.

**tJDBCCommit Standard properties**

These properties are used to configure tJDBCCommit running in the Standard Job framework.

The Standard tJDBCCommit component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connection Component</td>
<td>Select the component that opens the database connection to be reused by this component.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Select this check box to close the database connection once the component has performed its task. Clear this check box to continue to use the selected connection once the component has performed its task. If this component is linked to your Job via a Row &gt; Main connection, your data will be committed row by row. In this case, do not select the Close connection check box or your connection will be closed before the end of the first row commit.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global Variables**

| ERROR_MESSAGE | The error message generated by the component when an error occurs. This is an After variable and it returns a string. |

**Usage**

| Usage rule | This component is more commonly used with other JDBC* components, especially with the tJDBCConnection and tJDBCRollback components. |
### Dynamic settings

Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

For examples on using dynamic parameters, see [Reading data from databases through context-based dynamic connections](#) on page 2457 and [Reading data from different MySQL databases using dynamically loaded connection parameters](#) on page 491. For more information on **Dynamic settings** and context variables, see [Talend Studio User Guide](#).

### Related scenario

For **tJDBCCommit** related scenario, see [Inserting data in mother/daughter tables](#) on page 2437.
tJDBCConnection

Opens a connection to the specified database that can then be reused in the subsequent subjob or subjobs.

**tJDBCConnection Standard properties**

These properties are used to configure tJDBCConnection running in the Standard Job framework. The Standard tJDBCConnection component belongs to the Databases and the ELT families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property Type</td>
<td>Select the way the connection details will be set.</td>
</tr>
<tr>
<td>• Built-In</td>
<td>The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.</td>
</tr>
<tr>
<td>• Repository</td>
<td>The connection details stored centrally in Repository &gt; Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up Repository Content dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in.</td>
</tr>
<tr>
<td>JDBC URL</td>
<td>The JDBC URL of the database to be used. For example, the JDBC URL for the Amazon Redshift database is jdbc:redshift://endpoint:port/database.</td>
</tr>
<tr>
<td>Drivers</td>
<td>Complete this table to load the driver JARs needed. To do this, click the [+] button under the table to add as many rows as needed, each row for a driver JAR, then select the cell and click the [...] button at the right side of the cell to open the Select Module wizard from which you can select the driver JAR to be used. For example, the driver jar RedshiftJDBC41-1.1.13.1013.jar for the Redshift database.</td>
</tr>
<tr>
<td>Driver Class</td>
<td>Enter the class name for the specified driver between double quotation marks. For example, for the RedshiftJDBC41-1.1.13.1013.jar driver, the name to be entered is com.amazon.redshift.jdbc41.Driver.</td>
</tr>
<tr>
<td>Use Id and Password</td>
<td>The database user authentication data.</td>
</tr>
</tbody>
</table>
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

### Use or register a shared DB Connection

Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the **Shared DB Connection Name** field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child.

This option is incompatible with the **Use dynamic job** and **Use an independent process to run subjob** options of the **tRunJob** component. Using a shared connection together with a **tRunJob** component with either of these two options enabled will cause your Job to fail.

This check box is not available when the **Specify a data source alias** check box is selected.

### Specify a data source alias

Select this check box and in the **Data source alias** field displayed, specify the alias of a data source created on Talend Runtime side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in Talend Runtime.

This check box is not available when the **Use or register a shared DB Connection** check box is selected.

### Advanced settings

<table>
<thead>
<tr>
<th><strong>Use Auto-Commit</strong></th>
<th>Select this check box to activate the auto commit mode.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Auto Commit</strong></td>
<td>Select this check box to commit any changes to the database automatically upon the transaction. With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component. Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component.</td>
</tr>
</tbody>
</table>

| **tStatCatcher Statistics** | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

### Global Variables

| **ERROR_MESSAGE** | The error message generated by the component when an error occurs. This is an After variable and it returns a string. |
Usage

| Usage rule | This component is more commonly used with other JDBC* components, especially with the tJDBCCommit and tJDBCRollback components. |

Related scenario

For tJDBCConnection related scenario, see tMysqlConnection on page 2436
**tJDBCInput**

Reads any database using a JDBC API connection and extracts fields based on a query.

tJDBCInput executes a database query with a strictly defined order which must correspond to the schema definition. Then it passes on the field list to the next component via a Main row link.

**tJDBCInput Standard properties**

These properties are used to configure tJDBCInput running in the Standard Job framework. The Standard tJDBCInput component belongs to the Databases family. The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Database</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property Type</td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
</tbody>
</table>

**Database**

Select the way the connection details will be set.

- **Built-in:** The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.
- **Repository:** The connection details stored centrally in Repository > Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up Repository Content dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in.

This property is not available when other connection component is selected from the Connection Component drop-down list.

**Connection Component**

Select the component that opens the database connection to be reused by this component.

**JDBC URL**

The JDBC URL of the database to be used. For example, the JDBC URL for the Amazon Redshift database is `jdbc:redshift://endpoint:port/database`.

**Drivers**

Complete this table to load the driver JARs needed. To do this, click the [+] button under the table to add as many rows as needed, each row for a driver JAR, then select the
cell and click the [...] button at the right side of the cell to open the **Select Module** wizard from which you can select the driver JAR to be used. For example, the driver jar RedshiftJDBC41-1.1.13.1013.jar for the Redshift database.

| **Driver Class** | Enter the class name for the specified driver between double quotation marks. For example, for the RedshiftJDBC41-1.1.13.1013.jar driver, the name to be entered is com.amazon.redshift.jdbc41.Driver. |
| **Use Id and Password** | The database user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings. |
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.  
- **Built-In**: You create and store the schema locally for this component only.  
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.  
Click **Edit schema** to make changes to the schema. Note that if you make changes, the schema automatically becomes built-in.  
- **View schema**: choose this option to view the schema only.  
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.  
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window. |
| **Table Name** | The name of the table from which data will be retrieved. |
| **Query Type and Query** | Specify the database query statement paying particularly attention to the proper sequence of the fields which must correspond to the schema definition.  
- **Built-In**: Fill in the query statement in the **Query** field manually or click the [...] button next to the **Query** field to build the statement graphically using the SQLBuilder.  
- **Repository**: Select the relevant query stored in the Repository by clicking the [...] button next to it and in the pop-up **Repository Content** dialog box, select the query to be used, and the **Query** field will be automatically filled in. |
| **Guess Query** | Click this button to generate query in the **Query** field based on the defined table and schema. |
### Advanced settings

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Guess Schema</strong></td>
<td>Click this button to generate schema columns based on the query defined in the <em>Query</em> field.</td>
</tr>
<tr>
<td><strong>Specify a data source alias</strong></td>
<td>Select this check box and in the <em>Data source alias</em> field displayed, specify the alias of a data source created on Talend Runtime side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in Talend Runtime. This property is not available when other connection component is selected from the <em>Connection Component</em> drop-down list.</td>
</tr>
<tr>
<td><strong>Use cursor</strong></td>
<td>Select this check box to specify the number of rows you want to work with at any given time. This option optimises performance.</td>
</tr>
<tr>
<td><strong>Trim all the String/Char columns</strong></td>
<td>Select this check box to remove leading whitespace and trailing whitespace from all String/Char columns.</td>
</tr>
<tr>
<td><strong>Check column to trim</strong></td>
<td>Select the check box for corresponding column to remove leading whitespace and trailing whitespace from it. This property is not available when the <em>Trim all the String/Char columns</em> check box is selected.</td>
</tr>
</tbody>
</table>
| **Enable Mapping File for Dynamic** | Select this check box to use the specified metadata mapping file when reading data from a dynamic type column. This check box is cleared by default.  
With this check box selected, you can specify the metadata mapping file to use by selecting a type of database from the *Mapping File* drop-down list.  
For more information about metadata mapping files, see the section on type conversion of Talend Studio User Guide. |
| **tStatCatcher Statistics**      | Select this check box to gather the Job processing metadata at the Job level as well as at each component level.                            |

### Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>

<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Usage rule</strong></td>
<td>This component covers all possible SQL queries for any database using a JDBC connection.</td>
</tr>
</tbody>
</table>
Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenarios

For related topics, see:

Related topic in tContextLoad: see Reading data from different MySQL databases using dynamically loaded connection parameters on page 491.
tJDBCOutput

Executes the action defined on the data contained in the table, based on the flow incoming from the preceding component in the Job.

tJDBCOutput writes, updates, makes changes or suppresses entries in any type of database connected to a JDBC API.

**tJDBCOutput Standard properties**

These properties are used to configure tJDBCOutput running in the Standard Job framework.

The Standard tJDBCOutput component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property Type</td>
<td>Select the way the connection details will be set. • <strong>Built-in:</strong> The connection details will be set locally for this component. You need to specify the values for all related connection properties manually. • <strong>Repository:</strong> The connection details stored centrally in Repository &gt; Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up Repository Content dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in. This property is not available when other connection component is selected from the Connection Component drop-down list.</td>
</tr>
<tr>
<td><img src="" alt=" " /></td>
<td>Click this icon to open a database connection wizard and store the database connection parameters you set in the component Basic settings view. For more information about setting up and storing database connection parameters, see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Connection Component</td>
<td>Select the component that opens the database connection to be reused by this component.</td>
</tr>
<tr>
<td>JDBC URL</td>
<td>The JDBC URL of the database to be used. For example, the JDBC URL for the Amazon Redshift database is jdbc:redshift://endpoint:port/database.</td>
</tr>
<tr>
<td>Drivers</td>
<td>Complete this table to load the driver JARs needed. To do this, click the [+] button under the table to add as many rows as needed, each row for a driver JAR, then select the cell and click the [...] button at the right side of the cell to open the Select Module wizard from which you can select the driver JAR to be used. For example, the driver jar RedshiftJDBC41-1.1.13.1013.jar for the Redshift database.</td>
</tr>
<tr>
<td>---</td>
<td>---</td>
</tr>
<tr>
<td>Driver Class</td>
<td>Enter the class name for the specified driver between double quotation marks. For example, for the RedshiftJDBC41-1.1.13.1013.jar driver, the name to be entered is com.amazon.redshift.jdbc41.Driver.</td>
</tr>
<tr>
<td>Use Id and Password</td>
<td>The database user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Table Name</td>
<td>The name of the table into which data will be written.</td>
</tr>
</tbody>
</table>
| Data Action | Select an action to be performed on data of the table defined.  
- **Insert**: Add new entries to the table. If duplicates are found, job stops.  
- **Update**: Make changes to existing entries.  
- **Insert or update**: Insert a new record in the index pool. If the record with the given reference already exists, an update would be made.  
- **Update or insert**: Update the record with the given reference. If the record does not exist in the index pool, a new record would be inserted.  
- **Delete**: Remove entries corresponding to the input flow.  

**Warning:** It is necessary to specify at least one column as a primary key on which the Update and Delete operations are based. You can do that by clicking Edit Schema and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the Advanced settings view where you can simultaneously define primary keys for the Update and Delete operations. To do that: Select the Use field options check box and then in the Key in update column, select the check boxes next to the column names you want to use as a base for the Update operation. Do the same in the Key in delete column for the Delete operation. |
| Clear data in table | Select this check box to clear data in the table before performing the action defined. |
| Schema and Edit schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. |
• **Built-In**: You create and store the schema locally for this component only.
• **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Click **Edit schema** to make changes to the schema. Note that if you make changes, the schema automatically becomes built-in.
• **View schema**: choose this option to view the schema only.
• **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
• **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

---

## Advanced settings

### Commit every

Specify the number of rows to be processed before committing batches of rows together into the database.

This option ensures transaction quality (but not rollback) and, above all, better performance at executions.
**Additional Columns**

This option allows you to call SQL functions to perform actions on columns, which are not insert, update or delete actions, or actions that require particular preprocessing. It is not offered if you create (with or without drop) the database table.

- **Name**: The name of the schema column to be inserted, or the name of the schema column used to replace an existing column.
- **SQL expression**: The SQL statement to be executed in order to insert or replace relevant column.
- **Position**: Select Before, After, or Replace according to the action to be performed on the reference column.
- **Reference column**: The name of the reference column that can be used to locate the new column to be inserted or that will be replaced.

**Use field options**

Select this check box and in the **Fields options** table displayed, select the check box for the corresponding column to customize a request, particularly if multiple actions are being carried out on the data.

- **Key in update**: Select the check box for the corresponding column based on which data is updated.
- **Key in delete**: Select the check box for the corresponding column based on which data is deleted.
- **Updatable**: Select the check box if data in the corresponding column can be updated.
- **Insertable**: Select the check box if data in the corresponding column can be inserted.

**Enable debug mode**

Select this check box to display each step during processing entries in a database.

**Use Batch**

Select this check box to activate the batch mode for data processing, and in the **Batch Size** field displayed, specify the number of records to be processed in each batch.

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

**Enable parallel execution**

Select this check box to perform high-speed data processing by treating multiple data flows simultaneously. This feature depends on the database or the application ability to handle multiple inserts in parallel as well as the number of CPU affected. With this check box selected, you need to specify the number of parallel executions desired in the **Number of parallel executions** field displayed.

**Note**: When parallel execution is enabled, it is not possible to use global variables to retrieve return values.

**Global Variables**

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>ERROR_MESSAGE</strong></td>
<td>The error message generated by the component when an error occurs. This is an After variable and it returns a string.</td>
</tr>
<tr>
<td><strong>NB_LINE</strong></td>

<td>The number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>------------------</td>
<td>---------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>NB_LINEUPDATED</td>
<td>The number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>NB_LINE_DELETED</td>
<td>The number of rows deleted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>NB_LINE_REJECTED</td>
<td>The number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>QUERY</td>
<td>The query statement being processed. This is a Flow variable and it returns a string.</td>
</tr>
</tbody>
</table>

**Usage**

**Usage rule**

This component offers the flexibility benefit of the database query and covers all of the SQL queries possible.

This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in a JDBC database. It also allows you to create a reject flow using a Row > Rejects link to filter data in error. For an example of tMySqlOutput in use, see Retrieving data in error with a Reject link on page 2485.

**Dynamic settings**

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

**Related scenarios**

For tJDBCOutput related topics, see:

- Inserting a column and altering data using tMysqlOutput on page 2477.
tJDBCRollback

Avoids committing part of a transaction accidentally by canceling the transaction committed in the connected database.

tJDBCRollback Standard properties

These properties are used to configure tJDBCRollback running in the Standard Job framework.
The Standard tJDBCRollback component belongs to the Databases family.
The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>

<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connection Component</td>
<td>Select the component that opens the database connection to be reused by this component.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Select this check box to close the database connection once the component has performed its task. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

Advanced settings

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

Global Variables

| ERROR_MESSAGE | The error message generated by the component when an error occurs. This is an After variable and it returns a string. |

Usage

| Usage rule | This component is more commonly used with other tJDBC* components, especially with the tJDBCconnection and tJDBCCommit components. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using |
dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenario

For tJDBCRollback related scenario, see tMysqlRollback on page 2502
tJDBCRow

Acts on the actual DB structure or on the data (although without handling data) using the SQLBuilder tool to write easily your SQL statements.

tJDBCRow is the component for any type database using a JDBC API. It executes the SQL query stated onto the specified database. The row suffix means the component implements a flow in the job design although it doesn’t provide output.

**tJDBCRow Standard properties**

These properties are used to configure tJDBCRow running in the Standard Job framework.

The Standard tJDBCRow component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

<td>Complete this table to load the driver JARs needed. To do this, click the [+] button under the table to add as many rows as needed, each row for a driver JAR, then select the cell and click the [...] button at the right side of the cell to open the <strong>Select Module</strong> wizard from which you can select the driver JAR to be used. For example, the driver jar</td>
</tr>
</tbody>
</table>
RedshiftJDBC41-1.1.13.1013.jar for the Redshift database.

**Driver Class**
Enter the class name for the specified driver between double quotation marks. For example, for the RedshiftJDBC41-1.1.13.1013.jar driver, the name to be entered is com.amazon.redshift.jdbc41.Driver.

**Use Id and Password**
The database user authentication data.
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

**Schema and Edit schema**
A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.
- **Built-In**: You create and store the schema locally for this component only.
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

Click Edit schema to make changes to the schema. Note that if you make changes, the schema automatically becomes built-in.
- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

**Table Name**
The name of the table to be processed.

**Query Type and Query**
Specify the database query statement paying particularly attention to the properly sequence of the fields which must correspond to the schema definition.
- **Built-In**: Fill in the query statement in the Query field manually or click the [...] button next to the Query field to build the statement graphically using the SQLBuilder.
- **Repository**: Select the relevant query stored in the Repository by clicking the [...] button next to it and in the pop-up Repository Content dialog box, select the query to be used, and the Query field will be automatically filled in.

**Guess Query**
Click this button to generate query in the Query field based on the defined table and schema.

**Specify a data source alias**
Select this check box and in the Data source alias field displayed, specify the alias of a data source created on
Talend Runtime side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in Talend Runtime.

If you use the component’s own DB configuration, your data source connection will be closed at the end of the component. To prevent this from happening, use a shared DB connection with the data source alias specified.

This property is not available when other connection component is selected from the **Connection Component** drop-down list.

### Die on error

Select the check box to stop the execution of the Job when an error occurs.
Clear the check box to skip any rows on error and complete the process for error-free rows.
When errors are skipped, you can collect the rows on error using a **Row > Reject** connection.

### Advanced settings

#### Propagate QUERY’s recordset

Select this check box to propagate the result of the query to the output flow. From the **use column** list displayed, you need to select a column into which the query result will be inserted.

This option allows the component to have a different schema from that of the preceding component. Moreover, the column that holds the query’s recordset should be set to the Object type and this component is usually followed by a **tParseRecordSet** component.

#### Use PreparedStatement

Select this check box if you want to query the database using a prepared statement. In the **Set PreparedStatement Parameters** table displayed, specify the value for each parameter represented by a question mark `?` in the SQL statement defined in the **Query** field.

- **Parameter Index**: the position of the parameter in the SQL statement.
- **Parameter Type**: the data type of the parameter.
- **Parameter Value**: the value of the parameter.

For a related use case of this property, see Using **PreparedStatement objects to query data** on page 2509.

#### Commit every

Specify the number of rows to be processed before committing batches of rows together into the database.
This option ensures transaction quality (but not rollback) and, above all, better performance at executions.

#### tStatCatcher Statistics

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

| **ERROR_MESSAGE** | The error message generated by the component when an error occurs. This is an After variable and it returns a string. |
QUERY

The query statement being processed. This is a Flow variable and it returns a string.

### Usage

#### Usage rule

This component offers the flexibility of the DB query for any database using a JDBC connection and covers all possible SQL queries.

#### Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

### Related scenarios

For related topics, see:

- Combining two flows for selective output on page 2514.
- Procedure on page 625.
- Removing and regenerating a MySQL table index on page 2508.
**tJDBCSCDELT**

Tracks data changes in a source database table using SCD (Slowly Changing Dimensions) Type 1 method and/or Type 2 method and writes both the current and historical data into a specified SCD dimension table.

**tJDBCSCDELT Standard properties**

These properties are used to configure tJDBCSCDELT running in the Standard Job framework. The Standard tJDBCSCDELT component belongs to two families: Business Intelligence and Databases. The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Select the way the connection details will be set.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• <strong>Built-In</strong>: The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Repository</strong>: The connection details stored centrally in Repository &gt; Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up Repository Content dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in.</td>
</tr>
</tbody>
</table>

| Use an existing connection | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. |

| JDBC URL | The JDBC URL of the database to be used. For example, the JDBC URL for the Amazon Redshift database is jdbc:redshift://endpoint:port/database. |

| Driver JAR | Complete this table to load the driver JARs needed. To do this, click the [+] button under the table to add as many rows as needed, each row for a driver JAR, then select the cell and click the [...] button at the right side of the cell to open the Select Module wizard from which you can select the driver JAR to be used. For example, the driver jar RedshiftJDBC41-1.1.13.1013.jar for the Redshift database. |

| Driver Class | Enter the class name for the specified driver between double quotation marks. For example, for the RedshiftJDBC41-1.1.13.1013.jar driver, the name to be entered is com.amazon.redshift.jdbc41.Driver. |

<p>| Username and Password | The database user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the |</p>
<table>
<thead>
<tr>
<th><strong>password between double quotes and click OK to save the settings.</strong></th>

</tr>
</tbody>
</table>
### Source keys
Specify one or more columns used as the key(s) that ensure the unicity of the incoming data.

### Use SCD type 1 fields
Select this check box and in the **SCD type 1 fields** table displayed, specify the column(s) whose value changes will be tracked using Type 1 SCD.

### SCD type 1 fields
Click the [*] button to add as many rows as needed, each row for a column, then click the right side of the cell and from the drop-down list displayed select the column whose value changes will be tracked using Type 1 SCD.

### Use SCD type 2 fields
Select this check box and in the **SCD type 2 fields** table displayed, specify the column(s) whose value changes will be tracked using Type 2 SCD.

### SCD type 2 fields
Click the [*] button to add as many rows as needed, each row for a column, then click the right side of the cell and from the drop-down list displayed select the column whose value changes will be tracked using Type 2 SCD.

### Start date
Specify the column that holds the start date for type 2 SCD. This list is available only when the **Use SCD type 2 fields** option is selected.

### End date
Specify the column that holds the end date for type 2 SCD. This list is available only when the **Use SCD type 2 fields** option is selected.

### Log active status
Select this check box and from the **Active field** drop-down list displayed, select the column that holds the true or false status value, which helps to spot the active record for type 2 SCD. This option is available only when the **Use SCD type 2 fields** option is selected.

### Log versions
Select this check box and from the **Version field** drop-down list displayed, select the column that holds the version number of the record for type 2 SCD. This option is available only when the **Use SCD type 2 fields** option is selected.

### Mapping
Specify the metadata mapping file for the database to be used. The metadata mapping file is used for the data type conversion between database and Java. For more information about the metadata mapping, see the related documentation for Type mapping.

### Advanced settings

<table>
<thead>
<tr>
<th>Source fields value include Null</th>
<th>Select this check box to allow the source columns to have Null values. The source columns here refer to the fields</th>

<th>Usage Rule</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Usage rule</td>
<td>This component can be used as a standalone component of a Job or Subjob.</td>
</tr>
</tbody>
</table>

Tracking data changes in a Snowflake table using the tJDBCSCDELT component

This scenario describes a Job that captures the employee data changes in a Snowflake table using SCD (Slowly Changing Dimensions) Type 1 and Type 2 methods implemented by the tJDBCSCDELT component, and writes both the current and historical data in a SCD dimension table.

The input data contains various employee details including name, role, salary, and another id column is added to help ensuring the unicity of the input data.

At first, the following employee data is inserted to a new Snowflake table.

<table>
<thead>
<tr>
<th>#id;name;role;salary</th>
</tr>
</thead>
<tbody>
<tr>
<td>111;Mark Smith;tester;15000.00</td>
</tr>
<tr>
<td>222;Thomas Johnson;developer;18000.00</td>
</tr>
<tr>
<td>333;Teddy Brown;tester;16000.00</td>
</tr>
</tbody>
</table>

Later, the table is updated with the following renewed employee data.

<table>
<thead>
<tr>
<th>#id;name;role;salary</th>
</tr>
</thead>
<tbody>
<tr>
<td>111;Mark Smith;tester;15000.00</td>
</tr>
<tr>
<td>222;Thomas Johnson;tester;18000.00</td>
</tr>
<tr>
<td>333;Teddy Brown;writer;17000.00</td>
</tr>
<tr>
<td>444;John Clinton;developer;19000.00</td>
</tr>
</tbody>
</table>

You can see the role of Thomas Johnson is changed from developer to tester, the role of Teddy Brown is changed from tester to writer, and his salary is raised from 16000.00 to 17000.00. Besides, a new employee record with id 444 is inserted. In this scenario,

- the existing name and role data will be overwritten by the new data, so SCD Type 1 method will be performed on them, and
- the full history of the salary data will be retained, and a new record with the changed data will be always created and the previous record will be closed, so SCD Type 2 method will be performed on it.

For more information about SCD types, see SCD management methodology on page 2522.
Creating a Job for tracking data changes in a Snowflake table using tJDBCSCDELT

Procedure

1. Create a new Job and add a tJDBCConnection component, two tJDBCRow components, two tFixedFlowInput components, two tJDBCOutput components, two tJDBCSCDELT components, two tJDBCInput components, and two tLogRow components to the Job.
2. Link the first `tFixedFlowInput` component to the first `tJDBCOutput` component using a Row > Main connection.

3. Do the same to link the first `tJDBCInput` component to the first `tLogRow` component, the second `tFixedFlowInput` component to the second `tJDBCOutput` component, and the second `tJDBCInput` component to the second `tLogRow` component.

4. Link the `tJDBCConnection` component to the first `tJDBCRow` component using a Trigger > On Subjob Ok connection.

5. Do the same to link the first `tJDBCRow` component to the second `tJDBCRow` component, the second `tJDBCRow` component to the first `tFixedFlowInput` component, the first `tFixedFlowInput` component to the first `tJDBCSCDELT` component, the first `tJDBCSCDELT` component to the first `tJDBCInput` component, the first `tJDBCInput` component to the second `tFixedFlowInput` component, the second `tFixedFlowInput` component to the second `tJDBCSCDELT` component, the second `tJDBCSCDELT` component to the second `tJDBCInput` component.

Opening a connection to a Snowflake database

Procedure

1. Double-click the `tJDBCConnection` component to open its Basic settings view.

![tJDBCConnection_1](image)

2. In the JDBC URL field, enter the connection string to connect to Snowflake using the JDBC driver.

   For more information about how to use the JDBC driver to connect to Snowflake and how to specify the connection string, see JDBC Driver Connection String.

3. Click the [+] button below the Driver JAR table to add a line, and in the Jar name cell of the new line, enter the name of the jar file for the Snowflake JDBC driver, `snowflake-jdbc-3.2.2.jar` in this example.

4. In the Driver Class field, enter the Snowflake JDBC driver class, `com.snowflake.client.jdbc.SnowflakeDriver` in this example.

5. In the Username and Password fields, enter the authentication information accordingly.

Creating a Snowflake table and a Snowflake sequence

Procedure

1. Double-click the first `tJDBCRow` component to open its Basic settings view.
2. Select the **Use an existing connection** check box and from the **Component List** drop-down list displayed, select the connection component to reuse the connection created by it, `tJDBCConnection_1` in this example.

3. In the **Query** field, enter the SQL command used to create a new table.
   In this example, the SQL command is `CREATE OR REPLACE TABLE employee (id INTEGER, name VARCHAR(50), role VARCHAR(50), salary DOUBLE, PRIMARY KEY(id))`, which creates a new table `employee` with four columns, `id` of INTEGER type as the primary key, `name` and `role` of VARCHAR type, and `salary` of DOUBLE type. This table will be used to store the employee data.

4. Double-click the second `tJDBCRow` component to open its **Basic settings** view.

5. Select the **Use an existing connection** check box and from the **Component List** drop-down list displayed, select the connection component to reuse the connection created by it, `tJDBCConnection_1` in this example.

6. In the **Query** field, enter the SQL command used to create a Snowflake sequence.
   In this example, the SQL command is `create or replace sequence employee_sequence`, which creates a new sequence `employee_sequence`. This sequence will be used by the `tJDBCSCDELT` component to generate the surrogate key for SCD Type 2 method.

**Inserting data into the new Snowflake table**

**Procedure**

1. Double-click the first `tFixedFlowInput` component to open its **Basic settings** view.
2. Click the `[...]` button next to **Edit schema** and in the pop-up dialog box, define the schema by adding four columns: `id` of Integer type as the primary key, `name` and `role` of String type, and `salary` of Double type.

   ![Schema of tFixedFlowInput_1](image)

3. Click **OK** to save the schema changes. In the pop-up dialog box, click **Yes** to propagate the schema to the next component.

4. Select **Use Inline Content** in the **Mode** area. Then in the **Content** field displayed, enter the following employee data to be inserted:

   ```
   111;Mark Smith;tester;15000.00
   222;Thomas Johnson;developer;18000.00
   333;Teddy Brown;tester;16000.00
   ```
5. Double-click the first **tJDBCOutput** component to open its **Basic settings** view.

6. Select the **Use an existing connection** check box and from the **Component List** drop-down list displayed, select the connection component to reuse the connection created by it, **tJDBCConnection_1** in this example.

7. In the **Table** field, enter the name of the table into which the employee data will be written, **employee** in this example.

8. In the **Action on data** drop-down list, select **Insert** to insert the employee data transferred from the first **tFixedFlowInput** component.

### Tracking data insertion changes and writing the changes into a SCD dimension table

**Procedure**

1. Double-click the first **tJDBCSCDELT** component to open its **Basic settings** view.

2. Select the **Use an existing connection** check box and from the **Component List** drop-down list displayed, select the connection component to reuse the connection created by it, **tJDBCConnection_1** in this example.
3. In the **Source table** field, enter the name of the table whose data changes will be captured, `employee` in this example.

4. In the **Table** field, enter the name of the SCD dimension table that will store both the current and historical employee data, `employee_scd` in this example.

5. Select **Drop table if exists and create** from the **Action on table** drop-down list to create the SCD dimension table.

6. Click the [...] button next to **Edit schema** and in the pop-up dialog box, define the schema by adding nine columns: `sk` and `id` of Integer type as the primary key, `name` and `role` of String type, `salary` of Double type, `start_date` and `end_date` of Date type with the Date Pattern `yyyy-MM-dd`, and `active_status` and `version` of Integer type. When done, click **OK** to save the changes and close the dialog box.

7. From the **Surrogate key** drop-down list, select the name of the column that will be used as the primary key of the SCD dimension table, `sk` in this example.

8. Select **DB sequence** from the **Creation** drop-down list and in the **Sequence** field displayed, enter the name of the Snowflake sequence used to generate the surrogate key for the SCD Type 2 method.

9. Click the [...] button below the **Source keys** table to add a new line, and click the **Name** cell and select the key column of the source table from the drop-down list, `id` in this example.

10. Select the **Use SCD type 1 fields** check box, click the [...] button below the **SCD type 1 fields** table twice to add two lines. Then click each cell and from the drop-down list, select the column on which the SCD Type 1 method will be performed. In this example, they are `name` and `role`.

11. Select the **Use SCD type 2 fields** check box, click the [...] button below the **SCD type 2 fields** table to add a line. Then click the cell and select the column on which the SCD Type 2 method will be performed. In this example, it is `salary`.

12. From the **Start date** and **End date** drop-down lists, select the columns used to hold the start date and end date values for the SCD Type 2 method respectively, `start_date` and `end_date` in this example.
13. Select the Log active status check box and from the Active field drop-down list displayed, select the column used to hold the active status value for the SCD Type 2 method, which helps identify the active records, active_status in this example.

14. Select the Log versions check box and from the Version field drop-down list, select the column used to hold the version number of the records for the SCD Type 2 method, version in this example.

15. Select Mapping Snowflake from the Mapping drop-down list to use the Snowflake metadata mapping file.

Retrieving the data insertion updates from the SCD dimension table

Procedure

1. Double-click the first tJDBCInput component to open its Basic settings view.
2. Select the Use an existing connection check box and from the Component List drop-down list displayed, select the connection component to reuse the connection created by it, tJDBCConnection_1 in this example.
3. Click the [...] button next to Edit schema and in the pop-up dialog box, define the schema by adding nine columns: sk and id of Integer type as the primary key, name and role of String type, salary of Double type, start_date and end_date of Date type with the Date Pattern yyyy-MM-dd, and active_status and version of Integer type. When done, click OK to save the changes and close the dialog box.

   The schema of the first tJDBCInput component is the same as the schema of the tJDBCSCDELT component, you can just copy and paste it.

4. In the Query field, enter the SQL command used to retrieve data from the SCD dimension table, select * from employee_scd in this example.
5. Double-click the first tLogRow component and in the Mode area on its Basic settings view, select Table to display the retrieved data in a table.

Updating data in the Snowflake table

Procedure

1. Double-click the second tFixedFlowInput component to open its Basic settings view.
2. Click the [...] button next to Edit schema and in the pop-up dialog box, define the schema by adding four columns: id of Integer type as the primary key, name and role of String type, and salary of Double type.

   This schema is the same as the schema of the first tFixedFlowInput component, you can just copy and paste it.

3. Click OK to save the schema changes. In the pop-up dialog box, click Yes to propagate the schema to the next component.
4. Select Use Inline Content in the Mode area. Then in the Content field displayed, enter the following employee data to update the existing data.

   111;Mark Smith;tester;15000.00
   222;Thomas Johnson;tester;18000.00
   333;Teddy Brown;writer;17000.00
   444;John Clinton;developer;19000.00
5. Double-click the second tJDBCOutput component to open its Basic settings view.

6. Select the Use an existing connection check box and from the Component List drop-down list displayed, select the connection component to reuse the connection created by it, tJDBCConnection_1 in this example.

7. In the Table field, enter the name of the table, in which the data will be updated, employee in this example.

8. Select Insert or update from the Action on data drop-down list.

Tracking data update changes and writing the changes into the SCD dimension table

Procedure
1. Double-click the second tJDBCSCDELT component to open its Basic settings view.

2. Repeat 2 on page 1864 through 15 on page 1866 in the procedure Tracking data insertion changes and writing the changes into a SCD dimension table on page 1864 to configure the second tJDBCSCDELT component.

Retrieve the data update changes from the SCD dimension table

Procedure
1. Double-click the second tJDBCInput component to open its Basic settings view.

2. Repeat 2 on page 1866 through 4 on page 1866 in the procedure Retrieving the data insertion updates from the SCD dimension table on page 1866 to configure the second tJDBCInput component.

3. Double-click the second tLogRow component and in the Mode area on its Basic settings view, select Table to display the retrieved data in a table.

Executing the Job to track data changes in a Snowflake table using tJDBCSCDELT

Procedure
1. Press Ctrl + S to save the Job.

2. Press F6 to execute the Job.
As shown above, the old role developer for Thomas Johnson is overwritten directly by the new role tester because SCD Type 1 is performed on the role column, and a new record with the surrogate key value set to 4 is created for Teddy Brown’s salary update from 16000.00 to 17000.00 because SCD Type 2 is performed on the salary column.
tJDBCSP

Centralizes multiple or complex queries in a database in order to call them easily.

tJDBCSP Standard properties

These properties are used to configure tJDBCSP running in the Standard Job framework.

The Standard tJDBCSP component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property Type</td>
<td>Select the way the connection details will be set.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Built-in</strong>: The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Repository</strong>: The connection details stored centrally in Repository &gt; Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up Repository Content dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in.</td>
</tr>
<tr>
<td>Connection Component</td>
<td>Select the component that opens the database connection to be reused by this component.</td>
</tr>
<tr>
<td>JDBC URL</td>
<td>The JDBC URL of the database to be used. For example, the JDBC URL for the Amazon Redshift database is <code>jdbc:redshift://endpoint:port/database</code>.</td>
</tr>
<tr>
<td>Drivers</td>
<td>Complete this table to load the driver JARs needed. To do this, click the [+] button under the table to add as many rows as needed, each row for a driver JAR, then select the cell and click the [...] button at the right side of the cell to open the Select Module wizard from which you can select the driver JAR to be used. For example, the driver jar <code>RedshiftJDBC41-1.1.13.1013.jar</code> for the Redshift database.</td>
</tr>
</tbody>
</table>
| Driver Class | Enter the class name for the specified driver between double quotation marks. For example, for the `RedshiftJDBC41-1.1.13.1013.jar`
driver, the name to be entered is `com.amazon.redshift.jdbc41.Driver`.

### Use Id and Password

The database user authentication data. To enter the password, click the `[...]` button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

### SP Name

The name of the stored procedure.

### Is function

Select this check box if the stored procedure is a function and a value will be returned from the stored procedure. With this check box selected, you need to select the column in which the returned value will be saved from the **Return result in** drop-down list.

### Set SP Parameters

Specify the parameters for the stored procedure by clicking the `[+]` button to add as many rows as needed, each row for a parameter, and setting the following value for each parameter.

- **Schema Column**: The column that holds the parameter value.
- **Parameter Type**: The type of the parameter.
  - **IN**: The input parameter.
  - **OUT**: The output parameter/return value.
  - **IN OUT**: The combination of input and output parameters. It means the parameter can be passed to the stored procedure, modified by the procedure, and returned with a new value.
  - **RECORDSET**: The input parameter will be returned as a set of values, rather than a single value.

### Schema and Edit schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

- **Built-In**: You create and store the schema locally for this component only.
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

Click **Edit schema** to make changes to the schema. Note that if you make changes, the schema automatically becomes built-in.

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

### Specify a data source alias

Select this check box and in the **Data source alias** field displayed, specify the alias of a data source created on
Talend Runtime side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in Talend Runtime.

If you use the component’s own DB configuration, your data source connection will be closed at the end of the component. To prevent this from happening, use a shared DB connection with the data source alias specified.

This property is not available when other connection component is selected from the Connection Component drop-down list.

### Advanced settings

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
<th>Select this check box to gather the Job processing metadata at the Job level as well as at each component level.</th>
</tr>
</thead>
</table>

### Global Variables

<table>
<thead>
<tr>
<th>ERROR_MESSAGE</th>
<th>The error message generated by the component when an error occurs. This is an After variable and it returns a string.</th>
</tr>
</thead>
</table>

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is used as intermediary component. It can be used as start component but only input parameters are thus allowed.</th>
</tr>
</thead>
</table>

| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |

</thead>
</table>

### Related scenario

For related scenarios, see:

- Executing a stored procedure using tMDMSP on page 2159.
- Checking number format using a stored procedure on page 2754
Check as well [Inserting data in mother/daughter tables](#) on page 2437 if you want to analyze a set of records from a database table or DB query and return single records.
tJDBCTableList

Lists the names of a given set of JDBC tables using a select statement based on a Where clause.
tJDBCTableList iterates on a set of table names through a defined JDBC connection.

**tJDBCTableList Standard properties**

These properties are used to configure tJDBCTableList running in the Standard Job framework.
The Standard tJDBCTableList component belongs to the Databases family.
The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Database type</th>
<th>Select a database from the list, such as Mysql, Oracle, etc.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tJDBCConnection component or a database-specific connection component if the relevant database is selected from the Database type list.</td>
</tr>
</tbody>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th>Use filter</th>
<th>Select this check box to filter the tables to be iterated on.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Regular expression for tables name</td>
<td>Enter the regular expression to identify table names.</td>
</tr>
<tr>
<td></td>
<td>Available when Use filter is selected.</td>
</tr>
<tr>
<td>Filter criteria</td>
<td>Select the criteria for filtering table names.</td>
</tr>
<tr>
<td>Include</td>
<td>iterates on the table names identified by the regular expression only.</td>
</tr>

<td>NB_TABLE: the number of tables iterated upon so far. This is a Flow variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>ERROR.MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
</tbody>
</table>
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

| Usage rule | This component is to be used along with JDBC components, especially with tJDBCConnection. |

Related scenario

For tJDBCTableList related scenario, see Iterating on a DB table and listing its column names on page 2430.
# tJIRAInput

Retrieves the issue information based on a JQL query or retrieve the project information based on a specified project ID from JIRA.

## tJIRAInput Standard properties

These properties are used to configure tJIRAInput running in the Standard Job framework.

The Standard tJIRAInput component belongs to the Business family.

The component in this framework is available in all Talend products.

### Basic settings

<table>
<thead>
<tr>
<th>Host URL</th>
<th>Specify the URL used to access JIRA.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>User Id and Password</strong></td>
<td>Specify the user authentication data used to access JIRA. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>JIRA resource</strong></td>
<td>Select the JIRA resource from the drop-down list, either ISSUE or PROJECT.</td>
</tr>
<tr>
<td><strong>Schema and Edit schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. Note that the schema of this component is read-only with a single column json of String type. It stores the issue or project information in JSON format. You can click Edit schema to view the schema.</td>
</tr>
<tr>
<td><strong>JQL</strong></td>
<td>Specify the JQL (JIRA Query Language) query based on which you will search for issues in JIRA. For more information about the JQL, see <a href="https://confluence.atlassian.com/jirasoftwareserver072/advanced-searching-829057400.html">https://confluence.atlassian.com/jirasoftwareserver072/advanced-searching-829057400.html</a>. This field is available only when ISSUE is selected from the Jira resource drop-down list.</td>
</tr>
<tr>
<td><strong>Project ID</strong></td>
<td>Enter the ID of the project whose information you want to retrieve from JIRA. This field is available only when PROJECT is selected from the Jira resource drop-down list.</td>
</tr>
</tbody>
</table>

### Advanced settings

| **Batch size** | Specify the number of issues to be processed in each batch. This field is available only when ISSUE is selected from the Jira resource drop-down list. |
tStatCatcher Statistics

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

Global Variables

Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NB_LINE</td>
<td>the number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>ERROR_MESSAGE</td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule

This component is usually used as a start component of a Job or Subjob and it always needs an output link.

Limitation

This component doesn't support retrieving the comments of issues from JIRA.

Retrieving the project information from JIRA application

Here is an example of using Talend components to retrieve the information of a project from JIRA application, extract the information needed based on the JSONPath query, and finally write the extracted information into a JSON file.

Creating a Job for retrieving the project information from JIRA application

Before you begin

A project with the key DOC has been created in JIRA application.
Procedure
1. Create a new Job and add a **tJIRAInput** component, a **tExtractJSONFields** component, and a **tFileOutputJSON** component to the Job.
2. Link the **tJIRAInput** component to the **tExtractJSONFields** component using a **Row > Main** connection.
3. Link the **tExtractJSONFields** component to the **tFileOutputJSON** component using a **Row > Main** connection.

Configuring the Job for retrieving the project information from JIRA application

Procedure
1. Double-click the **tJIRAInput** component to open its **Basic settings** view.

   ![tJIRAInput](image1)

2. In the **Host URL**, **User Id**, and **Password** fields, specify the user authentication information required to access the JIRA application.
3. Select **Project** from the **JIRA resource** drop-down list, in the **Project ID** field displayed, enter the key of the project, whose information will be retrieved. In this example, it is **DOC**.
4. Double-click the **tExtractJSONFields** component to open its **Basic settings** view.

   ![tExtractJSONFields](image2)

   - **Property Type**: Built-In
   - **Schema**: Built-In
   - **Read By**: JsonPath
   - **JSON field**: json
   - **Mapping**:
     - Column: id, Json query: "$id"
     - Column: key, Json query: "$.key"
     - Column: name, Json query: "$.name"
     - Column: description, Json query: "$.description"
     - Column: assigneeType, Json query: "$.assigneeType"
     - Column: projectTypeKey, Json query: "$.projectTypeKey"
5. Click the […] button next to **Edit schema**, and in the schema dialog box displayed, define the schema by adding six columns of **String type**, id, key, name, description, assigneeType, and ProjectTypeKey, which will hold the corresponding information of the specified project. When done, click **OK** to save the changes and close the dialog box.

6. Select the JSON field to be extracted from the **JSON field** drop-down list. In this example, it is json, which is passed from the **tJIRAinput** component.

7. In the **Loop Jsonpath query** field, specify the path to the node on which the loop is based. In this example, it is $, which is the root node of the JSON field.

8. In the **Mapping** table, the **Column** cells are automatically filled with the schema columns, and you need to specify the corresponding JSON node that holds the desired data for each schema column. In this example, $.id for the id column, $.key for the key column, $.name for the name column, $.description for the description column, $.assigneeType for the assigneeType column, and $.projectTypeKey for the projectTypeKey column.

9. Double-click the **tFileOutputJSON** component to open its **Basic settings** view.

10. In the **File Name** field, specify the path to the file into which the extracted project information will be written, D:/JiraComponents/project_info.json in this example. And in the **Name of data block** field, enter the name of the data block, project in this example.

**Executing the Job to retrieve the project information from JIRA application**

**Procedure**

1. Press **Ctrl + S** to save the Job.
2. Press **F6** to execute the Job.
3. Open the JSON file **project_info.json** generated.

   Note that all extracted project information is displayed in one line in the generated JSON file, and you can use some editor tool to format and indent the data into an organized manner for better display of the result.

   As shown above, the desired project information has been successfully extracted and written into the JSON file.
tJIRAOutput

Inserts, updates, or deletes the issue or project information in JIRA.

**tJIRAOutput Standard properties**

These properties are used to configure tJIRAOutput running in the Standard Job framework.

The Standard tJIRAOutput component belongs to the Business family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Host URL</th>
<th>Specify the URL used to access JIRA.</th>
</tr>
</thead>
<tbody>
<tr>
<td>User Id and Password</td>
<td>Specify the user authentication data used to access JIRA. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td>JIRA resource</td>
<td>Select the JIRA resource from the drop-down list, either ISSUE or PROJECT.</td>
</tr>
<tr>
<td>Schema and Edit schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. Note that the schema of this component is read-only with a single column <em>json</em> of <em>String</em> type. It stores the issue or project information in JSON format. You can click <strong>Edit schema</strong> to view the schema.</td>
</tr>
</tbody>
</table>
| Output Action | Select an operation to be performed from the drop-down list.  
- **INSERT**: insert new issue or project information into JIRA.  
- **UPDATE**: modify existing issue or project information in JIRA.  
- **DELETE**: remove issue or project data in JIRA corresponding to the input flow. |

**Advanced settings**

| Delete subtasks | Select this check box to delete the subtask(s). This check box is available only when ISSUE is selected from the JIRA resource drop-down list and DELETE is selected from the Output Action drop-down list. |
| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |
Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_LINE: the number of rows processed. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>NB_SUCCESS: the number of rows successfully processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>NB_REJECT: the number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td></td>
<td>For further information about variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

Usage

| Usage rule | This component is usually used as an end component of a Job or Subjob and it always needs an input link. |

Creating an issue in JIRA application

Here is an example of using Talend components to create a new issue in JIRA application, then retrieve the information of the new issue from JIRA application, finally extract the information needed based on the JSONPath query and write the extracted information into a JSON file.

Setting up a Job for creating an issue in JIRA application

![Diagram showing the setup of a Job for creating an issue in JIRA application]
Before you begin

A project with the key **DOC** has been created in JIRA application and only one issue with the key **DOC-1** has already been created under this project.

**Procedure**

1. Create a new Job and add a **tFileInputDelimited** component, a **tJIRAOutput** component, a **tJIRAInput** component, a **tExtractJSONFields** component, and a **tFileOutputJSON** component to the Job.
2. Double-click the **tJIRAOutput** component to open its **Basic settings** view.
3. Select **Issue** from the **JIRA resource** drop-down list and **Insert** from the **Output Action** drop-down list to insert an issue.
4. Link the **tFileInputDelimited** component to the **tJIRAOutput** component using a **Row > Main** connection. In the pop-up dialog box, click **Yes** to let the **tFileInputDelimited** component get the schema of the **tJIRAOutput** component.
5. Do the same to link the **tJIRAInput** component to the **tExtractJSONFields** component and the **tExtractJSONFields** component to the **tFileOutputJSON** component.
6. Link the **tFileInputDelimited** component to the **tJIRAInput** component using a **Trigger > On Subjob Ok** connection.

Creating a new issue in JIRA application

**Procedure**

1. Double-click the **tFileInputDelimited** component to open its **Basic settings** view.
2. In the **File name/Stream** field, specify the path to the JSON file used to create the issue.

   In this example, a simple JSON file D:/JiraComponents/issue_create.json will be used to insert a new issue under the project with the key **DOC** and the data in this file reads as follows:

   ```json
   {"fields": {
       "issuetype": {
           "id": "10001",
           "name": "Task"
       },
       "project": {
           "key": "DOC",
           "name": "Documentation"
       },
       "description": "Create an issue under the DOC project",
       "summary": "Add the documentation for new components tJIRA***"
   }}
   ```

   Note that the **tJIRAOutput** component now only supports creating project/issue in JIRA application with the single line JSON file, so you need to join all lines in the input JSON file into one line before executing the Job.

   For more information about the types of issues, see the JIRA official documentation **Issue types**.

   For more information about how to find the id for issue types, see the JIRA official documentation **Finding the Id for Issue Types**.
3. Double-click the **tJIRAOutput** component to open its **Basic settings** view.
4. In the Host URL, User Id, and Password fields, specify the user authentication information required to access the JIRA application.

**Retrieving the new issue information from JIRA application**

**Procedure**

1. Double-click the **tJIRAInput** component to open its Basic settings view.

   ![tJIRAInput](image1)

   - Select Issue from the JIRA resource drop-down list.
   - In the JQL field, enter the JQL query used to retrieve issues in JIRA application.
     - In this example, the query is `project = DOC ORDER BY created DESC`. All issues under the project DOC will be retrieved and they will be sorted by the creation date in descending order.

2. Double-click the **tExtractJSONFields** component to open its Basic settings view.

   ![tExtractJSONFields](image2)

   - Click the [...] button next to Edit schema, and in the schema dialog box displayed, define the schema by adding five columns of String type, id, key, project, description, and summary, which will hold the corresponding information of each issue retrieved.
     - When done, click OK to save the changes and close the dialog box.

3. Select the JSON field to be extracted from the JSON field drop-down list. In this example, it is json, which is passed from the tJIRAInput component.
7. In the **Loop Jsonpath query** field, specify the path to the node on which the loop is based. In this example, it is $, which is the root node of the JSON field.

8. In the **Mapping** table, the **Column** cells are automatically filled with the schema columns, and you need to specify the corresponding JSON node that holds the desired data for each schema column. In this example, $.id for the id column, $.key for the key column, $.fields.project.key for the project column, $.fields.description for the description column, and $.fields.summary for the summary column.

9. Double-click the **tFileOutputJSON** component to open its **Basic settings** view.

10. In the **File Name** field, specify the path to the file into which the extracted issue information will be written, D:/JiraComponents/issue_info.json in this example. And in the **Name of data block** field, enter the name of the data block, issue in this example.

**Executing the Job to create an issue in JIRA application**

**Procedure**

1. Press **Ctrl + S** to save the Job.
2. Press **F6** to execute the Job.
3. Open the JSON file issue_info.json generated.

   Note that all extracted issue information is displayed in one line in the generated JSON file, and you can use some editor tool to format and indent the data into an organized manner for better display of the result.

   ![issue_info.json](image)

   As shown above, a new issue with the key **DOC-2** has been created, and the desired information for each issue in the project **DOC** has been successfully extracted and written into the JSON file.

**Updating an issue in JIRA application**

Here is an example of using Talend components to update an existing issue in JIRA application, then retrieve the information of the updated issue from JIRA application, finally extract the information needed based on the JSONPath query and write the extracted information into a JSON file.
tJIRAOutput

Creating a Job for updating an issue in JIRA application

Before you begin
A project with the key DOC has been created in JIRA application and an issue with the key DOC-2 as
shown below has already been created under this project.

Procedure
1. Create a new Job and add a tFileInputDelimited component, a tJIRAOutput component, a
tJIRAInput component, a tExtractJSONFields component, and a tFileOutputJSON component to the
Job.
2. Double-click the tJIRAOutput component to open its Basic settings view.
3. Select Issue from the JIRA resource drop-down list and Update from the Output Action dropdown list to update an issue.
4. Link the tFileInputDelimited component to the tJIRAOutput component using a Row > Main
connection. In the pop-up dialog box, click Yes to let the tFileInputDelimited component get the
schema of the tJIRAOutput component.
5. Do the same to link the tJIRAInput component to the tExtractJSONFields component and the
tExtractJSONFields component to the tFileOutputJSON component.
6. Link the tFileInputDelimited component to the tJIRAInput component using a Trigger > On
Subjob Ok connection.

Updating an issue in JIRA application

1884


Procedure

1. Double-click the `tFileInputDelimited` component to open its Basic settings view.
2. In the File name/Stream field, specify the path to the JSON file used to update the issue.

   In this example, a simple JSON file `D:/JiraComponents/issue_update.json` will be used to update an existing issue with the key `DOC-2` that is under the DOC project, and the data in this file reads as follows:

   ```json
   DOC-2;
   { "fields": {
     "description": "Update an issue under the DOC project",
     "summary": "Add the documentation for new components tJIRAInput and tJIRAOutput"
   }}
   
   Note that the `tJIRAOutput` component now only supports updating project/issue in JIRA application with the single line JSON file, so you need to join all lines in the input JSON file into one line before executing the Job.

3. Double-click the `tJIRAOutput` component to open its Basic settings view.
4. In the Host URL, User Id, and Password fields, specify the user authentication information required to access the JIRA application.

Retrieving the updated issue information from JIRA application

Procedure

1. Double-click the `tJIRAInput` component to open its Basic settings view.

   ![tJIRAInput_1](image)

2. Select Issue from the JIRA resource drop-down list.
3. In the JQL field, enter the JQL query used to retrieve the issue in JIRA application.

   In this example, the query is `project = DOC AND issuekey = DOC-2`. The issue with the key `DOC-2` under the project `DOC` will be retrieved.
4. Double-click the `tExtractJSONFields` component to open its Basic settings view.
5. Click the [...] button next to **Edit schema**, and in the schema dialog box displayed, define the schema by adding five columns of String type, **id**, **key**, **project**, **description**, and **summary**, which will hold the corresponding information of each issue retrieved. When done, click **OK** to save the changes and close the dialog box.

6. Select the JSON field to be extracted from the **JSON field** drop-down list. In this example, it is **json**, which is passed from the **tJIRAInput** component.

7. In the **Loop jsonpath query** field, specify the path to the node on which the loop is based. In this example, it is `$$`, which is the root node of the JSON field.

8. In the **Mapping** table, the **Column** cells are automatically filled with the schema columns, and you need to specify the corresponding JSON node that holds the desired data for each schema column. In this example, `$.id` for the **id** column, `$.key` for the **key** column, `$.fields.project.key` for the **project** column, `$.fields.description` for the **description** column, and `$.fields.summary` for the **summary** column.

9. Double-click the **tFileOutputJSON** component to open its **Basic settings** view.

10. In the **File Name** field, specify the path to the file into which the extracted issue information will be written, `D:/JiraComponents/issue_info_update.json` in this example. And in the **Name of data block** field, enter the name of the data block, **issue** in this example.

### Executing the Job to update an issue in JIRA application

**Procedure**

1. Press **Ctrl + S** to save the Job.
2. Press **F6** to execute the Job.
3. Open the JSON file **issue_info_update.json** generated.

   Note that all extracted issue information is displayed in one line in the generated JSON file, and you can use some editor tool to format and indent the data into an organized manner for better display of the result.
As shown above, the issue with the key DOC-2 has been updated, and the desired information for the issue has been successfully extracted and written into the JSON file.
tJMSInput

Creates an interface between a Java application and a Message-Oriented middleware system. Using a JMS server, tJMSInput makes it possible to have loosely coupled, reliable, and asynchronous communication between different components in a distributed application.

For further information about the messaging brokers supported by this component, see Messaging brokers supported by Talend messaging components.

tJMSInput Standard properties

These properties are used to configure tJMSInput running in the Standard Job framework.

The Standard tJMSInput component belongs to the Internet family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Module List</th>
<th>Select the library to be used from the list.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Context Provider</td>
<td>Type in the context URL, for example <code>com.tibco.tibms.naming.TibjmsInitialContextFactory</code>. However, be careful, the syntax can vary according to the JMS server used.</td>
</tr>
<tr>
<td>Server URL</td>
<td>Type in the server URL, respecting the syntax, for example <code>tibjmsnaming://localhost:7222</code>.</td>
</tr>
<tr>
<td>Connection Factory JDNI Name</td>
<td>Type in the JDNI name.</td>
</tr>
<tr>
<td>Use Specified User Identity</td>
<td>If you have to log in, select the check box and type in your login and password. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td>Enable Durable Subscription</td>
<td>Select this check box to enable the durable subscription.</td>
</tr>
<tr>
<td>ClientID</td>
<td>Enter the client ID for the durable subscription. This field is available only when the <strong>Enable Durable Subscription</strong> check box is selected.</td>
</tr>
<tr>
<td>Subscriber Name</td>
<td>Enter the subscriber name for the durable subscription. This field is available only when the <strong>Enable Durable Subscription</strong> check box is selected.</td>
</tr>
<tr>
<td>Use JNDI Name Lookup Destination</td>
<td>Select this check box to look up a destination with the JNDI (Java Naming and Directory Interface) name.</td>
</tr>
<tr>
<td>Message Type</td>
<td>Select the message type, either: <strong>Topic</strong> or <strong>Queue</strong>.</td>
</tr>
</tbody>
</table>
**Message From**
Type in the message source, exactly as expected by the server; this must include the type and name of the source. e.g.: queue/A or topic/testtopic
Note that the field is case-sensitive.

**Timeout for Next Message (in sec)**
Type in the number of seconds before passing to the next message.

**Maximum Messages**
Type in the maximum number of messages to be processed.

**Message Selector Expression**
Set your filter.

**Processing Mode**
Select the processing mode for the messages.
- Raw Message
- Message Content

**Schema and Edit Schema**
A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

The schema of this component is read-only. You can click **Edit schema** to view the schema.

**Advanced settings**

**Properties**
Click the plus button underneath the table to add lines that contains username and password required for user authentication.

**tStatCatcher Statistics**
Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

**Global Variables**

**Global Variables**
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.
- **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

**Usage**

**Usage rule**
This component is generally used as an input component. It must be linked to an output component.
**Limitation**

Make sure the JMS server is launched. Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

**Related scenarios**

For related scenarios, see Enqueuing/dequeuing a message on the ActiveMQ server on page 1892.
**tJMSOutput**

Creates an interface between a Java application and a Message-Oriented middleware system.

Using a JMS server, tJMSOutput makes it possible to have loosely coupled, reliable, and asynchronous communication between different components in a distributed application.

For further information about the messaging brokers supported by this component, see [Messaging brokers supported by Talend messaging components](#).

**tJMSOutput Standard properties**

These properties are used to configure tJMSOutput running in the Standard Job framework.

The Standard tJMSOutput component belongs to the Internet family.

The component in this framework is available in all [Talend products](#).

**Basic settings**

<table>
<thead>
<tr>
<th><strong>Module List</strong></th>
<th>Select the library to be used from the list.</th>

<th>Usage rule</th>
<th>This component is generally used as an output component. It must be linked to an input component.</th>
</tr>
</thead>
</table>

| Limitation | Make sure the JMS server is launched. Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |

Enqueuing/dequeuing a message on the ActiveMQ server

In this scenario, JMSOutput sends a message to a queue on the ActiveMQ server, which is then retrieved by JMSInput. This message is finally displayed on the console via tLogRow.
Linking the components

Procedure
1. Drop tFixedFlowInput, JMSOutput, JMSInput, and tLogRow onto the workspace.
2. Link tFixedFlowInput to JMSOutput using a Row > Main connection.
3. Link tFixedFlowInput to JMSInput using the OnSubjobOk trigger.
4. Link JMSInput to tLogRow using a Row > Main connection.

Configuring the components

Procedure
1. Double-click tFixedFlowInput to open its Basic settings view.

![Diagram showing component connections]

Select Use Inline Content (delimited file) in the Mode area.

In the Content field, enter the content of the message to be sent to the ActiveMQ server:

message transferred

2. Click the Edit schema button to open the schema editor.
3. Click the [+\] button to add one column, namely messageContent, of the string type. Click OK to validate the setup and close the editor.

4. Now appears the pop-up box that asks for schema propagation.

Click Yes to propagate the schema to the subsequent component.

5. Double-click JMSOutput to open its Basic settings view.

6. In the Module List list, select the library to be used, namely the activemq jar in this case.

7. In the Context Provider field, enter the context URI, \"org.apache.activemq.jndi.ActiveMQInitialContextFactory\" in this case.

8. In the Server URL field, enter the ActiveMQ Server URI.

9. In the Connection Factory JNDI Name field, enter the JNDI name, "QueueConnectionFactory" in this case.
10. Select the **Use Specified User Identity** check box to show the **User Name** and **Password** fields, where you can enter the authentication data.

11. In the **Message type** list, select **Queue**.

12. In the **Processing Mode** list, select **Message Content**.

13. Perform the same setup in the **Basic settings** view of **JMSInput**.

![JMSInput_1](image)

**Executing the Job**

**Procedure**

1. Press **Ctrl + S** to save the Job.
2. Press **F6** to run the Job. Note that the ActiveMQ server has started at tcp://192.168.30.46:61616.

   
   ```
   [statistics] connecting to socket on port 3999
   [statistics] connected
   Ready to receive message
   Waiting ...
   message transferred
   ```

   As shown above, the message is correctly transferred and displayed.

**Related scenarios**

For related scenarios, see Asynchronous communication via a MOM server on page 2247 and Transmitting XML files via a MOM server on page 2250.
tJoin

Performs inner or outer joins between the main data flow and the lookup flow.

tJoin joins two tables by doing an exact match on several columns. It compares columns from the main flow with reference columns from the lookup flow and outputs the main flow data and/or the rejected data.

**tJoin Standard properties**

These properties are used to configure tJoin running in the Standard Job framework.

The Standard tJoin component belongs to the Processing family.

The component in this framework is available in all Talend products.

**Basic settings**

| **Schema and Edit schema** | A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either **Built-in** or stored remotely in the **Repository**.
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:
- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-in</strong>: You create and store the schema locally for this component only. Related topic: see <strong>Talend Studio User Guide</strong>.</td>
<td></td>
</tr>
<tr>
<td><strong>Repository</strong>: The schema already exists and is stored in the Repository, hence can be reused in various projects and Job flowcharts. Related topic: see <strong>Talend Studio User Guide</strong>.</td>
<td></td>
</tr>
<tr>
<td><strong>Include lookup columns in output</strong></td>
<td>Select this check box to include the lookup columns you define in the output flow.</td>
</tr>
<tr>
<td><strong>Input key attribute</strong></td>
<td>Select the column(s) from the main flow that needs to be checked against the reference (lookup) key column.</td>
</tr>
<tr>
<td><strong>Lookup key attribute</strong></td>
<td>Select the lookup key columns that you will use as a reference against which to compare the columns from the input flow.</td>
</tr>
</tbody>
</table>
Inner join (with reject output)

Select this check box to join the two tables first and gather the rejected data from the main flow.

Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | This component is not startable and it requires two input components and one or more output components. |

Doing an exact match on two columns and outputting the main and rejected data

This scenario describes a five-component Job aiming at carrying out an exact match between the firstnameClient column of an input file against the data of the reference input file, and the lastnameClient column against the data of the reference input file. The outputs of this exact match are written in two separate files: exact data are written in an Excel file, and inaccurate data are written in a delimited file.

In this scenario, we have already stored the input schemas of the input and reference files in the Repository. For more information about storing schema metadata in the Repository tree view, see Talend Studio User Guide.

Dropping and linking the components

Procedure

1. In the Repository tree view, expand Metadata and the file node where you have stored the input schemas and drop the relevant file onto the design workspace. The Components dialog box appears.
2. Select tFileInputDelimited from the list and click OK to close the dialog box. The tFileInputDelimited component displays in the workspace. The input file used in this scenario is called ClientSample. It holds four columns including the two columns firstnameClient and lastnameClient we want to do the exact match on.

3. Do the same for the second input file you want to use as a reference, ClientSample_Update in this scenario.

4. Drop the following components from the Palette onto the design workspace: tJoin, tFileOutputExcel, and tFileOutputDelimited.

5. Connect the main and reference input files to tJoin using Main links. The link between the reference input file and tJoin appears as a lookup link on the design workspace.

6. Connect tJoin to tFileOutputExcel using the Main link and tJoin to tFileOutputDelimited using the Inner join reject link.
Configuring the components

Procedure

1. If needed, double-click the main and reference input files to display their Basic settings views. All their property fields are automatically filled in. If you do not define your input files in the Repository, fill in the details manually after selecting Built-in in the Property Type field.

2. Double click tJoin to display its Basic settings view and define its properties.

3. Click the Edit schema button to open a dialog box that displays the data structure of the input files, define the data you want to pass to the output components, three columns in this scenario, idClient, firstnameClient and lastnameClient, and then click OK to validate the schema and close the dialog box.

4. In the Key definition area of the Basic settings view of tJoin, click the plus button to add two columns to the list and then select the input columns and the output columns you want to do the exact matching on from the Input key attribute and Lookup key attribute lists respectively, firstnameClient and lastnameClient in this example.

5. Select the Inner join (with reject output) check box to define one of the outputs as inner join reject table.

6. Double click tFileOutputExcel to display its Basic settings view and define its properties.
7. Set the destination file name and the sheet name, and select the **Include header** check box.

8. Double click **tFileOutputDelimited** to display its **Basic settings** view and define its properties.

9. Set the destination file name, and select the **Include header** check box.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl+S** to save your Job.

2. Press **F6**, or click **Run** on the **Run** tab to execute the Job.
The output of the exact match on the *firstnameClient* and *lastnameClient* columns is written to the defined Excel file.

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>idClient</td>
<td>firstnameClient</td>
<td>lastnameClient</td>

</tbody>
</table>
tKafkaCommit

Saves the current state of the tKafkaInput to which it is connected.

The tKafkaCommit component connects to a given tKafkaInput to perform a consumer offset commit. Note that the term 'commit' in this component means saving what messages are consumed by this tKafkaInput component at the moment of committing.

**tKafkaCommit Standard properties**

These properties are used to configure tKafkaCommit running in the Standard Job framework.

The Standard tKafkaCommit component belongs to the Internet family.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| Commit offsets from | Select the tKafkaInput component from which the consumed messages are committed. |

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the processing metadata at the Job level as well as at each component level. |

**Usage**

| Usage rule | Although tKafkaCommit can be used as an end component in a subjob flow or can be called independently as its own subjob, it is typically used standalone to commit a batch of offsets in one go. If you need to commit offsets regularly, it is recommended to use the Auto-commit feature in tKafkaInput. |

**Related scenarios**

No scenario is available for the Standard version of this component yet.
tKafkaConnection

Opens a reusable Kafka connection.

The tKafkaConnection component opens a connection to a given Kafka cluster so that the other Kafka component in subjobs can reuse this connection.

tKafkaConnection Standard properties

These properties are used to configure tKafkaConnection running in the Standard Job framework.

The Standard tKafkaConnection component belongs to the Internet family.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

Basic settings

<table>
<thead>
<tr>
<th>Version</th>
<th>Select the version of the Kafka cluster to be used.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zookeeper quorum list</td>
<td>Enter the address of the Zookeeper service of the Kafka cluster to be used. The form of this address should be hostname:port. This information is the name and the port of the hosting node in this Kafka cluster. If you need to specify several addresses, separate them using a comma (,).</td>
</tr>
<tr>
<td>Broker list</td>
<td>Enter the addresses of the broker nodes of the Kafka cluster to be used. The form of this address should be hostname:port. This information is the name and the port of the hosting node in this Kafka cluster. If you need to specify several addresses, separate them using a comma (,).</td>
</tr>
<tr>
<td>Use SSL/TLS</td>
<td>Select this check box to enable the SSL or TLS encrypted connection. Then you need to use the tSetKeystore component in the same Job to specify the encryption information. For further information about tSetKeystore, see tSetKeystore on page 3464. This check box is available since Kafka 0.9.0.1.</td>
</tr>
</tbody>
</table>
| Use Kerberos authentication | If the Kafka cluster to be used is secured with Kerberos, select this check box to display the related parameters to be defined:  
  • JAAS configuration path: enter the path, or browse to the JAAS configuration file to be used by the Job to authenticate as a client to Kafka. This JAAS file describes how the clients, the Kafka-related Jobs in terms of Talend, can connect to the Kafka broker nodes, using either the kinit mode or the |
keytab mode. It must be stored in the machine where these Jobs are executed.

_Talend_ , Kerberos or Kafka does not provide this JAAS file. You need to create it by following the explanation in Configuring Kafka client depending on the security strategy of your organization.

- **Kafka brokers principal name**: enter the primary part of the Kerberos principal you defined for the brokers when you were creating the broker cluster. For example, in this principal `kafka/kafka1.hostname.com@EXAMPLE.COM`, the primary part to be used to fill in this field is `kafka`.

- **Set kinit command path**: Kerberos uses a default path to its kinit executable. If you have changed this path, select this check box and enter the custom access path. If you leave this check box clear, the default path is used.

- **Set Kerberos configuration path**: Kerberos uses a default path to its configuration file, the `krb5.conf` file (or `krb5.ini` in Windows) for Kerberos 5 for example. If you have changed this path, select this check box and enter the custom access path to the Kerberos configuration file.

For further information about how a Kafka cluster is secured with Kerberos, see Authenticating using SASL.

This check box is available since Kafka 0.9.0.1.

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the processing metadata at the Job level as well as at each component level. |

**Usage**

| Usage rule | This component is used standalone to create the Kafka connection that the other Kafka components can reuse. |

**Related scenarios**

No scenario is available for the Standard version of this component yet.

**Kafka and AVRO in a Job**

In a Talend Job, the Kafka components (the regular Kafka components) and the Kafka components for AVRO handle AVRO data differently, as is reflected in the approaches AVRO provides to (de)serialize the data of AVRO format.
• The regular Kafka components read and write the JSON format only. Therefore, if your Kafka produces or consumes AVRO data and for some reason, the Kafka components for AVRO are not available, you must use an avro-tools library to convert your data between AVRO and JSON outside your Job.

For example,

```
java -jar C:\2_Prod\Avro\avro-tools-1.8.2.jar tojson out.avro
```

You can download the `avro-tools-1.8.2.jar` library used in this example from the MVN Repository. This command converts the `out.avro` file to json.

Or

```
java -jar avro-tools-1.8.2.jar fromjson --schema-file twitter.avsc twitter.json > twitter.avro
```

This command converts the `twitter.json` file to `twitter.avro` using the schema from `twitter.avsc`.

• The Kafka components for AVRO are available in the Spark framework only; they handle data directly in the AVRO format. If your Kafka cluster produces and consumes AVRO data, use `tKafkaInputAvro` to read data directly from Kafka and `tWriteAvroFields` to send AVRO data to `tKafkaOutput`.

However, these components do not handle the AVRO data created by an avro-tools library, because the avro-tools libraries and the components for AVRO do not use the same approach provided by AVRO.

The two approaches AVRO provides to (de)serialize the data of AVRO format are as follows:

1. AVRO files are generated with the embedded AVRO schema in each file (via `org.apache.avro.file.{DataFileWriter/DataFileReader}`). The avro-tools libraries use this approach.

2. AVRO records are generated without embedding the schema in each record (via `org.apache.avro.io.{BinaryEncoder/BinaryDecoder}`). The Kafka components for AVRO use this approach.

This approach is highly recommended and favored when AVRO encoded messages are constantly written to a Kafka topic, because in this approach, no overhead is incurred to re-embed the AVRO schema in every single message. This is a significant advantage over the other approach when using Spark Streaming to read data from or write data to Kafka, since records (messages) are usually small while the size of the AVRO schema is relatively large, so embedding the schema in each message is not cost-effective.

The outputs of the two approaches cannot be mixed in the same read-write process.
**tKafkaCreateTopic**

Creates a Kafka topic that the other Kafka components can use.

This component allows you to visually issue the command to create a topic with various topic-level properties.

**tKafkaCreateTopic Standard properties**

These properties are used to configure tKafkaCreateTopic running in the Standard Job framework.

The Standard tKafkaCreateTopic component belongs to the Internet family.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<tr>
<td>Set topic retention time (ms)</td>
<td>Select this check box to define the maximum time in milliseconds during which the contents of the topic are retained. At the end of the time, the contents are removed or compacted depending on the policy you define in the Topic properties table in the Advanced settings view.</td>
</tr>
</tbody>
</table>
**Advanced settings**

| Topic properties | Add the Kafka topic properties you need to customize to this table.
|                  | For further information about the topic-level properties you can define in this table, see the section describing the topic-level configuration in Kafka’s documentation in http://kafka.apache.org/documentation.html#topic-config. |

| tStatCatcher Statistics | Select this check box to gather the processing metadata at the Job level as well as at each component level. |

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is used standalone to create a topic that the other Kafka components can use in the other Jobs or subjobs.</th>
</tr>
</thead>
</table>

| Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |

**Related scenarios**

No scenario is available for the Standard version of this component yet.
tKafkaInput

Transmits messages you need to process to the components that follow in the Job you are designing. tKafkaInput is a generic message broker that transmits messages to the Job that runs transformations over these messages.

**tKafkaInput Standard properties**

These properties are used to configure tKafkaInput running in the Standard Job framework.

The Standard tKafkaInput component belongs to the Internet family.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th><strong>Schema and Edit schema</strong></th>
<th>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <code>line</code> when naming the fields. Note that the schema of this component is read-only. It stores the messages sent from the message producer.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Output type</strong></td>
<td>Select the type of the data to be sent to the next component. Typically, using <strong>String</strong> is recommended, because <strong>tKafkaInput</strong> can automatically translate the Kafka byte[] messages into strings to be processed by the Job. However, in case that the format of Kafka messages is not known to <strong>tKafkaInput</strong>, such as <strong>Protobuf</strong>, you can select <strong>byte</strong> and then use a Custom code component such as <strong>tJavaRow</strong> to deserialize the messages into strings so that the other components of the same Job can process these messages.</td>
</tr>
<tr>
<td><strong>Use an existing connection</strong></td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td><strong>Version</strong></td>
<td>Select the version of the Kafka cluster to be used.</td>
</tr>
<tr>
<td><strong>Zookeeper quorum list</strong></td>
<td>Enter the address of the Zookeeper service of the Kafka cluster to be used. The form of this address should be <code>hostname:port</code>. This information is the name and the port of the hosting node in this Kafka cluster. If you need to specify several addresses, separate them using a comma (,). This field is available to Kafka 0.8.2.0 only.</td>
</tr>
<tr>
<td><strong>Broker list</strong></td>
<td>Enter the addresses of the broker nodes of the Kafka cluster to be used.</td>
</tr>
</tbody>
</table>
The form of this address should be *hostname:port*. This information is the name and the port of the hosting node in this Kafka cluster.

If you need to specify several addresses, separate them using a comma (,).

This field is available since Kafka 0.9.0.1.

<table>
<thead>
<tr>
<th>Reset offsets on consumer group</th>
<th>Select this check box to clear the offsets saved for the consumer group to be used so that this consumer group is handled as a new group that has not consumed any messages.</th>
</tr>
</thead>
<tbody>
<tr>
<td>New consumer group starts from</td>
<td>Select the starting point from which the messages of a topic are consumed. In Kafka, the increasing ID number of a message is called <em>offset</em>. When a new consumer group starts, from this list, you can select <em>beginning</em> to start consumption from the oldest message of the entire topic, or select <em>latest</em> to wait for a new message. Note that the consumer group takes into account only the offset-committed messages to start from. Each consumer group has its own counter to remember the position of a message it has consumed. For this reason, once a consumer group starts to consume messages of a given topic, a consumer group recognizes the latest message only with regard to the position where this group stops the consumption, rather than to the entire topic. Based on this principle, the following behaviors can be expected: • If you are resuming an existing consumer group, this option determines the starting point for this consumer group only if it does not already have a committed starting point. Otherwise, this consumer group starts from this committed starting point. For example, a topic has 100 messages. If an existing consumer group has successfully processed 50 messages, and has committed their offsets, then the same consumer group restarts from the offset 51. • If you create a new consumer group or reset an existing consumer group, which, in either case, means this group has not consumed any message of this topic, then when you start it from latest, this new group starts and waits for the offset 101.</td>
</tr>
<tr>
<td>Offset storage</td>
<td>Select the system to which you want to commit the offsets of the consumed messages.</td>
</tr>
<tr>
<td>Enable dual commit</td>
<td>If you select <em>Kafka</em> as the offset storage system, the Enable dual commit check box is displayed. By default it is selected to let the Job commit the messages to both Zookeeper and Kafka. If you want the Job to commit only to Kafka, clear this check box.</td>
</tr>
<tr>
<td>Auto-commit offsets</td>
<td>Select this check box to make <em>tKafkaInput</em> automatically save its consumption state at the end of each given time interval. You need to define this interval in the Interval field that is displayed. Note that the offsets are committed only at the end of each interval. If your Job stops in the middle of an interval,</td>
</tr>
</tbody>
</table>
the message consumption state within this interval is not committed.

<tr>
<td>Consumer group ID</td>
<td>Enter the name of the consumer group to which you want the current consumer (the <code>tKafkaInput</code> component) to belong. This consumer group will be created at runtime if it does not exist at that moment.</td>
</tr>
<tr>
<td>Stop after a maximum total duration (ms)</td>
<td>Select this check box and in the pop-up field, enter the duration (in milliseconds) at the end of which <code>tKafkaInput</code> stops running.</td>
</tr>
<tr>
<td>Stop after receiving a maximum number of messages</td>
<td>Select this check box and in the pop-up field, enter the maximum number of messages you want <code>tKafkaInput</code> to receive before it automatically stops running.</td>
</tr>
<tr>
<td>Stop after maximum time waiting between messages (ms)</td>
<td>Select this check box and in the pop-up field, enter the waiting time (in milliseconds) by <code>tKafkaInput</code> for a new message. If <code>tKafkaInput</code> does not receive any new message when this waiting time meets its end, it automatically stops running.</td>
</tr>
<tr>
<td>Use SSL/TLS</td>
<td>Select this check box to enable the SSL or TLS encrypted connection. Then you need to use the <code>tSetKeystore</code> component in the same Job to specify the encryption information. For further information about <code>tSetKeystore</code>, see <code>tSetKeystore</code> on page 3464. This check box is available since Kafka 0.9.0.1.</td>
</tr>
</tbody>
</table>
| Use Kerberos authentication | If the Kafka cluster to be used is secured with Kerberos, select this check box to display the related parameters to be defined:  
  • **JAAS configuration path**: enter the path, or browse to the JAAS configuration file to be used by the Job to authenticate as a client to Kafka. This JAAS file describes how the clients, the Kafka-related Jobs in terms of `Talend`, can connect to the Kafka broker nodes, using either the kinit mode or the keytab mode. It must be stored in the machine where these Jobs are executed. `Talend`, Kerberos or Kafka does not provide this JAAS file. You need to create it by following the explanation in `Configuring Kafka client` depending on the security strategy of your organization.  
  • **Kafka brokers principal name**: enter the primary part of the Kerberos principal you defined for the brokers when you were creating the broker cluster. For example, in this principal `kafka/kafka1.hostname.com@EXAMPLE.COM`, the primary part to be used to fill in this field is `kafka`.  
  • **Set kinit command path**: Kerberos uses a default path to its kinit executable. If you have changed this path, select this check box and enter the custom access path. |
If you leave this check box clear, the default path is used.

- **Set Kerberos configuration path:** Kerberos uses a default path to its configuration file, the `krb5.conf` file (or `krb5.ini` in Windows) for Kerberos 5 for example. If you have changed this path, select this check box and enter the custom access path to the Kerberos configuration file.

If you leave this check box clear, a given strategy is applied by Kerberos to attempt to find the configuration information it requires. For details about this strategy, see the **Locating the krb5.conf Configuration File** section in Kerberos requirements.

For further information about how a Kafka cluster is secured with Kerberos, see Authenticating using SASL.

This check box is available since Kafka 0.9.0.1.

### Advanced settings

| Kafka properties | Add the Kafka consumer properties you need to customize to this table. For example, you can set a specific `zookeeper.connection.timeout.ms` value to avoid `ZkTimeoutException`.

For further information about the consumer properties you can define in this table, see the section describing the consumer configuration in Kafka’s documentation in [http://kafka.apache.org/documentation.html#consumerconfigs](http://kafka.apache.org/documentation.html#consumerconfigs). |
|------------------|--------------------------------------------------|
| Timeout precision(ms) | Enter the time duration in millisecond at the end of which you want a timeout exception to be returned if no message is available for consumption.

The value `-1` indicates that no timeout is set. |
| Load the offset with the message | Select this check box to output the offsets of the consumed messages to the next component. When selecting it, a read-only column called `offset` is added to the schema. |
| Custom encoding | You may encounter encoding issues when you process the stored data. In that situation, select this check box to display the **Encoding** list.

Select the encoding from the list or select **Custom** and define it manually. |
| tStatCatcher Statistics | Select this check box to gather the processing metadata at the Job level as well as at each component level. |

### Usage

| Usage rule | This component is used as a start component and requires an output link. When the Kafka topic it needs to use does not exist, it can be used along with the tKafkaCreateTo pic component to read the topic created by the latter component. |
Related scenarios

No scenario is available for the Standard version of this component yet.
tKafkaOutput

Publishes messages into a Kafka system.

This component receives messages serialized into byte arrays by its preceding component and issues these messages into a given Kafka system.

**tKafkaOutput Standard properties**

These properties are used to configure tKafkaOutput running in the Standard Job framework.

The Standard tKafkaOutput component belongs to the Internet family.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.
Note that the schema of this component is read-only. It stores the messages to be published. |
| **Use an existing connection** | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. |
| **Version** | Select the version of the Kafka cluster to be used. |
| **Broker list** | Enter the addresses of the broker nodes of the Kafka cluster to be used.
The form of this address should be hostname:port. This information is the name and the port of the hosting node in this Kafka cluster.
If you need to specify several addresses, separate them using a comma (,). |
| **Topic name** | Enter the name of the topic you want to publish messages to. This topic must already exist. |
| **Compress the data** | Select the Compress the data check box to compress the output data. |
| **Use SSL/TLS** | Select this check box to enable the SSL or TLS encrypted connection.
Then you need to use the tSetKeystore component in the same Job to specify the encryption information.
For further information about tSetKeystore, see tSetKeystore on page 3464.
This check box is available since Kafka 0.9.0.1. |
### Use Kerberos authentication

If the Kafka cluster to be used is secured with Kerberos, select this check box to display the related parameters to be defined:

- **JAAS configuration path**: enter the path, or browse to the JAAS configuration file to be used by the Job to authenticate as a client to Kafka.

  This JAAS file describes how the clients, the Kafka-related Jobs in terms of Talend, can connect to the Kafka broker nodes, using either the kinit mode or the keytab mode. It must be stored in the machine where these Jobs are executed.

  Talend, Kerberos or Kafka does not provide this JAAS file. You need to create it by following the explanation in Configuring Kafka client depending on the security strategy of your organization.

- **Kafka brokers principal name**: enter the primary part of the Kerberos principal you defined for the brokers when you were creating the broker cluster. For example, in this principal `kafka/kafka1.hostname.com@EXAMPLE.COM`, the primary part to be used to fill in this field is `kafka`.

- **Set kinit command path**: Kerberos uses a default path to its kinit executable. If you have changed this path, select this check box and enter the custom access path. If you leave this check box clear, the default path is used.

- **Set Kerberos configuration path**: Kerberos uses a default path to its configuration file, the `krb5.conf` file (or `krb5.ini` in Windows) for Kerberos 5 for example. If you have changed this path, select this check box and enter the custom access path to the Kerberos configuration file.

  If you leave this check box clear, a given strategy is applied by Kerberos to attempt to find the configuration information it requires. For details about this strategy, see the Locating the `krb5.conf Configuration File` section in Kerberos requirements.

For further information about how a Kafka cluster is secured with Kerberos, see Authenticating using SASL.

This check box is available since Kafka 0.9.0.1.

### Advanced settings

<table>
<thead>
<tr>
<th><strong>Kafka properties</strong></th>
<th>Add the Kafka new producer properties you need to customize to this table. For further information about the new producer properties you can define in this table, see the section describing the new producer configuration in Kafka's documentation in <a href="http://kafka.apache.org/documentation.html#newproducerconfigs">http://kafka.apache.org/documentation.html#newproducerconfigs</a>.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to gather the processing metadata at the Job level as well as at each component level.</td>
</tr>
</tbody>
</table>
**Usage**

| Usage rule | This component is an end component. It requires a `tJavaRow` or `tJava` component to transform the incoming data into serialized byte arrays.

The following sample shows how to construct a statement to perform this transformation:

```java
output_row.serializedValue = 
input_row.users.getBytes();
```

In this code, the `output_row` variable represents the schema of the data to be output to `tKafkaOutput` and `output_row.serializedValue` the single read-only column of that schema; the `input_row` variable represents the schema of the incoming data and `input_row.users` the input column called `users` to be transformed to byte arrays by the `getBytes()` method. |

**Related scenarios**

No scenario is available for the Standard version of this component yet.
tLDAPAttributesInput

Analyses each object found via the LDAP query and lists a collection of attributes associated with the object.

tLDAPAttributesInput executes an LDAP query based on the given filter and corresponding to the schema definition. Then it passes on the field list to the next component via a **Main row** link.

**tLDAPAttributesInput Standard properties**

These properties are used to configure tLDAPAttributesInput running in the Standard Job framework.
The Standard tLDAPAttributesInput component belongs to the Databases family.
The component in this framework is available in all **Talend products**.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-in or Repository</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>

<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>password between double quotes and click <strong>OK</strong> to save the settings.</td>
<td></td>
</tr>
<tr>
<td><strong>Filter</strong></td>
<td>Type in the filter as expected by the LDAP directory db.</td>
</tr>
<tr>
<td><strong>Multi valued field separator</strong></td>
<td>Type in the value separator in multi-value fields.</td>
</tr>
</tbody>
</table>
| **Alias dereferencing** | Select the option on the list. **Never** improves search performance if you are sure that no alias is to be dereferenced. By default, **Always** is to be used:  
- **Always**: Always dereference aliases  
- **Never**: Never dereferences aliases.  
- **Searching**: Dereferences aliases only after name resolution.  
- **Finding**: Dereferences aliases only during name resolution |
| **Referral handling** | Select the option on the list:  
- **Ignore**: does not handle request redirections  
- **Follow**: does handle request redirections |
| **Limit** | Fill in a limit number of records to be read if needed. |
| **Time Limit** | Fill in a timeout period for the directory access. |
| **Paging** | Specify the number of entries returned at a time by the LDAP server. |
| **Die on error** | This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a **Row > Rejects** link. |
| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.  
- **Built-in**: The schema is created and stored locally for this component only. Related topic: see **Talend Studio User Guide**.  
- **Repository**: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see **Talend Studio User Guide**.  
  
  **Warning**:  
  *As this component is intended to list the attributes associated with a LDAP object, its schema is then pre-defined. You should retain these established columns, even though you may need to add some new columns. Hence you should use the Built-in mode.* |
|  | Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
- **View schema**: choose this option to view the schema only. |
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

The pre-defined schema lists:
- `objectclass`: list of object classes
- `mandatoryattributes`: list of mandatory attributes to these classes
- `optionalattributes`: list of optional attributes to these classes
- `objectattributes`: list of attributes that are essential for the analysed object.

### Advanced settings

</tr>
</tbody>
</table>
Related scenario

The `tLDAPAttributesInput` component follows the usage similar to that of `tLDAPInput`. Hence for `tLDAPInput` related scenario, see Displaying LDAP directory's filtered content on page 1925.
tLDAPClose

Disconnects one connection to the LDAP Directory server so as to release occupied resources.

**tLDAPClose Standard properties**

These properties are used to configure tLDAPClose running in the Standard Job framework.

The Standard tLDAPClose component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Basic settings**

| Component list | Select the tLDAPConnection component in the list if more than one connection is planned for the current Job. |

**Advanced settings**

| tStat Catcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Usage**

| Usage rule | This component is to be used along with other LDAP components, especially with tLDAPConnection. |

**Dynamic settings**

Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

**Related scenarios**

No scenario is available for the Standard version of this component yet.
tLDAPConnection

Creates a connection to an LDAP Directory server.

tLDAPConnection can be invoked by other components that need to access the LDAP Directory server, e.g., tLDAPInput, tLDAPOutput, etc.

**tLDAPConnection Standard properties**

These properties are used to configure tLDAPConnection running in the Standard Job framework. The Standard tLDAPConnection component belongs to the Databases family. The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>

</tr>
<tr>
<td>Alias dereferencing</td>
<td>Select the option on the list. Never improves search performance if you are sure that no aliases is to be dereferenced. By default, Always is to be used:</td>
</tr>
</tbody>
</table>
### tLDAPConnection

| | Always: Always dereference aliases  
| Never: Never dereferences aliases.  
| Searching: Dereferences aliases only after name resolution.  
| Finding: Dereferences aliases only during name resolution |

### Referral handling

| | Select the option on the list:  
| Ignore: does not handle request redirections  
| Follow: does handle request redirections |

### Advanced settings

| tStatCatcher Statistics | Select this check box to gather the job processing metadata at a job level as well as at each component level. |

### Usage

| Usage rule | This component is to be used with other LDAP components, especially with tLDAPInput and tLDAPOutput. |

### Related scenarios

This component is closely related to tLDAPInput and tLDAPOutput as it frees you from filling in the connection details repeatedly if multiple LDAP input/output components exist.

For tLDAPConnection related scenarios, see Inserting data in mother/daughter tables on page 2437.
tLDAPInput

Executes an LDAP query based on the given filter and corresponding to the schema definition. Then it passes on the field list to the next component via a Row > Main link.

tLDAPInput Standard properties

These properties are used to configure tLDAPInput running in the Standard Job framework.
The Standard tLDAPInput component belongs to the Databases family.
The component in this framework is available in all Talend products.

Basic settings

<table>

If the current schema is of the <strong>Repository</strong> type, three options are available: • <strong>View schema</strong>: choose this option to view the schema only. • <strong>Change to built-in property</strong>: choose this option to change the schema to <strong>Built-in</strong> for local changes. • <strong>Update repository connection</strong>: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate...</td>
</tr>
</tbody>
</table>
the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

**Warning:**
Only three data types are supported here: String, byte[], and List. tMap can be used for data type conversion if needed.

| **Built-in:** | The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide. |
| **Repository:** | The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide. |

**Global Variables**

| **NB_LINE:** | the number of rows processed. This is an After variable and it returns an integer. |
| **RESULT_NAME:** | the name of the current LDAP entry satisfying the search filter. This is a flow variable, and it returns a string. |
| **ERROR_MESSAGE:** | the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. |

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

**Usage**

| **Usage rule** | This component covers all possible LDAP queries. |
| **Note:** | Press Ctrl + Space bar to access the global variable list, including the GetResultName variable to retrieve automatically the relevant Base. |

**Displaying LDAP directory’s filtered content**

The Job described below simply filters the LDAP directory and displays the result on the console.
Adding and linking the components

Procedure

Drop the **tLDAPInput** component along with a **tLogRow** from the *Palette* to the design workspace.

Configuring the components

Procedure

1. Set the **tLDAPInput** properties.
2. Set the **Property type** on **Repository** if you stored the LDAP connection details in the **Metadata Manager** in the **Repository**. Then select the relevant entry on the list.
3. In **Built-In** mode, fill in the **Host** and **Port** information manually. Host can be the IP address of the LDAP directory server or its DNS name.
4. No particular **Base DN** is to be set.
5. Then select the relevant **Protocol** on the list. In this example: a simple **LDAP** protocol is used.
6. Select the **Authentication** check box and fill in the login information if required to read the directory. In this use case, no authentication is needed.
7. In the **Filter** area, type in the command, the data selection is based on. In this example, the filter is: `(&(objectClass=inetorgperson)&(uid=PIERRE DUPONT))`.
8. Fill in **Multi-valued field separator** with a comma as some fields may hold more than one value, separated by a comma.

9. As we do not know if some aliases are used in the LDAP directory, select **Always** on the list.

10. Set **Ignore** as **Referral handling**.

11. Set the limit to **100** for this use case.

12. Set the **Schema** as required by your LDAP directory. In this example, the schema is made of 6 columns including the **objectClass** and **uid** columns which get filtered on.

<table>
<thead>
<tr>

13. In the **tLogRow** component, no particular setting is required.

**Results**

Starting job testLDAPInput at 18:05 18-09-2007.

| DATA: tcp.person, organizationalPerson, inetorgperson, s4400user|ahirt70@talend.com|PIERRE DUPONT|

JOB testLDAPInput ended at 18:05 18-09-2007. [exit code=0]

Only one entry of the directory corresponds to the filter criteria given in the **tLDAPInput** component.
tLDAPOutput

Executes an LDAP query based on the given filter and corresponding to the schema definition. Then it passes on the field list to the next component via a Row > Main link.

**tLDAPOutput Standard properties**

These properties are used to configure tLDAPOutput running in the Standard Job framework.

The Standard tLDAPOutput component belongs to the Databases family.

The component in this framework is available in all Talend products.

### Basic settings

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-in or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><img src="image" alt=" " /> Click this icon to open a database connection wizard and store the database connection parameters you set in the component Basic settings view.</td>
<td>For more information about setting up and storing database connection parameters, see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level.</td>
</tr>
<tr>
<td>Host</td>
<td>LDAP Directory server IP address.</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of server.</td>
</tr>
<tr>
<td>Base DN</td>
<td>Path to user’s authorized tree leaf.</td>
</tr>
<tr>
<td>Protocol</td>
<td>Select the protocol type on the list. LDAP: no encryption is used LDAPS: secured LDAP. When this option is chosen, the Advanced CA check box appears. Once selected, the advanced mode allows you to specify the directory and the keystore password of the certificate file for storing a specific CA. However, you can still deactivate this certificate validation by selecting the Trust all certs check box. TLS: certificate is used When this option is chosen, the Advanced CA check box appears and is used the same way as that of the LDAPS type.</td>
</tr>
<tr>
<td><strong>User and Password</strong></td>
<td>Fill in the <strong>User</strong> and <strong>Password</strong> as required by the directory. Note that the login must match the LDAP syntax requirement to be valid. E.g.: “cn=Directory Manager”. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td>-----------------------</td>
<td>--------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>Multi valued field separator</strong></td>
<td>Type in the value separator in multi-value fields.</td>
</tr>
</tbody>
</table>
| **Alias dereferencing** | Select the option on the list. **Never** improves search performance if you are sure that no aliases is to be dereferenced. By default, **Always** is to be used:  
  **Always**: Always dereference aliases  
  **Never**: Never dereferences aliases.  
  **Searching**: Dereferences aliases only after name resolution.  
  **Finding**: Dereferences aliases only during name resolution. |
| **Referral handling** | Select the option on the list:  
  **Ignore**: does not handle request redirections  
  **Follow**: does handle request redirections |
| **Insert mode** | Select the editing mode on the list:  
  **Add**: add a value in a multi-value attribute,  
  **Insert**: insert new data,  
  **Update**: updates the existing data,  
  **Delete**: remove the selected data from the directory,  
  **Insert or update**: Insert a new record. If the record with the given reference already exists, an update would be made. |
| **DN Column Name** | Select in the list the type of the LDAP input entity used. |
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word **line** when naming the fields.  
  **Built-In**: You create and store the schema locally for this component only.  
  **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.  
  When the schema to be reused has default values that are integers or functions, ensure that these default values are... |
not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

### Die on error

This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a **Row > Reject** link.

### Advanced settings

<table>
<thead>
<tr>
<th>Use Attribute Options (for update mode)</th>
<th>Select this check box to choose the desired attribute (including dn, dc, ou, objectClass, mail and uid) and the corresponding operation (including Add, Replace, Remove Attribute and Remove Value).</th>
</tr>
</thead>
</table>

| tStatCatcher Statistics | Select this check box to gather the job processing metadata at a job level as well as at each component level. |

### Global Variables

| Global Variables | **NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.  
|------------------|----------------------------------------------------------|
|                  | **NB_LINE_REJECTED**: the number of rows rejected. This is an After variable and it returns an integer.  
|                  | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
|                  | A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
|                  | To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
|                  | For further information about variables, see **Talend Studio User Guide**. |

---

1930
Usage

| Usage rule | This component covers all possible LDAP queries. Note: Press Ctrl + Space bar to access the global variable list, including the GetResultName variable to retrieve the relevant DN Base automatically. This component allows you to carry out actions on a table or on the data of a table in an database. It also allows you to create a reject flow using a Row > Rejects link to filter data in error. For an example of tMySqlOutput in use, see Retrieving data in error with a Reject link on page 2485. |

Editing data in a LDAP directory

The following scenario describes a Job that reads an LDAP directory, updates the email of a selected entry and displays the output before writing the LDAP directory. To keep it simple, no alias dereferencing nor referral handling is performed. This scenario is based on Displaying LDAP directory’s filtered content on page 1925. The result returned was a single entry, related to an organisational person, whom email is to be updated.

The output shows the following fields: dn, uid and mail as defined in the Job.

Dropping the components

Procedure

1. Drop the tLDAPInput, tLDAPOutput, tMap and tLogRow components from the Palette to the design workspace.
2. Link tLDAPInput to tMap using the Row > Main connection.
3. Link tMap to tLogRow using the Row > Main connection.
4. Link tLogRow to tLDAPOutput using the Row > Main connection.

Configuring the components

Procedure

1. In the tLDAPInput Component view, set the connection details to the LDAP directory server as well as the filter as described in Displaying LDAP directory’s filtered content on page 1925.
   Change the schema to make it simpler, by removing the unused fields: dc, ou, objectclass.
2. Then open the mapper to set the edit to be carried out.

Drag & drop the uid column from the input table to the output as no change is required on this column.

3. In the Expression field of the dn column (output), fill in with the exact expression expected by the LDAP server to reach the target tree leaf and allow directory writing only if you haven’t set it already in the Base DN field of the tLDAPOutput component.

4. In this use case, the GetResultName global variable is used to retrieve this path automatically. Press Ctrl+Space bar to access the variable list and select tLDAPInput_1_RESULT_NAME.

5. In the mail column’s expression field, type in the new email that will overwrite the current data in the LDAP directory. In this example, we change to Pierre.Dupont@talend.com. Click OK to validate the changes.

6. Then select the tLDAPOutput component to set the directory writing properties.

7. Set the Port and Host details manually if they aren’t stored in the Repository.

8. In Base DN field, set the highest tree leaf you have the rights to access. If you have not set previously the exact and full path of the target DN you want to access, then fill in it here. In this use case, the full DN is provided by the dn output from the tMap component, therefore only the highest accessible leaf is given: o=directoryRoot.

9. Select the relevant protocol to be used: LDAP for this example. Fill in the User and Password as expected by the LDAP directory.
Fill in **Multi-valued field separator** with a comma as some fields may hold more than one value, separated by a comma.

10. Use the default setting of **Alias Dereferencing** and **Referral Handling** fields, respectively **Always** and **Ignore**.

   The **Insert mode** for this use case is **Update** (the email address).

   The schema was provided by the previous component through the propagation operation.

11. In the **Advanced settings** view, select the **Use Attribute Options (for update mode)** check box to show the **Attribute Options** table.

   Select the attribute **mail** under the **Attribute Name** part and the choose **Replace** under the **Option** part.

---

**Executing the Job**

**Procedure**

1. Press Ctrl+S to save the Job.

2. Press F6 to run the Job.

    *Starting job LDAPInputnew at 14:17 20/09/2007.*
    
    *uid=PIERRE DUPONT,ou=DATA, o=TALEND, o=TALEND|PIERRE DUPONT|Pierre Dupont@talend.com*
    
    *Job LDAPInputnew ended at 14:17 20/09/2007. (exit code=0)*
tLDAPRenameEntry

Renames ones or more entries in a specific LDAP directory.

### tLDAPRenameEntry Standard properties

These properties are used to configure tLDAPRenameEntry running in the Standard Job framework.

The Standard tLDAPRenameEntry component belongs to the Databases family.

The component in this framework is available in all Talend products.

#### Basic settings

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-in or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and click the relevant tLDAPConnection component on the Component list to reuse the connection details you already defined.

**Host**

LDAP directory server IP address.

**Port**

Number of the listening port of the server.

**Base DN**

Path to user’s authorized tree leaf.

**Protocol**

Select the protocol type on the list.

- **LDAP**: no encryption is used,
- **LDAPS**: secured LDAP. When this option is chosen, the Advanced CA check box appears. Once selected, the advanced mode allows you to specify the directory and the keystore password of the certificate file for storing a specific CA. However, you can still deactivate this certificate validation by selecting the Trust all certs check box.
- **TLS**: certificate is used. When this option is chosen, the Advanced CA check box appears and is used the same way as that of the LDAPS type.

**User and Password**

Fill in user authentication information.

Note that the login must match the LDAP syntax requirement to be valid. e.g.: "cn=Directory Manager".

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.
### Alias dereferencing

Select the option on the list. **Never** improves search performance if you are sure that no alias is to be dereferenced. By default, **Always** is to be used:

- **Always**: Always dereference aliases,
- **Never**: Never dereferences aliases,
- **Searching**: Dereferences aliases only after name resolution,
- **Finding**: Dereferences aliases only during name resolution.

### Referrals handling

Select the option on the list:

- **Ignore**: does not handle request redirections,
- **Follow**: does handle request redirections.

### Previous DN and New DN

Select from the list the schema column that holds the old DN (**Previous DN**) and the column that holds the new DN (**New DN**).

### Schema and Edit Schema

A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either **Built-in** or stored remotely in the **Repository**.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-in</strong></td>
<td>The schema is created and stored locally for this component only. Related topic: see <em>Talend Studio User Guide</em>.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>The schema already exists and is stored in the Repository, hence can be reused. Related topic: see <em>Talend Studio User Guide</em>.</td>
</tr>
</tbody>
</table>

### Die on error

This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a **Row > Reject** link.

### Advanced settings

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |
Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_LINE: the number of rows processed. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td></td>

</tr>
</tbody>
</table>

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component covers all possible LDAP queries. It is usually used as a one-component subjob but you can use it with other components as well.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Note: Press Ctrl + Space bar to access the global variable list, including the GetResultName variable to retrieve automatically the relevant DN Base.</td>
</tr>
</tbody>
</table>

Related scenarios

For use cases in relation with tLDAPRenameEntry, see the following scenarios:

- Displaying LDAP directory’s filtered content on page 1925.
- Editing data in a LDAP directory on page 1931.
**tLibraryLoad**

Loads useable Java libraries in a Job.

### tLibraryLoad Standard properties

These properties are used to configure tLibraryLoad running in the Standard Job framework.

The Standard tLibraryLoad component belongs to the Custom Code family.

The component in this framework is available in all Talend products.

#### Basic settings

<table>
<thead>
<tr>
<th>Library</th>
<th>Select the library you want to import from the list, or click on the [...] button to browse to the library in your directory.</th>
</tr>
</thead>
</table>

#### Advanced settings

<table>
<thead>
<tr>
<th>Dynamic Libs</th>
<th>Lib Paths: Enter the access path to your library, between double quotation marks.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Import</td>
<td>Enter the Java code required to import, if required, the external library used in the code editing field of the Basic settings tab of the components such as tJava, or tJavaFlex.</td>
</tr>
</tbody>
</table>

#### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td></td>
<td>For further information about variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

#### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component may be used alone, although it is more logical to use it as part of a Job.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limitation</td>
<td>The library is loaded locally.</td>
</tr>
</tbody>
</table>
Checking the format of an e-mail address

This scenario uses two components, a **tLibraryLoad** and a **tJava**. The goal of this scenario is to check the format of an e-mail address and verify whether the format is valid or not.

Setting up the Job

**Procedure**

1. In the **Palette**, open the **Custom_Code** folder, and slide a **tLibraryLoad** and **tJava** component onto the workspace.
2. Connect **tLibraryLoad** to **tJava** using a **Trigger > OnSubjobOk** link.

Configuring the **tLibraryLoad** component

**Procedure**

1. Double-click on **tLibraryLoad** to display its **Basic settings**. From the **Library** list, select *jakarta-ororo-2.0.8.jar*.
2. In the **Import** field of the **Advanced settings** tab, type `import org.apache.oro.text.regex.*;`
Configuring the tJava component

**Procedure**

1. Double-click on tJava to display its Component view.
2. In the Basic settings tab, enter your code, as in the screenshot below. The code allows you to check whether the character string pertains to an e-mail address, based on the regular expression: 
   
   "^[\\w_.-]+@[\\w_.-]+\.[\\w]+$".

   ![tJava Component View]

   ```java
   String email="ma3cocomon";
   
   //Validate if the email string is correct or not based on a regexp pattern
   
   Perl5Matcher matcher = new Perl5Matcher();
   Perl5Compiler compiler = new Perl5Compiler();
   Pattern pattern = compiler.compile("^[\\w_.-]+@[\\w_.-]+\.[\\w]+$");
   
   if (!matcher.matches(email, pattern)) {
       System.out.println(email + " is not a valid email. ");
   }
   else
       System.out.println(email + " is a valid email. ");
   ```

**Job execution**

Press F6 to save and run the Job.

```
Starting job LibraryLoad at 16:51 18/02/2010.

[statistics] connecting to socket on port 3979
[statistics] connected
ma@cocomon : false
[statistics] disconnected

Job LibraryLoad ended at 16:51 18/02/2010. [exit code=0]
```

The Console displays the boolean false. Hence, the e-mail address is not valid as the format is incorrect.
tLineChart

Reads data from an input flow and transforms the data into a line chart in a PNG image file to ease technical analysis.

**tLineChart Standard properties**

These properties are used to configure tLineChart running in the Standard Job framework.
The Standard tLineChart component belongs to the Business Intelligence family.
The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Schema and Edit Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td>Note:</td>
<td>The schema of tLineChart contains three read-only columns named series (string), x (integer), and y (integer) respectively, in a fixed order. The data in any extra columns will be only passed to the next component, if any, without being presented in the generated line chart.</td>
</tr>
<tr>
<td><strong>Built-in</strong></td>
<td>The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide.</td>
</tr>
<tr>
<td><strong>Sync columns</strong></td>
<td>Click to synchronize the output file schema with the input file schema. The Sync function only displays once the Row connection is linked with the output component.</td>
</tr>
<tr>
<td><strong>Generated image path</strong></td>
<td>Name and path of the output image file.</td>
</tr>
<tr>
<td><strong>Chart title</strong></td>
<td>Enter the title of the line chart to be generated.</td>
</tr>
<tr>
<td><strong>Domain axis label and Range axis label</strong></td>
<td>Enter the domain axis (X axis) and range axis (Y axis) labels.</td>
</tr>
<tr>
<td><strong>Plot orientation</strong></td>
<td>Select the plot orientation of the range axis: Vertical or Horizontal.</td>
</tr>
<tr>
<td><strong>Include legend</strong></td>
<td>Select this check box if you want your line chart to include a legend, indicating the lines of different series in different colors.</td>
</tr>
<tr>
<td><strong>Image width and Image height</strong></td>
<td>Enter the width and height of the image, in pixels.</td>
</tr>
</tbody>
</table>
### Moving average
Select this check box to show a moving average for each series on your line chart. With this check box selected, the **Period** field appears, letting you define a period of which you want to show the moving average.

### Lower bound and Upper bound
Define the lowest and highest values to be displayed on the range axis.

### Chart background and Plot background
Select the chart background color and the plot area background color.

### Advanced settings

<table>
<thead>
<tr>
<th>tStat Catcher Statistics</th>
<th>Select this check box to collect log data at the component level.</th>
</tr>
</thead>
</table>

<thead>
<tr>
<th>Global Variables</th>
<th><strong>NB LINE</strong>: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press <strong>Ctrl + Space</strong> to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td></td>
<td><em>For further information about variables, see</em> <a href="#">Talend Studio User Guide</a>.</td>
</tr>
</tbody>
</table>

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is mainly used as Output component. It requires an Input component and <strong>Row</strong> main link as input.</th>
</tr>
</thead>
</table>
Creating a line chart to ease trend analysis

This scenario describes a Job that reads data from a CSV file and transforms the data into a line chart to facilitate trend analysis. The input file records how long (in minutes) per week a person watches different TV channels over ten weeks, as shown below:

<table>
<thead>
<tr>
<th>Week</th>
<th>TV_A</th>
<th>TV_B</th>
<th>TV_C</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>327</td>
<td>286</td>
<td>244</td>
</tr>
<tr>
<td>2</td>
<td>326</td>
<td>285</td>
<td>243</td>
</tr>
<tr>
<td>3</td>
<td>325</td>
<td>283</td>
<td>245</td>
</tr>
<tr>
<td>4</td>
<td>323</td>
<td>282</td>
<td>246</td>
</tr>
<tr>
<td>5</td>
<td>322</td>
<td>285</td>
<td>248</td>
</tr>
<tr>
<td>6</td>
<td>321</td>
<td>288</td>
<td>247</td>
</tr>
<tr>
<td>7</td>
<td>322</td>
<td>291</td>
<td>245</td>
</tr>
<tr>
<td>8</td>
<td>321</td>
<td>292</td>
<td>244</td>
</tr>
<tr>
<td>9</td>
<td>320</td>
<td>293</td>
<td>243</td>
</tr>
<tr>
<td>10</td>
<td>319</td>
<td>294</td>
<td>242</td>
</tr>
</tbody>
</table>

Because the input file has a different structure than required by the tLineChart component, this use case uses the tMap component to adapt the source data to the three-column schema of tLineChart so that a temporary CSV file can be created as the input to the tLineChart component.

Note:
You will usually use the tMap component to adjust the input schema in accordance with the schema structure of the tLineChart component. For more information about how to use the tMap component, see Talend Studio User Guide and tMap on page 1962.

To ensure correct generation of the temporary input file, a pre-treatment subJob is used to delete the temporary file in case it already exists before the main Job is executed; as this temporary file serves this specific Job only, a post-treatment subJob is used to deleted it after the main Job is executed.

Dropping and linking components

Procedure

1. Drop the following components from the Palette to the design workspace: two tFileDelete components, two tFileInputDelimited components, a tMap, three tFileOutputDelimited components, and a tLineChart.
2. Connect the first tFileInputDelimited to the tMap component using a Row > Main connection.
3. Connect the tMap component to the first tFileOutputDelimited component using a Row > Main connection, and name the connection TV_A.
4. Repeat the step above to connect the tMap component to the other two tFileOutputDelimited components using Row > Main connections, and name the connections TV_B and TV_C respectively.
5. Connect the section tFileInputDelimited to the tLineChart component using a Row > Main connection. When questioned whether to get the schema from the target component, click Yes.
6. Connect the first tFileInputDelimited component to the second tFileInputDelimited component using a Trigger > On Subjob Ok connection.
7. Connect the first tFileDelete component to the first tFileInputDelimited component, and then the second tFileInputDelimited component to the second tFileDelete component, using Trigger > On Subjob Ok connections.
8. Relabel the components to best describe their functionality.
Results

**Procedure**

1. Double-click the first `tFileInputDelimited` component, which is labelled `Source_data`, to display its **Basic settings** view.

2. Fill in the **File name** field by browsing to the input file.

3. Specify the header row. In this use case, the first row of the input file is the header row. And leave the other parameters as they are.
4. Click **Edit schema** to describe the data structure of the input file. In this use case, the input schema is made of four columns: *Week*, *Mins_TVA*, *Mins_TVB*, and *Mins_TVC*. Upon defining the column names and data type, click **OK** to close the schema dialog box.

![Image of Schema Editor]

**Adapting the source data to the tLineChart schema**

**Procedure**

1. Double-click the **tMap** to open the **Map Editor**.
   
   You can see an input table on the input panel, *row1* in this example, and three empty output tables, named *TV_A*, *TV_B*, and *TV_C* on the output panel.

2. Use the **Schema editor** to add three columns to each output table: *series* (string), *x* (integer), and *y* (integer).

3. In the relevant **Expression** field of the output tables, enter the text to be presented in the legend area of the line chart, *TV A*, *TV B*, and *TV C* respectively in this example.

4. Drop the *Week* column of the input table onto the *x* column of each output table.

5. Drop the *Mins_TVA* column of the input table onto the *y* column of the *TV_A* table.

6. Drop the *Mins_TVB* column of the input table onto the *y* column of the *TV_B* table.

7. Drop the *Mins_TVC* column of the input table onto the *y* column of the *TV_C* table.
8. Click OK to save the mappings and close the Map Editor and propagate the output schemas to the output components.

Generating the temporary input file

Procedure

1. Double-click the first tFileOutputDelimited component to display its Basic settings view.

2. In the File Name field, define a temporary CSV file to send the mapped data flows to. In this use case, we name this file Temp.csv. This file will be used as the input to the tLineChart component.

3. Select the Append check box.

4. Repeat the steps above to define the properties of the other two tFileOutputDelimited components, using exactly the same settings as in the first tFileOutputDelimited component.
Note:
Note that the order of output flows from the $tMap$ component is not necessarily the actual order of writing data to the target file. To ensure the target file is correctly generated, we need to delete the file by the same name if it already exists before Job execution and select the $Append$ check box in all the $tFileOutputDelimited$ components in this step.

Configuring line chart generation

Procedure

1. Double-click the second $tFileInputDelimited$ component, which is labelled $Temp\_Input$, to display its $Basic\ settings$ view.

2. Fill in the $File\ name$ field with the path to the temporary input file generated by the $tFileOutputDelimited$ components. In this use case, the temporary input file to the $tLineChart$ is $Temp.csv$.

3. Double-click the $tLineChart$ component to display its $Basic\ settings$ view.

4. Click $Edit\ schema$ to open the schema dialog box.
5. Check that the input and output schemas are synchronized. If needed, copy all the columns from the output schema to the input schema by clicking the left-pointing double arrow button. Then, click OK to close the schema dialog box.

6. In the **Generated image path** field, define the path of the image file to be generated.

7. In the **Chart title** field, define a title for the line chart. In this use case, enter **Average Weekly Viewing (per person) as the chart title**.

8. Define the domain (X) and range (Y) axis labels. In this use case, enter **Week** and **Minutes** respectively the axis labels.

9. Define the image size, the moving average period, the lower and upper bounds, the chart background color, and the background color of the plot area, as you prefer.

   In this use case, we set the image size to 450 by 450, set the lower and upper bounds to 210 and 340 respectively, select **light gray** as the chart background color, and keep the rest settings as they are.

**Deleting the temporary file**

**Procedure**

1. Double-click the first **tFileDelete** component to display its Basic settings view.
2. Fill in the File name field with the path to the temporary input file, and clear the Fail on error check box to allow the main Job to be executed if the file to delete does not exist.
3. Specify the same file path in the other tFileDelete component.

 Executing the Job

Procedure

1. Press Ctrl+S to save your Job.
2. Press F6 to launch the Job.

A line chart is generated as defined, showing a graphical comparison of the average weekly viewing time and the viewing trends of different TV channels over the past ten weeks.
**tLogCatcher**

Operates as a log function triggered by one of the three: Java exception, tDie or tWarn, to collect and transfer log data.

Both the tDie and tWarn components are closely related to the tLogCatcher component. They generally make sense when used alongside a tLogCatcher component in order for the log data collected to be encapsulated and passed on to the output defined.

Fetches set fields and messages from Java Exception, tDie and/or tWarn and passes them on to the next component.

**tLogCatcher Standard properties**

These properties are used to configure tLogCatcher running in the Standard Job framework.

The Standard tLogCatcher component belongs to the Logs & Errors family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Schema and Edit Schema</th>
<th>A schema is a row description, it defines the fields to be processed and passed on to the next component. The schema of this component is read-only. It describes the properties of the log data. You can click the [...] button next to <strong>Edit schema</strong> to view the predefined schema which contains the following fields:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• <strong>moment</strong>: the time when the message is caught.</td>
</tr>
<tr>
<td></td>
<td>• <strong>pid</strong>: the process ID of the Job.</td>
</tr>
<tr>
<td></td>
<td>• <strong>root_pid</strong>: the root process ID.</td>
</tr>
<tr>
<td></td>
<td>• <strong>father_pid</strong>: the father process ID.</td>
</tr>
<tr>
<td></td>
<td>• <strong>project</strong>: the name of the project.</td>
</tr>
<tr>
<td></td>
<td>• <strong>job</strong>: the name of the Job.</td>
</tr>
<tr>
<td></td>
<td>• <strong>context</strong>: the context used to run the Job.</td>
</tr>
<tr>
<td></td>
<td>• <strong>priority</strong>: the priority level of the message.</td>
</tr>
<tr>
<td></td>
<td>• <strong>type</strong>: the type of the message.</td>
</tr>
<tr>
<td></td>
<td>• <strong>origin</strong>: the name of the component that triggers the message.</td>
</tr>
<tr>
<td></td>
<td>• <strong>message</strong>: the message content.</td>
</tr>
<tr>
<td></td>
<td>• <strong>code</strong>: the error code level.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Catch Java Exception</th>
<th>Select this check box to trigger the <strong>tCatch</strong> function when a Java Exception occurs in the Job.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Catch tDie</td>
<td>Select this check box to trigger the <strong>tCatch</strong> function when a <strong>tDie</strong> component is called in a Job.</td>
</tr>
<tr>
<td>Catch tWarn</td>
<td>Select this check box to trigger the <strong>tCatch</strong> function when a <strong>tWarn</strong> component is called in a Job.</td>
</tr>
</tbody>
</table>
Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it. For further information about variables, see *Talend Studio User Guide.* |

Usage

| Usage rule | This component is usually used as the start component of a secondary Job which is automatically triggered at the end of the main Job. |

Catching messages triggered by a tWarn component

This example shows you how to use the **tLogCatcher** component to catch the messages triggered by a **tWarn** component.

Creating a Job for catching messages triggered by a tWarn component

Create a Job to trigger some messages using the **tWarn** component, then catch the messages using the **tLogCatcher** component and display the messages on the console.

Procedure

1. Create a new Job and add a **tRowGenerator** component, a **tWarn** component, a **tLogCatcher** component, and a **tLogRow** component by typing their names in the design workspace or dropping them from the **Palette.**
2. Link the **tRowGenerator** component to the **tWarn** component using a **Row > Main** connection.
3. Link the **tLogCatcher** component to the **tLogRow** component using a **Row > Main** connection.
Configuring the Job for catching messages triggered by the tWarn component

Configure the components used in the Job that catches the messages triggered by the tWarn component and then displays the messages on the console.

Procedure

1. Double-click the tRowGenerator component to open its row generator editor.

2. Define the schema by adding one column id of Integer type, and select the predefined function Numeric.sequence(String,int,int) in the Functions column.

3. Enter the number of records to be generated in the Number of Rows for RowGenerator field, 3 in this example. When done, click OK to close the dialog box.

4. Double-click the tWarn component to open its Basic settings view.

5. Select Info from the Priority drop-down list.

6. In the Warn message field, enter the message to be triggered when a new record is generated, a new record is generated in this example.

7. Double-click the tLogCatcher component to open its Basic settings view.
8. Select the **Catch tWarn** check box to catch the messages triggered by the **tWarn** component.

9. Double-click the **tLogRow** component to open its **Basic settings** view, and then select **Table (print values in cells of a table)** in the **Mode** area for better readability of the result.

### Executing the Job to catch messages triggered by a tWarn component

After setting up the Job and configuring the components used in the Job for catching messages triggered by the **tWarn** component, you can then execute the Job and verify the Job execution result.

**Procedure**

1. Press **Ctrl + S** to save the Job.

2. Press **F6** to execute the Job.

   ```plaintext
   As shown above, all messages triggered are collected and displayed on the console.
   ```

### Catching the message triggered by a tDie component

This example shows you how to use the **tLogCatcher** component to catch the message triggered by a **tDie** component.

### Creating a Job for catching the message triggered by a tDie component

Create a Job to trigger a message using the **tDie** component, then catch the message using the **tLogCatcher** component and display the message on the console.
Procedure

1. Create a new Job and add a `tRowGenerator` component, a `tFileOutputDelimited` component, a `tDie` component, a `tJava` component, a `tLogCatcher` component, and a `tLogRow` component by typing their names in the design workspace or dropping them from the Palette.

2. Link the `tRowGenerator` component to the `tFileOutputDelimited` component using a Row > Main connection.

3. Link the `tFileOutputDelimited` component to the `tDie` component using a Trigger > Run if connection.

4. Link the `tRowGenerator` component to the `tJava` component using a Trigger > On Subjob Ok connection.

5. Link the `tLogCatcher` component to the `tLogRow` component using a Row > Main connection.

Configuring the Job for catching the message triggered by the `tDie` component

Configure the components used in the Job that catches the message triggered by the `tDie` component and then displays the message on the console.

Procedure

1. Double-click the `tRowGenerator` component to open its row generator editor.
2. Define the schema by adding one column \textit{id} of Integer type, and select the predefined function \texttt{Numeric.sequence(String,int,int)} in the \textbf{Functions} column.

3. Enter the number of rows to be generated in the \textbf{Number of Rows for RowGenerator} field, 0 in this example. When done, click \textbf{OK} to close the dialog box.

4. Double-click the \texttt{tFileOutputDelimited} component to open its \textbf{Basic settings} view, and in the \textbf{File Name} field, specify the path to the file that will hold the data to be generated.

5. Click the \texttt{If} connection, and in the \textbf{Condition} field on the \textbf{Basic settings} view, specify the condition based on which the \texttt{tDie} component will be triggered. In this example, it is \((\texttt{(Integer)globalMap.get("tRowGenerator\_1\_NB\_LINE")}) \leq 0\), which means the \texttt{tDie} component will be triggered when the number of rows to be generated is less than or equal to zero.

6. Double-click the \texttt{tDie} component to open its \textbf{Basic settings} view, and in the \textbf{Die message} field, enter the message to be triggered before the Job is killed. In this example, it is \textit{no row generated}.

7. Double-click the \texttt{tJava} component to open its \textbf{Basic settings} view, and in the \textbf{Code} field, enter

\begin{verbatim}
System.out.println("The number of rows generated is " + ((Integer)globalMap.get("tRowGenerator\_1\_NB\_LINE"))) + ". #This message will not be displayed if no row is generated.");
\end{verbatim}

Note that this message will be displayed only when the number of rows generated is greater than zero. In this example, the number of rows to be generated is 0, so the Job will be killed and this message will not be displayed.
8. Double-click the **tLogCatcher** component to open its **Basic settings** view and select the **Catch tDie** check box to catch the message triggered by the **tDie** component.

9. Double-click the **tLogRow** component to open its **Basic settings** view, and then select **Table (print values in cells of a table)** in the **Mode** area for better readability of the result.

**Executing the Job to catch the message triggered by the tDie component**

After setting up the Job and configuring the components used in the Job for catching the message triggered by the **tDie** component, you can then execute the Job and verify the Job execution result.

**Procedure**

1. Press **Ctrl + S** to save the Job.
2. Press **F6** to execute the Job.

```
[statistics] connecting to socket on port 3448

</tr>
</tbody>
</table>
[statistics] disconnected
```

As shown above, the message triggered is collected and displayed on the console.

3. Change the number of rows to be generated (10 for example) in the **Number of Rows for RowGenerator** field of the **tRowGenerator** component, save and execute the Job again to find a different result.
tLogRow

Displays data or results in the Run console to monitor data processed.

**tLogRow Standard properties**

These properties are used to configure tLogRow running in the Standard Job framework.

The Standard tLogRow component belongs to the Logs & Errors family.

The component in this framework is available in all Talend products.

**Basic settings**

| Schema and Edit schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
  • View schema: choose this option to view the schema only.  
  • Change to built-in property: choose this option to change the schema to Built-in for local changes.  
  • Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-In:</strong> You create and store the schema locally for this component only. <strong>Repository:</strong> You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
<td></td>
</tr>
<tr>
<td>Sync columns</td>
<td>Click to synchronize the output file schema with the input file schema. The Sync function is available only when the component is linked with the preceding component using a Row connection.</td>
</tr>
<tr>
<td>Basic</td>
<td>Displays the output flow in basic mode.</td>
</tr>
<tr>
<td>Table</td>
<td>Displays the output flow in table cells.</td>
</tr>
<tr>
<td>Vertical</td>
<td>Displays each row of the output flow as a key-value list. With this mode selected, you can choose to show either the unique name or the label of component, or both of them, for each output row.</td>
</tr>
<tr>
<td>Separator</td>
<td>Enter the separator which will delimit data on the Log display.</td>
</tr>
</tbody>
</table>
### Global Variables

| Global Variables | NB_LINE: the number of rows processed. This is an After variable and it returns an integer. ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

### Usage

| Usage rule | This component can be used as intermediate step in a data flow or as a n end object in the Job flowchart. |

### Related scenarios

For related scenarios, see:

- Reading master data from an MDM hub on page 2117.
- Reading data from different MySQL databases using dynamically loaded connection parameters on page 491.
- Catching messages triggered by a tWarn component on page 1950.
- Catching the message triggered by a tDie component on page 1952.
tLoop

Executes a task or a Job automatically, based on a loop

tLoop Standard properties

These properties are used to configure tLoop running in the Standard Job framework.
The Standard tLoop component belongs to the Orchestration family.
The component in this framework is available in all Talend products.

Basic settings

<table>
<thead>
<tr>
<th>Loop Type</th>
<th>Select a type of loop to be carried out: either For or While.</th>
</tr>
</thead>
<tbody>
<tr>
<td>For</td>
<td>• From: enter the first instance number which the loop should start from. A start instance number of 2 with a step of 2 means the loop takes on every even number instance.</td>
</tr>
<tr>
<td></td>
<td>• To: enter the last instance number which the loop should finish with.</td>
</tr>
<tr>
<td></td>
<td>• Step: enter the step the loop should be incremented of. A step of 2 means every second instance.</td>
</tr>
<tr>
<td></td>
<td>• Values are increasing: select this check box to only allow an increasing sequence. Deselect this check box to only allow a decreasing sequence.</td>
</tr>
<tr>
<td>While</td>
<td>• Declaration: enter an expression initiating the loop.</td>
</tr>
<tr>
<td></td>
<td>• Condition: enter the condition that should be met for the loop to end.</td>
</tr>
<tr>
<td></td>
<td>• Iteration: enter the expression showing the operation to be performed at each loop.</td>
</tr>
</tbody>
</table>

Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. |
|                 | CURRENT_VALUE: the current value. Only available for a For type loop. This is a Flow variable and it returns an integer. |
|                 | CURRENT_ITERATION: the sequence number of the current iteration. This is a Flow variable and it returns an integer. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. |
|                 | To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. |
Job execution in a loop

This scenario describes a Job composed of a parent Job and a child Job. The parent Job implements a loop which executes a child Job five times, with a pause of three seconds between each two executions.

Procedure

1. Create a Parent Job, and drop **tLoop**, **tRunJob**, and **tSleep** components to the workspace.
2. Connect **tLoop** to **tRunJob** using a Row > Iterate connection, and connect **tRunJob** to **tSleep** using a Row > Main connection.
3. Create a Child Job, and drop **tRowGenerator** and **tLogRow** components to the workspace.
4. Connect **tRowGenerator** to **tLogRow** using a Row > Main connection.
5. On the **Basic settings** view of the **tLoop** component, choose **For** loop type and type in the instance number to start from (1), to finish with (5) and the step (1).

![tLoop Component](image)

6. On the **Basic settings** view of the **tRunJob** component, select **Child Job** in the **Job** field.

![tRunJob Component](image)

7. On the **Basic settings** view of the **tSleep** component, enter 3 in the **Pause** field.

8. Double-click **tRowGenerator** to open the schema editor. Then click the plus button to add four new columns:
   - `id`, to generate sequence numbers
   - `firstname`, to generate random first names
   - `lastname`, to generate random last names
   - `city`, to generate random city names

   For more information about **tRowGenerator**, see **tRowGenerator** on page 3224.
9. Press **F6** to run the *Parent Job.*

The *Child Job* will be executed five times with a three-second pause between each two executions, displaying random personal information on the *Run* console as configured in the *tRowGenerator* component.
tMap

Transforms and routes data from single or multiple sources to single or multiple destinations.

tMap is an advanced component, which integrates itself as plugin to Talend Studio.

Tip:
There is no order among the output flows of tMap. To make the output flows to be executed one by one, you can output them to temporary files or memory, and then read and insert them into files or databases using different subjobs linked by Trigger > OnSubjobOK connections.

tMap Standard properties

These properties are used to configure tMap running in the Standard Job framework.

The Standard tMap component belongs to the Processing family.

The component in this framework is available in all Talend products.

Basic settings

<table>
<thead>
<tr>
<th>Map editor</th>
<th>It allows you to define the tMap routing and transformation properties.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>If needed, click the button at the top of the input area to open the Property Settings dialog box, which provides the following options:</td>
</tr>
<tr>
<td></td>
<td>• Die on error: Select this check box if you want to kill the Job if there is an error. This check box is selected by default.</td>
</tr>
<tr>
<td></td>
<td>• Enable Auto-Conversion of types: If your input and output columns across a mapping are of different data types, select this check box to enable automatic type conversion at the run time to avoid compiling errors.</td>
</tr>
<tr>
<td></td>
<td>This option is enabled by default if the Enable Auto-Conversion of types check box is selected in the Project Settings view when this component is added.</td>
</tr>
<tr>
<td></td>
<td>You can also override the default conversion behavior of this component by setting conversion rules in the Project Settings view. For more information, see Talend Studio User Guide.</td>
</tr>
<tr>
<td></td>
<td>Note that auto conversion between Date and BigDecimal is not supported.</td>
</tr>
<tr>
<td></td>
<td>• Store on disk: The options provided in this area are identical to the relevant options provided on the Basic settings and Advanced settings tabs respectively. Settings made in the Property Settings dialog box are reflected in the respective tab views and vice versa.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Mapping links display as</th>
<th>Auto: the default setting is curves links</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Curves: the mapping display as curves</td>
</tr>
</tbody>
</table>
**tMap**

**Lines:** The mapping displays as straight lines. This last option allows to slightly enhance performance.

<table>
<thead>
<tr>
<th>Temp data directory path</th>
<th>Enter the path where you want to store the temporary data generated for lookup loading. For more information on this folder, see <em>Talend Studio User Guide</em>.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Preview</strong></td>
<td>The preview is an instant shot of the Mapper data. It becomes available when Mapper properties have been filled in with data. The preview synchronization takes effect only after saving changes.</td>
</tr>
</tbody>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th>Max buffer size (nb of rows)</th>
<th>Type in the size of physical memory, in number of rows, you want to allocate to processed data.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ignore trailing zeros for BigDecimal</td>
<td>Select this check box to ignore trailing zeros for BigDecimal data.</td>
</tr>
<tr>
<td>tStatCatcher Statistics</td>
<td>Select this check box to gather the Job processing metadata at the Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

**Global Variables**

**Global Variables**

**ERROR_MESSAGE:** The error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

- A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.
- To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.
- For further information about variables, see *Talend Studio User Guide*.

**Usage**

**Usage rule**

Possible uses are from a simple reorganization of fields to the most complex Jobs of data multiplexing or demultiplexing transformation, concatenation, inversion, filtering and more...

**Limitation**

The use of **tMap** supposes minimum Java knowledge in order to fully exploit its functionalities.

This component is a junction step, and for this reason cannot be a start nor end component in the Job.
Mapping data using a filter and a simple explicit join

The Job described below aims at reading data from a csv file with its schema stored in the Repository, looking up at a reference file, the schema of which is also stored in the Repository, then extracting data from these two files based on a defined filter to an output file and reject files.

Linking the components

Procedure

1. Drop two tFileInputDelimited components, tMap and three tFileOutputDelimited components onto the design workspace.
2. Rename the two tFileInputDelimited components as Cars and Owners, either by double-clicking the label in the design workspace or via the View tab of the Component view.
3. Connect the two input components to tMap using Row > Main connections and label the connections as Cars_data and Owners_data respectively.
4. Connect tMap to the three output components using Row > New Output (Main) connections and name the output connections as Insured, Reject_NoInsur and Reject_OwnerID respectively.

Configuring the components

Procedure

1. Double-click the tFileInputDelimited component labelled Cars to display its Basic settings view.
2. Select **Repository** from the **Property type** list and select the component’s schema, `cars` in this scenario, from the **Repository Content** dialog box. The rest fields are automatically filled.

3. Double-click the component labelled **Owners** and repeat the setting operation. Select the appropriate metadata entry, `owners` in this scenario.

**Note:**

In this scenario, the input schemas are stored in the **Metadata** node of the **Repository** tree view for easy retrieval. For further information regarding metadata creation in the Repository, see *Talend Studio User Guide*.

4. Double-click the **tMap** component to open the **Map Editor**.

   Note that the input area is already filled with the defined input tables and that the top table is the main input table, and the respective row connection labels are displayed on the top bar of the table.

5. Create a join between the two tables on the `ID_Owner` column by simply dropping the `ID_Owner` column from the `Cars_data` table onto the `ID_Owner` column in the `Owners_data` table.

6. Define this join as an inner join by clicking the **tMap settings** button, clicking in the **Value** field for **Join Model**, clicking the small button that appears in the field, and selecting **Inner Join** from the **Options** dialog box.
7. Drag all the columns of the `Cars_data` table to the `Insured` table.

8. Drag the `ID_Owner`, `Registration`, and `ID_Reseller` columns of the `Cars_data` table and the `Name` column of the `Owners_data` table to the `Reject_NoInsur` table.

9. Drag all the columns of the `Cars_data` table to the `Reject_OwnerID` table.

   For more information regarding data mapping, see the [Talend Studio User Guide](#).

10. Click the plus arrow button at the top of the `Insured` table to add a filter row.

    Drag the `ID_Insurance` column of the `Owners_data` table to the filter condition area and enter the formula meaning 'not undefined': `Owners_data.ID_Insurance != null`.

    With this filter, the `Insured` table will gather all the records that include an insurance ID.
11. Click the **tMap settings** button at the top of the *Reject_NoInsur* table and set **Catch output reject** to **true** to define the table as a standard reject output flow to gather the records that do not include an insurance ID.

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Catch output reject</td>
<td>true</td>
</tr>
<tr>
<td>Catch lookup inner join reject</td>
<td>false</td>
</tr>
<tr>
<td>Schema Type</td>
<td>Built-In</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Expression</th>
<th>Column</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cars_data.ID_Owner</td>
<td>ID_Owner</td>
</tr>
<tr>
<td>Cars_data.Registration</td>
<td>Registration</td>
</tr>
<tr>
<td>Cars_data.ID_Reseller</td>
<td>ID_Reseller</td>
</tr>
<tr>
<td>Owners_data.Name</td>
<td>Name</td>
</tr>
</tbody>
</table>

12. Click the **tMap settings** button at the top of the *Reject.OwnerID* table and set **Catch lookup inner join reject** to **true** so that this output table will gather the records from the *Cars_data* flow with missing or unmatched owner IDs.

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Catch output reject</td>
<td>false</td>
</tr>
<tr>
<td>Catch lookup inner join reject</td>
<td>true</td>
</tr>
<tr>
<td>Schema Type</td>
<td>Built-In</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Expression</th>
<th>Column</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cars_data.ID_Owner</td>
<td>ID_Owner</td>
</tr>
<tr>
<td>Cars_data.Registration</td>
<td>Registration</td>
</tr>
<tr>
<td>Cars_data.Make</td>
<td>Make</td>
</tr>
<tr>
<td>Cars_data.Color</td>
<td>Color</td>
</tr>
<tr>
<td>Cars_data.ID_Reseller</td>
<td>ID_Reseller</td>
</tr>
</tbody>
</table>

Click **OK** to validate the mappings and close the **Map Editor**.

13. Double-click each of the output components, one after the other, to define their properties. If you want a new file to be created, browse to the destination output folder, and type in a file name including the extension.
Select the **Include header** check box to reuse the column labels from the schema as header row in the output file.

**Executing the Job**

**Procedure**

1. Press **Ctrl + S** to save your Job.
2. Press **F6** to run the Job.

The output files are created, which contain the relevant data as defined.

**Mapping data using inner join rejections**

This scenario, based on scenario 1, adds one input file containing details about resellers and extra fields in the main output table. Two filters on inner joins are added to gather specific rejections.

**Linking the components**

**Procedure**

1. Drop a **tFileInputDelimited** component and a **tFileOutputDelimited** component to the design workspace, and label the components as **Resellers** and **No_Reseller_ID** respectively.
2. Connect it to the Mapper using a **Row > Main** connection, and label the connection as **Resellers_data**.
3. Connect the **tMap** component to the new **tFileOutputDelimited** component by using the **Row** connection named **Reject_ResellerID**.
Configuring the components

Procedure

1. Double-click the Resellers component to display its Basic settings view.

2. Select Repository from the Property type list and select the component’s schema, resellers in this scenario, from the Repository Content dialog box. The rest fields are automatically filled.

   **Note:**

   In this scenario, the input schemas are stored in the Metadata node of the Repository tree view for easy retrieval. For further information regarding metadata creation in the Repository, see Talend Studio User Guide.

3. Double-click the tMap component to open the Map Editor.

   Note that the schema of the new input component is already added in the Input area.
4. Create a join between the main input flow and the new input flow by dropping the \textit{ID\_Reseller} column of the \textit{Cars\_data} table to the \textit{ID\_Reseller} column of the \textit{Resellers\_data} table.

5. Click the \textbf{tMap settings} button at the top of the \textit{Resellers\_data} table and set \textbf{Join Model} to \textbf{Inner Join}.

6. Drag all the columns except \textit{ID\_Reseller} of the \textit{Resellers\_data} table to the main output table, \textit{Insured}. 
Note:
When two inner joins are defined, you either need to define two different inner join reject tables to differentiate the two rejections or, if there is only one inner join reject output, both inner join rejections will be stored in the same output.

7. Click the [+] button at the top of the output area to add a new output table, and name this new output table `Reject_ResellerID`.

8. Drag all the columns of the `Cars_data` table to the `Reject_ResellerID` table.

9. Click the tMap settings button and select Catch lookup inner join reject to true to define this new output table as an inner join reject output.

If the defined inner join cannot be established, the information about the relevant cars will be gathered through this output flow.
10. Now apply filters on the two Inner Join reject outputs, in order for to distinguish the two types of rejection.

In the first Inner Join output table, `Reject_OwnerID`, click the plus arrow button to add a filter line and fill it with the following formula to gather only owner ID related rejection:

```
Owners_data.ID_Owner==null
```

11. In the second Inner Join output table, `Reject_ResellerID`, repeat the same operation using the following formula:

```
Resellers_data.ID_Reseller==null
```

Click **OK** to validate the map settings and close the **Mapper Editor**.

12. Double-click the `No_Reseller_ID` component to display its **Basic settings** view.
Specify the output file path and select the **Include Header** check box, and leave the other parameters as they are.

13. To demonstrate the work of the Mapper, in this example, remove reseller IDs 5 and 8 from the input file *Resellers.csv*.

**Executing the Job**

**Procedure**

1. Press **Ctrl + S** to save your Job.
2. Press **F6** to run the Job.

**Results**

The four output files are all created in the specified folder, containing information as defined. The output file *No Reseller ID.csv* contains the cars information related to reseller IDs 5 and 8, which are missing in the input file *Resellers.csv*.

As third advanced use scenario, based on the scenario 2, add a new Input table containing Insurance details for example.

Set up an Inner Join between two lookup input tables (Owners and Insurance) in the Mapper to create a cascade lookup and hence retrieve Insurance details via the Owners table data.

**Advanced mapping using filters, explicit joins and rejections**

This scenario introduces a Job that allows you to find BMW owners who have two to six children (inclusive), for sales promotion purpose for example.
Linking the components

Procedure

1. Drop three `tFileInputDelimited` components, a `tMap` component, and two `tFileOutputDelimited` components from the Palette onto the design workspace, and label them to best describe their functions.

2. Connect the input components to the `tMap` using Row > Main connections. Pay attention to the file you connect first as it will automatically be set as Main flow, and all the other connections will be Lookup flows. In this example, the connection for the input componentOwners is the Main flow.

Configuring the components

Procedure

1. Define the properties of each input components in the respective Basic settings view. Define the properties of Owners.

2. Select Repository from the Property type list and select the component’s schema, owners in this scenario, from the Repository Content dialog box. The rest fields are automatically filled.
Note:
In this scenario, the input schemas are stored in the Metadata node of the Repository tree view for easy retrieval. For further information regarding metadata creation in the Repository, see *Talend Studio User Guide*.

In the same way, set the properties of the other input components: *Cars* and *Resellers*. These two **Lookup** flows will fill in secondary (lookup) tables in the input area of the **Map Editor**.

3. Then double-click the **tMap** component to launch the **Map Editor** and define the mappings and filters.

Set an explicit join between the **Main flow** *Owner* and the **Lookup flow** *Cars* by dropping the *ID_Owner* column of the *Owners* table to the *ID_Owner* column of the *Cars* table.

The explicit join is displayed along with a hash key.

4. In the **Expr. Key** field of the *Make* column, type in a filter. In this use case, simply type in "BMW" as the search is focused on the owners of this particular make.
5. Implement a cascading join between the two lookup tables *Cars* and *Resellers* on the *ID_Reseller* column in order to retrieve resellers' information.

6. As you want to reject the null values into a separate table and exclude them from the standard output, click the tMap settings button and set **Join Model** to **Inner Join** in each of the **Lookup** tables.

7. In the tMap settings, you can set **Match Model** to **Unique match**, **First match**, or **All matches**. In this use case, the **All matches** option is selected. Thus if several matches are found in the Inner Join, rows matching the explicit join as well as the filter, all of them will be added to the output flow (either in rejection or the regular output).

   **Note:**
   The **Unique match** option functions as a **Last match**. The **First match** and **All matches** options function as named.

8. On the output area of the **Map Editor**, click the plus button to add two tables, one for the full matches and the other for the rejections.

9. Drag all the columns of the *Owners* table, the *Registration*, *Make* and *Color* columns of the *Cars* table, and the *ID_Reseller* and *Name_Reseller* columns of the *Resellers* table to the main output table.

10. Drag all the columns of the *Owners* table to the reject output table.

11. Click the **Filter** button at the top of the main output table to display the **Filter** expression area.
Type in a filter statement to narrow down the number of rows loaded in the main output flow. In this use case, the statement reads: Owners.Children_Nr >= 2 && Owners.Children_Nr <= 6.

12. In the reject output table, click the tMap settings button and set the reject types.
   Set Catch output reject to true to collect data about BMW car owners who have less than two or more than six children.
   Set Catch lookup inner join reject to true to collect data about owners of other car makes and owners for whom the reseller information is not found.

   ![Image of tMap settings](image)

Click OK to validate the mappings and close the Map Editor.

On the design workspace, right-click the tMap and pull the respective output link to the relevant output components.

13. Define the properties of the output components in their respective Basic settings view.
   In this use case, simply specify the output file paths and select the Include Header check box, and leave the other parameters as they are.
Executing the Job

Procedure

1. Press Ctrl + S to save your Job.
2. Press F6 to run it.

The main output file contains the information related to BMW owners who have two to six children, and the reject output file contains the information about the rest of the car owners.

Advanced mapping with filters and different rejections

This scenario is a modified version of the preceding scenario. It describes a Job that applies filters to limit the search to BMW and Mercedes owners who have two to six children and divides unmatched data into different reject output flows.

Linking the components

Procedure

1. Take the same Job as in Advanced mapping using filters, explicit joins and rejections on page 1973.
2. Drop a new tFileOutputDelimited component from the Palette on the design workspace, and name it Rejects_BMW_Mercedes to present its functionality.
3. Connect the tMap component to the new output component using a Row connection and label the connection according to the functionality of the output component.

This connection label will appear as the name of the new output table in the Map Editor.
4. Relabel the existing output connections and output components to reflect their functionality. The existing output tables in the Map Editor will be automatically renamed according to the connection labels. In this example, relabel the existing output connections `BMW_Mercedes_w ithChildren` and `Owners_Other_Makes` respectively.

**Configuring the components**

**Procedure**

1. Double-click the tMap component to launch the Map Editor to change the mappings and the filters.
   
   Note that the output area contains a new, empty output table named `Rejects_BMW_Mercedes`. You can adjust the position of the table by selecting it and clicking the Up or Down arrow button at the top of the output area.

2. Remove the Expr. key filter ("BMW") from the Cars table in the input area.

3. Click the Filters button to display the Filter field, and type in a new filter to limit the search to BMW or Mercedes car makes. The statement reads as follows: `Cars.Make.equals("BMW") || Cars.Make.equals("Mercedes")`
4. Select all the columns of the main output table and drop them down to the new output table. Alternatively, you can also drag the corresponding columns from the relevant input tables to the new output table.

5. Click the **tMap settings** button at the top of the new output table and set **Catch output reject** to **true** to collect data about BMW and Mercedes owners who have less than two or more than six children.

6. In the **Owners_Other_Makes** table, set **Catch lookup inner join reject** to **true** to collect data about owners of other car makes and owners for whom the reseller information is not found.
7. Click **OK** to validate the mappings and close the **Map Editor**.
8. Define the properties of the output components in their respective **Basic settings** view. In this use case, simple specify the output file paths and select the **Include Header** check box, and leave the other parameters as they are.
Executing the Job

Procedure

1. Press Ctrl + S to save the Job.
2. Press F6 to run it.

The output files contain content of the main output flow shows that the filtered rows have correctly been passed on.

Advanced mapping with lookup reload at each row

The following scenario describes a Job that retrieves people details from a lookup database, based on a join on the age. The main flow source data is read from a MySQL database table called `people_age` that contains people details such as numeric id, alphanumeric first name and last name and numeric age. The people age is either 40 or 60. The number of records in this table is intentionally restricted.

The reference or lookup information is also stored in a MySQL database table called `large_data_volume`. This lookup table contains a number of records including the city where people from the main flow have been to. For the sake of clarity, the number of records is restricted but, in a normal use, the usefulness of the feature described in the example below is more obvious for very large reference data volume.
To optimize performance, a database connection component is used in the beginning of the Job to open the connection to the lookup database table in order not to do that every time we want to load a row from the lookup table.

An Expression Filter is applied to this lookup source flow, in order to select only data from people whose age is equal to 60 or 40. This way only the relevant rows from the lookup database table are loaded for each row from the main flow.

Therefore this Job shows how, from a limited number of main flow rows, the lookup join can be optimized to load only results matching the expression key.

**Note:**
Generally speaking, as the lookup loading is performed for each main flow row, this option is mainly interesting when a limited number of rows is processed in the main flow while a large number of reference rows are to be looked up to.

The join is solved on the *age* field. Then, using the relevant loading option in the *tMap* component editor, the lookup database information is loaded for each main flow incoming row.

For this Job, the metadata has been prepared for the source and connection components. For more information on how to set up the DB connection schema metadata, see the relevant section in the *Talend Studio User Guide*.

This Job is formed with five components, four database components and a mapping component.

**Linking the components**

**Procedure**

1. Drop the DB Connection under the *Metadata* node of the *Repository* to the design workspace. In this example, the source table is called *people_age*.
2. Select *tMysqlInput* from the list that pops up when dropping the component.
3. Drop the lookup DB connection table from the **Metadata** node to the design workspace selecting **tMysqlInput** from the list that pops up. In this Job, the lookup is called *large_data_volume*.

4. The same way, drop the DB connection from the **Metadata** node to the design workspace selecting **tMysqlConnection** from the list that pops up. This component creates a permanent connection to the lookup database table in order not to do that every time we want to load a row from the lookup table.

5. Then pick the **tMap** component from the **Processing** family, and the **tMysqlOutput** and **tMysqlCommit** components from the **Database** family in the **Palette** to the right hand side of the editor.

6. Now connect all the components together. To do so, right-click the **tMysqlInput** component corresponding to the *people* table and drag the link towards **tMap**.

7. Release the link over the **tMap** component, the main row flow is automatically set up.

8. Rename the **Main** row link to *people*, to identify more easily the main flow data.

9. Perform the same operation to connect the lookup table (*large_data_volume*) to the **tMap** component and the **tMap** to the **tMysqlOutput** component.

10. A dialog box prompts for a name to the output link. In this example, the output flow is named: *people_mixandmatch*.

11. Rename also the lookup row connection link to *large_volume*, to help identify the reference data flow.

12. Connect **tMysqlConnection** to **tMysqlInput** using the trigger link **OnSubjobOk**.

13. Connect the **tMysqlInput** component to the **tMysqlCommit** component using the trigger link **OnSubjobOk**.
Configuring the components

Procedure

1. Double-click the \texttt{tMap} component to open the graphical mapping editor.

2. The \texttt{Output} table (that was created automatically when you linked the \texttt{tMap} to the \texttt{tMySQLOutput}) will be formed by the matching rows from the lookup flow (\textit{large_data_volume}) and the main flow (\textit{people_age}).

   Select the main flow rows that are to be passed on to the output and drag them over to paste them in the Output table (to the right hand side of the mapping editor).

   In this example, the selection from the main flow include the following fields: \textit{id}, \textit{first\_name}, \textit{last\_Name} and \textit{age}.

   From the lookup table, the following column is selected: \textit{city}.

   Drop the selected columns from the input tables (\textit{people} and \textit{large\_volume}) to the output table.

3. Now set up the join between the main and lookup flows.

   Select the \textit{age} column of the main flow table (on top) and drag it towards the \textit{age} column of the lookup flow table (\textit{large\_volume} in this example).

   A key icon appears next to the linked expression on the lookup table. The join is now established.

4. Click the \texttt{tMap settings} button, click the three-dot button corresponding to \texttt{Lookup Model}, and select the \textit{Reload at each row} option from the \texttt{Options} dialog box in order to reload the lookup for each row being processed.
5. In the same way, set Match Model to All matches in the Lookup table, in order to gather all instances of age matches in the output flow.

6. Now implement the filtering, based on the age column, in the Lookup table. The GlobalMapKey field is automatically created when you selected the Reload at each row option. Indeed you can use this expression to dynamically filter the reference data in order to load only the relevant information when joining with the main flow.

As mentioned in the introduction of the scenario, the main flow data contains only people whose age is either 40 or 60. To avoid the pain of loading all lookup rows, including ages that are different from 40 and 60, you can use the main flow age as global variable to feed the lookup filtering.
7. Drop the Age column from the main flow table to the Expr. field of the lookup table.

8. Then in the globalMap Key field, put in the variable name, using the expression. In this example, it reads: "people.Age"

Click OK to save the mapping setting and go back to the design workspace.

9. To finalize the implementation of the dynamic filtering of the lookup flow, you need now to add a WHERE clause in the query of the database input.

10. At the end of the Query field, following the Select statement, type in the following WHERE clause: WHERE AGE = "" + ((Integer)globalMap.get("people.Age")) + ""
11. Make sure that the type corresponds to the column used as variable. In this use case, Age is of Integer type. And use the variable the way you set in the globalMap key field of the map editor.

12. Double-click the tMysqloutput component to define its properties.

13. Select the Use an existing connection check box to leverage the created DB connection. Define the target table name and relevant DB actions.

Executing the Job

Procedure

1. Press Ctrl + S to save the Job.
2. Click the Run tab at the bottom of the design workspace, to display the Job execution tab.
3. From the Debug Run view, click the Traces Debug button to view the data processing progress.
   For more comfort, you can maximize the Job design view while executing by simply double-clicking on the Job name tab.

   The lookup data is reloaded for each of the main flow's rows, corresponding to the age constraint. All age matches are retrieved in the lookup rows and grouped together in the output flow.

   Therefore if you check out the data contained in the newly created people_mixandmatch table, you will find all the age duplicates corresponding to different individuals whose age equals to 60 or 40 and the city where they have been to.
Mapping with join output tables

The following scenario describes a Job that processes reject flows without separating them from the main flow.

Linking the components

Procedure

1. In the Repository tree view, click Metadata > File delimited. Drag and drop the customers metadata onto the workspace.
   The customers metadata contains information about customers, such as their ID, their name or their address, etc.
   For more information about centralizing metadata, see Talend Studio User Guide.
2. In the dialog box that asks you to choose which component type you want to use, select tFileInputDelimited and click OK.
3. Drop the states metadata onto the design workspace. Select the same component in the dialog box and click OK.
   The states metadata contains the ID of the state, and its name.
4. Drop a tMap and two tLogRow components from the Palette onto the design workspace.
5. Connect the customers component to the tMap, using a Row > Main connection.
6. Connect the states component to the tMap, using a Row > Main connection. This flow will automatically be defined as Lookup.
Configuring the components

Procedure

1. Double-click the **tMap** component to open the **Map Editor**. Drop the *idState* column from the main input table to the *idState* column of the lookup table to create a join.
   
   Click the **tMap settings** button and set **Join Model** to **Inner Join**.

2. Click the **Property Settings** button at the top of the input area to open the **Property Settings** dialog box, and clear the **Die on error** check box in order to handle the execution errors.
   
   The **ErrorReject** table is automatically created.
3. Select the id, idState, RegTime and RegisterTime in the input table and drag them to the ErrorReject table.

4. Click the [+ ] button at the top right of the editor to add an output table. In the dialog box that opens, select New output. In the field next to it, type in the name of the table, out1. Click OK.

5. Drag the following columns from the input tables to the out1 table: id, CustomerName, idState, and LabelState.

Add two columns, RegTime and RegisterTime, to the end of the out1 table and set their date formats: "dd/MM/yyyy HH:mm" and "yyyy-MM-dd HH:mm:ss.SSS" respectively.

6. Click in the Expression field for the RegTime column, and press Ctrl+Space to display the auto-completion list. Find and double-click TalendDate.parseDate. Change the pattern to ("dd/MM/yyyy HH:mm", row1.RegTime).

7. Do the same thing for the RegisterTime column, but change the pattern to ("yyyy-MM-dd HH:mm:ss.SSS", row1.RegisterTime).

8. Click the [+] button at the top of the output area to add an output table. In the dialog box that opens, select Create join table from, choose Out1, and name it rejectInner. Click OK.

9. Click the tMap settings button and set Catch lookup inner join reject to true in order to handle rejects.
10. Drag the id, CustomerName, and idState columns from the input tables to the corresponding columns of the rejectInner table.
   Click in the Expression field for the LabelState column, and type in "UNKNOWN".

11. Click in the Expression field for the RegTime column, press Ctrl+Space, and select TalendDate.parseDate. Change the pattern to ("dd/MM/yyyy HH:mm", row1.RegTime).

12. Click in the Expression field for the RegisterTime column, press Ctrl+Space, and select TalendDate.parseDate, but change the pattern to ("yyyy-MM-dd HH:mm:ss.SSS", row1.RegisterTime).
   If the data from row1 has a wrong pattern, it will be returned by the ErrorReject flow.
   
   ![Image of mapping and join table]

   Click OK to validate the changes and close the editor.

13. Double-click the first tLogRow component to display its Component view.
   Click Sync columns to retrieve the schema structure from the mapper if needed.
   In the Mode area, select Table.
   Do the same thing with the second tLogRow.

** Executing the Job 

**Procedure**

1. Press Ctrl + S to save your Job.
2. Press F6 to execute it.
**Results**

The **Run** console displays the main out flow and the ErrorReject flow. The main output flow unites both valid data and inner join rejects, while the ErrorReject flow contains the error information about rows with unparsable date formats.

tMapRDBClose

Closes an MapRDB connection you have established in a same Job.

**tMapRDBClose Standard properties**

These properties are used to configure tMapRDBClose running in the Standard Job framework.

The Standard tMapRDBClose component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| Component list | Select the tMapRDBConnection component in the list if more than one connection are planned for the current Job. |

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Global Variables**

**Global Variables**

ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

**Usage**

| Usage rule | This component is to be used along with MapRDB components, especially with tMapRDBConnection. |

| Prerequisites | Before starting, ensure that you have met the Loopback IP prerequisites expected by your database.

The Hadoop distribution must be properly installed, so as to guarantee the interaction with Talend Studio. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. |
According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native. For example, the library for Windows is \lib\native\MapRClient.dll in the MapR client jar file. For further information, see the following link from MapR: http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr.

Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path.

- Set the -Djava.library.path argument, for example, in the Job Run VM arguments area of the Run/Debug view in the Preferences dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

Related scenario

This component is similar to tHBaseClose. For a scenario about how to use tHBaseClose, see Exchanging customer data with HBase on page 1402.
tMapRDBConnection

Establishes a MapRDB connection to be reused by other MapRDB components in a same Job.

**tMapRDBConnection Standard properties**

These properties are used to configure tMapRDBConnection running in the Standard Job framework.

The Standard tMapRDBConnection component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| Property type | Either **Built-In** or **Repository**.  
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Built-In</strong>: No property data stored centrally.</td>
</tr>
</tbody>
</table>
|               | **Repository**: Select the repository file where the properties are stored.  
|               | The properties are stored centrally under the **Hadoop Cluster** node of the **Repository** tree. |

**Distribution and Version**

Select the MapR distribution to be used. Only MapR V5.2 onwards is supported by the MapRDB components.

If the distribution you need to use with your MapRDB database is not officially supported by this MapRBD component, that is to say, this distribution is MapR but is not listed in the **Version** drop-down list of this components or this distribution is not MapR at all, select **Custom**.

1. Select **Import from existing version** to import an officially supported distribution as base and then add other required jar files which the base distribution does not provide.

2. Select **Import from zip** to import the configuration zip for the custom distribution to be used. This zip file should contain the libraries of the different Hadoop elements and the index file of these libraries.

In Talend Exchange, members of Talend community have shared some ready-for-use configuration zip files which you can download from this Hadoop configuration list and directly use them in your connection accordingly. However, because of the ongoing evolution of the different Hadoop-related projects, you might not be able to find the configuration zip corresponding to your distribution from this list; then it is recommended to use the **Import from existing version** option to take an existing distribution as base to add the jars required by your distribution.

Note that custom versions are not officially supported by Talend. Talend and its community provide you with the opportunity to connect to custom versions from the Studio but cannot guarantee that the configuration of whichever version you choose will...
be easy, due to the wide range of different Hadoop distributions and versions that are available. As such, you should only attempt to set up such a connection if you have sufficient Hadoop experience to handle any issues on your own.

Note:
In this dialog box, the active check box must be kept selected so as to import the jar files pertinent to the connection to be created between the custom distribution and this component.

For a step-by-step example about how to connect to a custom distribution and share this connection, see Connecting to a custom Hadoop distribution on page 1569.

| Hadoop version of the distribution | This list is displayed only when you have selected Custom from the distribution list to connect to a cluster not yet officially supported by the Studio. In this situation, you need to select the Hadoop version of this custom cluster, that is to say, Hadoop 1 or Hadoop 2. |

| Zookeeper quorum | Type in the name or the URL of the Zookeeper service you use to coordinate the transaction between your Studio and your database. Note that when you configure the Zookeeper, you might need to explicitly set the zookeeper.znode.parent property to define the path to the root znode that contains all the znodes created and used by your database; then select the Set Zookeeper znode parent check box to define this property. |

| Zookeeper client port | Type in the number of the client listening port of the Zookeeper service you are using. |

| Inspect the classpath for configurations | Select this check box to allow the component to check the configuration files in the directory you have set with the $HADOOP_CONF_DIR variable and directly read parameters from these files in this directory. This feature allows you to easily change the Hadoop configuration for the component to switch between different environments, for example, from a test environment to a production environment. In this situation, the fields or options used to configure Hadoop connection and/or Kerberos security are hidden. If you want to use certain parameters such as the Kerberos parameters but these parameters are not included in these Hadoop configuration files, you need to create a file called talend-site.xml and put this file into the same directory defined with $HADOOP_CONF_DIR. This talend-site.xml file should read as follows:

```
<!-- Put site-specific property overrides in this file. -->
<configuration>
  <property>
    <name>talend.kerberos.authentication</name>
    <value>kinit</value>
    <description>Set the Kerberos authentication method to
```

1997
<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>talend.kerberos.keytab.principal</code></td>
<td><a href="mailto:user@BIGDATA.COM">user@BIGDATA.COM</a></td>
<td>Set the keytab's principal name.</td>
</tr>
<tr>
<td><code>talend.kerberos.keytab.path</code></td>
<td>/kdc/user.keytab</td>
<td>Set the keytab's path.</td>
</tr>
<tr>
<td><code>talend.encryption</code></td>
<td>none</td>
<td>Set the encryption method to use. Valid values are: none or ssl.</td>
</tr>
<tr>
<td><code>ssl.trustStore.path</code></td>
<td>/ssl</td>
<td>Set SSL trust store path.</td>
</tr>
<tr>
<td><code>ssl.trustStore.password</code></td>
<td>/ssl</td>
<td>Set SSL trust store password.</td>
</tr>
</tbody>
</table>

The parameters read from these configuration files override the default ones used by the Studio. When a parameter does not exist in these configuration files, the default one is used.

### Use Kerberos Authentication

If the database to be used is running with Kerberos security, select this check box, then, enter the principal names in the displayed fields. You should be able to find the information in the `hbase-site.xml` file of the cluster to be used.

- If this cluster is a MapR cluster of the version 5.0.0 or later, you can set the MapR ticket authentication configuration in addition or as an alternative by following the explanation in Connecting to a Security-Enabled MapR on page 1629.
Keep in mind that this configuration generates a new MapR security ticket for the username defined in the Job in each execution. If you need to reuse an existing ticket issued for the same username, leave both the `Force MapR ticket authentication` check box and the `Use Kerberos authentication` check box clear, and then MapR should be able to automatically find that ticket on the fly.

If you need to use a Kerberos keytab file to log in, select `Use a keytab to authenticate`. A keytab file contains pairs of Kerberos principals and encrypted keys. You need to enter the principal to be used in the `Principal` field and the access path to the keytab file itself in the `Keytab` field. This keytab file must be stored in the machine in which your Job actually runs, for example, on a Talend Jobserver.

Note that the user that executes a keytab-enabled Job is not necessarily the one a principal designates but must have the right to read the keytab file being used. For example, the user name you are using to execute a Job is `user1` and the principal to be used is `guest`; in this situation, ensure that `user1` has the right to read the keytab file to be used.

For further information about how Kerberos can be configured for your database in a MapR cluster, see Configuring Kerberos Authentication.

### Advanced settings

**Properties**

If you need to use custom configuration for your database, complete this table with the property or properties to be customized. Then at runtime, the customized property or properties will override those corresponding ones defined earlier for your database.

For example, you need to define the value of the `dfs.replication` property as `1` for the database configuration. Then you need to add one row to this table using the plus button and type in the name and the value of this property in this row.

**tStatCatcher Statistics**

Select this check box to collect the log data at a component level.

### Global Variables

**Global Variables**

`ERROR_MESSAGE`: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the `Die on error` check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press `Ctrl + Space` to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.
## Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is generally used with other MapRDB components, particularly tMapRDBCClose.</th>
</tr>
</thead>
</table>

### Prerequisites

Before starting, ensure that you have met the Loopback IP prerequisites expected by your database.

The Hadoop distribution must be properly installed, so as to guarantee the interaction with Talend Studio. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native. For example, the library for Windows is \lib\native\MapRClient.dll in the MapR client jar file. For further information, see the following link from MapR: [http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr](http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr).

Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path.

- Set the -Djava.library.path argument, for example, in the Job Run VM arguments area of the Run/Debug view in the Preferences dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

### Related scenario

This component is similar to tHBaseConnection. For a scenario about how to use tHBaseConnection, see Exchanging customer data with HBase on page 1402.
tMapRDBInput

Reads data from a given MapRDB database and extracts columns of selection.
tMapRDBInput extracts columns corresponding to schema definition. Then it passes these columns to the next component via a Main row link.

tMapRDBInput Standard properties

These properties are used to configure tMapRDBInput running in the Standard Job framework.
The Standard tMapRDBInput component belongs to the Big Data and the Databases NoSQL families.
The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

Basic settings

| Property type | Either Built-In or Repository.  
|              | Built-In: No property data stored centrally.  
|              | Repository: Select the repository file where the properties are stored.  
|              | The properties are stored centrally under the Hadoop Cluster node of the Repository tree.  

Use an existing connection

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

Distribution and Version

Select the MapR distribution to be used. Only MapR V5.2 onwards is supported by the MapRDB components.

If the distribution you need to use with your MapRDB database is not officially supported by this MapRDB component, that is to say, this distribution is MapR but is not listed in the Version drop-down list of this component or this distribution is not MapR at all, select Custom.

1. Select Import from existing version to import an officially supported distribution as base and then add other required jar files which the base distribution does not provide.

2. Select Import from zip to import the configuration zip for the custom distribution to be used. This zip file should contain the libraries of the different Hadoop elements and the index file of these libraries.

In Talend Exchange, members of Talend community have shared some ready-for-use configuration zip files which you can download from this Hadoop configuration list and directly use them in your connection accordingly. However, because of the ongoing evolution of the different Hadoop-related projects, you might not be able to find the configuration zip corresponding to your distribution from this list; then it is recommended to use the Import from existing version option to take an existing
distribution as base to add the jars required by your distribution.

Note that custom versions are not officially supported by Talend. Talend and its community provide you with the opportunity to connect to custom versions from the Studio but cannot guarantee that the configuration of whichever version you choose will be easy, due to the wide range of different Hadoop distributions and versions that are available. As such, you should only attempt to set up such a connection if you have sufficient Hadoop experience to handle any issues on your own.

**Note:**

In this dialog box, the active check box must be kept selected so as to import the jar files pertinent to the connection to be created between the custom distribution and this component.

For a step-by-step example about how to connect to a custom distribution and share this connection, see Connecting to a custom Hadoop distribution on page 1569.

| **Hadoop version of the distribution** | This list is displayed only when you have selected Custom from the distribution list to connect to a cluster not yet officially supported by the Studio. In this situation, you need to select the Hadoop version of this custom cluster, that is to say, Hadoop 1 or Hadoop 2. |
| **Zookeeper quorum** | Type in the name or the URL of the Zookeeper service you use to coordinate the transaction between your Studio and your database. Note that when you configure the Zookeeper, you might need to explicitly set the zookeeper.znode.parent property to define the path to the root znode that contains all the znodes created and used by your database; then select the Set Zookeeper znode parent check box to define this property. |
| **Zookeeper client port** | Type in the number of the client listening port of the Zookeeper service you are using. |
| **Use kerberos authentication** | If the database to be used is running with Kerberos security, select this check box, then, enter the principal names in the displayed fields. You should be able to find the information in the hbase-site.xml file of the cluster to be used. |
| | • If this cluster is a MapR cluster of the version 5.0.0 or later, you can set the MapR ticket authentication configuration in addition or as an alternative by following the explanation in Connecting to a security-enabled MapR on page 1629. |
| | Keep in mind that this configuration generates a new MapR security ticket for the username defined in the Job in each execution. If you need to reuse an existing ticket issued for the same username, leave both the Force MapR ticket authentication check box and the Use Kerberos authentication check box clear, and then MapR should be able to automatically find that ticket on the fly. |
If you need to use a Kerberos keytab file to log in, select **Use a keytab to authenticate**. A keytab file contains pairs of Kerberos principals and encrypted keys. You need to enter the principal to be used in the Principal field and the access path to the keytab file itself in the Keytab field. This keytab file must be stored in the machine in which your Job actually runs, for example, on a Talend Jobserver.

Note that the user that executes a keytab-enabled Job is not necessarily the one a principal designates but must have the right to read the keytab file being used. For example, the user name you are using to execute a Job is user1 and the principal to be used is guest; in this situation, ensure that user1 has the right to read the keytab file to be used.

---

**Schema and Edit schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

---

**Built-In**: You create and store the schema locally for this component only.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

---

**Set table Namespace mappings**

Enter the string to be used to construct the mapping between an Apache HBase table and a MapR table.

For the valid syntax you can use, see [http://doc.mapr.com/display/MapR40x/Mapping+Table+Namespace+Between+Apache+HBase+Tables+and+MapR+Tables](http://doc.mapr.com/display/MapR40x/Mapping+Table+Namespace+Between+Apache+HBase+Tables+and+MapR+Tables).

**Table name**

Type in the name of the table from which you need to extract columns.

---

**Define a row selection**

Select this check box and then in the **Start row** and the **End row** fields, enter the corresponding row keys to specify the range of the rows you want the current component to extract.

Different from the filters you can set using **Is by filter** requiring the loading of all records before filtering the ones to be used, this feature allows you to directly select only the rows to be used.
### Mapping

Complete this table to map the columns of the table to be used with the schema columns you have defined for the data flow to be processed.

### Advanced settings

#### tStatCatcher Statistics

Select this check box to collect log data at the component level.

#### Properties

If you need to use custom configuration for your database, complete this table with the property or properties to be customized. Then at runtime, the customized property or properties will override the corresponding ones used by the Studio.

For example, you need to define the value of the `dfs.replication` property as 1 for the database configuration. Then you need to add one row to this table using the plus button and type in the name and the value of this property in this row.

**Note:**

This table is not available when you are using an existing connection by selecting the Using an existing connection check box in the Basic settings view.

#### Is by filter

Select this check box to use filters to perform fine-grained data selection from your database, such as selection of keys, or values, based on regular expressions.

Once selecting it, the Filter table that is used to define filtering conditions becomes available.

This feature leverages filters provided by HBase and subject to constraints explained in Apache HBase documentation. Therefore, advanced knowledge of HBase is required to make full use of these filters.

**Logical operation**

Select the operator you need to use to define the logical relation between filters. This available operators are:

- **And**: every defined filtering conditions must be satisfied. It represents the relationship `FilterList.Operator.MUST_PASS_ALL`
- **Or**: at least one of the defined filtering conditions must be satisfied. It represents the relationship: `FilterList.Operator.MUST_PASS_ONE`

**Filter**

Click the button under this table to add as many rows as required, each row representing a filter. The parameters you may need to set for a filter are:

- **Filter type**: the drop-down list presents pre-existing filter types that are already defined by HBase. Select the type of the filter you need to use.
- **Filter column**: enter the column qualifier on which you need to apply the active filter. This parameter becomes mandatory depending on the type of the filter and of the comparator you are using. For example, it is not used by the **Row Filter** type but is required by the **Single Column Value Filter** type.
• **Filter family**: enter the column family on which you need to apply the active filter. This parameter becomes mandatory depending on the type of the filter and of the comparator you are using. For example, it is not used by the **Row Filter** type but is required by the **Single Column Value Filter** type.

• **Filter operation**: select from the drop-down list the operation to be used for the active filter.

• **Filter Value**: enter the value on which you want to use the operator selected from the **Filter operation** drop-down list.

• **Filter comparator type**: select the type of the comparator to be combined with the filter you are using.

Depending on the **Filter type** you are using, some or each of the parameters become mandatory. For further information, see HBase filters on page 1396

### Global Variables

| Global Variables          | **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.  
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
For further information about variables, see **Talend Studio User Guide**. |

### Usage

| Usage rule | This component is a start component of a Job and always needs an output link. |

### Prerequisites

Before starting, ensure that you have met the Loopback IP prerequisites expected by your database.

The Hadoop distribution must be properly installed, so as to guarantee the interaction with **Talend Studio**. The following list presents MapR related information for example.

• Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under **MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native**. For example, the library for Windows is **\lib\native\MapRClient.dll** in the MapR client jar file. For further information, see the following link from MapR: [http://www.mapr.com/blog/basic-notes-](http://www.mapr.com/blog/basic-notes-)
Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path.

- Set the `-Djava.library.path` argument, for example, in the Job Run VM arguments area of the Run/Debug view in the Preferences dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

**Related scenario**

This component is similar to tHBaseInput. For related scenario to tHBaseInput, see Exchanging customer data with HBase on page 1402.
**tMapRDBOutput**

Writes columns of data into a given MapRDB database.

tMapRDBOutput receives data from its preceding component, creates a table in a given MapRDB database and writes the received data into this table.

**tMapRDBOutput Standard properties**

These properties are used to configure tMapRDBOutput running in the Standard Job framework.
The Standard tMapRDBOutput component belongs to the Big Data and the Databases NoSQL families.
The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| Property type                  | Either Built-In or Repository.  
|--------------------------------|---------------------------------|
| Built-In: No property data stored centrally.  
| Repository: Select the repository file where the properties are stored.  |
| Use an existing connection    | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.  |
| Distribution and Version      | Select the MapR distribution to be used. Only MapR V5.2 onwards is supported by the MapRDB components.  
| If the distribution you need to use with your MapRDB database is not officially supported by this MapRDB component, that is to say, this distribution is MapR but is not listed in the Version drop-down list of this component or this distribution is not MapR at all, select Custom.  
| 1. Select Import from existing version to import an officially supported distribution as base and then add other required jar files which the base distribution does not provide.  
| 2. Select Import from zip to import the configuration zip for the custom distribution to be used. This zip file should contain the libraries of the different Hadoop elements and the index file of these libraries.  
| In Talend Exchange, members of Talend community have shared some ready-for-use configuration zip files which you can download from this Hadoop configuration list and directly use them in your connection accordingly. However, because of the ongoing evolution of the different Hadoop-related projects, you might not be able to find the configuration zip corresponding to your distribution from this list; then it is recommended to use the Import from existing version option to take an existing distribution as base to add the jars required by your distribution. |
Note that custom versions are not officially supported by Talend. Talend and its community provide you with the opportunity to connect to custom versions from the Studio but cannot guarantee that the configuration of whichever version you choose will be easy, due to the wide range of different Hadoop distributions and versions that are available. As such, you should only attempt to set up such a connection if you have sufficient Hadoop experience to handle any issues on your own.

**Note:**
In this dialog box, the active check box must be kept selected so as to import the jar files pertinent to the connection to be created between the custom distribution and this component.

For a step-by-step example about how to connect to a custom distribution and share this connection, see Connecting to a custom Hadoop distribution on page 1569.

### Hadoop version of the distribution
This list is displayed only when you have selected Custom from the distribution list to connect to a cluster not yet officially supported by the Studio. In this situation, you need to select the Hadoop version of this custom cluster, that is to say, Hadoop 1 or Hadoop 2.

### Zookeeper quorum
Type in the name or the URL of the Zookeeper service you use to coordinate the transaction between your Studio and your database. Note that when you configure the Zookeeper, you might need to explicitly set the `zookeeper.znode.parent` property to define the path to the root znode that contains all the znodes created and used by your database; then select the **Set Zookeeper znode parent** check box to define this property.

### Zookeeper client port
Type in the number of the client listening port of the Zookeeper service you are using.

### Use kerberos authentication
If the database to be used is running with Kerberos security, select this check box, then, enter the principal names in the displayed fields. You should be able to find the information in the `hbase-site.xml` file of the cluster to be used.

- If this cluster is a MapR cluster of the version 5.0.0 or later, you can set the MapR ticket authentication configuration in addition or as an alternative by following the explanation in Connecting to a security-enabled MapR on page 1629.

Keep in mind that this configuration generates a new MapR security ticket for the username defined in the Job in each execution. If you need to reuse an existing ticket issued for the same username, leave both the **Force MapR ticket authentication** check box and the **Use Kerberos authentication** check box clear, and then MapR should be able to automatically find that ticket on the fly.

If you need to use a Kerberos keytab file to log in, select **Use a keytab to authenticate**. A keytab file contains pairs of Kerberos principals and encrypted keys. You need to
enter the principal to be used in the **Principal** field and the access path to the keytab file itself in the **Keytab** field. This keytab file must be stored in the machine in which your Job actually runs, for example, on a Talend Jobserver.

Note that the user that executes a keytab-enabled Job is not necessarily the one a principal designates but must have the right to read the keytab file being used. For example, the user name you are using to execute a Job is `user1` and the principal to be used is `guest`; in this situation, ensure that `user1` has the right to read the keytab file to be used.

### Schema and Edit schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

#### Built-In

- **Built-In**: You create and store the schema locally for this component only.

#### Repository

- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

### Set table Namespace mappings

Enter the string to be used to construct the mapping between an Apache HBase table and a MapR table.

For the valid syntax you can use, see [http://doc.mapr.com/display/MapR40x/Mapping+Table+Namespace+Between+Apache+HBase+Tables+and+MapR+Tables](http://doc.mapr.com/display/MapR40x/Mapping+Table+Namespace+Between+Apache+HBase+Tables+and+MapR+Tables).

#### Table name

- **Table name**: Type in the name of the HBase table you need to create.

#### Action on table

- **Action on table**: Select the action you need to take for creating a table.

#### Custom Row Key

- **Custom Row Key**: Select this check box to use the customized row keys. Once selected, the corresponding field appears. Then type in the user-defined row key to index the rows of the table being created.
For example, you can type in "France"+Numeric.sequence("s1",1,1) to produce the row key series: France1, France2, France3 and so on.

<table>
<thead>
<tr>
<th>Families</th>
<th>Complete this table to specify the column or columns to be created and the corresponding column family or families they belong to respectively. The <strong>Column</strong> column of this table is automatically filled once you have defined the schema.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Die on error</td>
<td>This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.</td>
</tr>
</tbody>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th>Use batch mode</th>
<th>Select this check box to activate the batch mode for data processing.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Batch size</strong></td>
<td>Specify the number of records to be processed in each batch. This field appears only when the <strong>Use batch mode</strong> check box is selected.</td>
</tr>
</tbody>
</table>

**Properties**

If you need to use custom configuration for your database, complete this table with the property or properties to be customized. Then at runtime, the customized property or properties will override the corresponding ones used by the Studio.

For example, you need to define the value of the **dfs.replication** property as 1 for the database configuration. Then you need to add one row to this table using the plus button and type in the name and the value of this property in this row.

**Note:**
This table is not available when you are using an existing connection by selecting the **Using an existing connection** check box in the **Basic settings** view.

**tStatCatcher Statistics**

Select this check box to collect log data at the component level.

**Family parameters**

Type in the names and, when needed, the custom performance options of the column families to be created. This feature leverages attributes defined by the HBase data model, so for further explanation about these options, see Apache HBase documentation.

**Note:** The parameter **Compression type** allows you to select the format for output data compression.

**Global Variables**

| Global Variables | **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer. |
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

#### Usage rule

This component is normally an end component of a Job and always needs an input link.

#### Prerequisites

Before starting, ensure that you have met the Loopback IP prerequisites expected by your database.

The Hadoop distribution must be properly installed, so as to guarantee the interaction with *Talend Studio*. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under *MAPR_INSTALL\hadoop\version\native*. For example, the library for Windows is *\lib\native\MapRClient.dll* in the MapR client jar file. For further information, see the following link from MapR: [http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr](http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr).

Without adding the specified library or libraries, you may encounter the following error: *no MapRClient in java.library.path.*

- Set the **-Djava.library.path** argument, for example, in the **Job Run VM arguments** area of the **Run/Debug** view in the **Preferences** dialog box in the **Window** menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the **Data viewer** to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

### Related scenario

This component is similar to **tHBaseOutput**. For related scenario to **tHBaseOutput**, see [Exchanging customer data with HBase](#) on page 1402.
**tMapROjaiInput**

Reads documents from a MapR-DB database to load the data in a given Job.

You must have properly installed and configured your MapR Client before using this component. A \opt\mapr\conf\mapr-clusters.conf file is automatically generated out of the Client configuration process to store the connection information to your MapR cluster and your MapR-DB database. At runtime, this OJAI component reads this connection information by itself to connect to the MapR-DB database to be used.

For further information about how to install and configure your MapR client, see Setting up the Client from the MapR documentation.

**tMapROjaiInput Standard properties**

These properties are used to configure tMapROjaiInput running in the Standard Job framework.

The Standard tMapROjaiInput component belongs to the Databases NoSQL family.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Distribution and Version</th>
<th>Select the version of your MapR cluster. This cluster must host the MapR-DB database to be used.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Schema and Edit schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Built-In</strong>: You create and store the schema locally for this component only.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Repository</strong>: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
</tr>
<tr>
<td></td>
<td>Click <strong>Edit schema</strong> to make changes to the schema. Note that if you make changes, the schema automatically becomes built-in.</td>
</tr>
<tr>
<td></td>
<td>• <strong>View schema</strong>: choose this option to view the schema only.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Change to built-in property</strong>: choose this option to change the schema to <strong>Built-in</strong> for local changes.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Update repository connection</strong>: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select <strong>No</strong> upon completion and choose this schema metadata again in the <strong>Repository Content</strong> window.</td>
</tr>
<tr>
<td></td>
<td>This component supports the Document type. If a field is for entire documents, select <strong>Document</strong> in the <strong>Type</strong> column for this field in the schema editor.</td>
</tr>
</tbody>
</table>
Click `Sync columns` to retrieve the schema from the previous component connected in the Job.

### Use kerberos authentication

If you are accessing a MapR-DB as-OJAI database running with Kerberos security, select this check box, then, enter the Kerberos principal name and password in the displayed fields.

Every time when you launch your Job, the component submits this authentication information to Kerberos for a new kinit ticket.

- If the MapR ticket security mechanism is also set up along with Kerberos, this component issues a `mapr login` command to obtain a MapR ticket at the same time.
- If only the MapR ticket security mechanism is set up for your cluster while Kerberos is not, keep this check box clear. The component obtains a MapR ticket itself via your MapR Client.

### Use a keytab to authenticate

Select the `Use a keytab to authenticate` check box to log into a Kerberos-enabled system using a given keytab file. A keytab file contains pairs of Kerberos principals and encrypted keys. You need to enter the principal to be used in the `Principal` field and the access path to the keytab file itself in the `Keytab` field. This keytab file must be stored in the machine in which your Job actually runs, for example, on a Talend Jobserver.

Note that the user that executes a keytab-enabled Job is not necessarily the one a principal designates but must have the right to read the keytab file being used. For example, the user name you are using to execute a Job is `user1` and the principal to be used is `guest`; in this situation, ensure that `user1` has the right to read the keytab file to be used.

### Restrict partial sorts with Secondary Indexes

Select this check box to force the query to explicitly sort on the actual data. This way, you avoid in your query the partial sorts that could otherwise occur due to the asynchronous secondary indexes.

For further information about this partial sorts issue of MapR OJAI, see `Asynchronous Secondary Index Updates` from the MapR documentation.

Do not select this check box if you do not expect to encounter the lags in the asynchronous indexes or you know that the impact of the lags is trivial. By keeping this check box clear, your query benefits from the ordering advantages provided by the secondary indexes of MapR-DB JSON tables.

### Table name

Enter the name of the table to be processed.

### Query

Specify the where clause of the query to be performed by tMapROjaiInput.

For example, type in `{id:{$eq: 4}}` or `{id:4}` to retrieve the record in which `id` is 4.

As OJAI uses MongoDB query format for queries, see `Query Operators` from the MongoDB documentation for available operators.
Each column of the schema defined for this component represents a field of the documents to be read. In this table, you need to specify the parent nodes of these fields, if any.

For example, in the document reading as follows:

```json
{
   _id: ObjectId("5099803df4948bd2f98391"),
   person: { first: "Joe", last: "Walker" }
}
```

The first and the last fields have `person` as their parent node but the _id field does not have any parent node. So once completed, this Mapping table should read as follows:

<table>
<thead>
<tr>
<th>Column</th>
<th>Parent node path</th>
</tr>
</thead>
<tbody>
<tr>
<td>_id</td>
<td></td>
</tr>
<tr>
<td>first</td>
<td>&quot;person&quot;</td>
</tr>
<tr>
<td>last</td>
<td>&quot;person&quot;</td>
</tr>
</tbody>
</table>

**Advanced settings**

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

**Global Variables**

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

**NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see **Talend Studio User Guide**.

**Usage**

**Usage rule**

tMapROjaiInput executes queries to read data from a given MapR-DB database. It is a starting component of a Job and requires an outgoing link to send data to its following component.
tMapROjaiOutput

Inserts, replaces or deletes documents in a MapR-DB database to be used as document database, based on the incoming flow from the preceding component in the Job.

You must have properly installed and configured your MapR Client before using this component. A `\opt\mapr\conf\mapr-clusters.conf` file is automatically generated out of the Client configuration process to store the connection information to your MapR cluster and your MapR-DB database. At runtime, this OJAI component reads this connection information by itself to connect to the MapR-DB database to be used.

For further information about how to install and configure your MapR client, see Setting up the Client from the MapR documentation.

**tMapROjaiOutput Standard properties**

These properties are used to configure tMapROjaiOutput running in the Standard Job framework.

The Standard tMapROjaiOutput component belongs to the Databases NoSQL family.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Distribution and Version</th>
<th>Select the version of your MapR cluster. This cluster must host the MapR-DB database to be used.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Schema and Edit schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <code>line</code> when naming the fields.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Built-In</strong>: You create and store the schema locally for this component only.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Repository</strong>: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
</tr>
<tr>
<td></td>
<td>Click <strong>Edit schema</strong> to make changes to the schema. Note that if you make changes, the schema automatically becomes built-in.</td>
</tr>
<tr>
<td></td>
<td>• <strong>View schema</strong>: choose this option to view the schema only.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Change to built-in property</strong>: choose this option to change the schema to <strong>Built-in</strong> for local changes.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Update repository connection</strong>: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select <strong>No</strong> upon completion and choose this schema metadata again in the <strong>Repository Content</strong> window.</td>
</tr>
</tbody>
</table>

This component supports the Document type. If a field is for entire documents, select **Document** in the **Type** column for this field in the schema editor.
Click **Sync columns** to retrieve the schema from the previous component connected in the Job.

### Use kerberos authentication

If you are accessing a MapR-DB as-OJAI database running with Kerberos security, select this check box, then, enter the Kerberos principal name and password in the displayed fields.

Every time when you launch your Job, the component submits this authentication information to Kerberos for a new kinit ticket.

- If the MapR ticket security mechanism is also set up along with Kerberos, this component issues a `mapr login` command to obtain a MapR ticket at the same time.
- If only the MapR ticket security mechanism is set up for your cluster while Kerberos is not, keep this check box clear. The component obtains a MapR ticket itself via your MapR Client.

### Use a keytab to authenticate

Select the **Use a keytab to authenticate** check box to log into a Kerberos-enabled system using a given keytab file. A keytab file contains pairs of Kerberos principals and encrypted keys. You need to enter the principal to be used in the **Principal** field and the access path to the keytab file itself in the **Keytab** field. This keytab file must be stored in the machine in which your Job actually runs, for example, on a Talend Jobserver.

Note that the user that executes a keytab-enabled Job is not necessarily the one a principal designates but must have the right to read the keytab file being used. For example, the user name you are using to execute a Job is `user1` and the principal to be used is `guest`; in this situation, ensure that `user1` has the right to read the keytab file to be used.

### Table

Enter the name of the table to be processed.

### Action on table

Select an operation to be performed on the table defined.

- **None**: No operation is carried out.
- **Drop and create table**: The table is removed and created again.
- **Create table**: The table does not exist and gets created.
- **Create table if does not exist**: The table is created if it does not exist.
- **Drop table if exist and create**: The table is removed if it already exists and created again.
- **Truncate**: The table content is deleted.

### Action on data

Select an action to be performed on data of the table defined.

- **Insert**: Add new entries to the table. If duplicates are found, job stops.
- **Replace**: if the table already contains data, delete all the existing data and insert the new data. If the table is empty, insert the new data.
- **Insert or Replace**: it looks at the document IDs, replaces the documents whose IDs exist in both the database and the data to be written, and inserts the documents whose IDs do not exist in the database.
**Delete**: Remove entries corresponding to the input flow.

**Bulk write**
Select this check box to insert, update or remove data in bulk.
In the **Bulk write size** field, enter the size of each query group to be processed by MapR-DB.

**Mapping**
Each column of the schema defined for this component represents a field of the documents to be read. In this table, you need to specify the parent nodes of these fields, if any.
For example, in the document reading as follows

```json
{
    _id: ObjectId("5099803df3f4948bd2f98391"),
    person: { first: "Joe", last: "Walker" }
}
```
The **first** and the **last** fields have **person** as their parent node but the **_id** field does not have any parent node. So once completed, this **Mapping** table should read as follows:

<table>
<thead>
<tr>
<th>Column</th>
<th>Parent node path</th>
</tr>
</thead>
<tbody>
<tr>
<td>_id</td>
<td></td>
</tr>
<tr>
<td>first</td>
<td>&quot;person&quot;</td>
</tr>
<tr>
<td>last</td>
<td>&quot;person&quot;</td>
</tr>
</tbody>
</table>

**Die on error**
This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

**Advanced settings**

**tStatCatcher Statistics**
Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

**Global Variables**

**Global Variables**

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

**NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.

**NB_LINE_REJECTED**: the number of rows rejected. This is an After variable and it returns an integer.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.
Usage

| Usage rule | tMapROjaiOutput executes the action defined on the documents in a given MapR-DB database based on the flow incoming from the preceding component in your Job. |

Writing candidate data in a MapR-DB OJAI database

This scenario uses tMapROjaiOutput to write data about some candidates in a MapR-DB OJAI database.

This scenario applies only to Talend products with Big Data.

- **tFixedFlowInput**: it provides the sample data to be written in the database.
- **tMapROjaiOutput**: it writes the sample data to the database.

![Diagram](image)

Reading the sample candidate data

Procedure

1. Ensure that the MapR client has been properly installed and configured in the machine in which the current Job runs.
2. Drop **tFixedFlowInput** and **tMapROjaiOutput** onto the workspace.
3. Connect **tFixedFlowInput** to **tMapROjaiOutput** using a **Row > Main** link and accept the propagation of the schema from **tMapROjaiOutput**.
4. Double-click **tFixedFlowInput** to open its **Component** view.
5. Click the […] button to open the schema editor.

- The _id column exists already because this column was retrieved from tMapROjaiOutput in the previous steps to provide the technical IDs of the documents to be stored in a MapR Ojai database. This column is required by tMapROjaiOutput.
- Click the [+] button to add the other columns and rename them to firstname, lastname, sex, married, age and salary, respectively. The type of the married column should be Boolean, the type of the age column Integer and the salary column Float.

6. Click OK to close the schema editor and accept the propagation of the schema.

7. In the Mode area, select the Use Inline table radio button to display the table in which you add the sample data.
8. Click the [+] button to add four rows and enter the sample data as is displayed in the image above.

This sample data is used for demonstration purposes only.

The data of the String type should be put in double quotation marks and the data of the three other types should be put without any quotation marks.

**Writing the sample data to the MapR OJAI database**

**Procedure**

1. Double-click tMapROjaiOutput to open its Component view.

2. In the **Table** field, enter the name of the table to be used in your MapR OJAI database.

3. From the **DB Version** list, select the MapR OJAI database version you are using.

At runtime, tMapROjaiOutput automatically reads the connection information to the database from the `\opt\mapr\conf\mapr-clusters.conf` file of your MapR client.

In this example, the content of this file reads as follows:

```
mapr521    mapr521:7222
```

4. From the **Action on table** drop-down list, select **Drop table if exists and create** and then from the **Action on data** drop-down list, select **Insert**.
5. In the **Mapping** table, the columns from the schema have automatically appeared in the **Column** column. In the **Parent field path** column, enter *Name* within double quotation marks in the *firstname* row and the *lastname* row and enter *Status* within double quotation marks in the *sex* row, the *married* row and the *age* row.

   This configuration groups the candidates’ first names and last names in the *Name* field and their sexes, marriage status and ages in the *Status* field in the outputted data flow.

6. Press **F6** to run the Job.
**tMapRStreamsCommit**

Connects to a given tMapRStreamsInput to perform a consumer offset commit.

tMapRStreamsCommit saves the current state of the tMapRStreamsInput to which it is connected. Note that the term 'commit' in this component means saving what messages are consumed by this tMapRStreamsInput component at the moment of committing.

**tMapRStreamsCommit Standard properties**

These properties are used to configure tMapRStreamsCommit running in the Standard Job framework.

The Standard tMapRStreamsCommit component belongs to the Internet family.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Commit offsets from</th>
<th>Select the tMapRStreamsInput component from which the consumed messages are committed.</th>
</tr>
</thead>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
<th>Select this check box to gather the processing metadata at the Job level as well as at each component level.</th>
</tr>
</thead>
</table>

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>Although tMapRStreamsCommit can be used as an end component in a sublob flow or can be called independently as its own sublob, it is typically used standalone to commit a batch of offsets in one go. If you need to commit offsets regularly, it is recommended to use the Auto-commit feature in tMapRStreamsInput.</th>
</tr>
</thead>
</table>

**Related scenarios**

No scenario is available for the Standard version of this component yet.
tMapRStreamsConnection

Opens a reusable connection to a given MapR Streams cluster so that the other MapR Streams components can reuse this connection.

**tMapRStreamsConnection Standard properties**

These properties are used to configure tMapRStreamsConnection running in the Standard Job framework.

The Standard tMapRStreamsConnection component belongs to the Big Data family.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| Property type | Either Built-In or Repository.  
|---------------|---------------------------------
| Built-In: No property data stored centrally.  
| Repository: Select the repository file where the properties are stored.  
| The properties are stored centrally under the Hadoop Cluster node of the Repository tree. |

**Distribution and Version**

Select the MapR distribution to be used. Only MapR V5.2 onwards is supported by the MapRDB components.

If the distribution you need to use with your MapRDB database is not officially supported by this MapRBD component, that is to say, this distribution is MapR but is not listed in the Version drop-down list of this components or this distribution is not MapR at all, select Custom.

1. Select Import from existing version to import an officially supported distribution as base and then add other required jar files which the base distribution does not provide.

2. Select Import from zip to import the configuration zip for the custom distribution to be used. This zip file should contain the libraries of the different Hadoop elements and the index file of these libraries.

In Talend Exchange, members of Talend community have shared some ready-for-use configuration zip files which you can download from this Hadoop configuration list and directly use them in your connection accordingly. However, because of the ongoing evolution of the different Hadoop-related projects, you might not be able to find the configuration zip corresponding to your distribution from this list; then it is recommended to use the Import from existing version option to take an existing distribution as base to add the jars required by your distribution.

Note that custom versions are not officially supported by Talend. Talend and its community provide you with the opportunity to connect to custom versions from the Studio but cannot guarantee that the
configuration of whichever version you choose will be easy, due to the wide range of different Hadoop distributions and versions that are available. As such, you should only attempt to set up such a connection if you have sufficient Hadoop experience to handle any issues on your own.

Note:
In this dialog box, the active check box must be kept selected so as to import the jar files pertinent to the connection to be created between the custom distribution and this component.

For a step-by-step example about how to connect to a custom distribution and share this connection, see Connecting to a custom Hadoop distribution on page 1569.

NameNode URI
Type in the URI of the Hadoop NameNode, the master node of a Hadoop system. For example, we assume that you have chosen a machine called masternode as the NameNode, then the location is hdfs://masternode:portnumber. If you are using WebHDFS, the location should be webhdfs://masternode:portnumber; WebHDFS with SSL is not supported yet.

Force MapR ticket authentication
If the MapR cluster to be used is secured with the MapR ticket authentication mechanism, set the MapR ticket authentication configuration by following the explanation in Setting up the MapR ticket authentication on page 1630.

In addition, if your cluster also uses Kerberos to secure your MapR Streams, select the Use Kerberos authentication check box to configure Kerberos for your Job.

- You can also find an example of how to configure Kerberos authentication for a Talend Job in Talend Help Center (https://help.talend.com). Although this example uses Cloudera for demonstration, the operations it describes are generic and thus applicable to MapR as well.

Advanced settings

Hadoop properties
Talend Studio uses a default configuration for its engine to perform operations in a Hadoop distribution. If you need to use a custom configuration in a specific situation, complete this table with the property or properties to be customized. Then at runtime, the customized property or properties will override those default ones.

- Note that if you are using the centrally stored metadata from the Repository, this table automatically inherits the properties defined in that metadata and becomes uneditable unless you change the Property type from Repository to Built-in.

tStatCatcher Statistics
Select this check box to collect the log data at a component level.
Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | This component is generally used with other MapR Streams components. |

Prerequisites

| Prerequisites | The Hadoop distribution must be properly installed, so as to guarantee the interaction with Talend Studio. The following list presents MapR related information for example. • Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native. For example, the library for Windows is \lib\native\MapRClient.dll in the MapR client jar file. For further information, see the following link from MapR: http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr. Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path. • Set the -Djava.library.path argument, for example, in the Job Run VM arguments area of the Run/Debug view in the Preferences dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR. For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using. |

Related scenarios

No scenario is available for the Standard version of this component yet.
tMapRStreamsCreateStream

Creates a MapR Streams stream or topic that the other MapR Streams components can use. This component allows you to visually issue the command to create or update a stream or a topic.

tMapRStreamsCreateStream Standard properties

These properties are used to configure tMapRStreamsCreateStream running in the Standard Job framework.

The Standard tMapRStreamsCreateStream component belongs to the Internet family.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| Property type | Either Built-In or Repository.  
|               | Built-In: No property data stored centrally.  
|               | Repository: Select the repository file where the properties are stored.  
|               | The properties are stored centrally under the Hadoop Cluster node of the Repository tree. |

| tMapRStreamsConnection | Select the tMapRStreamsConnection component to reuse the connection details you already defined. This parameter is mandatory for this component to connect to MapR Streams. |

<table>
<thead>
<tr>
<th>Action</th>
<th>Select how a stream or a topic is created. The related parameters to each action are displayed only when this action is selected.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• Create stream: it creates a stream. If this stream exists already, the entire Job is stopped.</td>
</tr>
<tr>
<td></td>
<td>• Create stream if not exists: it creates a stream when this stream does not exist. If this stream exists, the Job skip the creation to move to the next step.</td>
</tr>
<tr>
<td></td>
<td>• Alter stream: it changes the configuration of a stream.</td>
</tr>
<tr>
<td></td>
<td>• Create topic: it creates a topic. If this topic exists already, the entire Job is stopped.</td>
</tr>
<tr>
<td></td>
<td>Note that the stream to which this topic belongs must already exist.</td>
</tr>
<tr>
<td></td>
<td>• Create topic if not exists: it creates a topic when this topic does not exist. If this topic exists, the Job skip the creation to move to the next step.</td>
</tr>
<tr>
<td></td>
<td>Note that the stream to which this topic belongs must already exist.</td>
</tr>
<tr>
<td></td>
<td>• Alter topic: it changes the configuration of a topic.</td>
</tr>
</tbody>
</table>

| Stream path | Enter the path to the stream to be created or updated in MapR-FS.                                                                      |

| Stream permissions | Grant the permissions to a user account over the stream to be created or updated. These permissions are about |
- Adminperm
- Consumeperm
- Copyperm
- Produceperm
- Topicperm

The syntax you need to use is `u:username_or_userid_of_the_account` within double quotation marks.

When you have selected Alter stream from the Action list, a list of check boxes are displayed in the Stream permissions area so that you can select the check box corresponding to each permission to be changed and then grant this permission to a different user account.

For details about these permissions, see MapR documentation at MapR Streams Security.

<table>
<thead>
<tr>
<th>Stream settings</th>
<th>Define the configuration of the stream to be created or updated. The parameters to be set are</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• Automatic topic creation: select the Enable automatic topic creation check box to allow a topic to be automatically created when a producer creates the first message for it and this topic does not already exist.</td>
</tr>
<tr>
<td></td>
<td>• Default number of partitions: this parameter defines how many partitions are created in each new topic in a stream.</td>
</tr>
<tr>
<td></td>
<td>• Message time to live: this parameters defines the length of time (in seconds) messages persist in a stream.</td>
</tr>
<tr>
<td></td>
<td>• Compression: this is the type of the compression algorithms MapR provides to compress files stored in the MapR cluster.</td>
</tr>
<tr>
<td></td>
<td>When you have selected Alter stream from the Action list, a list of check boxes are displayed in the Stream settings area so that you can select the check box corresponding to each parameter to be changed and then update this parameter.</td>
</tr>
</tbody>
</table>

| Topic name | Enter the name of the topic to be created. This field is displayed when you have selected one of the actions about topics from the Action list. |

| Number of partitions or Set number of partitions | Enter the number of partitions to be created for the topic. This field is displayed when you have selected one of the actions about topics from the Action list. |
Advanced settings

| tStatCatcher Statistics | Select this check box to gather the processing metadata at the Job level as well as at each component level. |

Usage

| Usage rule | This component is used standalone to create or update a topic or a stream to be used by the other MapR Streams components. |
| Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |

Related scenarios

No scenario is available for the Standard version of this component yet.
tMapRStreamsInput

Transmits messages to the Job that runs transformations over these messages. Only MapR V5.2 onwards is supported by this component.

**tMapRStreamsInput Standard properties**

These properties are used to configure tMapRStreamsInput running in the Standard Job framework.

The component tMapRStreamsInput belongs to the Internet family.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th><strong>Schema and Edit schema</strong></th>
<th>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Note that the schema of this component is read-only. It stores the messages sent from the message producer.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Output type</strong></td>
<td>Select the type of the data to be sent to the next component. Typically, using <strong>String</strong> is recommended, because tMapRStreamsInput can automatically translate the MapR Streams byte[] messages into strings to be processed by the Job. However, in case that the format of MapR Streams messages is not known to tMapRStreamsInput, such as Protobuf, you can select <strong>byte</strong> and then use a Custom code component such as <strong>tJavaRow</strong> to deserialize the messages into strings so that the other components of the same Job can process these messages.</td>
</tr>
<tr>
<td><strong>Use an existing connection</strong></td>
<td>Select this check box and from the list displayed select the relevant connection component to reuse the connection details you have already defined.</td>
</tr>
<tr>
<td><strong>Distribution and Version</strong></td>
<td>Select the MapR distribution to be used. Only MapR V5.2 onwards is supported by the MapRDB components. If the distribution you need to use with your MapRDB database is not officially supported by this MapRBD component, that is to say, this distribution is MapR but is not listed in the <strong>Version</strong> drop-down list of this component or this distribution is not MapR at all, select <strong>Custom</strong>. 1. Select <strong>Import from existing version</strong> to import an officially supported distribution as base and then add other required jar files which the base distribution does not provide. 2. Select <strong>Import from zip</strong> to import the configuration zip for the custom distribution to be used. This zip file should contain the libraries of the different Hadoop elements and the index file of these libraries.</td>
</tr>
</tbody>
</table>
In **Talend Exchange**, members of **Talend** community have shared some ready-for-use configuration zip files which you can download from this **Hadoop configuration** list and directly use them in your connection accordingly. However, because of the ongoing evolution of the different Hadoop-related projects, you might not be able to find the configuration zip corresponding to your distribution from this list; then it is recommended to use the **Import from existing version** option to take an existing distribution as base to add the jars required by your distribution.

Note that custom versions are not officially supported by **Talend**. **Talend** and its community provide you with the opportunity to connect to custom versions from the Studio but cannot guarantee that the configuration of whichever version you choose will be easy, due to the wide range of different Hadoop distributions and versions that are available. As such, you should only attempt to set up such a connection if you have sufficient Hadoop experience to handle any issues on your own.

**Note:**

In this dialog box, the active check box must be kept selected so as to import the jar files pertinent to the connection to be created between the custom distribution and this component.

For a step-by-step example about how to connect to a custom distribution and share this connection, see [Connecting to a custom Hadoop distribution](#) on page 1569.

| Topic name | Enter the name of the topic from which **tMapRStreamsInput** receives the feed of messages. You must enter the name of the stream to which this topic belongs. The syntax is `path_to_the_stream:topic_name`. |
| Consumer group ID | Enter the name of the consumer group to which you want the current consumer (the **tMapRStreamsInput** component) to belong. This consumer group will be created at runtime if it does not exist at that moment. |
| Reset offsets on consumer group | Select this check box to clear the offsets saved for the consumer group to be used so that this consumer group is handled as a new group that has not consumed any messages. |
| New consumer group starts from | Select the starting point from which the messages of a topic are consumed. In MapR Streams, the increasing ID number of a message is called offset. When a new consumer group starts, from this list, you can select **beginning** to start consumption from the oldest message of the entire topic, or select **latest** to wait for a new message. Note that the consumer group takes into account only the offset-committed messages to start from. |
Each consumer group has its own counter to remember the position of a message it has consumed. For this reason, once a consumer group starts to consume messages of a given topic, a consumer group recognizes the latest message only with regard to the position where this group stops the consumption, rather than to the entire topic. Based on this principle, the following behaviors can be expected:

- If you are resuming an existing consumer group, this option determines the starting point for this consumer group only if it does not already have a committed starting point. Otherwise, this consumer group starts from this committed starting point. For example, a topic has 100 messages. If an existing consumer group has successfully processed 50 messages, and has committed their offsets, then the same consumer group restarts from the offset 51.
- If you create a new consumer group or reset an existing consumer group, which, in either case, means this group has not consumed any message of this topic, then when you start it from latest, this new group starts and waits for the offset 101.

### Advanced settings

<table>
<thead>
<tr>
<th>Consumer properties</th>
<th>Add the MapR Streams consumer properties you need to customize to this table. For further information about the consumer properties you can define in this table, see the MapR Streams documentation at MapR Streams Overview.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Timeout precision(ms)</td>
<td>Enter the time duration in millisecond at the end of which you want a timeout exception to be returned if no message is available for consumption. The value -1 indicates that no timeout is set.</td>
</tr>
</tbody>
</table>
Load the offset with the message

Select this check box to output the offsets of the consumed messages to the next component. When selecting it, a read-only column called offset is added to the schema.

Custom encoding

You may encounter encoding issues when you process the stored data. In that situation, select this check box to display the Encoding list.
Select the encoding from the list or select Custom and define it manually.

tStatCatcher Statistics

Select this check box to gather the processing metadata at the Job level as well as at each component level.

Global Variables

Global Variables

ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule

This component is used as a start component and requires an output link. When the MapR Streams topic it needs to use does not exist, you can first create this topic using either the tMapRStreamsCreateTopic component or your MapR command-line interface.

Prerequisites

The Hadoop distribution must be properly installed, so as to guarantee the interaction with Talend Studio. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native. For example, the library for Windows is \lib\native\MapRClient.dll in the MapR client jar file. For further information, see the following link from MapR: http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr.

  Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path.

- Set the -Djava.library.path argument, for example, in the Job Run VM arguments area of the
Run/Debug view in the Preferences dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

## Related scenarios

No scenario is available for the Standard version of this component yet.
**tMapRStreamsOutput**

Publishes messages into a MapR Streams system. Only MapR V5.2 onwards is supported by this component.

This component receives messages serialized into byte arrays by its preceding component and issues these messages into a given MapR Streams system.

**tMapRStreamsOutput Standard properties**

These properties are used to configure tMapRStreamsOutput running in the Standard Job framework.

The Standard tMapRStreamsOutput component belongs to the Internet family.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th><strong>Schema and Edit schema</strong></th>
<th>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <code>line</code> when naming the fields. Note that the schema of this component is read-only. It stores the messages to be published.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Use an existing connection</strong></td>
<td>Select this check box and from the list displayed select the relevant connection component to reuse the connection details you have already defined.</td>
</tr>
</tbody>
</table>
| **Distribution and Version** | Select the MapR distribution to be used. Only MapR V5.2 onwards is supported by the MapRDB components.  
If the distribution you need to use with your MapRDB database is not officially supported by this MapRBD component, that is to say, this distribution is MapR but is not listed in the Version drop-down list of this components or this distribution is not MapR at all, select Custom.  
1. Select **Import from existing version** to import an officially supported distribution as base and then add other required jar files which the base distribution does not provide.  
2. Select **Import from zip** to import the configuration zip for the custom distribution to be used. This zip file should contain the libraries of the different Hadoop elements and the index file of these libraries.  
In Talend Exchange, members of Talend community have shared some ready-for-use configuration zip files which you can download from this Hadoop configuration list and directly use them in your connection accordingly. However, because of the ongoing evolution of the different Hadoop-related projects, you might not be able to find the configuration zip corresponding to your distribution from this list; then it is recommended to use the **Import from existing version** option to take an existing |
distribution as base to add the jars required by your distribution.

Note that custom versions are not officially supported by Talend. Talend and its community provide you with the opportunity to connect to custom versions from the Studio but cannot guarantee that the configuration of whichever version you choose will be easy, due to the wide range of different Hadoop distributions and versions that are available. As such, you should only attempt to set up such a connection if you have sufficient Hadoop experience to handle any issues on your own.

**Note:**
In this dialog box, the active check box must be kept selected so as to import the jar files pertinent to the connection to be created between the custom distribution and this component.

For a step-by-step example about how to connect to a custom distribution and share this connection, see Connecting to a custom Hadoop distribution on page 1569.

### Topic name
Enter the name of the topic you want to publish messages to. This topic must already exist. You must enter the name of the stream to which this topic belongs. The syntax is `path_to_the_stream:topic_name`.

### Compress the data
Select the **Compress the data** check box to compress the output data.

### Advanced settings

**Producer properties**
Add the MapR Streams producer properties you need to customize to this table.

For further information about the producer configuration you can define in this table, see the section describing the important producer configuration properties for MapR Streams in MapR documentation at MapR Streams Overview.

### tStatCatcher Statistics
Select this check box to gather the processing metadata at the Job level as well as at each component level.

### Global Variables

**ERROR_MESSAGE:** the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule

This component is an end component. It requires a tJavaRow or tJava component to transform the incoming data into serialized byte arrays.

The following sample shows how to construct a statement to perform this transformation:

```java
output_row.serializedValue = input_row.users.getBytes();
```

In this code, the `output_row` variable represents the schema of the data to be output to tMapRStreamsOutput and `output_row.serializedValue` the single read-only column of that schema; the `input_row` variable represents the schema of the incoming data and `input_row.users` the input column called `users` to be transformed to byte arrays by the `getBytes()` method.

Prerequisites

The Hadoop distribution must be properly installed, so as to guarantee the interaction with Talend Studio. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under `MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native`. For example, the library for Windows is `\lib\native\MapRClient.dll` in the MapR client jar file. For further information, see the following link from MapR: http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr.

Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path.

- Set the `-Djava.library.path` argument, for example, in the Job Run VM arguments area of the Run/Debug view in the Preferences dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.
Related scenarios

No scenario is available for the Standard version of this component yet.
**tMarketoBulkExec**

Imports leads or custom objects into Marketo from a local file in the REST API mode.

**tMarketoBulkExec Standard properties**

These properties are used to configure tMarketoBulkExec running in the Standard Job framework.

The Standard tMarketoBulkExec component belongs to two families: Business and Cloud.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Property Type</strong></td>
<td>Select the way the connection details will be set.</td>
</tr>
<tr>
<td>• <strong>Built-In</strong></td>
<td>The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.</td>
</tr>
<tr>
<td>• <strong>Repository</strong></td>
<td>The connection details stored centrally in Repository &gt; Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up Repository Content dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in. This property is not available when other connection component is selected from the Connection Component drop-down list.</td>
</tr>
</tbody>
</table>

| Connection component | Select the component whose connection details will be used to set up the connection to Marketo from the drop-down list. |

| Endpoint address | Enter the API Endpoint URL of the Marketo Web Service. The API Endpoint URL can be found on the Marketo Admin > Web Services panel. |

| Client access ID | Enter the client ID for the access to the Marketo Web Service. The client ID and client secret key can be found on the Marketo Admin > LaunchPoint panel, by clicking View Details for the service to be accessed. You can also contact Marketo Support via support@marketo.com for further information. |

| Secret key | Enter the client secret key for the access to the Marketo Web Service. To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |

| Schema and Edit schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. |
The schema of this component is predefined and it will be slightly different according to the type of the data (Leads or CustomObjects) to be imported. You can click next to Edit schema to view its schema.

- batchId: the id of the batch.
- importId (for Leads only): the id of the import.
- importTime (for CustomObjects only): the time spent on the batch.
- message: the status message of the batch.
- numOfLeadsProcessed/numOfObjectsProcessed: the number of rows processed so far.
- numOfRowsFailed: the number of rows failed so far.
- numOfRowsWithWarning: the number of rows with a warning so far.
- objectApiName (for CustomObjects only): the API name of the custom object.
- operation (for CustomObjects only): the bulk operation type.
- status: the status of the batch.
- failuresLogFile: the log for the failures.
- warningsLogFile: the log for the warnings.

### Import to
Select the type of the data to be imported, either Leads or CustomObjects.

### File format
Select the type of the file containing the data to be imported, csv, tsv or ssv.

### Lookup field
Select the lookup field that will be used for deduplication. This property is available only when Leads is selected from the Import to drop-down list.

### List Id
Specify the ID of the static list to import to. This property is available only when Leads is selected from the Import to drop-down list.

### Partition name
Specify the name of the lead partition to import to. This property is available only when Leads is selected from the Import to drop-down list.

### CustomObject name
Specify the API name of the custom object. This property is available only when CustomObjects is selected from the Import to drop-down list.

### Bulk file path
Specify the path to the file containing the data to be imported.

### Poll wait time in seconds
Specify the amount of time (in seconds) for polling for the data.

### Batch log download path
Specify the path to the batch log file(s) to be downloaded, including the failures log file and the warnings log file. When importing leads, the failures log file will be named bulk_leads_<batchId>_failures.csv and the warnings log file will be named bulk_leads_<batchId>_warnings.csv.
When importing custom objects, the failures log file will be named `bulk_customobjects_<customObjectName>_ <batchId>_failures.csv` and the warnings log file will be named `bulk_customobjects_<customObjectName>_ <batchId>_warnings.csv`.

### Advanced settings

| **API Mode** | Specify the Marketo API mode. Note that only the REST API mode is available to use for this component. For more information about the Marketo REST API, see [http://developers.marketo.com/documentation/rest/](http://developers.marketo.com/documentation/rest/). |
| **Timeout** | Enter the timeout value (in milliseconds) for the connection to the Marketo Web Service before terminating the attempt. |
| **Max reconnection attempts** | Enter the maximum number of reconnect attempts to the Marketo Web Service before giving up. |
| **Attempt interval time** | Enter the time period (in milliseconds) between subsequent reconnection attempts. |
| **tStatCatcher Statistics** | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

### Global Variables

| **NUMBER_CALL** | The number of calls. This is an After variable and it returns an integer. |
| **ERROR_MESSAGE** | The error message generated by the component when an error occurs. This is an After variable and it returns a string. |

### Usage

| **Usage rule** | This component can be used as a standalone component or as a start component of a Job or Subjob. |

### Related scenario

No scenario is available for this component yet.
tMarketoConnection

Opens a connection to Marketo that can then be reused by other Marketo components.

**tMarketoConnection Standard properties**

These properties are used to configure tMarketoConnection running in the Standard Job framework.

The **Standard** tMarketoConnection component belongs to two families: Business and Cloud.

The component in this framework is available in all **Talend products**.

**Basic settings**

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>

### Related scenario

For a related scenario, see [Transmitting data with Marketo using REST API](#) on page 2062.
tMarketoCampaign

Retrieves campaign records, activity and campaign changes related data from Marketo.

**tMarketoCampaign Standard properties**

These properties are used to configure tMarketoCampaign running in the Standard Job framework. The Standard tMarketoCampaign component belongs to two families: Business and Cloud. The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Select the way the connection details will be set.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• <strong>Built-In:</strong> The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Repository:</strong> The connection details stored centrally in <strong>Repository &gt; Metadata</strong> will be reused by this component. You need to click the [...] button next to it and in the pop-up <strong>Repository Content</strong> dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in. This property is not available when other connection component is selected from the <strong>Connection Component</strong> drop-down list.</td>
</tr>
</tbody>
</table>

| Connection Component | Select the component whose connection details will be used to set up the connection to Marketo from the drop-down list. |

| Endpoint address | Enter the API Endpoint URL of the Marketo Web Service. The API Endpoint URL can be found on the Marketo **Admin > Web Services** panel. |

| Client access ID | Enter the client ID for the access to the Marketo Web Service. The client ID and client secret key can be found on the Marketo **Admin > LaunchPoint** panel, by clicking **View Details** for the service to be accessed. You can also contact Marketo Support via support@marketo.com for further information. |

| Secret key | Enter the client secret key for the access to the Marketo Web Service. To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings. |

| Schema and Edit schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word **line** when naming the fields. |
- **Built-in**: You create and store the schema locally for this component only.
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

The schema of this component is predefined and it will be different according to the API mode selected, the operation chosen or the custom object specified.

Note that when the API mode is changed, you need to refresh the schema columns manually by switching back and forth the components in the **Connection Component** drop-down list (only when reusing the connection created by a **tMarketoConnection** component) and changing the operation to be performed in the **Operation** drop-down list.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

Note that the dynamic schema feature for this component is only supported in the REST API mode.

### Action

Select one of the following operations to be performed from the drop-down list.

- **get**: Retrieves the details of a campaign, including **Ids** (Commas separated), **Campaign(s)** (Commas separated), **Program(s)** (Commas separated) and **Workspace(s)** (Commas separated).
- **getById**: Retrieves the details of a campaign by campaign ID.
- **schedule**: Plans a campaign.
- **trigger**: Triggers a campaign by:
  - **request**: Request a campaign.
  - **activate**: Activates a campaign.
  - **deactivate**: Deactivates a campaign.

### Process leads in batch

Select this check box to process the leads in batch.

This check box is available only when **trigger** is selected from the **Action** drop-down list and **request** is selected from the **Trigger** drop-down list.

### Batch size

Specify the number of leads to be processed in a batch, with the maximum size of 100 leads.

This field is available only when:

- **get** is selected from the **Action** drop-down list,
<table>
<thead>
<tr>
<th><strong>Clone to ProgramName</strong></th>
<th>Specify the program that you want to clone the campaign to. This field is available only when <code>schedule</code> is selected from the <code>Action</code> drop-down list.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Run At</strong></td>
<td>Specify the time when you run the campaign. This field is available only when <code>schedule</code> is selected from the <code>Action</code> drop-down list.</td>
</tr>
<tr>
<td><strong>Tokens</strong></td>
<td>Add the tokens that you want to use in a program. This field is available only when <code>schedule</code> or <code>trigger</code> is selected from the <code>Action</code> drop-down list.</td>
</tr>
<tr>
<td><strong>Mappings</strong></td>
<td>Complete this table to map the column names of the component schema with the column names in Marketo. By default, the column names in <code>Column name</code> fields are the same as what they are in the schema. Note that because some column names in Marketo may contain blank space, which is not allowed in the component schema, you need to specify the corresponding column fields in the <code>Marketo column name</code> column. If the defined column names in schema are the same as column names in Marketo, it is not necessary to set the columns mapping. This table is not available when <code>CustomObject</code> is selected from the <code>Operation</code> list in the REST API mode.</td>
</tr>
<tr>
<td><strong>Die on error</strong></td>
<td>Select the check box to stop the execution of the Job when an error occurs.</td>
</tr>
</tbody>
</table>

### Advanced settings

<table>
<thead>
<tr>
<th><strong>API Mode</strong></th>
<th>Select the Marketo API mode, either REST API (default) or SOAP API. <td>Enter the timeout value (in milliseconds) for the connection to the Marketo Web Service before terminating the attempt.</td>
</tr>
<tr>
<td><strong>Max reconnection attempts</strong></td>
<td>Enter the maximum number of reconnect attempts to the Marketo Web Service before giving up.</td>
</tr>
<tr>
<td><strong>Attempt interval time</strong></td>
<td>Enter the time period (in milliseconds) between subsequent reconnection attempts.</td>
</tr>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to gather the Job processing metadata at the Job level as well as at each component level.</td>
</tr>
</tbody>
</table>
### Global Variables

<table>
<thead>
<tr>
<th>NUMBER_CALL</th>
<th>The number of calls. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERROR_MESSAGE</td>
<td>The error message generated by the component when an error occurs. This is an After variable and it returns a string.</td>
</tr>
</tbody>
</table>

### Usage

| Usage rule | This component is usually used as a start component of a Job or Subjob and it always needs an output link. |
tMarketInput

Retrieves lead records, activity history, lead changes, and custom object related data from Marketo.

**tMarketInput Standard properties**

These properties are used to configure tMarketInput running in the Standard Job framework.

The Standard tMarketInput component belongs to two families: Business and Cloud.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Select the way the connection details will be set.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• <strong>Built-In:</strong> The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Repository:</strong> The connection details stored centrally in Repository &gt; Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up Repository Content dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in.</td>
</tr>
</tbody>
</table>

This property is not available when other connection component is selected from the Connection Component drop-down list.

**Connection Component**

Select the component whose connection details will be used to set up the connection to Marketo from the drop-down list.

**Endpoint address**

Enter the API Endpoint URL of the Marketo Web Service.

The API Endpoint URL can be found on the Marketo Admin > Web Services panel.

**Client access ID**

Enter the client ID for the access to the Marketo Web Service.

The client ID and client secret key can be found on the Marketo Admin > LaunchPoint panel, by clicking View Details for the service to be accessed. You can also contact Marketo Support via support@marketo.com for further information.

**Secret key**

Enter the client secret key for the access to the Marketo Web Service.

To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

**Schema and Edit schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.
### Built-In
You create and store the schema locally for this component only.

### Repository
You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

The schema of this component is predefined and it will be different according to the API mode selected, the operation chosen or the custom object specified.

Note that when the API mode is changed, you need to refresh the schema columns manually by switching back and forth the components in the **Connection Component** drop-down list (only when reusing the connection created by a **tMarketoConnection** component) and changing the operation to be performed in the **Operation** drop-down list.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: Choose this option to view the schema only.
- **Change to built-in property**: Choose this option to change the schema to **Built-In** for local changes.
- **Update repository connection**: Choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

Note that the dynamic schema feature for this component is only supported in the REST API mode.

<table>
<thead>
<tr>
<th>Operation</th>
<th>Select one of the following operations to be performed from the drop-down list.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• <strong>getLead</strong>: This operation retrieves a single lead record.</td>
</tr>
<tr>
<td></td>
<td>• <strong>getMultipleLeads</strong>: This operation retrieves a batch of lead records that match the specified lead selector search condition.</td>
</tr>
<tr>
<td></td>
<td>• <strong>getLeadActivity</strong>: This operation retrieves the activity history that matches the specified search condition.</td>
</tr>
<tr>
<td></td>
<td>• <strong>getLeadChanges</strong>: This operation retrieves data value changes and new lead activities after a given time.</td>
</tr>
<tr>
<td></td>
<td>• <strong>CustomObject</strong>: Select this item to perform specific action on a custom object. This item is available only in the REST API mode.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Company</strong>: This operation retrieves the company. Also referred to as an account, that a person belongs to.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Opportunity</strong>: This operation retrieves the opportunity that is associated with a lead or contact and a company.</td>
</tr>
<tr>
<td></td>
<td>• <strong>OpportunityRole</strong>: This operation retrieves the specific role within an opportunity.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Mappings</th>
<th>Complete this table to map the column names of the component schema with the column names in Marketo. By default, the column names in <strong>Column name</strong> fields are the same as what they are in the schema.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Note that because some column names in Marketo may contain blank space, which is not allowed in the component.</td>
</tr>
</tbody>
</table>

2048
schema, you need to specify the corresponding column fields in the Marketo column name column. If the defined column names in schema are the same as column names in Marketo, it is not necessary to set the columns mapping.

This table is not available when CustomObject is selected from the Operation list in the REST API mode.

### Lead selector

Select one of the following lead selector types from the drop-down list.

- **LeadKeySelector**: Select this type to retrieve lead records that are identified by the specified lead key.
- **StaticListSelector**: Select this type to retrieve lead records that are members of the given static list. With this option selected, you need to specify the static list by its name or id. To do this, select STATIC_LIST_NAME or STATIC_LIST_ID from the List param drop-down list and then enter the key value of the name or id in the List param value field.
- **LastUpdateAtSelector**: Select this type to retrieve lead records that were updated on specific dates. This item is available only in the SOAP API mode.

This list is available only when getMultipleLeads is selected from the Operation list.

### Lead key type

Select a field by which you want to query the lead from the drop-down list. This list is available when:

- getLead is selected from the Operation list, or
- getMultipleLeads is selected from the Operation list and LeadKeySelector is selected from the Lead selector list, or
- getLeadActivity is selected from the Operation list in the SOAP API mode.

### Lead key value

Specify the value of the field by which you want to query the lead. This field is available when:

- getLead is selected from the Operation list, or
- getLeadActivity is selected from the Operation list in the SOAP API mode, or
- getMultipleLeads is selected from the Operation list and LeadKeySelector is selected from the Lead Selector list.

### Set Include Types

Select this check box and in the Activity table displayed, specify the types of activity you want to retrieve by clicking the [*] button to add as many rows as needed, each row for an activity type, then clicking the right side of each cell and selecting an activity type from the drop-down list. This check box is available when:

- getLeadActivity is selected from the Operation list, or
- getLeadChanges is selected from the Operation list in the SOAP API mode.

### Set Exclude Types

Select this check box and in the Activity table displayed, specify the types of activity you do not want to retrieve by clicking the [*] button to add as many rows as needed, each row for an activity type, then clicking the right side of each...
cell and selecting an activity type from the drop-down list. This check box is available when:
- `getLeadActivity` is selected from the **Operation** list, or
- `getLeadChanges` is selected from the **Operation** list in the SOAP API mode.

### Oldest update date
Specify the time of the earliest update to retrieve only the leads updated since the specified time. It supports the time format that Marketo supports. For the supported time format, see [http://developers.marketo.com/documentation/soap/getmultipleleads/](http://developers.marketo.com/documentation/soap/getmultipleleads/).

This field is available only in the SOAP API mode when `getMultipleLeads` is selected from the **Operation** list and `LastUpdateAtSelector` is selected from the **Lead selector** list.

### Latest update date
Specify the time of the latest update to retrieve only the leads updated before the specified time. It supports the time format that Marketo supports. For the supported time format, see [http://developers.marketo.com/documentation/soap/getmultipleleads/](http://developers.marketo.com/documentation/soap/getmultipleleads/).

This field is available only in the SOAP API mode when `getMultipleLeads` is selected from the **Operation** list and `LastUpdateAtSelector` is selected from the **Lead selector** list.

### Oldest create date
Type in the time of the earliest creation to retrieve only the data since the specified time. It supports the time format that Marketo supports.

This field is available only in the SOAP API mode when `getLeadChanges` is selected from the **Operation** list.

### Latest creation date
Type in the time of the latest creation to retrieve only the data before the specified time. It supports the time format that Marketo supports.

This field is available only in the SOAP API mode when `getLeadChanges` is selected from the **Operation** list.

Note that **Oldest create date** and **Latest creation date** can be specified together or separately.

### Field list
Enter the comma separated list of field names.

This field is available when `getLeadChanges` is selected from the **Operation** list in the REST API mode.

### Since DateTime
Specify the timestamp used to filter results to only include leads with activity since then.

This field is available when `getLeadActivity` or `getLeadChanges` is selected from the **Operation** list in the REST API mode.

### Action
Select the operation to be performed on the specified custom object.
- **describe**: Returns the metadata regarding a given custom object.
- **list**: Returns a list of custom object types available in the target instance, along with id and deduplication.
information for each type. With this option selected, you need to specify a comma-separated list of names to filter types in the CustomObject names field.

This property is available only when CustomObject is selected from the Operation drop-down list.

- **get**: Retrieves a list of custom objects records based on filter and set of values.

This field is available only when CustomObject, Company, Opportunity or OpportunityRole is selected from the Operation drop-down list.

### Fetch schema

Click this button to retrieve the schema of the specified custom object.

This button is available only when CustomObject is selected from the Operation list and get is selected from the Action list.

### Filter type

Specify the field to filter on. Searchable fields can be retrieved by performing a describe action with the custom object.

This field is available only when CustomObject is selected from the Operation list and get is selected from the Action list.

### Filter values

Specify a comma-separated list of field values to match against.

This field is available only when CustomObject is selected from the Operation list and get is selected from the Action list.

### Batch size

Specify the number of records to be processed in each batch.

This field is available when:

- **getMultipleLeads** is selected from the Operation list and StaticListSelector or LastUpdateAtSelector is selected from the Lead Selector list.
- **getLeadActivity** or **getLeadChanges** is selected from the Operation list.
- **CustomObject** is selected from the Operation list and get is selected from the Action list.

### Die on error

Select the check box to stop the execution of the Job when an error occurs.

### Advanced settings

#### API Mode

Select the Marketo API mode, either REST API (default) or SOAP API.

For more information about the Marketo REST API, see [http://developers.marketo.com/documentation/rest/](http://developers.marketo.com/documentation/rest/).

For more information about the Marketo SOAP API, see [http://developers.marketo.com/documentation/soap/](http://developers.marketo.com/documentation/soap/).
### Timeout
Enter the timeout value (in milliseconds) for the connection to the Marketo Web Service before terminating the attempt.

### Max reconnection attempts
Enter the maximum number of reconnect attempts to the Marketo Web Service before giving up.

### Attempt interval time
Enter the time period (in milliseconds) between subsequent reconnection attempts.

### tStatCatcher Statistics
Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

<table>

### Related Scenario
For a related use case, see Transmitting data with Marketo using REST API on page 2062.
tMarketoListOperation

Adds/removes one or more leads to/from a list in Marketo. Also, it helps you verify the existence of one or more leads in a list in Marketo.

**tMarketoListOperation Standard properties**

These properties are used to configure tMarketoListOperation running in the Standard Job framework. The Standard tMarketoListOperation component belongs to two families: Business and Cloud. The component in this framework is available in all Talend products.

**Basic settings**

<table>

</tr>
</thead>
</table>

| Schema and Edit schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next |
component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

- **Built-In**: You create and store the schema locally for this component only.
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

Click **Sync columns** to retrieve the schema from the previous component connected in the Job.

Note that the dynamic schema feature for this component is only supported in the REST API mode.

**Operation**

Select an operation to be performed from the drop-down list.

- **addTo**: This operation adds one or more leads to a list.
- **isMemberOf**: This operation verifies whether the specific leads exist in the list.
- **removeFrom**: This operation removes one or more leads from a list.

**Add or remove many prospects**

Select this check box to add multiple leads to or remove multiple leads from a list.

This check box is available only when `addTo` or `removeFrom` is selected from the **Operation** list.

**Die on error**

Select the check box to stop the execution of the Job when an error occurs.

Clear the check box to skip any rows on error and complete the process for error-free rows.

When errors are skipped, you can collect the rows on error using a **Row > Reject** connection if the **Add or remove many prospects** check box is cleared.

### Advanced settings

**API Mode**

Select the Marketo API mode, either **REST API** (default) or **SOAP API**.

For more information about the Marketo REST API, see [http://developers.marketo.com/documentation/rest/](http://developers.marketo.com/documentation/rest/).

For more information about the Marketo SOAP API, see [http://developers.marketo.com/documentation/soap/](http://developers.marketo.com/documentation/soap/).

**Timeout**

Enter the timeout value (in milliseconds) for the connection to the Marketo Web Service before terminating the attempt.

**Max reconnection attempts**

Enter the maximum number of reconnect attempts to the Marketo Web Service before giving up.

**Attempt interval time**

Enter the time period (in milliseconds) between subsequent reconnection attempts.

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

Usage

| Usage rule | This component is usually used as an intermediate component, and it requires an input component and an output component. |

Adding a lead record to a Marketo list using SOAP API

The following scenario describes a three-component Job that adds a lead record into a specified list in Marketo using SOAP API.

Setting up the Job for adding a lead record to a Marketo list

Procedure

1. Create a new Job and add a tFixedFlowInput component, a tMarketoListOperation component, and a tLogRow component by typing their names in the design workspace or dropping them from Palette.
2. Double-click the tMarketoListOperation component and on the Component tab click Advanced settings to open its advanced settings view, then select SOAP from the API Mode drop-down list.
3. Connect tFixedFlowInput to tMarketoListOperation using a Row > Main connection. In the pop-up dialog box, click Yes to get the schema from the target component.
4. Connect tMarketoListOperation to tLogRow using a Row > Main connection.

Configuring the Job for adding a lead record to a Marketo list

Procedure

1. Double-click the tFixedFlowInput component to open its Basic settings view.
2. Click the [...] button next to Edit schema to view its schema.

3. In the Mode area, select Use Inline Table, and then click the [+] button to add one row and fill the row with respective values. In this example, these values are: MKTOLISTNAME for ListKeyType, Test_Comp_QA for ListKeyValue, IDNUM for LeadKeyType and 9300203 for LeadKeyValue.

4. Double-click the tMarketToListOperation component to open its Basic settings view.

5. In the Endpoint address field, enter the Marketo SOAP API endpoint URL that can be found on the Marketo Admin > Web Services panel.

6. In the Client Access ID and Secret key fields, enter the user ID and encryption key required to access Marketo.
7. From the **Operation** list, select **addTo** to add the lead with the ID 9300203 into the list **Test_Comp_QA**.

8. Double-click the **tLogRow** component to open its **Basic settings** view.

9. Click the **Sync columns** button to synchronize the schema with the input schema.

10. In the **Mode** area, select **Table (print values in cells of a table)** for better readability of the result.

### Executing the Job to add a lead record to a Marketo list

#### Procedure

1. Press **Ctrl + S** to save the Job.

2. Press **F6** or click **Run** on the **Run** tab to run the Job.

   ```
   [statistics] connecting to socket on port 3520
   [statistics] connected
   tLogRow_1
   ListKeyType | ListKeyValue | LoadKeyType | LoadKeyValue | Success
   ------------|--------------|-------------|---------------|--------
   | Test_Comp_QA | IDNUM | 9300203 | true |
   [statistics] disconnected
   ```

   As shown above, the result of the operation is displayed on the **Run** console.

3. Double-check the result in Marketo.

   ![Image of Marketo interface](image.png)

   The lead with the ID 9300203 in Marketo is added into the list **Test_Comp_QA**.
tMarketoOutput

Writes lead records or custom object records from the incoming data flow into Marketo.

**tMarketoOutput Standard properties**

These properties are used to configure tMarketoOutput running in the Standard Job framework. The Standard tMarketoOutput component belongs to two families: Business and Cloud. The component in this framework is available in all Talend products.

**Basic settings**

<tr>
<td></td>
<td>- <strong>deleteOpportunityRoles</strong>: Delete a list of opportunity roles.</td>
</tr>
</tbody>
</table>

**Operation type**

Select a type of sync operation to be performed from the drop-down list.

- **createOnly**: creates new leads.
### Sync Method Options

- **updateOnly**: updates existing leads.
- **createOrUpdate**: creates new leads, or updates the leads if they already exist.
- **createDuplicate**: creates new leads. If they already exist, then creates duplicated leads.

This list is available only in the REST API mode when `syncLead` or `syncMultipleLeads` is selected from the **Operation** list.

### Lookup Field

Select the lookup field that will be used to find the duplicate.

This list is available only in the REST API mode when `syncLead` or `syncMultipleLeads` is selected from the **Operation** list.

### Mappings

Complete this table to map the column names of the component schema with the column names in Marketo. By default, the column names in **Column name** fields are the same as what they are in the schema.

Note that because some column names in Marketo may contain blank space, which is not allowed in the component schema, you need to specify the corresponding column fields in the **Marketo column name** column. If the defined column names in schema are the same as column names in Marketo, it is not necessary to set the columns mapping.

This table is available only in the SOAP API mode.

### De-duplicate Lead Record on Email Address

Select this check box to de-duplicate records using email address.

Clear this check box to create another record which contains the same email address.

### Delete Leads in Batch

Select this check box to delete the leads in batch.

This check box is available only when `deleteLeads` is selected from the **Operation** list.

### Batch Size

Specify the number of records to be processed in each batch.

This field is available when:
- `syncMultipleLeads` is selected from the **Operation** list, or
- `deleteLeads` is selected from the **Operation** list and the **Delete leads in batch** check box is selected.

### Sync Method

Select a type of sync operation to be performed from the drop-down list.

- **createOnly**: Create new custom objects, companies, opportunities or opportunity roles.
- **updateOnly**: Updates existing custom objects, companies, opportunities or opportunity roles.
- **createOrUpdate**: Create new custom objects, companies, opportunities or opportunity roles, or updates them if they already exist.

This list is available only when `syncCustomObjects`, `syncCompanies`, `syncOpportunities`
<table>
<thead>
<tr>
<th><strong>tMarketoOutput</strong></th>

For more information about the Marketo SOAP API, see <a href="http://developers.marketo.com/documentation/soap/">http://developers.marketo.com/documentation/soap/</a>.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Timeout</strong></td>
<td>Enter the timeout value (in milliseconds) for the connection to the Marketo Web Service before terminating the attempt.</td>
</tr>
<tr>
<td><strong>Max reconnection attempts</strong></td>
<td>Enter the maximum number of reconnect attempts to the Marketo Web Service before giving up.</td>
</tr>
<tr>
<td><strong>Attempt interval time</strong></td>
<td>Enter the time period (in milliseconds) between subsequent reconnection attempts.</td>
</tr>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to gather the Job processing metadata at the Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

### Global Variables

<table>
<thead>
<tr>
<th><strong>NUMBER_CALL</strong></th>
<th>The number of calls. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>ERROR_MESSAGE</strong></td>
<td>The error message generated by the component when an error occurs. This is an After variable and it returns a string.</td>
</tr>
</tbody>
</table>

### Usage

| **Usage rule** | This component is usually used as an end component of a Job or Subjob and it always needs an input link. |
Transmitting data with Marketo using REST API

Here is an example of using Talend components to connect to Marketo, insert several lead records into Marketo, then retrieve these records from Marketo and display them on the console.

Setting up the Job for data transmission with Marketo using REST API

Procedure

1. Add a `tMarketoConnection` component, two `tFixedFlowInput` components, a `tMarketoOutput` component, a `tMarketoinput` component, and a `tLogRow` component by typing their names on the design workspace or dropping them from the Palette.

2. Make sure REST is selected from the API Mode drop-down list on the Advanced settings view of `tMarketoOutput` and `tMarketoinput`.

3. Connect the first `tFixedFlowInput` component to the `tMarketoOutput` component using a Row > Main connection. In the pop-up dialog box, click Yes so that the first `tFixedFlowInput` component can get the schema from the target `tMarketoOutput` component.

4. Connect the second `tFixedFlowInput` component to the `tMarketoinput` component using a Row > Main connection. In the pop-up dialog box, click No and the second `tFixedFlowInput` component will not get the schema from the target `tMarketoinput` component.

5. Connect the `tMarketoinput` component to the `tLogRow` component using a Row > Main connection.

6. Connect the `tMarketoConnection` component to the first `tFixedFlowInput` component using a Trigger > On Subjob Ok connection.

7. Do the same to connect the first `tFixedFlowInput` component to the second `tFixedFlowInput` component.

Connecting to Marketo using REST API

Before you begin

Before connecting to Marketo using the REST API endpoint, you need to make sure a custom service, which provides credentials to authenticate with Marketo and allows you to access the data in Marketo,
has been created and associated with a single API-only user by your Marketo administrator. For more information about the Marketo Custom Service, see Custom Services.

Procedure

1. Double-click the tMarketoConnection component to open its Basic settings view.

![tMarketoConnection_1](image)

2. In the Endpoint address field, enter the REST API endpoint URL that can be found on the Marketo Admin > Web Services panel.

3. In the Client Access ID and Secret key fields, enter the client Id and client secret required to access Marketo.

   The client Id and client secret can be found on the Marketo Admin > LaunchPoint panel, by clicking View Details for the service to be accessed.

Inserting lead records into Marketo using REST API

Procedure

1. Double-click the first tFixedFlowInput component to open its Basic settings view.

   ![tFixedFlowInput_1](image)

2. Click the [...] button next to Edit schema to open the schema dialog box.

   ![Content](image)
3. In the schema dialog box, select the id and Status columns that don’t need input values and click the Remove selected items button to remove them. Then click OK to save the settings and close the schema dialog box.

4. In the Mode area, select Use Inline Content(delimited file) and enter the following input data in the Content field.

```
dev@talend.com;Peter;Wang
doc@talend.com;Judy;Zhang
dev@talend.com;Nick;Liu
dev@talend.com;Mark;Zhao
doc@talend.com;Alex;Sun
```

5. Double-click the tMarketoOutput component to open its Basic settings view.

6. From the Connection Component drop-down list, select the component whose connection details will be used to set up the connection to Marketo, tMarketoConnection_1 in this example.

7. From the Operation drop-down list, select SyncMultipleLeads to insert multiple lead records.

8. From the Operation type drop-down list, select createDuplicate to allow duplicated leads to be created.

Retrieving lead records from Marketo using REST API

Procedure

1. Double-click the second tFixedFlowInput component to open its Basic settings view.
2. Click the button next to **Edit schema** and in the schema dialog box displayed, define the schema by adding one column `mail` of **String** type. Then click **OK** to save the changes and close the schema dialog box.

3. In the **Mode** area, select **Use Inline Table**. Then click the button twice below the table displayed to add two rows and fill each row with respective values. In this example, two email values `dev@talend.com` and `doc@talend.com` are added so that the lead records identified by these email values can be retrieved.

4. Double-click the **tMarketToInput** component to open its **Basic settings** view.
5. From the **Connection Component** drop-down list, select the component whose connection details will be used to set up the connection to Marketo, `tMarketoConnection_1` in this example.

6. Select **getMultipleLeads** from the **Operation** drop-down list to retrieve a batch of lead records.

7. Select **LeadKeySelector** from the **Lead selector** drop-down list, and select **email** from the **Lead key type** list and **email** from the **Lead key values** list to retrieve the leads identified by the email values passed from the second `tFixedFlowInput` component.

8. Double-click the **tLogRow** component to open its **Basic settings** view.

9. In the **Mode** area, select **Table (print values in cells of a table)** for better readability of the result.

**Executing the Job to transmit data with Marketo using REST API**

**Procedure**

1. Press **Ctrl + S** to save the Job.
2. Press **F6** to execute the Job.

```

[statistics] disconnected
```

As shown above, the inserted lead records in Marketo are retrieved and displayed on the console.
tMarkLogicBulkLoad

Imports local files into a MarkLogic server database in bulk mode using the MarkLogic Content Pump (MLCP) tool.

tMarkLogicBulkLoad Standard properties

These properties are used to configure tMarkLogicBulkLoad running in the Standard Job framework.

The Standard tMarkLogicBulkLoad component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

Basic settings

| Property Type | Either Built-In or Repository.  
|              | • Built-In: No property data stored centrally.  
|              | • Repository: Select the repository file in which the properties are stored. The database connection fields that follow are completed automatically using the data retrieved.  
| Use an existing connection | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.  

Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:  
1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.  
2. In the child level, use a dedicated connection component to read that registered database connection.  

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

| Host | Enter the IP address or hostname of the MarkLogic server.  
| Port | Enter the listening port number of the MarkLogic server.  
| Database | Enter the name of the MarkLogic database you want to use.  
| Username and Password | Enter the user authentication data to access the MarkLogic database.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the
password between double quotes and click **OK** to save the settings.

| **Load Folder** | Specify the directory to the local files to be imported into the MarkLogic database. |
| **DocId Prefixed As** | Specify the prefix used to construct the URI of the imported files. For more information about the URI construction, see [https://docs.marklogic.com/guide/ingestion/content-pump#id_14982](https://docs.marklogic.com/guide/ingestion/content-pump#id_14982). |

**Advanced settings**

| **Additional MLCP Parameters** | Specify additional options for the MLCP import command. For more information about the import options, see [https://docs.marklogic.com/guide/ingestion/content-pump#id_63999](https://docs.marklogic.com/guide/ingestion/content-pump#id_63999). |
| **Use external MLCP process** | As the MarkLogic Content Pump (MLCP) program is required on the machine where you run your Job that involves this component, you can do either of the following:

  - Keep this check box clear to use a built-in MLCP library when running this component to load data. In this case, your Job is memory demanding.
  - If you need to use your own MLCP, that is to say, an MLCP external to the Studio, select this check box. In this case, your Job itself is not memory demanding but your MLCP process is.

For further information about MLCP, see the related MarkLogic documentation: [Loading Content Using Marklogic Content Pump](https://docs.marklogic.com/guide/ingestion/content-pump#id_63999). |
| **tStatCatcher Statistics** | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global Variables**

| **Global Variables** | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see **Talend Studio User Guide**. |

| **Global Variables** | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. |

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see **Talend Studio User Guide**. |
# Usage

## Usage rule

This component can be used together with the `tMarkLogicInput` component to check if the files are imported as expected.

## Dynamic settings

Click the `[+]` button to add a row in the table and fill the `Code` field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

## Limitation

The MarkLogic Content Pump (MLCP) tool needs to be installed on the machine where you run the Job that involves this component.

# Related scenario

No scenario is available for the Standard version of this component yet.
**tMarkLogicClose**

Closes an active connection to a MarkLogic database to release the occupied resources.

**tMarkLogicClose Standard properties**

These properties are used to configure tMarkLogicClose running in the Standard Job framework.

The Standard tMarkLogicClose component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>

For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenario

No scenario is available for the Standard version of this component yet.
tMarkLogicConnection

Opens a connection to a MarkLogic database that can then be reused by other MarkLogic components.

**tMarkLogicConnection Standard properties**

These properties are used to configure tMarkLogicConnection running in the Standard Job framework.

The Standard tMarkLogicConnection component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all *Talend products with Big Data* and in *Talend Data Fabric*.

**Basic settings**

| Property Type     | Either *Built-In* or *Repository*.  
|-------------------|-----------------------------------|
|                   | • *Built-In*: No property data stored centrally.  
|                   | • *Repository*: Select the repository file in which the properties are stored. The database connection fields that follow are completed automatically using the data retrieved.  
| Host              | Enter the IP address or hostname of the MarkLogic server.  
| Port              | Enter the listening port number of the MarkLogic server.  
| Database          | Enter the name of the MarkLogic database you want to use.  
| Username and Password| Enter the user authentication data to access the MarkLogic database.  
|                   | To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.  
| Authentication Type| Select an authentication type from the list, either *DIGEST* or *BASIC*. For more information about the types of authentication, see [http://docs.marklogic.com/guide/security/authentication#id_56266](http://docs.marklogic.com/guide/security/authentication#id_56266).  

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level.  

**Global Variables**

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

### Usage

| Usage rule | This component is more commonly used with other MarkLogic components. |

### Related scenario

No scenario is available for the Standard version of this component yet.
tMarkLogicInput

Searches document content in a MarkLogic database based on a string query.

tMarkLogicInput passes on the document URI and content to the next component via a Row > Main connection.

**tMarkLogicInput Standard properties**

These properties are used to configure tMarkLogicInput running in the Standard Job framework.

The Standard tMarkLogicInput component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Either Built-In or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>

</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the</td>
</tr>
</tbody>
</table>
password between double quotes and click **OK** to save the settings.

### Authentication
Select an authentication type from the list, either **DIGEST** or **BASIC**. For more information about the types of authentication, see [http://docs.marklogic.com/guide/security/authentication#id_56266](http://docs.marklogic.com/guide/security/authentication#id_56266).

### Schema and Edit schema
A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `LINE` when naming the fields.

The schema of this component is read-only. You can click the [...] button next to **Edit schema** to view the predefined schema that contains the following two columns:

- **docId**: the URI of the document.
- **docContent**: the content of the document.

### Query Criteria
Specify the string query based on which the search is performed. For more information about the string query, see [https://docs.marklogic.com/guide/search-dev/string-query](https://docs.marklogic.com/guide/search-dev/string-query).

### Advanced settings

<table>
<thead>
<tr>
<th><strong>Maximal Retrieve Number</strong></th>
<th>Enter the maximum number of documents to be retrieved.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Use Query Option</strong></td>
<td>Select this check box to customize the query with a query option. The query option will be stored on the REST server and can then be referenced by name by other queries. For more information about the query options, see <a href="http://docs.marklogic.com/guide/java/query-options#id_20346">http://docs.marklogic.com/guide/java/query-options#id_20346</a>.</td>
</tr>
<tr>
<td><strong>Query Literal Type</strong></td>
<td><strong>Query Literal Type</strong>: select a type of presentation from which the query option is created, either <strong>XML</strong> or <strong>JSON</strong>.</td>

<td><strong>Query Option Name</strong>: specify the name of the query option.</td>
</tr>
<tr>
<td><strong>Query Option Literals</strong></td>
<td><strong>Query Option Literals</strong>: implement the query option from a raw XML or JSON representation according to the selected representation type.</td>
</tr>
</tbody>
</table>

### tStatCatcher Statistics
Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

<table>
<thead>
<tr>
<th><strong>Global Variables</strong></th>
<th><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press <strong>Ctrl + Space</strong> to access the variable list and choose the variable to use from it.</td>
</tr>
</tbody>
</table>
For further information about variables, see *Talend Studio User Guide*.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is usually used as a start component and it needs an output flow.</th>
</tr>
</thead>
</table>

#### Dynamic settings

Click the `[+]` button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see *Reading data from databases through context-based dynamic connections* on page 2457 and *Reading data from different MySQL databases using dynamically loaded connection parameters* on page 491. For more information on **Dynamic settings** and context variables, see *Talend Studio User Guide*.

### Related scenario

No scenario is available for the Standard version of this component yet.
tMarkLogicOutput

Creates, updates or deletes document content in a MarkLogic database.

tMarkLogicOutput allows you to maintain document content in a MarkLogic database according to the predefined operation and the input flow from the preceding component.

**tMarkLogicOutput Standard properties**

These properties are used to configure tMarkLogicOutput running in the Standard Job framework.

The Standard tMarkLogicOutput component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| Property Type | Either Built-In or Repository.  
|               | • Built-In: No property data stored centrally.  
|               | • Repository: Select the repository file in which the properties are stored. The database connection fields that follow are completed automatically using the data retrieved. |

Use an existing connection

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

| Host | Enter the IP address or hostname of the MarkLogic server. |
| Port | Enter the listening port number of the MarkLogic server. |
| Database | Enter the name of the MarkLogic database you want to use. |
| Username and Password | Enter the user authentication data to access the MarkLogic database. |

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the
Select an authentication type from the list, either DIGEST or BASIC. For more information about the types of authentication, see http://docs.marklogic.com/guide/security/authentication\#id_56266.

**Action**

Select an operation to be performed:

- **UPSERT**: create documents if they do not exist or update the content of existing documents.
- **PATCH**: perform a partial update to the content of the documents.
- **DELETE**: delete documents corresponding to the input flow.

Note that when `DELETE` is selected from the **Action** list, the input schema should contain one column `docId` that describes the URI of the documents to be deleted, and other columns will be ignored if there is any.

**Schema and Edit schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

The schema of this component is read-only. You can click the [...] button next to `Edit schema` to view the predefined schema that contains the following two columns:

- `docId`: the URI of the document.
- `docContent`: the content of the document.

**Advanced settings**

**Doc Type**

Select the type of the documents to be processed: **MIXED**, **PLAIN TEXT**, **JSON**, **XML**, or **BINARY**.

**Auto Generate Doc ID**

Select this check box to generate automatically the document URIs and in the **Doc Id Prefix** field displayed enter the prefix used to construct the document URIs.

This check box is available only when **UPSERT** is selected from the **Action** list and **MIXED** is not selected from the **Doc Type** list.

- If this check box is selected, the input schema should contain one column `docContent` that describes the document content, and other columns will be ignored if there is any.
- If this check box is clear, the input schema should contain two columns `docId` and `docContent` that describe the document URI and the document content correspondingly.

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.
## Global Variables

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see *Talend Studio User Guide*. |

## Usage

| Usage rule | This component is usually used as an end component and it always needs an input flow. |

| Dynamic settings | Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the Component List box in the **Basic settings** view becomes unusable. For examples on using dynamic parameters, see *Reading data from databases through context-based dynamic connections* on page 2457 and *Reading data from different MySQL databases using dynamically loaded connection parameters* on page 491. For more information on **Dynamic settings** and context variables, see *Talend Studio User Guide*. |

## Related scenario

No scenario is available for the Standard version of this component yet.
tMaxDBInput

Reads a database and extracts fields based on a query.

tMaxDBInput executes a DB query with a strictly defined order which must correspond to the schema definition. Then it passes on the field list to the next component via a Main row link.

**tMaxDBInput Standard properties**

These properties are used to configure tMaxDBInput running in the Standard Job framework.
The Standard tMaxDBInput component belongs to the Databases family.
The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either <strong>Built-in</strong> or <strong>Repository</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Built-in</strong>: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><img src="image" alt="icon" /></td>
<td>Click this icon to open a database connection wizard and store the database connection parameters you set in the component <strong>Basic settings</strong> view. For more information about setting up and storing database connection parameters, see <em>Talend Studio User Guide</em>.</td>
</tr>
<tr>
<td>Host name</td>
<td>Database server IP address</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-in</strong>: The schema is created and stored locally for this component only. Related topic: see <em>Talend Studio User Guide</em>.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see <em>Talend Studio User Guide</em>.</td>
</tr>
</tbody>
</table>
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

<table>
<thead>
<tr>
<th>Table name</th>
<th>Type in the table name.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Query type</strong> and <strong>Query</strong></td>
<td>Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.</td>
</tr>
<tr>
<td><strong>Guess Query</strong></td>
<td>Click the <strong>Guess Query</strong> button to generate the query which corresponds to your table schema in the <strong>Query</strong> field.</td>
</tr>
<tr>
<td><strong>Guess schema</strong></td>
<td>Click the <strong>Guess schema</strong> button to retrieve the table schema.</td>
</tr>
</tbody>
</table>

### Advanced settings

| Trim all the String/Char columns | Select this check box to remove leading and trailing whitespace from all the String/Char columns. |
| Trim column | Remove leading and trailing whitespace from defined columns. |
| **tStat Catcher Statistics** | Select this check box to collect log data at the component level. |

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE</strong>: the number of rows processed. This is an After variable and it returns an integer.</td>
<td></td>
</tr>
<tr>
<td><strong>QUERY</strong>: the query statement being processed. This is a Flow variable and it returns a string.</td>
<td></td>
</tr>
<tr>
<td><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</td>
<td></td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.
For further information about variables, see *Talend Studio User Guide*.

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component offers the flexibility of the DB query and covers all possible SQL queries.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limitation</td>
<td>This component requires installation of its related jar files.</td>
</tr>
</tbody>
</table>

**Related scenario**

For a related scenario, see:
tMaxDBOutput

Writes, updates, makes changes or suppresses entries in a database.

tMaxDBOutput executes the action defined on the table and/or on the data contained in the table, based on the flow incoming from the preceding component in the job.

tMaxDBOutput Standard properties

These properties are used to configure tMaxDBOutput running in the Standard Job framework.
The Standard tMaxDBOutput component belongs to the Databases family.
The component in this framework is available in all Talend products.

Basic settings

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-in or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

- **Host**: Database server IP address.
- **Port**: Listening port number of DB server.
- **Database**: Name of the database.
- **Username and Password**: DB user authentication data.
  - To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.
- **Table**: Name of the table to be written. Note that only one table can be written at a time and that the table must exist for the insert operation to succeed.
- **Action on table**: On the table defined, you can perform one of the following operations:
  - **None**: No operation is carried out.
  - **Drop and create table**: The table is removed and created again.
  - **Create table**: The table does not exist and gets created.
  - **Create table if not exists**: The table is created if it does not exist.
### Action on data

On the data of the table defined, you can perform:

- **Insert**: Add new entries to the table. If duplicates are found, job stops.
- **Update**: Make changes to existing entries
- **Insert or update**: Insert a new record. If the record with the given reference already exists, an update would be made.
- **Update or insert**: Update the record with the given reference. If the record does not exist, a new record would be inserted.
- **Delete**: Remove entries corresponding to the input flow.

#### Warning:

It is necessary to specify at least one column as a primary key on which the **Update** and **Delete** operations are based. You can do this by clicking **Edit Schema** and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the **Advanced settings** view where you can simultaneously define primary keys for the Update and Delete operations. To do that:

- Select the **Use field options** check box and then in the **Key in update** column, select the check boxes next to the column names you want to use as a base for the Update operation. Do the same in the **Key in delete** column for the Delete operation.

### Schema and Edit Schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

**Built-In**: You create and store the schema locally for this component only.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
**Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Die on error**
This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a **Row > Rejects** link.

**Advanced settings**

**Commit every**
Enter the number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and, above all, better performance at execution.

**Additional Columns**
This option is not offered if you create (with or without drop) the DB table. This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing.

- **Name**: Type in the name of the schema column to be altered or inserted as new column
- **SQL expression**: Type in the SQL statement to be executed in order to alter or insert the relevant column data.
- **Position**: Select **Before**, **Replace** or **After** following the action to be performed on the reference column.
- **Reference column**: Type in a column of reference that the tMaxDBOutput can use to place or replace the new or altered column.

**Use field options**
Select this check box to customize a request, especially when there is double action on data.

**Enable debug mode**
Select this check box to display each step during processing entries in a database.

**tStatCatcher Statistics**
Select this check box to collect log data at the component level.

**Global Variables**

**Global Variables**

- **NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.
- **NB_LINE_UPDATED**: the number of rows updated. This is an After variable and it returns an integer.
- **NB_LINE_INSERTED**: the number of rows inserted. This is an After variable and it returns an integer.
- **NB_LINE_DELETED**: the number of rows deleted. This is an After variable and it returns an integer.
### Usage

**Usage rule**

This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible.

This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in a database. It also allows you to create a reject flow using a `Row > Rejects` link to filter data in error. For an example of `tMysqlOutput` in use, see **Retrieving data in error with a Reject link** on page 2485.

**Limitation**

This component requires installation of its related jar files.

### Related scenario

For a related scenario, see:

- Inserting a column and altering data using `tMysqlOutput` on page 2477.
tMaxDBRow

Acts on the actual DB structure or on the data (although without handling data), depending on the nature of the query and the database.

tMaxDBRow is the specific component for this database query. It executes the SQL query stated onto the specified database. The row suffix means the component implements a flow in the job design although it doesn’t provide output.

The SQLBuilder tool helps you write easily your SQL statements.

tMaxDBRow Standard properties

These properties are used to configure tMaxDBRow running in the Standard Job framework.
The Standard tMaxDBRow component belongs to the Databases family.
The component in this framework is available in all Talend products.

Basic settings

<table>
<thead>
<tr>
<th>Property type</th>

<td>Name of the database.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Schema and Edit Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td></td>
<td>Built-in: The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide.</td>
</tr>
<tr>
<td></td>
<td>Repository: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide.</td>
</tr>
<tr>
<td></td>
<td>Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:</td>
</tr>
</tbody>
</table>
- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

<table>
<thead>
<tr>
<th>Table name</th>
<th>Type in the table name.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Query type</td>
<td>The query can be <strong>Built-in</strong> for a particular Job, or for commonly used query, it can be stored in the <strong>Repository</strong> to ease the query reuse.</td>
</tr>
<tr>
<td><strong>Built-in</strong>: Fill in manually the query statement or build it graphically using SQLBuilder.</td>
<td></td>
</tr>
<tr>
<td><strong>Repository</strong>: Select the relevant query stored in the Repository. The <strong>Query</strong> field gets accordingly filled in.</td>
<td></td>
</tr>
<tr>
<td>Query</td>
<td>Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.</td>
</tr>
<tr>
<td><strong>Guess Query</strong></td>
<td>Click the <strong>Guess Query</strong> button to generate the query which corresponds to your table schema in the <strong>Query</strong> field.</td>
</tr>
<tr>
<td>Die on error</td>
<td>This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a <strong>Row &gt; Rejects</strong> link.</td>
</tr>
</tbody>
</table>

### Advanced settings

<table>
<thead>
<tr>
<th>Propagate QUERY’s recordset</th>
<th>Select this check box to insert the result of the query into a <strong>COLUMN</strong> of the current flow. Select this column from the <strong>use column</strong> list.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Use PreparedStatement</strong></td>
<td>Select this check box if you want to query the database using a PreparedStatement. In the <strong>Set PreparedStatement Parameter</strong> table, define the parameters represented by ’?’ in the SQL instruction of the <strong>Query</strong> field in the <strong>Basic Settings</strong> tab.</td>
</tr>
<tr>
<td><strong>Parameter Index</strong>: Enter the parameter position in the SQL instruction.</td>
<td></td>
</tr>
<tr>
<td><strong>Parameter Type</strong>: Enter the parameter type.</td>
<td></td>
</tr>
<tr>
<td><strong>Parameter Value</strong>: Enter the parameter value.</td>
<td></td>
</tr>
</tbody>
</table>

**Note:**
This option is very useful if you need to execute the same query several times. Performance levels are increased.
**Commit every**  
Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions.

**tStat Catcher Statistics**  
Select this check box to collect log data at the component level.

### Global Variables

**Global Variables**

**QUERY**: the query statement being processed. This is a Flow variable and it returns a string.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

### Usage

**Usage rule**  
This component offers the flexibility benefit of the DB query and covers all possible SQL queries.

**Limitation**  
This component requires installation of its related jar files.

### Related scenario

No scenario is available for this component yet.
tMDMBulkLoad

Uses bulk mode to write XML structured master data into the MDM server. Note that tMDMBulkLoad does not generate journal entries as part of the bulk load.

**tMDMBulkLoad Standard properties**

These properties are used to configure tMDMBulkLoad running in the Standard Job framework. The Standard tMDMBulkLoad component belongs to the Talend MDM family. The component in this framework is available in all Talend products.

**Basic settings**

| Schema and Edit Schema | A schema is a row description, it defines the number of fields that will be processed and passed on to the next component. The schema is either built-in or remote in the Repository.
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:
- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.
Click **Sync columns** to collect the schema from the previous component. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-in</strong>: You create the schema and store it locally for this component only. Related topic: see <a href="#">Talend Studio User Guide</a>.</td>
<td></td>
</tr>
<tr>
<td><strong>Repository</strong>: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see <a href="#">Talend Studio User Guide</a>.</td>
<td></td>
</tr>
<tr>
<td><strong>XML field</strong></td>
<td>Select the name of the column in which you want to write the XML data.</td>
</tr>
<tr>
<td><strong>URL</strong></td>
<td>Type in the URL required to access the MDM server.</td>
</tr>
<tr>
<td><strong>Username</strong> and <strong>Password</strong></td>
<td>Type in the user authentication data for the MDM server. To enter the password, click the <code>[…]</code> button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td>tMDMBulkLoad</td>
<td></td>
</tr>
<tr>
<td>---</td>
<td>---</td>
</tr>
<tr>
<td><strong>Data Model</strong></td>
<td>Type in the name of the data model against which the data to be written is validated.</td>
</tr>
<tr>
<td><strong>Data Container</strong></td>
<td>Type in the name of the data container where you want to write the master data.</td>
</tr>
<tr>
<td><strong>Entity</strong></td>
<td>Type in the name of the entity that holds the data record(s) you want to write.</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Select <strong>Master</strong> or <strong>Staging</strong> to specify the database on which the action should be performed.</td>
</tr>
</tbody>
</table>
| **Validate** | Select this check box to validate the data you want to write onto the MDM server against validation rules defined for the current data model.  
Note that for the PROVISIONING Data Container, validation checks will always be performed on incoming records, regardless of whether or not this check box is selected.  
For more information on how to set the validation rules, see *Talend Studio User Guide*. |
| **Generate ID** | Select this check box to generate an ID number for all of the data written.  
**Warning:**  
*If you need faster loading performance, do not select this check box.* |
| **Insert only** | Select this check box to skip the step of checking whether the data records to be inserted already exist on the MDM server, thus achieving a better performance.  
However, before using this option, you need to make sure that the data records do not exist in the database. |
| **Commit size** | Type in the row count of each batch to be written onto the MDM server. |
| **Use Transaction** | Select this check box then, in the Component List, click an existing connection component which will be used to commit the transaction. |

**Advanced settings**

| **tStatCatcher Statistics** | Select this check box to gather the processing metadata at the Job level as well as at each component level. |

**Global Variables**

| **Global Variables** | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable. |
and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

---

### Usage

#### Usage rule

This component needs always an incoming link to offer XML structured data. If your data offered is not yet in the XML structure, you need use components like **tWriteXMLField** to transform this data into the XML structure. For further information about **tWriteXMLField**, see *tWriteXMLField* on page 3994.

You can increase the timeout values for a Job using this component to help process a large number of data records. For more information, see advanced execution settings for JVM parameters on Talend Help Center (https://help.talend.com).

If you use a Job with the component **tMDMBulkLoad** to bulk load large volumes of data into MDM, you can tune the bulk load operation by adding a specific JVM argument (for example, `bulkload.concurrent.http.requests=25`) in the **Advanced settings** tab of the Job to limit the maximum number of concurrent requests sent to the MDM server. This avoids consuming all available Tomcat application server connections, which will lead to transaction and deadlock issues.

---

### Connections

Outgoing links (from this component to another):

- **Row**: Main,
- **Trigger**: Run if; On Component Ok; On Component Error; On Subjob Ok; On Subjob Error.

Incoming links (from one component to this one):

- **Row**: Main
- **Trigger**: Run if; On Component Ok; On Component Error; On Subjob Ok; On Subjob Error

For further information regarding connections, see *Talend Studio User Guide*.

---

### Loading records into a business entity

This scenario applies only to *Talend Open Studio for MDM*, *Talend MDM Platform* and *Talend Data Fabric*.

This scenario describes a Job that loads records into the *ProductFamily* business entity defined by a specific data model in the MDM hub.
Prerequisites:

- The Product data container: This data container is used to separate the product master data domain from the other master data domains.
- The Product data model: This data model is used to define the attributes, validation rules, user access rights and relationships of the entities of interest. Thus it defines the attributes of the ProductFamily business entity.
- The ProductFamily business entity: This business entity contains Id, Name, both defined by the Product data model.

For further information about how to create a data container, a data model, and a business entity along with its attributes, see the MDM part of your Talend Studio MDM Studio User Guide.

The Job in this scenario uses three components.

- tFixedFlowInput: This component generates the records to be loaded into the ProductFamily business entity. In a real-life project, your records to be loaded are often voluminous and stored in a specific file. However, to simplify the replication of this scenario, this Job uses tFixedFlowInput to generate four sample records.
- tWriteXMLField: This component transforms the incoming data into XML structure.
- tMDMBulkLoad: This component writes the incoming data into the ProductFamily business entity in bulk mode, generating ID value for each of the record data.

Dropping and linking components

Procedure
1. Drop tFixedFlowInput, tWriteXMLField and tMDMBulkLoad onto the design workspace.
2. Connect tFixedFlowInput to tWriteXMLField using the Main link.
3. Do the same to connect tWriteXMLField to tMDMBulkLoad.

Configuring the components

Generating the data records to be loaded into a business entity

Procedure
1. Double click tFixedFlowInput to open its Basic settings view.
2. Click the [...] button next to Edit schema to open the schema editor.

3. In the schema editor, click the [+] button to add one row.
4. Name the new column, family in this example.
5. Click OK to close the schema editor.
6. In the Mode area of the Basic settings view, select the Use Inline Table option.
7. Click the [+] button four times to add four rows in the table.
8. In the inline table, click each of the added rows and then enter their names between quotes: Shirts, Hats, Pets, and Mugs.

**Transforming the incoming data into XML structure**

**Procedure**

1. Double-click tWriteXMLField to open its Basic settings view.
2. Click the [...] button next to the Edit schema field to open the schema editor and then add a row by clicking the [+] button.

3. Click the newly added row to the right view of the schema editor and enter the name of the output column where you want to write the XML content. It is `xmlRecord` in this example.

4. Click OK to validate this output schema and close the schema editor.
   In the dialog box that pops up, click OK to propagate this schema to the following component.

5. In the Basic settings view, click the [...] button next to Configure XML Tree to open the dialog box where you can create the XML structure.
6. In the Link Target area, click rootTag and rename it to ProductFamily, which is the name of the business entity used in this scenario.

7. In the Linker source area, drop family to ProductFamily in the Link target area.
   A dialog box pops up, asking you to select one operation.
   Select Create as sub-element of target node to create a sub-element of the ProductFamily node.
   Then, the family element appears under the ProductFamily node.
   Right-click the Name node and select from the contextual menu Set As Loop Element.

8. In the Link target area, click the family node and rename it to Name, which is one of the attributes of the ProductFamily business entity.
   Click OK to validate the XML structure you defined.

Writing the incoming data into a business entity

Procedure

1. Double-click tMDMBulkLoad to open its Basic settings view.

2. Select xmlRecord from the XML Field drop-down list.

3. In the URL field, enter the bulk loader URL between quotes. For example, http://localhost:8180/talendmdm/services/bulkload.

4. In the Username and Password fields, enter your login and password to connect to the MDM server.

5. In the Data Model and the Data Container fields, enter the names corresponding to the data model and the data container you need to use. Both are Product for this scenario.
   In the Entity field, enter the name of the business entity into which you want to load the records. In this example, enter ProductFamily.

6. Select the Generate ID check box in order to generate ID values for the records to be loaded.

7. In the Commit size field, type in the batch size to be written into the MDM hub in bulk mode.

Saving and executing the Job

Procedure

1. Press Ctrl+S to save your Job.

2. Execute the Job by pressing F6 or clicking Run on the Run tab.
Log into your *Talend MDM Web UI* to check the newly added records for the *ProductFamily* business entity.
tMDMClose

Terminates an open MDM server connection after the execution of the proceeding subJob.

**tMDMClose Standard properties**

These properties are used to configure tMDMClose running in the Standard Job framework.

The Standard tMDMClose component belongs to the Talend MDM family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Component List</th>
<th>Select the tMDMConnection component from the list if more than one connection is planned for the current Job.</th>
</tr>
</thead>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
<th>Select this check box to gather the processing metadata at the Job level as well as at each component level.</th>
</tr>
</thead>
</table>

**Global Variables**

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.  
For further information about variables, see Talend Studio User Guide. |
|-------------------|--------------------------------------------------------------------------------------------------------|

**Usage**

| Usage rule | This component is to be used along with the tMDMConnection component.  
Note that the tMDMCommit and tMDMRollback components also include an option in their Basic settings to explicitly close a connection. |
|------------|--------------------------------------------------------------------------------------------------------|

| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your MDM server connection dynamically from multiple connections planned in your Job.  
Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. |
|------------------|--------------------------------------------------------------------------------------------------------|
Related scenario

For a related use case, see Deleting master data from an MDM Hub on page 2106.
tMDMCommit

Commits all changes to the database made within the scope of a transaction in MDM.

This component is used to control the point in an MDM Job at which any changes made to the database within the scope of an MDM transaction are committed, for example to prevent partial commits if an error occurs.

For more information about MDM transactions, see the article MDM Transactions on Talend Help Center (https://help.talend.com).

tMDMCommit Standard properties

These properties are used to configure tMDMCommit running in the Standard Job framework.

The Standard tMDMCommit component belongs to the Talend MDM family.

The component in this framework is available in all Talend products.

Basic settings

<table>
<thead>
<tr>
<th>Component List</th>
<th>Select the tMDMConnection component for which you want the commit action to be performed.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Close Connection</td>
<td>Select this check box to close the session for this connection to the MDM Server after committing the changes. Note that even if you do not select this check box, the connection can still not be used in a subsequent subjob unless the Autocommit mode has been enabled.</td>
</tr>
</tbody>
</table>

Advanced settings

| tStatCatcher Statistics | Select this check box to gather the processing metadata at the Job level as well as at each component level. |

Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | This component is to be used along with the tMDM Connection, tMDM.Rollback, tMDMSP, tMDMViewSearch, tMDMInput, tMDMDelete, tMDMRouteRecord, tMDMOutput, and tMDMClose components. |

Related scenario

For a related use case, see Deleting master data from an MDM Hub on page 2106.
tMDMConnection

Opens an MDM server connection for convenient reuse in the current Job or transaction.

**tMDMConnection Standard properties**

These properties are used to configure tMDMConnection running in the Standard Job framework.

The Standard tMDMConnection component belongs to the Talend MDM family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MDM version</td>
<td>By default, <strong>Server 6.0</strong> is selected. Although it is recommended to migrate existing Jobs for this new version, the <strong>Server 5.6</strong> option is available to ease the process of the migration of your Jobs so as to keep them working without modification with a 6.0 server. To do so, an option on the server must be enabled to accept and translate requests from such Jobs.</td>
</tr>
<tr>
<td>URL</td>
<td>Type in the URL required to access the MDM server.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>Type in the user authentication data for the MDM server. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Auto Commit</td>
<td>Select this check box to commit any changes to the database automatically upon the transaction. With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component. In the MDM context, with the Auto-Commit function enabled, queries sent to the MDM Server will be committed once they are executed. For this reason, if you need more precision in managing your transactions in a Job, it is recommended to use the component tMDMCommit.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics   | Select this check box to gather the processing metadata at the Job level as well as at each component level.                                                                                                                                                                                                                             |

**Global Variables**

| Global Variables          | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable                                                                                                                                                               |
and it returns a string. This variable functions only if the
Die on error check box is cleared, if the component has this
check box.

A Flow variable functions during the execution of a
component while an After variable functions after the
execution of the component.

To fill up a field or expression with a variable, press
Ctrl + Space to access the variable list and choose the variable to
use from it.

For further information about variables, see Talend Studio
User Guide.

Usage

Usage rule

This component is to be used along with the

- tMDMCommit
- tMDMRollback
- tMDMSP
- tMDMViewSearch
- tMDMInput
- tMDMDelete
- tMDMRouteRecord
- tMDMOutput
- tMDMClose

components.

Related scenario

For a related use case, see Deleting master data from an MDM Hub on page 2106.
# tMDMDelete

Deletes master data records from specific entities in the MDM Hub.

## tMDMDelete Standard properties

These properties are used to configure tMDMDelete running in the Standard Job framework.

The Standard tMDMDelete component belongs to the Talend MDM family.

The component in this framework is available in all Talend products.

### Basic settings

| Schema and Edit Schema | A schema is a row description, it defines the number of fields that will be processed and passed on to the next component. The schema is either built-in or remote in the Repository.  
Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
• View schema: choose this option to view the schema only.  
• Change to built-in property: choose this option to change the schema to Built-in for local changes.  
• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.  
Click Sync columns to collect the schema from the previous component. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-in</strong>: You create the schema and store it locally for this component only. Related topic: see Talend Studio User Guide.</td>
<td></td>
</tr>
<tr>
<td><strong>Repository</strong>: You have already created the schema and stored it in the Repository. You can reuse it in various projects and job designs. Related topic: see Talend Studio User Guide.</td>
<td></td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box if you want to use a configured tMDMConnection component.</td>
</tr>
<tr>
<td><strong>MDM version</strong>: By default, Server 6.0 is selected. Although it is recommended to migrate existing Jobs for this new version, the Server 5.6 option is available to ease the process of the migration of your Jobs so as to keep them working without modification with a 6.0 server. To do so, an option on the server must be enabled to accept and translate requests from such Jobs.</td>
<td></td>
</tr>
<tr>
<td><strong>URL</strong>: Type in the URL required to access the MDM server.</td>
<td></td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>Type in the user authentication data for the MDM server. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>--------------------------</td>
<td>--------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>Entity</strong></td>
<td>Type in the name of the entity that holds the data record(s) you want to delete.</td>
</tr>
<tr>
<td><strong>Data Container</strong></td>
<td>Type in the name of the data container that holds the data record(s) you want to delete.</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Select <strong>Master</strong> or <strong>Staging</strong> to specify the database on which the action should be performed.</td>
</tr>
</tbody>
</table>
| **Use multiple conditions** | Select this check box to filter the master data to be deleted, using certain conditions.  
  **Xpath**: Enter between quotes the path and the XML node to which you want to apply the condition.  
  **Function**: Select the condition to be used from the list.  
  **Value**: Enter between inverted commas the value you want to use.  
  **Predicate**: Select a predicate if you use more than one condition.  
  For more information about the operators and the predicates, see tMDMInput Standard properties on page 2114. |
| **Keys (in sequence order)** | Specify the field(s) (in sequence order) composing the key when the entity have a multiple key. |
| **Fire Delete event** | Select this check box so that a delete event will be generated and written into the **UpdateReport**, which provides a complete report on all create, update or delete actions on the master data.  
  • **Source Name**: Define a name between quotes for the source which generates the delete event.  
  • **Invoke before deleting process**: Select this check box to enable the execution of a **Before Deleting** Process to verify the delete event.  
  For further information about the **UpdateReport** and Process types, see Talend Studio User Guide. |
| **Logical delete** | Select this check box to send the master data to the Recycle bin and fill in the **Recycle bin path**. Once in the Recycle bin, the master data can be permanently deleted or restored. If you leave this check box clear, the master data will be permanently deleted. |
| **Die on error** | Select this check box to skip the row in error and complete the process for error-free rows. If needed, you can retrieve the rows in error via a **Row > Rejects** link. |
## Advanced settings

| tStatCatcher Statistics | Select this check box to gather the processing metadata at the Job level as well as at each component level. |

## Global Variables

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
**NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
For further information about variables, see *Talend Studio User Guide*. |

## Usage

| Usage rule | If the **Use multiple conditions** check box is selected, **tMDMDelete** can work as a standalone component. Otherwise, it needs an input connection.  
You can increase the timeout values for a Job using this component to help process a large number of data records. For more information, see advanced execution settings for JVM parameters on Talend Help Center ([https://help.talend.com](https://help.talend.com)). |

## Deleting master data from an MDM Hub

This scenario applies only to *Talend Open Studio for MDM, Talend MDM Platform* and *Talend Data Fabric*.  
This scenario describes a six-component Job that deletes the specified data record from the MDM Hub. It also makes use of the **tMDMCommit** and **tMDMRollback** components so that changes to the database are only made on successful completion of the Job.
Dropping and linking the components

Procedure

1. Drop tMDMConnection, tMDMCommit, tMDMClose, tMDMInput, tMDMDelete, and tMDMRollback from the Talend MDM family from the Palette onto the design workspace.
2. Connect tMDMInput to tMDMDelete using a Row > Main link.
3. Connect tMDMConnection to tMDMInput using a Trigger > OnSubjobOk link.
4. Connect tMDMDelete to tMDMCommit, tMDMCommit to tMDMClose and tMDMRollback to tMDMClose using Trigger > OnComponentOk links.
5. Connect tMDMDelete to tMDMRollback using a Trigger > OnComponentError link.

Configuring the MDM server connection

About this task

In this scenario, a tMDMConnection component is used to open an MDM server connection for convenient reuse in the subsequent subJob that performs the data record deletion task.

Procedure

1. Double-click tMDMConnection to display its Basic settings view and define the component properties.
   
   ![tMDMConnection](image)

   - **Basic settings**
     - MDM version: Server 6.0
     - URL: "http://localhost:8180/talendmdm/services/soap"
     - Username: "userName"
     - Password: 
     - Auto Commit

2. In the URL field, enter the MDM server URL, between quotation marks: for example, "http://localhost:8180/talendmdm/services/soap".
3. In the **Username** and **Password** fields, enter your user name and password to connect to the MDM server.

4. Double-click **tMDMCommit** to display its **Basic settings** view and define the component properties.

   ![tMDMCommit](image)

   This component commits the changes made to the database on successful completion of the proceeding subjob.

5. From the **Component List** list, select the component for the server connection you want to close if you have configured more than one MDM server connection. In this use case, there is only one MDM server connection open, so simply use the default setting.

6. Deselect the **Close Connection** check box if it is selected. In this example, the **tMDMClose** component closes the connection to the MDM Server.

7. Double-click **tMDMRollback** to display its **Basic settings** view and define the component properties.

   ![tMDMRollback](image)

   This component rolls back any changes and returns the database to its previous state if the proceeding subjob fails.

8. From the **Component List** list, select the component for the server connection you want to close if you have configured more than one MDM server connection. In this use case, there is only one MDM server connection open, so simply use the default setting.

9. Deselect the **Close Connection** check box if it is selected. In this example, the **tMDMClose** component closes the connection to the MDM Server.

10. Double-click **tMDMClose** to display its **Basic settings** view and define the component properties.

    The **tMDMClose** component is used to close the connection after the successful execution of the Job. You can also close the connection by selecting the **Close Connection** check box in the **tMDMCommit** and **tMDMRollback** components, but for the purposes of this scenario the **tMDMClose** component is used instead.
11. From the **Component List** list, select the component for the server connection you want to close if you have configured more than one MDM server connection. In this use case, there is only one MDM server connection open, so simply use the default setting.

### Configuring data retrieval

**Procedure**

1. Double-click **tMDMInput** to display its **Basic settings** view and define the component properties.

2. From the **Property Type** list, select **Built-in** to complete the fields manually. If you have stored the MDM connection information in the repository metadata, select **Repository** from the list and the fields will be completed automatically.

3. From the **Schema** list, select **Built-in** and click [...] next to **Edit schema** to open a dialog box. Here you can define the structure of the master data you want to read in the MDM hub.
4. The master data is collected in a three-column schema of the type **String**: Id, Name and Price. Click **OK** to close the dialog box and proceed to the next step.

5. Select the **Use an existing connection** check box, and from the **Component List** list that appears, select the component you have configured to open your MDM server connection.
   
   In this scenario, only one MDM server connection exists, so simply use the default selection.

6. In the **Entity** field, enter the name of the business entity that holds the data record(s) you want to read, between quotation marks. Here, we want to access the **Product** entity.

7. In the **Data Container** field, enter the name of the data container that holds the master data you want to read, between quotation marks. In this example, we use the **Product** container.

   **Note:**
   
   The **Use multiple conditions** check box is selected by default.

8. In the **Operations** table, define the conditions to filter the master data you want to delete as follows:
   
   a) Click the plus button to add a new line.
   b) In the **Xpath** column, enter the Xpath and the tag of the XML node on which you want to apply the filter, between quotation marks. This example works with the **Product** entity, so enter "Product/Name".
   c) In the **Function** column, select the function you want to use. In this scenario, use the **Contains** function.
   d) In the **Value** column, enter the value of your filter. This example is to filter the master data where the Name contains **mug**.

9. In the **Component** view, click **Advanced settings** to set the advanced parameters.
10. In the Loop XPath query field, enter the structure and the name of the XML node on which the loop is to be carried out, between quotation marks.

11. In the Mapping table and in the XPath query column, enter the name of the XML tag in which you want to collect the master data, next to the corresponding output column name, between quotation marks.

**Configuring data record deletion**

**Procedure**

1. In the design workspace, double-click the tMDMDelete component to display the Basic settings view and set the component properties.

2. From the Schema list, select Built-in and click the three-dot button next to the Edit Schema field to describe the structure of the master data in the MDM hub.
3. Click the plus button to the right to add one column of the type **String**. In this example, name this column *outputXML*. Click **OK** to close the dialog box and proceed to the next step.

4. Select the **Use an existing connection** check box, and from the **Component List** list that appears, select the component you have configured to open your MDM server connection.
   In this scenario, only one MDM server connection exists, so simply use the default selection.

5. In the **Entity** field, enter the name of the business entity that holds the master data you want to delete, the *Product* entity in this example.

6. In the **Data Container**, enter the name of the data container that holds the data to be deleted, *Product* in this example.

7. In the **Keys** table, click the plus button to add a new line. In the **Keys** column, select the column that holds the key of the *Product* entity. Here, the key of the *Product* entity is set on the *Id* field.

   **Note:**

   If the entity has multiple keys, add as many line as required for the keys and select them in sequential order.

8. If needed, select the **Fire Delete event** check box, so that the delete event will be generated and written into **UpdateReport**.

9. Select the **Logical delete** check box if you do not want to delete the master data permanently. This will send the deleted data to the Recycle bin. Once in the Recycle bin, the master data can be restored or permanently deleted. If you leave this check box clear, the master data will be permanently deleted.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl+S** to save your Job to ensure that all the parameters you have configured take effect.
2. Press **F6** to execute your Job.
Results

The master data with the Name containing "mug" have been deleted and sent to MDM Recycle bin.
**tMDMInput**

Reads data in an MDM Hub and thus makes it possible to process this data.

**tMDMInput Standard properties**

These properties are used to configure tMDMInput running in the Standard Job framework. The Standard tMDMInput component belongs to the Talend MDM family. The component in this framework is available in all Talend products.

**Basic Settings**

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Either Built in or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-in</strong></td>
<td>No property data stored centrally</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the repository file where properties are stored. The fields that follow are completed automatically using the fetched data</td>
</tr>
</tbody>
</table>

**Schema and Edit Schema**

A schema is a row description, it defines the number of fields that will be processed and passed on to the next component. The schema is either built-in or remote in the Repository.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Built-in**: The schema will be created and stored for this component only. Related Topic: see Talend Studio User Guide.

**Repository**: The schema already exists and is stored in the repository. You can reuse it in various projects and jobs. Related Topic: see Talend Studio User Guide.

**Use an existing connection**

Select this check box if you want to use a configured tMDMConnection component.

**MDM version**

By default, **Server 6.0** is selected. Although it is recommended to migrate existing jobs for this new version, the **Server 5.6** option is available to ease the process of the migration of your Jobs so as to keep them working without modification with a 6.0 server. To do so, an option on the
server must be enabled to accept and translate requests from such Jobs.

<table>
<thead>
<tr>
<th>URL</th>
<th>Type in the URL to access the MDM server.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Username and Password</td>
<td>Type in user authentication data for the MDM server. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Entity</td>
<td>Type in the name of the business entity that holds the data you want to read.</td>
</tr>
<tr>
<td>Data Container</td>
<td>Type in the name of the data container that holds the data you want to read.</td>
</tr>
<tr>
<td>Type</td>
<td>Select Master or Staging to specify the database on which the action should be performed.</td>
</tr>
</tbody>
</table>
| Use multiple conditions | Select this check box to filter the data using certain conditions. **Xpath**: Enter between quotes the path and the XML node to which you want to apply the condition. **Function**: Select the condition to be used from the list. Before using the conditions, bear in mind the following:

- Depending on the type of field the Xpath points to, only certain operators apply. For example, if the field is a boolean, only the Equal or Not Equal operators are appropriate.
- The operator Not Equal does not support multi-occurrence fields or complex type fields.

The following operators are available:

- Contains: Returns a result which contains the word or words entered. Note that full text search does not support special characters, for example, @, #, $.
- Contains the sentence: Returns one or more results which contain the sentence entered.
- Joins With: This operator is reserved for future use.
- Starts With: Returns a result which begins with the string entered.
- Equal: Returns a result which matches the value entered.
- Not Equal: Returns a result of any value other than the null value and the value entered.
- is greater than: Returns a result which is greater than the numerical value entered. Applies to number fields only.
- is greater or equal: Returns a result which is greater than or equal to the numerical value entered. Applies to number fields only.
- is lower than: Returns a result which is less than the numerical value entered. Applies to number fields only.
- is lower or equal: Returns a result which is less than or equal to the numerical value entered. Applies to number fields only.
- whole content contains: Performs a plain text search using the specified Xpath field in the selected data. |
If you enter an empty string "" in the XPath field and select whole content contains from the Function list, searches will be performed in all the fields of all entities in the selected data container.

- is empty or null: Returns an empty field or a null value.

**Value**: Enter between inverted commas the value you want to use. Note that if the value contains XML special characters such as /, you must also enter the value in single quotes ("ABC/XYZ") or the value will be considered as an XPath.

**Predicate**: Select a predicate if you use more than one condition.

The following predicates are available:

- Default: Interpreted as an and.
- or: One of the conditions applies.
- and: Both or all of the conditions apply.

The other predicates are reserved for future use and may be subject to unpredictable behavior.

If you clear this check box, you have the option of selecting particular IDs to be displayed in the ID value column of the IDS table.

**Note**: If you clear the Use multiple conditions check box, the Batch Size option in the Advanced Settings tab will no longer be available.

**Skip Rows**: Enter the number of lines to be ignored.

**Max Rows**: Maximum number of rows to be processed. If Limit = 0, no row is read or processed.

**Die on error**: Select this check box to skip the row in error and complete the process for error-free rows. If needed, you can retrieve the rows in error via a Row > Rejects link.

### Advanced settings

**Batch Size**: Number of lines in each processed batch.

**Note**: This option is not displayed if you have cleared the Use multiple conditions check box in the Basic settings view.

**Loop XPath query**: The XML structure node on which the loop is based.

**Mapping**

- **Column**: reflects the schema as defined in the Edit schema editor.
- **XPath query**: Type in the name of the fields to extract from the input XML structure.
- **Get Nodes**: Select this check box to retrieve the XML node together with the data.
### tMDMInput

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
<th>Select this check box to gather the processing metadata at the Job level as well as at each component level.</th>
</tr>
</thead>
</table>

### Global Variables

**Global Variables**

- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

- **NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

**Usage rule**

Use this component as a start component. It needs an output flow.

If an MDM entity has a large number of foreign key fields, it may take you a long time to query data records that pertain to the entity using the tMDMInput component.

For more information about the workaround, see the article How to read data effectively that pertains to an MDM entity with many foreign key fields on Talend Help Center (https://help.talend.com).

You can increase the timeout values for a Job using this component to help process a large number of data records. For more information, see advanced execution settings for JVM parameters on Talend Help Center (https://help.talend.com).

### Reading master data from an MDM hub

This scenario applies only to *Talend Open Studio for MDM, Talend MDM Platform and Talend Data Fabric*.

This scenario describes a two-component Job that fetches master data from an MDM server, and displays the data in the log console.
Prerequisites:

- Make sure the MDM server is up and running.
- You have imported the MDM demo project and loaded the sample data into the data container
  *Product* by running the Job *MDM_LoadAll*.

Creating a Job to read master data from MDM

Procedure

1. From the Palette, drop *tMDMInput* and *tLogRow* onto the design workspace.
2. Link the two components together using a *Row > Main* connection.

Configuring basic settings of *tMDMInput* to read master data from MDM

Procedure

1. Double-click *tMDMInput* to open the *Basic settings* view.

   ![Image of tMDMInput settings](image)

2. In the *Property Type* list, select *Built-In*.
3. In the *Schema* list, select *Built-In* and click the ... button next to *Edit schema* to open a dialog box and define the structure of the master data you want to read from the MDM server.

   In this example, three columns are defined to fetch three elements from the *Product* entity: *Name*, *Price*, and *Colors*.
4. After you have defined the schema, click OK to close this dialog box, and then click Yes in the Propagate dialog box to propagate the schema changes to tLogRow.

5. Enter the user name and password for accessing the MDM server.

6. In the Entity field, enter Product between quotes.

7. In the Data Container field, enter Product between quotes.

8. Select Master from the Type list.

9. Define the query conditions in the Operations area.
   
   In this example, we want to query the product data records whose names include Shirt.

   a) Click the [+] button to add a row.
   
   b) Enter Product/Name between quotes in the Xpath field.

   Apart from elements defined in entities, you can query metadata elements which are also known as built-in elements. To query metadata elements from records in master database, you need to follow the format of metadata:<timestamp|task_id> when defining the path expression to select the XML node to run the query on.

   c) Select Contains from the Function list.
   
   d) Enter Shirt between quotes in the Value field.

### Configuring advanced settings of tMDMInput to read master data from MDM

**Procedure**

1. In the Component view, click the Advanced settings tab.
2. In the Loop XPath query field, enter /Product between quotes on which the loop is based.

3. In the XPath query column of the Mapping table, enter the name of the XML node from which you want to collect the master data, next to the corresponding output column name.

4. Select the Get Nodes check box for the Colors row to retrieve the XML node together with its data.

**Configuring the data display mode and executing the Job**

**Procedure**

1. Double-click the tLogRow component to display its Basic settings view.

2. In the Mode area, select Table (print values in cells of a table) for better readability of the result.

3. Save the Job and press F6 to run it.

The Product data records whose names include "Shirt" are displayed on the console with the values of three specified columns.

```
<table>
<thead>
<tr>
<th>Name</th>
<th>Price</th>
<th>Colors</th>
</tr>
</thead>
<tbody>
<tr>
<td>Talent Dog T-Shirt</td>
<td>16.99</td>
<td>&lt;Colors&gt;White&lt;/Color&gt;Light Pink&lt;/Color&gt;&lt;/Colors&gt;</td>
</tr>
<tr>
<td>Talent Golf Shirt</td>
<td>16.99</td>
<td>&lt;Colors&gt;White&lt;/Color&gt;&lt;/Colors&gt;</td>
</tr>
<tr>
<td>Talent Fitted T-Shirt</td>
<td>15.99</td>
<td>&lt;Colors&gt;White&lt;/Color&gt;Light Blue&lt;/Color&gt;&lt;/Colors&gt;</td>
</tr>
</tbody>
</table>
```
tMDMOutput

Writes data into or removes data from the MDM server.

tMDMOutput receives data from the preceding component, generates an XML document, and then writes data in an MDM Hub using an output field.

**tMDMOutput Standard properties**

These properties are used to configure tMDMOutput running in the Standard Job framework.

The Standard tMDMOutput component belongs to the Talend MDM family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Either Built-in or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Built-in</strong>: No property data stored centrally</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: Select the repository file where the properties are stored. The fields which follow are filled in automatically using the fetched data.</td>
</tr>
</tbody>
</table>

**Input Schema and Edit schema**

An input schema is a row description, it defines the number of fields that will be processed and passed on to the next component. The schema is either built-in or remote in the Repository.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

Click **Sync columns** to collect the schema from the previous component.

**Built-in**: You create the schema and store it locally for this component only. Related topic: see *Talend Studio User Guide*.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and job designs. Related topic: see *Talend Studio User Guide*.
| **Build the document** | Select this check box if you want to build the document from a flat schema. If this is the case, double-click the component and map your schema in the dialog box that opens.

If the check box is not selected, you must select the column in your schema that contains the document from the **Predefined XML document** list. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Result of the XML serialization</strong></td>
<td>Lists the name of the XML output column that will hold the XML data.</td>
</tr>
<tr>
<td><strong>Use an existing connection</strong></td>
<td>Select this check box if you want to use a configured <strong>tMDMConnection</strong> component.</td>
</tr>
<tr>
<td><strong>MDM version</strong></td>
<td>By default, <strong>Server 6.0</strong> is selected. Although it is recommended to migrate existing Jobs for this new version, the <strong>Server 5.6</strong> option is available to ease the process of the migration of your Jobs so as to keep them working without modification with a 6.0 server. To do so, an option on the server must be enabled to accept and translate requests from such Jobs.</td>
</tr>
<tr>
<td><strong>URL</strong></td>
<td>Type in the URL of the MDM server.</td>
</tr>
</tbody>
</table>
| **Username and Password** | Type in the user authentication data for the MDM server. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.  

**Note:**
Ensure that the user has been assigned a role in **Talend MDM** enabling him or her to connect through a Job or any other web service call. For further information, see **Talend Studio User Guide**. |
| **Data Model** | Type in the name of the data model against which the data to be written is validated. |
| **Data Container** | Type in the name of the data container where you want to write the master data.  

**Note:**
This data container must already exist. |
| **Type** | Select **Master** or **Staging** to specify the database on which the action should be performed. |
| **Return Keys** | **Columns corresponding to IDs in order:** in sequential order, set the output columns that will store the return key values (primary keys) of the item(s) that will be created. |
| **Is Update** | Select this check box to update the modified fields. If you leave this check box unchecked, all fields will be replaced by the modified ones. |
| Fire a Create/Update event | Select this check box to add the actions carried out to a modification report.  
**Source Name:** Between quotes, enter the name of the application to be used to carry out the modifications.  
**Enable verification by before saving process:** Select this check box to verify the commit that has been just added, prior to saving.  
**Note:** The insert/update operation will fail, without any indication, if the Enable verification by before saving process check box is selected and the validation of the data record is not successful.  
For more information about the Before Saving process, see Talend Studio User Guide. |
| --- | --- |
| Use partial update | Select this check box if you need to update multi-occurrence elements (attributes) of an existing item (entity) based on the content of a source XML stream.  
Once selected, you need to set the parameters presented below:  
- **Pivot:** type in the xpath to the multi-occurrences sub-element where data need to be added, replaced or deleted in the item of interest.  
For example, if you need to add a child sub-element to the below existing item:  
```
<Person>
  <Id>1</Id> <!-- record key is mandatory -->
  <Children>
    <Child>[1234]</Child> <!-- FK to a Person Entity -->
  </Children>
</Person>
```
then the Xpath you enter in this **Pivot** field must read as follows: /Person/Children/Child where the **Overwrite** check box is cleared.  
And, if you need to replace a child sub-element in an existing item:  
```
<Person>
  <Id>1</Id>  
  <Addresses>
    <Address>
      <Type>office</Type>  
      (...address elements are here....)
    </Address>
    <Address>
      <Type>home</Type>  
      (...address elements are here....)
    </Address>
  </Addresses>
</Person>
```
then the Xpath you enter in this **Pivot** field must read as follows: /Person/Addresses/Address where the **Overwrite** check box is selected, and the **Key** field is set to /Type.
In such an example, assuming the item in MDM only has an office address, the office address will be replaced, and the home address will be added.

- **Overwrite**: select this check box if you need to replace or update the original sub-elements with the input sub-elements. Leave unselected if you want to add a sub-element.

- **Key**: type in the xpath relative to the pivot that will help match a sub-element of the source XML with a sub-element of the item. If a key is not supplied, all sub-elements of an item with an XPath matching that of the sub-element of the source XML will be replaced. If more than one sub-element matches the key, MDM will update the first one it encounters. If no sub-elements match the key, it is added at the end of the collection.

- **Position**: type in a number to indicate the position after which the new elements (those that do not match the key) will be added. If you do not provide a value in this field, the new element will be added at the end.

- **Delete**: select this check box if you need to remove one or more sub-elements from the original sub-elements.

For example, if you need to remove two houses from the existing item below:

```xml
<Person>
  <Id>1</Id>
  <Name>p1</Name>
  <Houses>
    <House>[1]</House>
    <House>[3]</House>
  </Houses>
  <Children>
    <Child>
      <Name>k1</Name>
      <Age>1</Age>
      <Habits>
        <Habit>Basketball</Habit>
        <Habit>Football</Habit>
        <Habit>Tennis</Habit>
        <Habit>Boxing</Habit>
      </Habits>
    </Child>
    <Child>
      <Name>k2</Name>
      <Age>2</Age>
    </Child>
  </Children>
</Person>
```

then the XPath you enter in this **Pivot** field must read as follows: `/Person/Houses/House` where the **Delete** check box is selected, and the **Key** field is set to **empty**. Moreover, you need to provide the source XML stream as follows:

```xml
<Person>
  <Id>1</Id>
  <Houses>
    <House>[1]</House>
  </Houses>
</Person>
```

In this case, the House [1] and House [2] will be deleted.
For more examples of the partial update operations, see Examples of partial update operations using tMDMOutput on page 2126.

| **Die on error** | Select this check box to skip the row in error and complete the process for error-free rows. If needed, you can retrieve the rows in error via a Row > Rejects link. |

### Advanced settings

| **Extended Output** | Select this check box to commit master data in batches. You can specify the number of lines per batch in the **Rows to commit** field. |
| **Configure Xml Tree** | Opens the interface which helps create the XML structure of the master data you want to write. |
| **Group by** | Select the column to be used to regroup the master data. |
| **Create empty element if needed** | This check box is selected by default. If the content of the interface’s **Related Column** which enables creation of the XML structure is null, or if no column is associated with the XML node, this option creates an opening and closing tag at the required places. |
| **Advanced separator (for number)** | Select this check box to modify the number of separators used by default.  
- **Thousands separator**: enter between inverted commas the separator for thousands.  
- **Decimal separator**: enter between inverted commas the decimal separator. |
| **Generation mode** | Select the appropriate generation mode according to your memory availability. The available modes are:  
- **Slow and memory-consuming (Dom4j)**  
  **Note:**  
  This option allows you to use dom4j to process the XML files of high complexity.  
- **Fast with low memory consumption** |
| **Encoding** | Select the encoding type from the list or else select **Custom** and define it manually. This is an obligatory field for the manipulation of data on the server. |
| **tStatCatcher Statistics** | Select this check box to gather the processing metadata at the Job level as well as at each component level. |

### Global Variables

| **Global Variables** | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. |
**tMDMOutput**

<p>| <strong>NB_LINE</strong> | the number of rows processed. This is an After variable and it returns an integer. |</p>
<table>
<thead>
<tr>
<th><strong>NB_LINE_REJECTED</strong></th>
<th>the number of rows rejected. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
<td></td>
</tr>
<tr>
<td>To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.</td>
<td></td>
</tr>
<tr>
<td>For further information about variables, see <a href="https://help.talend.com">Talend Studio User Guide</a>.</td>
<td></td>
</tr>
</tbody>
</table>

**Usage**

**Usage rule**

Use this component to write a data record and separate the fields using a specific separator.

You can increase the timeout values for a Job using this component to help process a large number of data records. For more information, see advanced execution settings for JVM parameters on Talend Help Center ([https://help.talend.com](https://help.talend.com)).

**Examples of partial update operations using tMDMOutput**

The section will demonstrate how to set the parameters in the component tMDMOutput to perform the partial update operations with several examples.

**Partial update with Overwrite enabled or disabled**

The following two examples explain how to add some elements to an existing item (entity) with multi-occurrence elements (attributes) and then update the newly added elements based on the content of a source XML stream.

Given an existing item as follows:

```xml
<Person>
  <Id>1</Id>
  <Name>p1</Name>
  <Houses>
    <House>[1]</House>
    <House>[3]</House>
  </Houses>
  <Children>
    <Child>
      <Name>k1</Name>
      <Age>1</Age>
      <Habits>
        <Habit>Basketball</Habit>
        <Habit>Football</Habit>
        <Habit>Tennis</Habit>
        <Habit>Boxing</Habit>
      </Habits>
    </Child>
  </Children>
</Person>
```

---

2126
Example 1: If you want to add two Child items to the existing item, then the Xpath you enter in the Pivot field must read as follows: /Person/Children/Child where the Overwrite check box is cleared, and the Key field is set to /Name. Note that the Child element is of complex type, and needs to be identified with the Key field. Moreover, you need to provide the source XML stream as follows:

```
<Person>
  <Id>1</Id>
  <Children>
    <Child>
      <Name>k2</Name>
    </Child>
    <Child>
      <Name>k3</Name>
    </Child>
  </Children>
</Person>
```

In this case, the two child items Child [k2] and Child [k3] will be added, and you will get the following result:

```
<Person>
  <Id>1</Id>
  <Name>p1</Name>
  <Houses>
    <House>[1]</House>
    <House>[3]</House>
  </Houses>
  <Children>
    <Child>
      <Name>k1</Name>
      <Age>1</Age>
      <Habits>
        <Habit>Basketball</Habit>
        <Habit>Football</Habit>
        <Habit>Tennis</Habit>
        <Habit>Boxing</Habit>
      </Habits>
    </Child>
    <Child>
      <Name>k2</Name>
    </Child>
    <Child>
      <Name>k3</Name>
    </Child>
  </Children>
</Person>
```

Example 2: If you want to change the names of the two child items Child [k2] and Child [k3], then the Xpath you enter in the Pivot field must read as follows: /Person/Children/Child where the Overwrite check box is selected, and the Key field is set to /Name. Moreover, you need to provide the source XML stream as follows:

```
<Person>
  <Id>1</Id>
  <Children>
    <Child>
      <Name>Tina</Name>
    </Child>
    <Child>
      <Name>k2</Name>
    </Child>
    <Child>
      <Name>k3</Name>
    </Child>
  </Children>
</Person>
```
In this case, the names of the two child items Child [k2] and Child [k3] will be updated, and you will get the following result:

```
<Person>
  <Id>1</Id>
  <Name>p1</Name>
  <Houses>
    <House>[1]</House>
    <House>[3]</House>
  </Houses>
  <Children>
    <Child>
      <Name>k1</Name>
      <Age>1</Age>
      <Habits>
        <Habit>Basketball</Habit>
        <Habit>Football</Habit>
        <Habit>Tennis</Habit>
        <Habit>Boxing</Habit>
      </Habits>
    </Child>
    <Child>
      <Name>Tina</Name>
    </Child>
    <Child>
      <Name>Tommy</Name>
    </Child>
  </Children>
</Person>
```

**Partial update with Delete enabled**

The following examples show how to remove some elements from an existing item (entity) with multi-occurrence elements (attributes) based on the content of a source XML stream.

Given an existing item as follows:

```
<Person>
  <Id>1</Id>
  <Name>p1</Name>
  <Houses>
    <House>[1]</House>
    <House>[3]</House>
  </Houses>
  <Children>
    <Child>
      <Name>k1</Name>
      <Age>1</Age>
      <Habits>
        <Habit>Basketball</Habit>
        <Habit>Football</Habit>
        <Habit>Tennis</Habit>
        <Habit>Boxing</Habit>
      </Habits>
    </Child>
  </Children>
</Person>
```
Example 1: If you want to remove two child items from the existing item, then the Xpath you enter in the Pivot field must read as follows: /Person/Children/Child where the Delete check box is selected, and the Key field is set to /Name. Note that the Child element is of a complex type, and needs to be identified with the Key field. Moreover, you need to provide the source XML stream as follows:

```
<Person>
  <Id>1</Id>
  <Children>
    <Child>
      <Name>k2</Name>
    </Child>
    <Child>
      <Name>k3</Name>
    </Child>
  </Children>
  <Habits>
    <Habit>Basketball</Habit>
    <Habit>Football</Habit>
    <Habit>Tennis</Habit>
    <Habit>Boxing</Habit>
  </Habits>
  <Pets>
    <Pet>Cat</Pet>
    <Pet>Dog</Pet>
    <Pet>Pig</Pet>
    <Pet>Cow</Pet>
  </Pets>
</Person>
```

In this case, the two items Child [k2] and Child [k3] will be removed, and you will get the following result:

```
<Person>
  <Id>1</Id>
  <Children>
    <Child>
      <Name>k1</Name>
      <Age>1</Age>
      <Habits>
        <Habit>Basketball</Habit>
        <Habit>Football</Habit>
        <Habit>Tennis</Habit>
      </Habits>
    </Child>
  </Children>
</Person>
```
Example 2: If you want to remove some habits for the Person element, then the Xpath you enter in the Pivot field must read as follows: /Person/Habits/Habit where the Delete check box is selected, and the Key field is set to . or empty. Moreover, you need to provide the source XML stream as follows:

```xml
<Person>
  <Id>1</Id>
  <Habits>
    <Habit>Basketball</Habit>
    <Habit>Football</Habit>
    <Habit>Boxing</Habit>
  </Habits>
</Person>
```

In this case, the three habit items Habit [Basketball], Habit [Football] and Habit [Boxing] will be removed, and you will get the following result:

```xml
<Person>
  <Id>1</Id>
  <Name>p1</Name>
  ...
  <Habits>
    <Habit>Tennis</Habit>
  </Habits>
  ...
</Person>
```

Example 3: If you want to remove some habits for the Child [k1] element, then the Xpath you enter in the Pivot field must read as follows: /Person/Children/Child[1]/Habits/Habit where the Delete check box is selected, and the Key field is set to . or empty. Note that Child[1] is used in the Pivot field to identify the habits of which child will be removed. Moreover, you need to provide the source XML stream as follows:

```xml
<Person>
  <Id>1</Id>
  <Children>
    <Child>
      <Habits>
        <Habit>Basketball</Habit>
        <Habit>Football</Habit>
      </Habits>
    </Child>
  </Children>
</Person>
```

In this case, the two items Habit [Basketball] and Habit [Football] will be removed, and you will get the following result:

```xml
<Person>
  <Id>1</Id>
  <Name>p1</Name>
  ...
  <Children>
    <Child>
      <Name>k1</Name>
      <Age>1</Age>
    </Child>
  </Children>
</Person>
```
Example 4: If you want to remove some pets for the Person element, then the Xpath you enter in the Pivot field must read as follows: /Person/Pets where the Delete check box is selected, and the Key field is set to /Pet. Moreover, you need to provide the source XML stream as follows:

```
<Person>
  <Id>1</Id>
  <Pets>
    <Pet>Cat</Pet>
  </Pets>
  <Pets>
    <Pet>Pig</Pet>
  </Pets>
</Person>
```

In this case, the two items Pet [Cat] and Pet [Pig] will be removed, and you will get the following result:

```
<Person>
  <Id>1</Id>
  <Name>p1</Name>
  <Pets>
    <Pet>Dog</Pet>
    <Pet>Cow</Pet>
  </Pets>
</Person>
```

Writing master data in an MDM hub

This scenario applies only to Talend Open Studio for MDM, Talend MDM Platform and Talend Data Fabric.

This scenario describes a two-component Job that generates a data record, transforms it into XML and loads it into the defined business entity in the MDM server.
In this example, we want to load a new agency in the Agency business entity. This new agency has an id, a name and three offices located in different cities.

For more information about entities, see Talend Studio User Guide.

Dropping and linking the components

Procedure
1. From the Palette, drop tFixedFlowInput and tMDMOutput onto the design workspace.
2. Connect the components using a Row Main link.

Configuring the components

Preparing the data to be loaded into the MDM server

Procedure
1. Double-click tFixedFlowInput to view its Basic settings in the Component tab.
2. In the Schema list, select Built-In and then click the three-dot button next to Edit schema to open a dialog box in which you can define the structure of the master data you want to write on the MDM server.
3. Click the [+ ] button and add five columns of the type **String**.
   In this example, name the columns *Id*, *Name*, *Office_R_and_D*, *Office_Sales*, and *Office_Services*.

4. Click **OK** to validate your changes.

5. In the **Number of rows** field, enter the number of rows you want to generate.

6. In the **Mode** area, select the **Use Single Table** option.

7. In the **Value** fields, enter between quotes the values which correspond to each of the schema columns.

**Basic settings of tMDMOutput**

**Procedure**

1. In the design workspace, click **tMDMOutput** to open its **Basic settings** view.

2. In the **Input Schema** list, select **Built-In** and then click the [...] button next to the **Edit Schema** field to define the structure of the master data you want to load into the MDM server.
The tMDMOutput component basically generates an XML document, writes it in an output field, and then sends it to the MDM server.

3. Click OK to proceed to the next step. The Result of the XML serialization list in the Basic settings view is automatically filled in with the output xml column.

4. In the URL field, enter the URL to access the MDM server.

5. In the Username and Password fields, enter the authentication information required to connect to the MDM server.

6. In the Data Model field, enter between quotes the name of the data model against which you want to validate the master data you want to write.

7. In the Data Container, enter between quotes the name of the data container into which you want to write the master data.

8. Select the Is Update checkbox if you only want to update some fields rather than the entire data record.

Advanced settings of tMDMOutput

Procedure

1. In the Component view, click Advanced settings to set the advanced parameters for the tMDMOutput component.
2. Select the **Extended Output** check box if you want to commit master data in batches, and specify the number of lines per batch in the **Rows to commit** field.

   Click the [...] next to **Configure XML Tree** to open the tMDMOutput editor.

   Alternatively, double-click **tMDMOutput** to open the editor.

3. In the **Link target** area to the right, click in the **XML Tree** field and then replace **rootTag** with the name of the business entity into which you want to insert the data record, **Agency** in this example.
4. In the **Linker source** area, select the two schema columns *Id* and *Name* and drop them on the *Agency* node respectively.

   The **Selection** dialog box is displayed.

   Select the **Create as sub-element of target node** option so that the two columns are linked to the two XML sub-elements of the *Agency* node.

5. Right-click the root node *Agency* and then select **Add Sub-element**.

   In the dialog box that pops up, enter a name for the new sub-element, *Offices* in this example. Repeat the same procedure to create three new sub-elements *Office* for the *Offices* node which corresponds to the multi-occurrence element *Offices* of the business entity *Agency*.

6. In the **Linker source** area, select the three schema columns *Office_R_and_D*, *Office_Sales* and *Office_Services* and drop them on the three new *Office* nodes respectively.

   The **Selection** dialog box is displayed.

   Select the **Create as sub-element of target node** option so that the three columns are linked to the three XML sub-elements of the *Offices* node.

7. Click **Ok** to proceed to the next step.

8. Right-click the element in the **Link Target** area you want to set as a loop element and select **Set As Loop Element** from the contextual menu.

   In this example, *Id* is the iterating object.

9. Click **OK** to validate your changes and close the dialog box.

### Saving and executing the Job

**Procedure**

1. Press **Ctrl+S** to save your Job.

2. Execute the Job by pressing **F6** or clicking **Run** on the **Run** tab.

   The new data record is inserted in the *Agency* business entity in the *DStar* data container on the MDM server. This data records holds, as you defined in the schema, the agency id, the agency name and the agency offices located in three cities.
**Removing master data partially from the MDM hub**

This scenario applies only to Talend Open Studio for MDM, Talend MDM Platform and Talend Data Fabric.

The scenario describes how to partially remove the master data which has been written into the MDM server in the scenario Writing master data in an MDM hub on page 2131.

In this example, one agency office will be removed from the Agency business entity. The agency now has an id, a name and three offices located in different cities.
For more information about entities, see *Talend Studio User Guide*.

Dropping and linking the components

Procedure

1. From the **Palette**, drop **tFixedFlowInput** and **tMDMOutput** onto the design workspace.
2. Connect the components using a **Row Main** link.

Configuring the components

Specifying the data to be removed from the MDM server

Procedure

1. Double-click **tFixedFlowInput** to view its **Basic settings** in the **Component** tab.
   - In the **Schema** list, select **Built-In** and then click the three-dot button next to **Edit schema** to open a dialog box in which you can define the structure of the master data to be used for partially removing the master data on the MDM server.
3. Click the [+] button and add three columns of the type **String**.
   In this example, name the columns *Id*, *Name*, and *Remove_Office*.
4. Click **OK** to save your changes.
5. In the **Number of rows** field, enter the number of rows you want to generate.
6. In the **Mode** area, select the **Use Single Table** option.
7. In the **Value** fields, enter values which correspond to each of the schema columns.
   In this example, the office in *Paris* will be removed.

**Basic settings of tMDMOutput**

**Procedure**

1. In the design workspace, click **tMDMOutput** to open its **Basic settings** view.
2. In the Input Schema list, select Built-In and then click Sync columns. After receiving data from the previous component, the tMDMOutput component basically generates an XML document, writes it in an output field, and then sends it to the MDM server.

3. Click OK to proceed to the next step.
The Result of the XML serialization list in the Basic settings view is automatically filled in with the output xml column.

4. In the URL field, enter the URL to access the MDM server.

5. In the Username and Password fields, enter the authentication information required to connect to the MDM server.

6. In the Data Model field, enter between quotes the name of the data model against which you want to validate the master data you want to write.

7. In the Data Container, enter between quotes the name of the data container into which you want to write the master data.

8. In the Partial Update area, select the Use Partial Update check box.
   In the Source Name filed that pops up with your selection, enter the name to be used in the modification report.

9. In the Pivot field, enter the xpath to the multi-occurrence sub-element where data need to be removed.
   In this example, enter “Agency/Offices/Office”.

10. Select the Delete check box, and then enter “.” in the Key field.

Advanced settings of tMDMOutput

Procedure

1. In the Component view, click Advanced settings to set the advanced parameters for the tMDMOutput component.

2. Click the [...] next to Configure XML Tree to open the tMDMOutput editor. Alternatively, double-click tMDMOutput to open the editor.

3. In the Link target area to the right, click in the XML Tree field and then replace rootTag with the name of the business entity in which you want to remove data partially, Agency in this example.
4. In the **Linker source** area, select the two schema columns *Id* and *Name* and drop them on the **Agency** node.  
   The **Selection** dialog box is displayed.  
   Select the **Create as sub-element of target node** option so that the two columns are linked to the two XML sub-elements of the **Agency** node.

5. Right-click the root node **Agency** and then select **Add Sub-element**.  
   In the dialog box that pops up, enter a name for the new sub-element, **Offices** in this example.  
   Repeat the same procedure to create a new sub-element **Office** for the **Offices** node which corresponds to the multi-occurrence element **Offices** of the business entity **Agency**.

6. In the **Linker source** area, select the schema column whose corresponding data entry you want to remove, **Remove_Office** in this example, and drop it on the new **Office** node.  
   The **Selection** dialog box is displayed.  
   Select the **Create as sub-element of target node** option so that the column is linked to the XML sub-element of the **Offices** node.

7. Click **Ok** to proceed to the next step.

8. Right-click the element in the **Link Target** area you want to set as a loop element and select **Set As Loop Element** from the contextual menu.  
   In this example, **Id** is the iterating object.

9. Click **OK** to validate your changes and close the dialog box.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl+S** to save your Job.

2. Execute the Job by pressing **F6** or clicking **Run** on the **Run** tab.
   The agency office located in Paris with the agency Id PA05 is removed from the Agency business entity in the **DStar** data container on the MDM server.
tMDMReceive

Decodes a context parameter holding MDM XML data and transforms it into a flat schema.
tMDMReceive receives an MDM record in XML from MDM triggers or MDM processes.

**tMDMReceive Standard properties**

These properties are used to configure tMDMReceive running in the Standard Job framework.
The Standard tMDMReceive component belongs to the Talend MDM family.
The component in this framework is available in all Talend products.

### Basic Settings

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Either Built in or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Built-in</strong>: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: Select the repository file where properties are stored. The fields that follow are completed automatically using the fetched data.</td>
</tr>
</tbody>
</table>

#### Schema and Edit Schema

A schema is a row description, it defines the number of fields that will be processed and passed on to the next component. The schema is either built-in or remote in the Repository.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No upon completion** and choose this schema metadata again in the **Repository Content** window.

**Built-in**: The schema will be created and stored for this component only. Related Topic: see [Talend Studio User Guide](#).

**Repository**: The schema already exists and is stored in the repository. You can reuse it in various projects and jobs. Related Topic: see [Talend Studio User Guide](#).

**XML Record**

Enter the context parameter allowing to retrieve the last changes made to the MDM server. For more information about creating and using a context parameter, see [Talend Studio User Guide](#).
**XPath Prefix**

If required, select from the list the looping xpath expression which is a concatenation of the prefix + looping xpath.

**/item**: select this xpath prefix when the component receives the record from a process because processes encapsulate the record within an item element only.

**/exchange/item**: select this xpath prefix when the component receives the record from a trigger because triggers encapsulate the record within an item element which is within an exchange element.

<table>
<thead>
<tr>
<th>Loop XPath query</th>
<th>Set the XML structure node on which the loop is based.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Mapping</strong></td>
<td><strong>Column</strong>: reflects the schema as defined in the <strong>Edit schema</strong> editor.</td>
</tr>
<tr>
<td><strong>XPath query</strong>:</td>
<td>Type in the name of the fields to extract from the input XML structure.</td>
</tr>
<tr>
<td><strong>Get Nodes</strong>:</td>
<td>Select this check box to retrieve the XML node together with the data.</td>
</tr>
<tr>
<td><strong>Limit</strong></td>
<td>Maximum number of rows to be processed. If Limit = 0, no row is read or processed.</td>
</tr>
<tr>
<td><strong>Die on error</strong></td>
<td>This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a <strong>Row &gt; Reject</strong> link.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the processing metadata at the Job level as well as at each component level. |

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE</strong>: the number of rows processed. This is an After variable and it returns an integer.</td>
<td></td>
</tr>
<tr>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
<td></td>
</tr>
<tr>
<td>To fill up a field or expression with a variable, press <strong>Ctrl + Space</strong> to access the variable list and choose the variable to use from it.</td>
<td></td>
</tr>
<tr>
<td>For further information about variables, see <strong>Talend Studio User Guide</strong>.</td>
<td></td>
</tr>
</tbody>
</table>

**Usage**

| Usage rule | Use this component as a start component. It needs an output flow. |
Extracting information from an MDM record in XML

This scenario applies only to Talend Open Studio for MDM, Talend MDM Platform and Talend Data Fabric.

The following scenario describes a simple Job which will extract the information of interest from an MDM record in XML and display it on the console.

Scenario prerequisites

A data container Product and a data model Product are created and deployed to MDM server. The Product and Store data entities are defined and some data records already exist in them.

The entities Product and Store are linked by a foreign key which is the Name of the Store.

This example is designed to obtain the store information for a new product. Therefore, when you create a new Product record, make sure that the Store information is also added for the new Product record.

The entities and their attributes are shown below.

For more information about MDM working principles, see the MDM part in Talend Studio User Guide.
Dropping and linking the components

Procedure
1. Drop the following components from the Palette onto the design workspace: **tMDMReceive**, and **tLogRow**.
2. Connect **tMDMReceive** to **tLogRow** using a **Row > Main** link.
3. Rename the components to better identify their functions.

Configuring the components

Defining a context variable

Procedure
1. From the Contexts tab, click the [+] button to add one variable and name it **exchangeMessage**.
2. Fill in the variable value in the Value field.
   
   Note that the XML record must conform to a particular schema. For more information about the schema, see the description of processes and schemas used in MDM processes to call Jobs in *Talend Studio User Guide*. 
One sample of XML record from the Update Report is as follows:

```xml
<exchange xmlns:mdm="java:com.amalto.core.plugin.base.xslt.MdmExtension">
  <report>
    <Update>
      <UserName>administrator</UserName>
      <Source>genericUI</Source>
      <TimeInMillis>1381486872930</TimeInMillis>
      <OperationType>ACTION</OperationType>
      <RevisionID>null</RevisionID>
      <DataCluster>Product</DataCluster>
      <DataModel>Product</DataModel>
      <Concept>Product</Concept>
      <Key>2</Key>
    </Update>
  </report>
  <item>
    <Product>
      <Id>001</Id>
      <Name>Computer</Name>
      <Description>Laptop series</Description>
      <Availability>true</Availability>
      <Price>400</Price>
      <OnlineStore>TalendShop@http://www.cafepress.com/Talend.2</OnlineStore>
      <Stores>
        <Store>Dell</Store>
        <Store.Lenovo</Store>
      </Stores>
    </Product>
  </item>
</exchange>
```

In this example, the XML record is trimmed like this:

```xml
<exchange><report/><item><Product><Id>001</Id><Name>Computer</Name><Description>Laptop series</Description><Availability>true</Availability><Price>400</Price><OnlineStore>TalendShop@http://www.cafepress.com/Talend.2</OnlineStore><Stores><Store>Dell</Store><Store.Lenovo</Store></Stores></Product></item></exchange>
```

3. Press Ctrl+S to save your changes.

### Configuring tMDMReceive and tLogRow

**Procedure**

1. Double-click the tMDMReceive component to open its Basic settings view in the Component tab.
2. Click the [...] button next to Edit schema to define the desired data structure. In this example, three columns are added: Product_ID, Product_Name, and Store_Name.

3. In the XML Record field, fill in the context variable context.exchangeMessage.
4. From the XPath Prefix list, select "/exchange/item".
5. In the Loop XPath query field, type in the name of the XML tree root tag. In this example, type in "/Product/Stores/Store".
6. The Column column in the Mapping table is populated with the columns defined in the schema. In the XPath query column, enter the XPath query accordingly. In this example, the information of product ID, product name and store name will be extracted.
7. Double-click the tLogRow component to open its Basic settings view in the Component tab.
8. Select Table (print values in cells of a table) in the Mode area.

Saving and executing the Job

Procedure

1. Press Ctrl+S to save your Job.
2. Execute the Job by pressing F6 or clicking Run on the Run tab.
   The product information of interest extracted from the XML record is displayed on the console.

```
[statistics] connecting to socket on port 3838
[statistics] connected

Product_ID|Product_Name|Store_Name |
-----------|------------|-----------|
001        |Computer    |Dell       |
001        |Computer    |Lenovo     |

[statistics] disconnected

Job Product_info exited at 17:48 17/10/2013. [exit code=0]
```
tMDMRollback

Rolls back any changes made in the database rather than definitively committing them, for example to prevent partial commits if an error occurs.

tMDMRollback returns a database to its original state before a Job was run, instead of committing any changes.

**tMDMRollback Standard properties**

These properties are used to configure tMDMRollback running in the Standard Job framework.
The Standard tMDMRollback component belongs to the Talend MDM family.
The component in this framework is available in all Talend products.

### Basic settings

<table>
<thead>
<tr>
<th>Component List</th>
<th>Select the <strong>tMDMConnection</strong> component for which you want the rollback action to be performed.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Close Connection</td>
<td>Select this check box to close the session for this connection to the MDM Server after rolling back the changes. Note that even if you do not select this check box, the connection can still not be used in a subsequent subjob unless the Autocommit mode has been enabled.</td>
</tr>
</tbody>
</table>

### Advanced settings

| tStatCatcher Statistics | Select this check box to gather the processing metadata at the Job level as well as at each component level. |

### Global Variables

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

### Usage

| Usage rule | This component is to be used along with the **tMDMConnection**, **tMDMCommit**, **tMDMSP**, **tMDMViewSearch**, **tMDMInput**, **tMDMDelete**. |
Related scenario

For a related use case, see Deleting master data from an MDM Hub on page 2106.
tMDMRouteRecord

Helps Event Manager to identify the changes you have made on your data so that correlative actions can be triggered.

tMDMRouteRecord submits the primary key of a record stored in your MDM Hub to **Event Manager** in order for **Event Manager** to trigger the due process(es) against some specific conditions that you can define in the process or trigger pages of the MDM Studio.

For more information on **Event Manager**, see Talend Studio User Guide.

### tMDMRouteRecord Standard properties

These properties are used to configure tMDMRouteRecord running in the Standard Job framework.

The Standard tMDMRouteRecord component belongs to the Talend MDM family.

The component in this framework is available in all Talend products.

#### Basic Settings

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box if you want to use a configured tMDMConnection component.</th>
</tr>
</thead>
<tbody>
<tr>
<td>MDM version</td>
<td>By default, <strong>Server 6.0</strong> is selected. Although it is recommended to migrate existing Jobs for this new version, the <strong>Server 5.6</strong> option is available to ease the process of the migration of your Jobs so as to keep them working without modification with a 6.0 server. To do so, an option on the server must be enabled to accept and translate requests from such Jobs.</td>
</tr>
<tr>
<td>URL</td>
<td>Type in the URL of the MDM server.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>Type in the user authentication data for the MDM server. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td>Data Container</td>
<td>Type in the name of the data container that holds the record you want <strong>Event Manager</strong> to read.</td>
</tr>
<tr>
<td>Type</td>
<td>Select <strong>Master</strong> or <strong>Staging</strong> to specify the database on which the action should be performed.</td>
</tr>
<tr>
<td>Entity Name</td>
<td>Type in the name of the business entity that holds the record you want <strong>Event Manager</strong> to read.</td>
</tr>
<tr>
<td>IDs</td>
<td>Specify the primary key(s) of the record(s) you want <strong>Event Manager</strong> to read.</td>
</tr>
</tbody>
</table>
Advanced settings

| tStatCatcher Statistics | Select this check box to gather the processing metadata at the Job level as well as at each component level. |

Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | Use this component as a start component. It needs an output flow. You can increase the timeout values for a Job using this component to help process a large number of data records. For more information, see advanced execution settings for JVM parameters on Talend Help Center (https://help.talend.com). |

Connections

| Connections | Outgoing links (from this component to another):
Row: Iterate
Trigger: Run if; On Component Ok; On Component Error, On Subjob Ok, On Subjob Error.
Incoming links (from one component to this one):
Row: Iterate;

Routing an update report record to Event Manager

This scenario applies only to Talend Open Studio for MDM, Talend MDM Platform and Talend Data Fabric.

In this scenario, the tMDMRouteRecord component is used to submit the primary key of an update report record to Event Manager so that a trigger is launched to call a Job which will print out the notification that a data record had been updated.
**Prerequisites**

- The MDM server is up and running.
- The MDM demo project has already been imported.
- The data container Product has already been populated with some data records.

For further information about how to create a data container and a data model, see your Talend Studio User Guide.

For further information about how to create a record and access its viewable attributes, see the Talend MDM Web UI User Guide.

**Creating a Job to notify users that a data record has been updated**

In this scenario, a Job called message is created with only one `tJava` component to inform the users of the update of an existing data record.

**Procedure**

1. Drop a `tJava` component onto the design workspace.
2. Double-click the component to display its Basic settings.
3. In the Code field, enter `System.out.println("------- A Product is Updated.--" + new java.util.Date());`.
4. Save your Job and deploy it to the MDM Server.

**Results**

For further information about the `tJava` component, see [tJava](#) on page 1804.

For further information about how to deploy a Job onto the MDM Server, see the Talend Studio User Guide.

**Generating a Job Caller Trigger and deploying it to the MDM server**

In this scenario, once the Job `message` is created, a trigger calling this Job can be generated.

**Procedure**

1. In the MDM Repository tree view, under the Job Designs node, right click the message Job.
2. In the contextual menu, select Generate Talend Job Caller Trigger, accept the default options and click Generate.
   
   A trigger used to call the message Job is generated and stored under Event Management > Trigger. Its name is CallJob_Message, and its Service JNDI Name is callJob.
3. In the Trigger XPath Expressions area, customize the conditions of the trigger according to your needs.

   In this example, add the following conditions:

<table>
<thead>
<tr>
<th>XPath</th>
<th>Operator</th>
<th>Value</th>
<th>Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Update/DataCluster</td>
<td>Matches</td>
<td>Product</td>
<td>C1</td>
</tr>
<tr>
<td>Update/DataModel</td>
<td>Matches</td>
<td>Product</td>
<td>C2</td>
</tr>
</tbody>
</table>
In the **Conditions** area, combine the conditions using the predicates.

In this example, enter the following:

```
C1 AND C2 AND C3
```

In this way, this Trigger will be executed on a record in the Update entity only when a Product data record has been updated.

5. Deploy the customized Trigger to the MDM server.

**Updating a data record in a specific data container**

**Procedure**

1. Log onto your Talend MDM Web UI.
   
   For further details about how to log onto the Talend MDM Web UI, see *Talend MDM Web UI User Guide*.

2. In the upper right corner of the web page, make sure the **Actions** panel is displayed.

3. In the **Domain Configuration** area, select the required data container and data model.
   
   In this example, select Product for both the data container and the data model.

4. Click **Save** to save your changes.

5. Go to the **Master Data Browser** page, and select the Product entity from the list.

6. Double-click one of the product records to display its viewable attributes in a new view dedicated to this product.
   
   In this example, open the product record *Talend Mug* with the Unique Id of 231035938.

7. Update one of the attribute values in the product record.
   
   In this example, update the record by selecting the **Availability** check box to make it available.

8. Click **Save** to validate this update.

**Accessing the Update Reports**

**Procedure**

1. In the **MDM Repository** tree view, double click **Data Container > System > UpdateReport** to open the **UpdateReport** view.

   An Update Report is a complete track of all create, update or delete actions on any master data.

   If the UpdateReport data container is not available, you may first have to import it from your MDM Server. For details of how to import system objects from the MDM Server to your local repository, see the Talend Studio User Guide.

2. Next to the **Entity** field of this view, click the **🔍** button to search all the action records in the **UpdateReport**.

   Note that the **Update** entity does not necessarily mean that the corresponding action recorded is update, since it is just the entity name defined by the data model of **UpdateReport** and may record different actions including create, delete, and update.
3. Locate the record that corresponds to your action of updating the data record as described in Updating a data record in a specific data container on page 2155.

The update report record will be routed to Event Manager, whose primary key is genericUI.1499236505686.

Setting up the Job to route the update report record to Event Manager

Procedure

1. In the Integration perspective, right-click Job Designs in the Repository tree view and select Create Standard Job in the contextual menu.
2. Enter RouteRecord in the Name field in the wizard that opens, and then click Finish.
3. Drop the tMDMRouteRecord component from the Palette onto the design workspace.
4. Double click this component to open its Component view.
5. In the URL field, enter the URL for accessing your MDM server.
   In this example, enter http://localhost:8180/talendmdm/services/soap.
6. In the Username and the Password fields, enter the credentials for accessing the MDM server.
7. In the Data Container field, enter the data container name that stores the record you want to route.
   It is UpdateReport in this example.
8. In the Entity Name field, enter the entity name that the record you want to route belongs to.
   It is Update in this example.
9. In the IDS area, click the plus button under the table to add a new line.
10. In the newly added line, fill in the primary key of the update report record to be routed to Event Manager, which was read earlier from the UpdateReport data container.
    In this example, the primary key is genericUI.1499236505686.

Saving and executing the Job

Procedure

1. Press Ctrl+S to save the Job.
2. Press F6 to run this Job.
   In this example, since the Product data record with the Unique Id of 231035938 is updated, the component tMDMRouteRecord submits the primary key of the corresponding update report record to the Event Manager. When the Event Manager checks this record and confirms that this record
meets the conditions in the trigger CallJob_Message’s configuration view, the Event Manager calls the trigger to invoke the message Job.

3. Verify the execution results of this Job by consulting the MDM server log to see that the notification ------- A Product is Updated.--- is printed out.

You can check the server log in one of the following ways:

- In the Server Explorer panel, right-click the connection to the server where MDM server is installed, and then click View Server Log. A Console opens displaying the most recent contents of the mdm.log file.
- You can also view the contents of the mdm.log file in a browser. For more information, see the Talend Studio User Guide.
- If you have direct access to the MDM server, you can also consult the file directly in the <$INSTALLDIR>/log directory, with INSTALLDIR indicating where the MDM server is installed.
tMDMSP

Offers a convenient way to centralize multiple or complex queries in an MDM Hub and calls the stored procedure easily.

### tMDMSP Standard properties

These properties are used to configure tMDMSP running in the Standard Job framework.

The Standard tMDMSP component belongs to the Talend MDM family.

The component in this framework is available in all Talend products.

#### Basic settings

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Schema and Edit Schema</strong></td>
<td>In SP principle, the schema is an input parameter. A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema of this component is read-only.</td>
</tr>
<tr>
<td><strong>Use an existing connection</strong></td>
<td>Select this check box if you want to use a configured tMDMConnection component.</td>
</tr>
<tr>
<td><strong>MDM version</strong></td>
<td>By default, <strong>Server 6.0</strong> is selected. Although it is recommended to migrate existing Jobs for this new version, the <strong>Server 5.6</strong> option is available to ease the process of the migration of your Jobs so as to keep them working without modification with a 6.0 server. To do so, an option on the server must be enabled to accept and translate requests from such Jobs.</td>
</tr>
<tr>
<td><strong>URL</strong></td>
<td>Type in the URL of the MDM server.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>Type in the user authentication data for the MDM server. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Data Container</strong></td>
<td>Type in the name of the data container that stores the procedure you want to call.</td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>Select Master or Staging to specify the database on which the action should be performed.</td>
</tr>
<tr>
<td><strong>Procedure Name</strong></td>
<td>Type in the exact name of the Stored Procedure.</td>
</tr>
<tr>
<td><strong>Parameters (in order)</strong></td>
<td>Click the Plus button and select the various <strong>Input Columns</strong> that will be required by the procedures.</td>
</tr>
</tbody>
</table>

**Note:**
The SP schema can hold more columns than there are parameters used in the procedure.
Advanced settings

| tStatCatcher Statistics | Select this check box to gather the processing metadata at the Job level as well as at each component level. |

Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | This component is used as intermediary component. It can be used as start component but only no input parameters are thus needed for the procedure to be called. An output link is required. You can increase the timeout values for a Job using this component to help process a large number of data records. For more information, see advanced execution settings for JVM parameters on Talend Help Center (https://help.talend.com). |

Connections

| Connections | Outgoing links (from this component to another):

Row: Main

Trigger: Run if; On Component Ok; On Component Error, On Subjob Ok, On Subjob Error.

Incoming links (from one component to this one):

Row: Main, Iterate;

Trigger: Run if, On Component Ok, On Component Error, On Subjob Ok, On Subjob Error

For further information regarding connections, see Talend Studio User Guide. |

Executing a stored procedure using tMDMSP

This scenario applies only to Talend Open Studio for MDM, Talend MDM Platform and Talend Data Fabric.
In this scenario, the Job first generates parameters and sends them to tMDMSP, which executes a predefined stored procedure, and then extracts data from the returned execution result and presents the extracted data in the console.

Prerequisites:

- Make sure the MDM server is up and running.
- You have imported the MDM demo project and loaded the sample data into the data container Product by running the Job MDM_LoadAll.
- You have created a store procedure called ProductSelection and deployed this stored procedure to the MDM server.

In this example, the stored procedure ProductSelection is designed to query two fields Name and Price of Product data records within a price range:

For more information on working with stored procedures, see Talend Studio User Guide.

Creating a Job to execute the stored procedure

Procedure

1. Drag and drop the following components onto the design workspace: tFixedFlowInput, tMDMSP, tExtractXMLField, and tLogRow.
2. Link the components using the Row > Main connections.

Configuring tFixedFlowInput to generate a price range

Procedure

1. Double-click tFixedFlowInput to open its Basic settings view.
2. Click the [...] button next to Edit schema to open the schema editor.

3. Click the [+] button to add two parameters min and max that are used to define the price range.

4. Click OK to close the schema editor.

5. In the Mode area, keep the default option Use Single Table, and enter 10 between quotes for the min parameter and 15 between quotes for the max parameter.

Configuring tMDMSP to execute the stored procedure

Procedure

1. Double-click tMDMSP to open its Basic settings view.
2. Enter the user name and password for accessing the MDM server.
3. In the Data Container field, enter Product between quotes.
4. In the Procedure Name field, enter ProductSelection between quotes.
5. In the Parameters table, click the [+ ] button to add two rows, and select min and max respectively.

Configuring tExtractXMLField to extract data from the returned execution result of the stored procedure

Procedure

1. Double-click tExtractXMLField to open its Basic settings view.
2. Click the [...] button next to Edit schema to open the schema editor.
3. Add two columns to define the structure of the output data: name and price.

4. Click OK to close the schema editor, and then click Yes in the Propagate dialog box.

5. In the Loop XPath query field, enter result between quotes on which the loop is based. Each result of the stored procedure has the following syntax: `<result><col0>val1</col1>...<colN>valn</colN></result>` (where colN is the nth column in the SELECT clause).

   Warning:
   If a null value exists in a data record to be returned by the execution result of the stored procedure, some inconsistencies will occur between the column number and the value for this column in the returned data record.

6. In XPath query column of the Mapping table, enter the exact node name on which the loop is applied: col0 and col1, respectively, between quotes.

**Configuring the data display mode and executing the Job**

**Procedure**

1. Double-click the tLogRow component to display its Basic settings view.
2. In the Mode area, select Table (print values in cells of a table) for better readability of the result.
3. Save the Job and press **F6** to run it.

   According to the stored procedure and the price range, the *Product* data records within the price range of 10 to 15 are displayed with the values of the *Name* and *Price* fields as expected.

<table>

</tbody>
</table>
tMDMTriggerInput

Reads the XML message (Document type) sent by MDM and passes the information to the component that follows.

Every time when you save a change in your MDM, the corresponding record is generated in XML format. At runtime, this component reads this record and sends the relative information to the following component. With tMDMTriggerInput, you do not need to configure your Job any more in order to communicate the data changes from MDM to your Job.

Note:
This component works alongside the new trigger service and process plug-in in MDM version 5.0 and higher. The MDM Jobs, triggers and processes developed in previous MDM versions remain supported. However, we recommend using this component when designing new MDM Jobs.

tMDMTriggerInput Standard properties

These properties are used to configure tMDMTriggerInput running in the Standard Job framework.
The Standard tMDMTriggerInput component belongs to the Talend MDM family.
The component in this framework is available in all Talend products.

Basic settings

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Either Built-in or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Built-in: No property data stored centrally. tMDMTriggerInput is expected to use this option in order to apply the default read-only schema. MDM_message is the only column of this schema.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file where properties are stored. The fields that follow are completed automatically using the fetched data. As tMDMTriggerInput provides a fixed read-only schema, you are expected to use the Built-in option.</td>
</tr>
</tbody>
</table>

Schema and Edit Schema

A schema is a row description, it defines the number of fields that will be processed and passed on to the next component. The schema is either built-in or remote in the Repository.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate
the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

**Built-in**: The schema will be created and stored for this component only. Related Topic: see Talend Studio User Guide.

This is the default option for tMDMTriggerInput. With this option, the read-only schema is used to deal with the XML-format MDM message.

**Repository**: The schema already exists and is stored in the repository. You can reuse it in various projects and jobs. Related Topic: see Talend Studio User Guide.

As tMDMTriggerInput provides a fixed read-only schema, you are expected to use the Built-in option.

**Advanced settings**

**tStatCatcher Statistics**

Select this check box to gather the processing metadata at the Job level as well as at each component level.

**Global Variables**

**Global Variables**

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

**Usage**

**Usage rule**

Use this component as a start component. It needs an output flow.

To receive the message from MDM, you need to deploy the Job using this component on your MDM server and generate the corresponding trigger and process in MDM to invoke this Job.

For further information about how to deploy a Job onto MDM server and how to generate a trigger or a process, see Talend Studio User Guide.

For further information about how to change a record in MDM, see Talend MDM Web UI User Guide.
Exchanging the event information about an MDM record

This scenario applies only to Talend Open Studio for MDM, Talend MDM Platform and Talend Data Fabric.

In this scenario, a four-component Job is used to exchange the event information about a product record. Using an MDM connection established from the Repository, this Job is called by an eligible trigger once you update an existing product record.

To replicate this scenario, accomplish the following tasks sequentially:

1. Create an MDM connection of the Receive type in the Repository of the Studio. This connection is to the MDM hub holding the record you want to update.
2. Create the Job to receive and send the MDM update message.
3. Generate the trigger to invoke this Job created.
4. Update a product record.

To create the MDM records, data model and data container used in this scenario, you can execute the Jobs in the MDM demo project in Talend Studio and then update the MDM server to deploy the objects thus created for them to be taken into account at runtime. You will use this server throughout this scenario.

You can search for further information about MDM event management, how to import a demo project and how to deploy objects to the MDM server on Talend Help Center (https://help.talend.com).

Creating an MDM connection to retrieve entities

Before you begin

Make sure the MDM server with which you need to communicate the update message is up and running.

Procedure

1. In the Integration perspective of Talend Studio, expand the Metadata node in the Repository.
2. Right-click the Talend MDM item and select Create MDM connection.
3. Enter the **Name** you want to use for this connection and if required, added the **Purpose** and the **Description** in the corresponding fields.
   For example, name this connection **Receive**.

4. In the **Next** step, enter the credentials for connecting to the MDM server which holds the record to be updated.
   Once you click the **Check** button and the connection is shown successful, the **Next** button becomes clickable.
5. In the Next step, select the Data model and the Data Container used by the record to be updated. In this scenario, the model and the container are both Product.
6. Click Finish to validate the creation. The connection created is displayed under the Metadata node in the Repository.

**Retrieving entities using the MDM connection**

**Procedure**

1. Right-click the connection created and from the contextual menu, select Retrieve Entity.
2. Select Receive MDM in the dialog box and click Next to continue.
3. Select the entity to be retrieved, and click Next.
   In this scenario, select Product, and the Name field is populated automatically.

4. Drop the elements you need to retrieve from the Source Schema area to the Target Schema area.
   In this scenario, the Features element is the field to be looped and the Id, Name and Description elements are the fields to be extracted.
5. Keep the default schema description and click **Finish** to finalize retrieving the schema of the **Product** entity.

You can see more information about the data container and the data model used by Talend MDM on Talend Help Center (https://help.talend.com).

**Creating a Job and linking the components for communicating the MDM message**

**Procedure**

1. Create a Job named **update_product**.
2. Drop **tMDMTriggerInput**, **tXMLMap**, **tMDMTriggerOutput** and **tLogRow** from Palette onto the workspace.
3. Right-click tMDMTriggerInput and from the contextual menu, select the Row > Main link to connect it to tXMLMap.

4. Do the same to connect tXMLMap to tMDMTriggerOutput, and name the connection output.

5. Double-click tMDMTriggerOutput to open its Component view.

6. Click the [...] button next to Edit schema to open the editor.

7. Select the single pre-defined column of tMDMTriggerOutput, and then click to reproduce this column on the input side (left).

8. Connect tMDMTriggerOutput to tLogRow using the Row > Main connection.

Configuring the transformation of the MDM message in the Job

Procedure

1. Double-click tXMLMap to open its editor.

2. In the table representing the input flow (upper left of the editor), right-click the column name MDM_Message on the top of the XML tree and select Import From Repository.

The Metadata wizard is displayed.

3. Select the entity schema ProductReceive retrieved earlier using the Receive MDM model, then click OK.

4. Click OK in the dialog box that prompts you to add the schema of the Update Report to the input XML tree.

This builds a complete input document for an MDM event. In the input XML tree, the Features element is set as the loop element automatically.
5. In the table representing the output flow (upper right of the editor), develop the output XML tree as presented in the figure below.

This tree is constructed depending on the required static model of the MDM output report. The XML construct required to return the validation-success message is `<report><message type="info">message</message></report>`, and the XML construct required to return the validation-failure message is `<report><message type="error">message</message></report>`.
6. Map the `OperationType` element on the input side to the `message` element on the output side.
   This will output the information about the type of the event occurring on the MDM record.
7. In the `Expression` column, enter "info" in the row corresponding to `@type`.
8. Click the pincer icon to display the output settings panel, and then set the `All in one` option to `true`.
9. Click OK to close the editor and validate these changes.
10. Double click `tLogRow` to open its `Component` view, then, click `Sync columns`.

**Deploying the Job onto the MDM server**

**Procedure**

1. Switch to the MDM perspective, and expand the `Job Designs` node in the MDM Repository tree view.
2. Right-click the Job `update_product` created previously in this scenario, and select `Deploy To...` from the contextual menu.
   The deployment wizard is displayed.
3. From the server list, select the MDM server you are using, and then click OK.
4. In the `Deploy to Talend MDM` window that pops up, keep the default settings: `Export type` is `Hosted (zip)` and `Context scripts` is `Default`.
   You can see more information about these settings on Talend Help Center ([https://help.talend.com](https://help.talend.com)).
5. Click Finish to validate these settings and start the deployment.
   When the deployment is done, a message box pops up to indicate that the deployment is successful.
6. Click OK to close this message box.
   A window pops up to indicate that the Job `update_product` is deployed successfully.
7. Click OK to finalize the deployment.
Generating the trigger used to call the Job

Procedure

1. Right-click the Job `update_product` and select `Generate Talend Job Caller Trigger` from the contextual menu.
2. In the pop-up window, keep the default settings for this scenario: `Integrated` and `Embedded`.
3. Click `Generate` to start the generation.
   Once done, a trigger named `CallJob_update_product` is displayed under the `Trigger` node in MDM Repository.
4. Right-click this trigger, and then select `Deploy To...` from the contextual menu to deploy it onto the MDM server.
5. In the pop-up wizard, select the server you are using, and click `OK`.
6. Click `OK` to finalize the deployment.

Updating a product record

Procedure

1. Log in to the web user interface.
2. In the `Actions` panel on the right side, select `Product` for both the `Data Container` and the `Data Model`.
3. In the `Master Data Browser` page, launch the search in the `Product` entity to list all the available product records.
4. Select the product record you need to update from the list, for example, `Talend Trucker Hat`.
   The details of this record are displayed in the `Product` tab view.
5. Update one of its attributes.
   In this example, update the price to `11.00` and then click `Save`.
   The message about the operation type of this event has been sent to the MDM server and this message is displayed on the window of this MDM server.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<root>
  <report>
    <message type="info">UPDATE</message>
  </report>
</root>
```
tMDMTriggerOutput

Receives an XML flow (Document type) from the preceding component in the Job.

tMDMTriggerOutput receives an XML flow to set an MDM message so that MDM retrieves this message at runtime. With this component, you do not need to configure your Job any more in order to communicate the data changes from MDM to your Job.

Note:
This component works alongside the new trigger service and process plug-in in MDM version 5.0 and higher. The MDM Jobs, triggers and processes developed in previous MDM versions remain supported. However, we recommend using this component when designing new MDM Jobs.

tMDMTriggerOutput Standard properties

These properties are used to configure tMDMTriggerOutput running in the Standard Job framework.
The Standard tMDMTriggerOutput component belongs to the Talend MDM family.
The component in this framework is available in all Talend products.

Basic settings

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Either Built-in or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Built-in: No property data stored centrally. tMDMTriggerOutput is expected to use this option in order to apply the default read-only schema. MDM_message is the only column of this schema.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file where properties are stored. The fields that follow are completed automatically using the fetched data. As tMDMTriggerOutput provides a fixed read-only schema, you are expected to use the Built-in option.</td>
</tr>
</tbody>
</table>

Schema and Edit Schema

A schema is a row description, it defines the number of fields that will be processed and passed on to the next component. The schema is either built-in or remote in the Repository.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- View schema: choose this option to view the schema only.
- Change to built-in property: choose this option to change the schema to Built-in for local changes.
- Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon
completion and choose this schema metadata again in the Repository Content window.

**Built-in**: The schema will be created and stored for this component only. Related Topic: see Talend Studio User Guide.

This is the default option for tMDMTriggerOutput. With this option, the read-only schema is used to deal with the XML-format MDM message.

**Repository**: The schema already exists and is stored in the repository. You can reuse it in various projects and jobs. Related Topic: see Talend Studio User Guide.

As tMDMTriggerOutput provides a fixed read-only schema, you are expected to use the Built-in option.

**Advanced settings**

**tStatCatcher Statistics**

Select this check box to gather the processing metadata at the Job level as well as at each component level.

**Global Variables**

**Global Variables**

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

**Usage**

**Usage rule**

Use this component as an end component. It needs an input flow.

To send message to MDM, you need to deploy the Job using this component on your MDM server and generate the corresponding trigger and process to invoke this Job in MDM.

For further information about how to deploy a Job onto MDM server and how to generate a trigger or a process, see Talend Studio User Guide.

**Related scenario**

For a related scenario, see Exchanging the event information about an MDM record on page 2167.
tMDMViewSearch

Retrieves the MDM records from an MDM hub by applying filtering criteria you have created in a specific view and puts out results in XML structure.

For more information on a view on which you can define filtering criteria, see *Talend Studio User Guide*.

**tMDMViewSearch Standard properties**

These properties are used to configure tMDMViewSearch running in the Standard Job framework.

The Standard tMDMViewSearch component belongs to the Talend MDM family.

The component in this framework is available in all *Talend products*.

**Basic settings**

| Schema and Edit Schema | A schema is a row description, it defines the number of fields that will be processed and passed on to the next component. The schema is either *Built-in* or remote in the *Repository*.
|------------------------|--------------------------------------------------------------------------------------------------|
|                        | Click **Edit schema** to make changes to the schema. If the current schema is of the *Repository* type, three options are available:
|                        | • **View schema**: choose this option to view the schema only.
|                        | • **Change to built-in property**: choose this option to change the schema to *Built-in* for local changes.
|                        | • **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the *Repository Content* window.
|                        | Click **Sync columns** to collect the schema from the previous component.
| Built-in | *Built-in*: You create the schema and store it locally for this component only. Related topic: see *Talend Studio User Guide*.
| Repository | *Repository*: You have already created the schema and stored it in the Repository. You can reuse it in various projects and job designs. Related topic: see *Talend Studio User Guide*.
| XML Field | Select the name of the column in which you want to write the XML data.
| Use an existing connection | Select this check box if you want to use a configured tMDMConnection component.
| MDM version | By default, *Server 6.0* is selected. Although it is recommended to migrate existing Jobs for this new version, the *Server 5.6* option is available to ease the process of the...
migration of your Jobs so as to keep them working without modification with a 6.0 server. To do so, an option on the server must be enabled to accept and translate requests from such Jobs.

<table>
<thead>
<tr>
<th>URL</th>
<th>Type in the URL of the MDM server.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Username and Password</td>
<td>Type in the user authentication data for the MDM server. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Data Container</td>
<td>Type in the name of the data container that holds the master data you want to read.</td>
</tr>
<tr>
<td>Type</td>
<td>Select Master or Staging to specify the database on which the action should be performed.</td>
</tr>
<tr>
<td>View Name</td>
<td>Type in the name of the view whose filters will be applied to process the records.</td>
</tr>
</tbody>
</table>

**Operations**

Complete this table to create the WHERE clause. The parameters to be set are:
- **XPath**: define the path expression to select the XML node at which point the filtering is operated.
- **Functions**: select an operator from the drop-down list, like Contains, Starts with, Equals, etc.
- **Value**: enter the value you want to retrieve. The value can be a string (for example, "Apple"), an Entity element (for example, "Product/Name") or a user-based variable (for example, "${user_context.language" or "${user_context.properties['location']}").
- **Predicate**: select the predicate to combine the filtering conditions in different manners. The predicate may be none, or, and, exactly, etc.

**Warning:**
The parameters are case sensitive.

For more information about the operators and the predicates, see tMDMInput Standard properties on page 2114.

**Order (One Row)**

Complete this table to decide the presentation order of the retrieved records. The parameters to be set are:
- **XPath**: define the path expression to select the XML node at which point the sorting operation is performed.
- **Order**: select the presentation order that may be asc (ascending) or desc (descending).

**Warning:**
The parameters are case sensitive.
Warning:
For the time being, only the first row created in the Order table is valid.

<table>
<thead>
<tr>
<th>Spell Threshold</th>
<th>Set it to -1 to deactivate this threshold. This threshold is used to decide the spell checking level.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Skip Rows</td>
<td>Type in the count of rows to be ignored to specify from which row the process should begin. For example, if you type 8 in the field, the process will begin from the 9th row.</td>
</tr>
<tr>
<td>Max Rows</td>
<td>Type in the maximum number of rows to be processed. If Limit = 0, no row is read or processed. By default, the limit is -1, meaning that no limit is set.</td>
</tr>
</tbody>
</table>

**Advanced settings**

<th>Batch Size</th>
<th>Number of lines in each processed batch. By default, the batch size is set to -1, meaning that all the lines are processed in one batch.</th>
</tr>
</thead>
<tbody>
<tr>
<td>tStatCatcher Statistics</td>
<td>Select this check box to gather the processing metadata at the Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERROR_MESSAGE</td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td>NB_LINE</td>
<td>the number of rows processed. This is an After variable and it returns an integer. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
</tbody>
</table>

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

**Usage**

**Usage rule** 
Use this component to retrieve specific records.

You can increase the timeout values for a Job using this component to help process a large number of data records. For more information, see advanced execution settings for JVM parameters on Talend Help Center (https://help.talend.com).

**Connections**

Outgoing links (from this component to another):

**Row:** Iterate
Retrieving records from an MDM hub via an existing view

This scenario applies only to Talend Open Studio for MDM, Talend MDM Platform and Talend Data Fabric.

This scenario describes a two-component Job that retrieves a data record in XML structure.

In this example, you will select the T-shirt information from the Product entity via the Browse_items_Product view created from Talend Studio. Each record in the entity contains the details defined as filtering criteria: Id, Name, Description and Price.

- From the Palette, drop tMDMViewSearch and tLogRow onto the design workspace.
- Connect the components using a Row Main link.
- Double-click tMDMViewSearch to view its Basic settings, in the Component tab and set the component properties.
• In the **Schema** list, select **Built-In** and click the three-dot button next to **Edit schema** to open a dialog box in which you can define the structure of the XML data you want to write in.

• Click the plus button and add one column of the type **String**. Name the column as **Tshirt**.

• Click **OK** to validate your creation and proceed to the next step.

• In the **XML Field** field, select **Tshirt** as the column you will write the retrieved data in.

• Use your MDM server address in the **URL** field and type in the corresponding connection data in the **Username** and the **Password** fields. In this example, use the default url, then enter **admin** as username as well as password.

• In the **Data Container** field, type in the container name: **Product**.

• In the **View Name** field, type in the view name: **Browse_item_Product**.

• Below the **Operations** table, click the plus button to add one row in this table.
• In the Operations table, define the XPath as Product/Name, meaning that the filtering operation will be performed at the Name node, then select Contains in the Function column and type in Tshirt in the Value column.

• Below the Order (One Row) table, click the plus button to add one row in this table.

• In the Order (One Row) table, define the XPath as Product/Id and select the asc order for the Order column.

• In the design workspace, click tLogRow to open its Basic settings view and set the properties.

[Image]

• Next to the three-dot button used for editing schema, click Sync columns to acquire the schema from the preceding component.

• Press F6 to execute the Job.

```
<result>
  <Id>1</Id>
  <Name>Tshirt-V</Name>
  <Description>green</Description>
  <Price>16.00</Price>
</result>
<result>
  <Id>2</Id>
  <Name>Tshirt-G</Name>
  <Description>Green</Description>
  <Price>17.00</Price>
</result>
```

In the console docked in the Run view, you can read the retrieved Tshirt records in XML structure, which are sorted in the ascending order.
tMemorizeRows

Memorizes a sequence of rows that passes through and allows the following component(s) to perform operations of your choice on the memorized rows.

tMemorizeRows temporarily memorizes an array of incoming data in a row by row sequence and instantiates this array by indexing each of the memorized rows from 0. The maximum number of rows to be memorized at any given time is defined in the Basic settings view.

tMemorizeRows Standard properties

These properties are used to configure tMemorizeRows running in the Standard Job framework. The Standard tMemorizeRows component belongs to the Misc family. The component in this framework is available in all Talend products.

Basic settings

<table>

| **Schema and Edit schema**     | A schema is a row description, it defines the number of fields that will be processed and passed on to the next component. The schema is either built-in or remote in the Repository. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
  • View schema: choose this option to view the schema only.  
  • Change to built-in property: choose this option to change the schema to Built-in for local changes.  
  • Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. Click Sync columns to retrieve the schema from the previous component connected in the Job. |
| **Built-in**                    | The schema will be created and stored locally for this component only. Related topic: see Talend Studio User Guide.                                                                |
| **Repository**                 | You have already created the schema and stored it in the Repository, hence can be reused in various projects and job designs. Related topic: see Talend Studio User Guide. |
| **Row count to memorize**      | Define the row count to be memorized.                                                                                                                                                       |
| **Columns to memorize**        | Select the columns to be memorized from the incoming data schema.                                                                                                                         |
Advanced settings

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

Global Variables

| Global Variables | NB_LINE_ROWS: the number of rows memorized. This is an After variable and it returns an integer.  
ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.  
For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | This component can be used as intermediate step in a data flow or the last step before beginning a subjob.  
Note: You can use the global variable NB_LINE_ROWS to retrieve the value of the Row count to memorize field of the tMemorizeRows component. |

Connections

| Outgoing links (from this component to another):  
Row: Main  
Trigger: Run if; On Component Ok; On Component Error.  
Incoming links (from one component to this one):  
Row: Main;  
For further information regarding connections, see Talend Studio User Guide. |

Retrieving the different ages and lowest age data

This scenario displays the number of occurrences of different ages and the lowest age within a group of customers. In this scenario, the customer data is entered manually.

You will see two ways to handle this data with the tMemorizeRows:

- Inside the same subJob (with the tJavaFlex)
- Outside the tMemorizeRows subJob (with the tJava)
This Job uses five components:

- **tFixedFlowInput**: it contains rows of customer data such as IDs, names and ages of the customers.
- **tSortRow**: it sorts the rows according to the age data.
- **tMemorizeRows**: it temporarily memorizes a specific number of incoming data rows at any given time and indexes the memorized data rows.
- **tJavaFlex**: it compares the age values of the data memorized by the preceding component, counts the occurrences of different ages and displays these ages in the Run view.
- **tJava**: it displays the number of occurrences of different ages and the lowest age.

To replicate this scenario, proceed as follows:

**Dropping and linking the components**

**Procedure**

1. Drop a **tFixedFlowInput**, a **tSortRow**, a **tMemorizeRows**, a **tJavaFlex** and a **tJava** component by typing their names in the design workspace or dropping them from the Palette.
2. Connect the **tFixedFlowInput** component to the **tSortRow** component using a **Row > Main** connection.
3. Do the same to link the **tSortRow** component to the **tMemorizeRows** component and the **tMemorizeRows** component to the **tJavaFlex** component.
4. Connect the **tFixedFlowInput** component to the **tJava** component using the **Trigger > OnSubjobOk** connection.

**Configuring the components**

**Configuring the tFixedFlowInput component**

**Procedure**

1. Double-click the **tFixedFlowInput** component to open its **Basic settings** view on the **Component** tab.
2. Click the [...] button next to Edit schema to open the Schema dialog box and define the data structure of the input data.

3. In this editor, click the [+] button three times to add three columns and name them id, name and age.

4. In the Type column, select Integer for id and age.

5. Click OK to close the editor, then click Yes to validate these changes and accept the propagation prompted by the dialog box that pops up.

6. Select Use Inline Content (delimited file) in the Mode area.

   In the Content field, enter the following customer data:

   1;Judy;27
   2;Lily;45
   3;Peter;59
   4;John;30
   5;Teddy;45
Configuring the `tSortRow` component

Procedure

1. Double-click the `tSortRow` to open its **Basic settings** view on the **Component** tab.

   ![tSortRow_1](image)

   - **Criteria**
     - Schema column: age
     - **sort num or alpha?** column: num
     - **Order asc or desc?** column: desc

   ![Criteria](image)

2. In the **Criteria** table, click the `[+]` button to add one row.

3. In the **Schema column** column, select the data column on which the sorting operation is based. In this example, select **age** as it is the ages that should be compared and counted.

4. In the **sort num or alpha?** column, select **num**, which means numerical, as **age** contains integer data.

5. In the **Order asc or desc?** column, select **desc** to display data on the console in descending order.

Configuring the `tMemorizeRows` component

Procedure

1. Double-click the `tMemorizeRows` component to open its **Basic settings** view on the **Component** tab.

   ![tMemorizeRows_1](image)

   - **Row count to memorize** field: 2
   - **Columns to memorize**
     - **Memorize**
       - **Column**
         - id
         - name
         - age

   ![Row count to memorize](image)

2. In the **Row count to memorize** field, type in the maximum number of rows to be memorized at any given time. As in this example you need to compare ages of two customers for each time, enter 2. This component memorizes two rows at maximum at any given moment and always indexes the new incoming row as 0 and the previous incoming row as 1.

3. In the **Memorize** column of the **Columns to memorize** table, select the check box(es) to determine the column(s) to be memorized. In this example, select the check box corresponding to **age**.
Configuring the tJavaFlex and tJava components

Procedure

1. Double-click the tJavaFlex component to open its Basic settings view on the Component tab.

   ![tJavaFlex component settings](image)

   - **Start code**: `int count=0;`
   - **Main code**: `if(!age_tMemorizeRows_1[0].equals(age_tMemorizeRows_1[1])) {
     count++;
   } System.out.println(age_tMemorizeRows_1[0]);`

   This code compares two ages memorized by the tMemorizeRows component each time and counts one change every time the ages are found to be different. This code then displays the age that has been indexed as 0 by the tMemorizeRows component. When the tJavaFlex component is in the same flow of the tMemorizeRows component, the variable format is ColumnName_ComponentName[index].

2. In the **Start code** area, enter the Java code that will be called during the initialization phase. In this example, type in `int count=0;` in order to declare a variable `count` and assign the value 0 to it.

3. In the **Main code** area, enter the Java code to be applied to each row in the data flow. In this scenario, type in: `if(!age_tMemorizeRows_1[0].equals(age_tMemorizeRows_1[1])) {
  count++;
} System.out.println(age_tMemorizeRows_1[0]);` This code compares two ages memorized by the tMemorizeRows component each time and counts one change every time the ages are found to be different. This code then displays the age that has been indexed as 0 by the tMemorizeRows component. When the tJavaFlex component is in the same flow of the tMemorizeRows component, the variable format is ColumnName_ComponentName[index].

4. In the **End code** area, enter the Java code that will be called during the closing phase. In this example, type in `globalMap.put("number", count);` to initialize the global variable `number` with the value of the `count` variable.
5. Double-click the **tJava** component to open its **Basic settings** view on the **Component** tab.

![Component settings]

6. In the **Code** area, enter the following code to display the number of occurrences of different ages and the lowest age within the customers on the console:

```java
System.out.println("Different ages: "+globalMap.get("number"));
System.out.println("Lowest age: " + ((Integer[])globalMap.get("tMemorizeRows_1_age")[0]);
```

The method `globalMap.get()` is used by the **tJava** to retrieve the array values. Note that here, the **tJava** is used outside the subjob **tMemorizeRows** so the variable format should be `ComponentName_ColumnName`, which is different from the variable format used by a component placed in the same flow.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl+S** to save your Job.
2. Press **F6**, or click **Run** on the **Run** console to execute the Job.

![Console output]

**Results**

In the console, you can read that there are four different ages and that the lowest age is 27 within the group of customers.
tMemSQLClose

Closes the transaction committed in the MemSQL database.

**tMemSQLClose Standard properties**

These properties are used to configure tMemSQLClose running in the Standard Job framework.

The Standard tMemSQLClose component belongs to the Big Data and the Databases families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tMemSQLConnection component in the list if more than one connection are planned for the current Job.</td>
</tr>
</tbody>
</table>

### Advanced settings

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

### Global Variables

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
  A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
  To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
  For further information about variables, see Talend Studio User Guide. |

### Usage

| Usage rule | This component is to be used along with the other MemSQL components, especially with tMemSQLConnection. |
Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenario

For a related scenario, see Writing data to and reading data from a MemSQL database table on page 2198.
tMemSQLConnection

Opens a connection to the specified database that can then be reused in the subsequent subjob or subjobs.

**tMemSQLConnection Standard properties**

These properties are used to configure tMemSQLConnection running in the Standard Job framework.
The Standard tMemSQLConnection component belongs to the Big Data and the Databases families.
The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

<tbody>
<tr>
<td>Limitation</td>
<td>Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
</tbody>
</table>

Related scenario

For a related scenario, see Writing data to and reading data from a MemSQL database table on page 2198.
tMemSQLInput

Executes a DB query with a strictly defined order which must correspond to the schema definition. tMemSQLInput connects to a given database and extracts fields based on a user-defined query. Then it passes the selected data to the next component via a Main row link.

**tMemSQLInput Standard properties**

These properties are used to configure tMemSQLInput running in the Standard Job framework. The Standard tMemSQLInput component belongs to the Big Data and the Databases families. The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-in:</strong> No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository:</strong> Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:</td>
</tr>
<tr>
<td></td>
<td>1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.</td>
</tr>
<tr>
<td></td>
<td>2. In the child level, use a dedicated connection component to read that registered database connection.</td>
</tr>
<tr>
<td></td>
<td>For an example about how to share a database connection across Job levels, see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Host</td>
<td>Enter the location of the server of the MemSQL database to be used.</td>
</tr>
<tr>
<td>Port</td>
<td>Enter the listening port number of the server of the MemSQL database to be used.</td>
</tr>
<tr>
<td>------</td>
<td>--------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Database</td>
<td>Enter the name of the MemSQL database to be used.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>Enter the authentication data used to connect to the MemSQL database to be used.</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
</tbody>
</table>

- **Built-In**: You create and store the schema locally for this component only.
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-In** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

<table>
<thead>
<tr>
<th>Table Name</th>
<th>Name of the table to be read.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Query type and Query</td>
<td>Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.</td>
</tr>
</tbody>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th>Additional JDBC parameters</th>
<th>Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the <strong>Use an existing connection</strong> check box in the Basic settings.</th>
</tr>
</thead>
</table>

**Note**: When you need to handle data of the time-stamp type `0000-00-00 00:00:00` using this component, set the parameter as `noDatetimeStringSync=true&zeroDateTimeBehavior=convertToNull.`

<table>
<thead>
<tr>
<th>Trim all the String/Char columns</th>
<th>Select this check box to remove leading and trailing whitespace from all the String/Char columns.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Trim column</td>
<td>Remove leading and trailing whitespace from defined columns.</td>
</tr>
</tbody>
</table>
tMemSQLInput

Note: Clear Trim all the String/Char columns to enable Trim columns in this field.

Global Variables

Global Variables

**NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.

**QUERY**: the query statement being processed. This is a Flow variable and it returns a string.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule

This component covers all possible SQL queries for MemSQL databases.

Dynamic settings

Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the
Writing data to and reading data from a MemSQL database table

This scenario applies only to Talend products with Big Data.

In this scenario a Job is built to write a table to a MemSQL database, and then retrieve the data from the table.

Dragging and dropping components and linking them together

About this task

Procedure

1. Drop a `tMemSQLConnection`, a `tRowGenerator`, a `tMemSQLInput`, a `tMemSQLOutput`, a `tMemSQLClose`, and a `tLogRow` from the Palette onto the workspace.
2. Link the `tMemSQLConnection` to the `tRowGenerator` using a Row > OnSubjobOk connection.
3. Link the `tRowGenerator` to the `tMemSQLOutput` using a Row > Main connection.
4. Link the `tRowGenerator` to the `tMemSQLInput` using a Row > OnSubjobOk connection.
5. Link the `tMemSQLInput` to the `tLogRow` using a Row > Main connection.
6. Link the `tMemSQLInput` to the `tMemSQLClose` using a Row > OnSubjobOk connection.
Configuring the components

Opening and closing connection to the database

Procedure

1. Double-click the **tMemSQLConnection** component to open its **Basic settings** in the **Component** tab.

2. In the **Property Type** list, select **Built-In**. Specify the connection details in the relevant fields, including the host name and listening port number of the database server, the user name and password for your database authentication, and the database name.

3. Double-click **tMemSQLClose** to set its **Basic settings** in the **Component** tab.

4. The **Component List** is filled in automatically with **tMemSQLConnection_1**.

Writing data in a database table

Procedure

1. Double-click the **tRowGenerator** component to open the Row Generator editor.
2. Add three columns as shown below to generate 10 data rows:
   - **id**, Integer type, using `Numeric.sequence` from the **Function** list to generate sequence numbers.
   - **firstName**, String type, using `TalendDataGenerator.getFirstName` from the **Function** list to generate random first names.
   - **lastName**, String type, using `TalendDataGenerator.getLastName` from the **Function** list to generate random family names.

3. In the **Basic settings** view of **tRowGenerator** in the **Component** tab, click the **Edit Schema** button to open the schema editor. Set the length of the **id**, **firstName**, **lastName** column to 4, 10, and 10.
When done, click **OK** to close the editor and click **Yes** when prompted to propagate the schema to the next component.

For more information about how to configure the **tRowGenerator** component, see **tRowGenerator** on page 3224.

4. Double-click **tMemSQLOutput** to open its **Basic Settings** view in the **Component** tab.

5. Select the **Use Existing Connection** check box. The **Component List** is filled in automatically with **tMemSQLConnection_1**.

   Fill the **Table** field with the database table, **customers** in this example.

   Select **Drop table if exists and create** in the **Action on table** list, and **Insert** in the **Action on table** list.

**Reading data from a database table**

**Procedure**

1. Double-click **tMemSQLInput** to open its **Basic Settings** view in the **Component** tab.
2. Select the **Use Existing Connection** check box. The **Component List** is filled in automatically with tMemSQLConnection_1.

3. Set the **Schema** as **Built-in** and click **Edit schema** to define the data structure of the database table to read data from.

   ![Schema of tMemSQLInput_1](image)

   Click the [+] button to add the rows that you will use to define the schema, three columns in this example: id, firstName, and lastName.

   Under **Column**, click in the fields to enter the corresponding column names.

   Click the field under **Type** to define the type of data.

   Click **OK** to close the schema editor.

4. Fill the **Table** field with the database table, customers in this example.

   Alternatively, click the [...] button next to the **Table Name** field to select the database table of interest. A dialog box opens showing a tree diagram of all the tables in the selected database. Select customers and click **OK** to close the dialog box.
5. Set the **Query Type** as **Built-In**. Click the **Guess Query** button. The **Query** box is filled in automatically to retrieve all columns from the selected table.

6. Double-click **tLogRow** to set its **Basic settings** in the **Component** tab.

7. In the **Mode** area, select **Table (print values in cells of a table)** for a better display of the results.

8. Save the Job.

**Executing the Job**

Press **F6** to run the Job and see the results in the console.
As shown above, the data with the desired column names is retrieved from the database table.

<table>
<thead>
<tr>
<th>id</th>
<th>firstName</th>
<th>lastName</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Thomas</td>
<td>Quincy</td>

<td>Clinton</td>
</tr>
</tbody>
</table>
tMemSQLOutput

Reads data incoming from the preceding component in the Job and executes the action defined on a given MemSQL table and/or on the data contained in the table.

tMemSQLOutput connects to a given MemSQL database and writes, updates, makes changes or suppresses entries in that database.

**tMemSQLOutput Standard properties**

These properties are used to configure tMemSQLOutput running in the Standard Job framework.

The Standard tMemSQLOutput component belongs to the Big Data and the Databases families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
<tr>
<td><strong>Property type</strong></td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td><strong>Host</strong></td>
<td>Enter the location of the server of the MemSQL database to be used.</td>
</tr>
</tbody>
</table>

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
<table>
<thead>
<tr>
<th><strong>Port</strong></th>
<th>Enter the listening port number of the database server.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Enter the name of the MemSQL database to be used.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>Enter the user authentication data for connecting to the database to be used.</td>
</tr>
<tr>
<td><strong>Table</strong></td>
<td>Enter the name of the table to be written. Note that only one table can be written at a time.</td>
</tr>
</tbody>
</table>
| **Action on table** | On the table defined, you can perform one of the following operations:  
| **None** | No operation is carried out. |
| **Drop and create a table** | The table is removed and created again. |
| **Create a table** | The table does not exist and gets created. |
| **Create a table if not exists** | The table is created if it does not exist. |
| **Drop a table if exists and create** | The table is removed if it already exists and created again. |
| **Clear a table** | The table content is deleted. |
| **Action on data** | On the data of the table defined, you can perform:  
| **Insert** | Add new entries to the table. If duplicates are found, the job stops. |
| **Update** | Make changes to existing entries. |
| **Insert or update** | Insert a new record. If the record with the given reference already exists, an update would be made. |
| **Update or insert** | Update the record with the given reference. If the record does not exist, a new record would be inserted. |
| **Delete** | Remove entries corresponding to the input flow. |

**Warning:**  
You must specify at least one column as a primary key on which the Update and Delete operations are based. You can do that by clicking Edit Schema and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the Advanced settings view where you can simultaneously define primary keys for the update and delete operations. To do that: Select the Use field options check box and then in the Key in update column, select the check boxes next to the column name on which you want to base the update operation. Do the same in the Key in delete column for the deletion operation.

<table>
<thead>
<tr>
<th><strong>Schema and Edit schema</strong></th>
<th>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-In</strong></td>
<td>You create and store the schema locally for this component only.</td>
</tr>
</tbody>
</table>
Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- View schema: choose this option to view the schema only.
- Change to built-in property: choose this option to change the schema to Built-in for local changes.
- Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

Die on error

This check box is clear by default. This allows you to skip the row in error and complete the process for error-free rows.

Advanced settings

Additional JDBC parameters

Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the Use an existing connection check box in the Basic settings.

Note:
You can press Ctrl+Space to access a list of predefined global variables.

Use batch size

Select this check box to activate the batch mode for data processing. In the Batch Size field that appears when this check box is selected, you can type in the number you need to define the batch size to be processed.

Additional Columns

This option is not available if you have just created the database table (even if you delete it beforehand). This option allows you to call SQL functions to perform actions on columns, provided that these are not insert, update or delete actions, or actions that require pre-processing.

Name: Type in the name of the schema column to be altered or inserted.

SQL expression: Type in the SQL statement to be executed in order to alter or insert the data in the corresponding column.
Position: Select **Before**, **Replace** or **After**, depending on the action to be performed on the reference column.

Reference column: Type in a reference column that **tMemSQLOutput** can use to locate or replace the new column, or the column to be modified.

Use field options: Select this check box to customize a request, particularly if multiple actions are being carried out on the data.

Enable debug mode: Select this check box to display each step involved in the process of writing data in the database.

tStatCatcher Statistics: Select this check box to collect log data at the component level.

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th><strong>NB_LINE</strong>: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>NB_LINE_UPDATED</strong>: the number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td><strong>NB_LINE_INSERTED</strong>: the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td><strong>NB_LINE_DELETED</strong>: the number of rows deleted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td><strong>NB_LINE_REJECTED</strong>: the number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td></td>
<td>For further information about variables, see <strong>Talend Studio User Guide</strong>.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
</tbody>
</table>

**Usage**

Usage rule: This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in a MemSQL database.

Dynamic settings: Click the **[*]** button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an
environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see [Reading data from databases through context-based dynamic connections on page 2457](#) and [Reading data from different MySQL databases using dynamically loaded connection parameters on page 491](#). For more information on **Dynamic settings** and context variables, see [Talend Studio User Guide](#).

| Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in [Talend Help Center](https://help.talend.com). |

---

**Related scenario**

For a related scenario, see [Writing data to and reading data from a MemSQL database table on page 2198](#).
tMemSQLRow

Acts on the actual database structure or on the data (although without handling data).

tMemSQLRow executes the MemSQL query stated in the specified database, depending on the nature of the query and the database. The row suffix means the component implements a flow in the job design although it does not provide output.

The SQLBuilder tool helps you write easily your SQL statements.

**tMemSQLRow Standard properties**

These properties are used to configure tMemSQLRow running in the Standard Job framework.

The Standard tMemSQLRow component belongs to the Big Data and the Databases families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

---

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 598.

---

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

---

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
<table>
<thead>
<tr>
<th><strong>Host</strong></th>
<th>Enter the location of the server of the MemSQL database to be used.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Port</strong></td>
<td>Enter the listening port number of the database server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Enter the name of the MemSQL database to be used.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>Enter the user authentication data for connecting to the database to be used.</td>
</tr>
<tr>
<td><strong>Table Name</strong></td>
<td>Name of the table to be processed.</td>
</tr>
<tr>
<td><strong>Schema and Edit Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <code>line</code> when naming the fields.</td>
</tr>
</tbody>
</table>

- **Built-In**: You create and store the schema locally for this component only.
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

<table>
<thead>
<tr>
<th><strong>Query type</strong></th>
<th>Either <strong>Built-in</strong> or <strong>Repository</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-in</strong>:</td>
<td>Fill in manually the query statement or build it graphically using SQLBuilder</td>
</tr>
<tr>
<td><strong>Repository</strong>:</td>
<td>Select the relevant query stored in the Repository. The <strong>Query</strong> field gets accordingly filled in.</td>
</tr>
</tbody>
</table>

**Guess Query**: Click the **Guess Query** button to generate the query which corresponds to your table schema in the **Query** field.
### Query
Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.

### Die on error
This check box is clear by default. This allows you to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a Row > Rejects link.

### Advanced settings

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Additional JDBC parameters</strong></td>
<td>Specify additional connection properties for the database connection you are creating. This option is not available if you have selected the Use an existing connection check box in the Basic settings.</td>
</tr>
</tbody>
</table>
| **Propagate QUERY’s record set** | Select this check box to insert the result of the query in a COLUMN of the current flow. Select this column from the use column list.  

**Note:**
This option allows the component to have a different schema from that of the preceding component. Moreover, the column that holds the QUERY’s record set should be set to the type of Object and this component is usually followed by tParseRecordSet. |
| **Use PreparedStatement** | Select this check box if you want to query the database using a PreparedStatement. In the Set PreparedStatement Parameter table, define the parameters represented by '?' in the SQL instruction of the Query field in the Basic Settings tab.  

**Parameter Index**: Enter the parameter position in the SQL instruction.  

**Parameter Type**: Enter the parameter type.  

**Parameter Value**: Enter the parameter value.  

**Note:**
This option is very useful if you need to execute the same query several times. Performance levels are increased |

### tStatCatcher Statistics
Select this check box to collect log data at the component level.

### Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>QUERY</strong></td>
<td>the query statement being processed. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td><strong>ERROR_MESSAGE</strong></td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component offers the flexibility of the database query and covers all possible SQL queries.</th>
</tr>
</thead>
</table>
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |

| Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |

**Related scenarios**

No scenario is available for the Standard version of this component yet.
**tMicrosoftCrmInput**

Extracts data from a Microsoft CRM database based on conditions set on specific columns.

**tMicrosoftCrmInput Standard properties**

These properties are used to configure tMicrosoftCrmInput running in the Standard Job framework.

The Standard tMicrosoftCrmInput component belongs to the Business family.

The component in this framework is available in all Talend products.

**Basic settings**

</tbody>
</table>
### Entity/EntityType
Select the relevant entity/entity set from the list or select CustomEntity/CustomEntitySet from the list, and then in the **Custom Entity Name** field displayed, specify the entity/entity set name and define the schema for the custom entity/entity set.

### Schema and Edit schema
A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

- **Built-in**: You create and store the schema locally for this component only.
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

The schema of this component is related to the specified entity.

### Custom filter
Select this check box and in the field displayed, specify the search criteria that uses the standard OData query functions such as `contains`, `endswith`, and `startswith`. For more information about the supported query functions, see the description of Standard query functions on Query Data using the Web API.

This property is available for Microsoft CRM ON-PREMISE 2016 and ONLINE 2016.

### Logical operator used to combine conditions
Select the logical operator used to combine the conditions defined in **Conditions** table.

- **And**: the record will be included in the result set when all of the conditions are met.
- **Or**: the record will be included in the result set when any of the conditions is met.

### Conditions
Click the `[+]` button to add as many conditions as needed and specify the following parameters for each condition:

- **Input column**: Click in the cell and select the column of the input schema on which the condition is to be set.
- **Operator**: Click in the cell and select the operator used to compare the value for the input column with the value defined in the **Value** column.

The values for this parameter are: **Equal**, **NotEqual**, **GreaterThan**, **LessThan**, **GreaterEqual**, **LessEqual**, and **Like**.
**Value**: Type in the value between quotes if needed.

**Order by**

Select this check box and in the table displayed, specify the column(s) based on which the retrieved data will be sorted in ascending or descending order. Multiple sort columns can be specified and the hierarchy of the sorting is based on the order of the columns specified. That is to say, the retrieved data will be sorted by the first column and then that ordered list is sorted by the second column, and so on.

This property is available for Microsoft CRM ON-PREMISE 2016 and ONLINE 2016.

---

**Advanced settings**

**Reuse Http Client**

Select this check box to retain the current connection or clear it to release the connection.

This property is not available for Microsoft CRM ON-PREMISE 2015.

**Max number of reconnection attempts**

The maximum number of reconnect attempts to the Microsoft CRM database after the token is expired. If the value is set to 0 or less than 0, no reconnect attempt will be made.

This property is available for Microsoft CRM ON-PREMISE 2016, ONLINE 2011, and ONLINE 2016.

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

---

**Global Variables**

**NB_LINE**

The number of rows processed. This is an After variable and it returns an integer.

**ERROR_MESSAGE**

The error message generated by the component when an error occurs. This is an After variable and it returns a string.

---

**Usage**

**Usage rule**

This component is usually used as a start component of a Job or Subjob and it always needs an output link.

**Limitation**

`tMicrosoftCrmInput` (both ONLINE 2016 and ON-PREMISE 2016) doesn't support retrieving data of the write-only properties. The corresponding schema columns for the write-only properties have been removed from the predefined schema.
Writing data in a Microsoft CRM database and putting conditions on columns to extract specified rows

This scenario describes a four-component Job which aims at writing the data included in a delimited input file in a custom entity in a Microsoft CRM database. It then extracts specified rows to an output file using the conditions set on certain input columns.

Warning:
If you want to write in a CustomEntity in Microsoft CRM database, make sure to name the columns in accordance with the naming rule set by Microsoft, that is "name_columnname" all in lower case.

Setting up the Job

Procedure

1. Drop the following components from the Palette to the design workspace: tFileInputDelimited, tFileOutputDelimited, tMicrosoftCrmInput, and tMicrosoftCrmOutput.

2. Connect tFileInputDelimited to tMicrosoftCrmOutput using a Row > Main connection.
3. Connect tMicrosoftCrmInput to tFileOutputDelimited using a Row > Main connection.
4. Connect tFileInputDelimited to tMicrosoftCrmInput using Trigger > OnSubjobOk connection.

Configuring tFileInputDelimited

Procedure

1. Double-click tFileInputDelimited to display its Basic settings view and define its properties.
2. Set the Property Type to Repository if you have stored the input file properties centrally in the Metadata node in the Repository tree view. Otherwise, select Built-In and fill the fields that follow manually. In this example, property is set to Built-In.

3. Click the three-dot button next to the File name/Stream field and browse to the delimited file that holds the input data. The input file in this example contains the following columns: new_id, new_status, new_firstname, new_email, new_city, new_initial and new_zipcode.

<table>
<thead>
<tr>
<th>new_id</th>
<th>new_status</th>
<th>new_firstname</th>
<th>new_email</th>

</tbody>
</table>

4. In the Basic settings view, define the Row Separator allowing to identify the end of a row. Then define the Field Separator used to delimit fields in a row.

5. If needed, define the header, footer and limit number of processed rows in the corresponding fields. In this example, the header, footer and limits are not set.

6. Click Edit schema to open a dialog box where you can define the input schema you want to write in Microsoft CRM database.
7. Click OK to close the dialog box.

**Configuring tMicrosoftCrmOutput**

**Procedure**

1. Double-click tMicrosoftCrmOutput to display the component **Basic settings** view and define its properties.

2. Enter the Microsoft Web Service URL as well as the user name and password in the corresponding fields.

3. In the **OrganizeName** field, enter the name that is given the right to access the Microsoft CRM database.

4. In the **Domain** field, enter the domain name of the server on which Microsoft CRM is hosted, and then enter the host IP address and the listening port number in the corresponding fields.

5. In the **Action** list, select the operation you want to carry on. In this example, we want to insert data in a custom entity in Microsoft Crm.

6. In the **Time out** field, set the amount of time (in seconds) after which the Job will time out.

7. In the **Entity** list, select one among those offered. In this example, **CustomEntity** is selected.
Note:

If CustomEntity is selected, a **Custom Entity Name** field displays where you need to enter a name for the custom entity.

The **Schema** is then automatically set according to the entity selected. If needed, click **Edit schema** to display a dialog box where you can modify this schema and remove the columns that you do not need in the output.

8. Click **Sync columns** to retrieve the schema from the preceding component.

---

**Configuring tMicrosoftCrmInput**

**Procedure**

1. Double-click **tMicrosoftCrmInput** to display the component **Basic settings** view and define its properties.
2. Set the **Property Type** to **Repository** if you have stored the input file properties centrally in the **Metadata** node in the **Repository** tree view. Otherwise, select **Built-In** and fill the fields that follow manually. In this example, property is set to **Built-In**.

3. Enter the Microsoft Web Service URL as well as the user name and password in the corresponding fields and enter the name that is given the right to access the Microsoft CRM database in the **OrganizeName** field.

4. In the **Domain field**, enter the domain name of the server on which Microsoft CRM is hosted, and then enter the host IP address and the listening port number in the corresponding fields.

5. In the **Timeout** field, set the amount of time (in seconds) after which the Job will time out.

6. In the **Entity** list, select the one among those offered you want to connect to. In this example, **CustomEntity** is selected.

7. The **Schema** is then automatically set according to the entity selected. But you can modify it according to your needs. In this example, you should set the schema manually since you want to access a custom entity. Copy the seven-column schema from **tMicrosoftCrmOutput** and paste it in the schema dialog box in **tMicrosoftCrmInput**.

![Schema of tMicrosoftCrmInput](image)

8. Click **OK** to close the dialog box. You will be prompted to propagate changes. Click **Yes** in the popup message.

9. In the **Basic settings** view, select **And** or **Or** as the logical operator you want to use to combine the conditions you set on the input columns. In this example, we want to set two conditions on two different input columns and we use **And** as the logical operator.

10. In the **Condition** area, click the plus button to add as many lines as needed and then click in each line in the **Input column** list and select the column you want to set condition on. In this example, we want to set conditions on two columns, **new_city** and **new_id**. We want to extract all customer rows whose city is equal to "New York" and whose id is greater than 2.

11. Click in each line in the **Operator** list and select the operator to bind the input column with its value, in this example **Equal** is selected for **new_city** and **Greater Than** for **new_id**.

12. Click in each line in the **Value** list and set the column value, **New York** for **new_city** and **2** for **new_id** in this example. You can use a fixed or a context value in this field.
Configuring tFileOutputDelimited

Procedure

1. Double-click tFileOutputDelimited to display the component Basic settings view and define its properties.

2. Set Property Type to Built-In and then click the [...] button next to the File Name field and browse to the output file.

3. Set row and field separators in the corresponding fields.

4. Select the Append check box if you want to add the new rows at the end of the records.

5. Select the Include Header check box if the output file includes a header.

6. Click Sync columns to retrieve the schema from the preceding component.

Executing the Job

Procedure

Save the Job and press F6 to execute it.

</tr>
</tbody>
</table>
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.  
  • **Built-In**: You create and store the schema locally for this component only.  
  • **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.  
  
  Click *Edit schema* to make changes to the schema. If the current schema is of the Repository type, three options are available:  
  • **View schema**: choose this option to view the schema only.  
  • **Change to built-in property**: choose this option to change the schema to Built-in for local changes.  
  • **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.  
  
  Click *Sync columns* to retrieve the schema from the previous component connected in the Job.  
  
  The schema of this component is related to the specified entity. |
| **Lookup Type Mapping** | Complete this table to map the lookup property with its related entity type or entity set value.  
  • **Input column**: the schema column name of the lookup property.  
  • **Type**: the related entity type for the corresponding lookup property. It is not available for ON-PREMISE 2016 and ONLINE 2016.  
  • **Reference entityset**: the name of the related entity set for the corresponding lookup property. It is available only for ON-PREMISE 2016 and ONLINE 2016. Refer to Web API EntityType Reference for more information about the entity set of the lookup property for each entity.  
  
  This property is not available for Microsoft CRM ON-PREMISE 2015. |

**Related Scenario**

For a related use case, see Writing data in a Microsoft CRM database and putting conditions on columns to extract specified rows on page 2218.
tMicrosoftMQInput

Retrieves the first message in a given Microsoft message queue (only support String).

tMicrosoftMQInput fetches messages one by one based on the ID sequence of these messages from the Microsoft message queue. Each execution retrieves only one message.

For further information about the messaging brokers supported by this component, see [Messaging brokers supported by Talend messaging components](#).

### tMicrosoftMQInput Standard properties

These properties are used to configure tMicrosoftMQInput running in the Standard Job framework.

The Standard tMicrosoftMQInput component belongs to the Internet family.

The component in this framework is available in all [Talend products](#).

#### Basic settings

<table>
<thead>
<tr>
<th>Property type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Always Built-in. Its schema has only one read-only column of string type: <code>message</code>.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally. Enter properties manually</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file where properties are stored. The fields that come after are pre-filled in using the fetched data.</td>
</tr>
<tr>
<td>Host</td>
<td>Type in the Host name or IP address of the host server.</td>
</tr>
<tr>
<td>Queue</td>
<td>Enter the queue name you want to retrieve messages from.</td>
</tr>
<tr>
<td>Queue type</td>
<td>Select a Microsoft message queue type from the drop-down list.</td>
</tr>
<tr>
<td>Private</td>
<td>a private queue, which is registered on the local machine.</td>
</tr>
<tr>
<td>Public</td>
<td>a public queue, which is registered in the directory service.</td>
</tr>
<tr>
<td>Die on error</td>
<td>This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.</td>
</tr>
</tbody>
</table>

#### Advanced settings

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |
Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | This component is generally used as a start component of a Job or subjob. It must be linked to an output component. |

Connections

| Connections | Outgoing links (from this component to another): Row: Main, Iterate Trigger: Run if; On Subjob Ok, On Subjob Error, On Component Ok; On Component Error. Incoming links (from one component to this one): Row: Iterate; Trigger: Run if, On Subjob Ok, On Subjob Error, On Component Ok, On Component Error. For further information regarding connections, see Talend Studio User Guide. |

Limitation

| Limitation | This component supports only String type. Also, it only works with the Windows systems. This component requires installation of its related jar files. |

Writing and fetching queuing messages from Microsoft message queue

This scenario is made of two Jobs. The first Job posts messages on a Microsoft message queue and the second Job fetches the message from the server.

Posting messages on a Microsoft message queue

In the first Job, a string message is created using a tRowGenerator and put on a Microsoft message queue using a tMicrosoftMQOutput. An intermediary tLogRow component displays the flow being passed.
**Dropping and linking components**

**Procedure**
1. Drop the three components required for the first Job from the Palette onto the design workspace.
2. Connect the components using a Row > Main link.

![Diagram of components connected](image)

**Configuring the components**

**Procedure**
1. Double-click tRowGenerator to open its editor.

<table>
<thead>
<tr>
<th>Schema</th>
<th>Functions</th>
<th>P</th>
</tr>
</thead>
<tbody>
<tr>
<td>Column</td>
<td>Key</td>
<td>Type</td>
</tr>
<tr>
<td>ID</td>
<td>✓</td>
<td>Integer</td>
</tr>
<tr>
<td>Name</td>
<td>✓</td>
<td>String</td>
</tr>
<tr>
<td>Address</td>
<td>✓</td>
<td>String</td>
</tr>
</tbody>
</table>

2. Click the plus button to add three rows into the schema table.
3. In the Column column, type a new name for each row to rename it. Here, we type in ID, Name and Address.
4. In the Type column, select Integer for the ID row from the drop-down list and leave the other rows as String.
5. In the Functions column, select random for the ID row, getFirstName for the Name row and getUsCity for the Address row.
6. In the Number of Rows for RowGenerator field on the right end of the toolbar, type in 12 to limit the number of rows to be generated. Then, Click Ok to validate this editing.

**Note:**
In real case, you may use an input component to load the data of your interest, instead of the tRowGenerator component.

7. Double click the tMicrosoftMQOutput component to open its Component view.
8. In the Host field, type in the host address. In this example, it is localhost.

9. In the Queue field, type in the queue name you want to write message in. In this example, name it AddressQueue.

10. In Message column (String Type) field, select Address from the drop-down list to determine the message body to be written.

Fetching the message

Procedure

1. Press Ctrl+S to save your Job.

2. Press F6 or click Run on the Run tab to execute the Job.

```
Starting job tMicrosoftMQ at 14:03 18/11/2010.

[statistics] connecting to socket on port 3852
[statistics] connected
Queue open failures: Cannot open queue. (hr=MQ_ERROR_QUEUE_NOT_FOUND)
OpenQueueWithAccess (DIRECT-OS: \localhost\private\AddressQueue)
open: fname(DIRECT-OS: \localhost\private\AddressQueue) accessmode(1) sharemode(0)
........................ attempting to create queue with
name= '\private\AddressQueue', label='Created by
org.talend.msmq.MsmqUtil.java'
OpenQueueWithAccess (DIRECT-OS: \private\AddressQueue)
open: fname(DIRECT-OS: \private\AddressQueue) accessmode(1) sharemode(0)
open: fname(DIRECT-OS: \private\AddressQueue) accessmode(2) sharemode(0)
7|Theodore|Atlanta
8|Andrew|Saint Paul
7|Benjamin|Oklahoma City
3|Abraham|Providence
4|Rutherford|Lincoln
6|Chester|Little Rock
11|Richard|Lincoln
8|Bill|Boston
9|Herbert|Jackson
10|James|Honolulu
5|Jimmy|Montpelier
9|Woodrow|Nashville
[statistics] disconnected
Job tMicrosoftMQ ended at 14:03 18/11/2010. [exit code=0]
```

You can see that this queue has been created automatically and that the messages have been written.
Fetching the first queuing message from the message queue

Now set the second Job in order to fetch the first queuing message from the message queue.

Arranging the flow of the message

Procedure

1. Drop tMicrosoftMQInput and tLogRow from the Palette to the design workspace.
2. Connect these two components using a Row > Main link.

Configuring how the message is processed

Procedure

1. Double-click the tMicrosoftMQInput to open its Component view.

2. In the Host field, type in the host name or address. Here, we type in localhost.
3. In the Queue field, type in the queue name from which you want to fetch the message. In this example, it is AddressQueue.

Saving and executing the Job

Procedure

1. Press Ctrl+S to save your Job.
2. Press F6 or click Run on the Run tab to execute the Job.
The message body *Atlanta* fetched from the queue is displayed on the console.
tMicrosoftMQOutput

Writes a defined column of given inflow data to Microsoft message queue (only support String type).

For further information about the messaging brokers supported by this component, see Messaging brokers supported by Talend messaging components.

**tMicrosoftMQOutput Standard properties**

These properties are used to configure tMicrosoftMQOutput running in the Standard Job framework.

The Standard tMicrosoftMQOutput component belongs to the Internet family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>

<td>Select the column as message to be written to Microsoft message queue. The selected column must be of String type.</td>
</tr>
<tr>
<td>Die on error</td>
<td>This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.</td>
</tr>
</tbody>
</table>
### Advanced settings

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

### Global Variables

**Global Variables**

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERROR_MESSAGE</td>
<td>The error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

### Usage

**Usage rule**

This component must be linked to an input or intermediary component.

**Connections**

Outgoing links (from this component to another):

- **Row**: Main, Iterate
- **Trigger**: Run if, On Component Ok; On Component Error.

Incoming links (from one component to this one):

- **Row**: Main; Reject; Iterate;
- **Trigger**: Run if, On Subjob Ok, On Subjob Error; On Component Ok, On Component Error.

For further information regarding connections, see Talend Studio User Guide.

**Limitation**

The message to be output cannot be null.

This component requires installation of its related jar files.

### Related scenario

For a related scenario, see Writing and fetching queuing messages from Microsoft message queue on page 2229.
tMomCommit

Commits data on the MQ Server.

tMomCommit commits in one go, using a unique connection, a global transaction instead of doing that on every row or every batch and thus provides gain in performance.

**tMomCommit Standard properties**

These properties are used to configure tMomCommit running in the Standard Job framework.

The Standard tMomCommit component belongs to the Internet family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Component List</th>
<th>Select the Connection component used in your Job.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Global Variables**

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

Warning:
If you want to use a Row > Main connection to link tMomCommit to your Job, your data will be committed row by row. In this case, do not select the Close connection check box or your connection will be closed before the end of your first row commit.
**Usage**

| Usage rule | This component is more commonly used with other tMom* components, especially with the tMomConnection and tMomRollback components. |

**Related scenario**

For **tMomCommit** related scenario, see *Inserting data in mother/daughter tables* on page 2437.
**tMomConnection**

Opens a connection to the MQ Server for communication.

**tMomConnection Standard properties**

These properties are used to configure tMomConnection running in the Standard Job framework.

The Standard tMomConnection component belongs to the Internet family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>

<td>Select this check box to share your connection or use a connection shared by a parent or child Job. This allows you to share one single connection among several connection components from different Job levels that can be either parent or child. This option is incompatible with the <strong>Use dynamic job</strong> and <strong>Use an independent process to run subjob</strong> options of the <strong>tRunJob</strong> component. Using a shared connection together with a <strong>tRunJob</strong> component with either of these two options enabled will cause your Job to fail.</td>
</tr>
<tr>
<td>Shared Connection Name</td>
<td>Enter the shared connection name. This field is available only when the <strong>Use or register a shared Connection</strong> check box is selected.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| Additional options | Define the additional transport options in the table. This table is available only when the **Failover** or **Static Discovery** check box in the **Basic settings** view is selected.  
- **Option name**: the name of the option.  
- **Option value**: the value of the option.  
  For example, enter `maxReconnectAttempts` in the **Option name** field and then `0` in the **Option value** field so that no attempt is made to retry the connection when no server is available.  
  For more information about the failover transport options, see [Failover Transport Reference](#).  
  For more information about the static discovery transport options, see [Static Transport Reference](#). |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Set Cipher Suite | Select this check box to enable the Cipher Suite list from which you can specify the Cipher Suite to be used with WebSphere MQ SSL.  
  For further information about Cipher Suite, see [CipherSpecs and their equivalent CipherSuites supported by IBM WebSphere MQ](#).  
  Available when **WebSphere MQ** is selected in the **MQ Server** list. |
| Custom Cipher Suite | Select this check box to allow you to customize Cipher Suite. |
IBM Cipher Mappings: Use the IBM Java Cipher Suite to IBM MQ Cipher Spec Mappings.
Oracle Cipher Mappings: Use the Oracle Cipher Suite to IBM MQ Cipher Spec Mappings.

| StatCatcher Statistics | Select this check box to collect log data at the component level. |

**Global Variables**

**ERROR_MESSAGE**: The error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

**Usage**

This component is more commonly used with other tMom* components, especially with the tMomCommit and tMomRollback components.

| Limitation | This component supports ActiveMQ and WebSphere MQ servers. |

**Related scenario**

For a similar scenario, see tMysqlConnection on page 2436.
**tMomInput**

Fetches a message from a queue on a Message-Oriented Middleware (MOM) system and passes it on to the next component.

`tMomInput` makes it possible to set up asynchronous communications via a MOM server.

For further information about the messaging brokers supported by this component, see [Messaging brokers supported by Talend messaging components](#).

**tMomInput Standard properties**

These properties are used to configure `tMomInput` running in the Standard Job framework.

The Standard `tMomInput` component belongs to the Internet family.

The component in this framework is available in all [Talend products](#).

</tr>
<tr>
<td><strong>Commit (delete message after read from the queue)</strong></td>
<td>Select this check box to force a commit after reading each message from the queue. This check box is available only when <em>WebSphere MQ</em> is selected from the <em>MQ server</em> list and the <em>Browse message</em> check box in the <em>Advanced settings</em> view is cleared.</td>
</tr>
<tr>
<td><strong>Backout messages to input queue</strong></td>
<td>Select this check box to put the message back into the queue after reading it. This check box and the <em>Browse message</em> check box in the <em>Advanced settings</em> view enable you to read messages non-destructively from the queue. For further information, see <a href="https://publib.boulder.ibm.com/iseries/v5r2/ic2924/books/csqzaw07.pdf">https://publib.boulder.ibm.com/iseries/v5r2/ic2924/books/csqzaw07.pdf</a>. This check box is available only when <em>WebSphere MQ</em> is selected from the <em>MQ server</em> list and the <em>Keep Listening</em>, <em>Commit (delete message after read from the queue)</em> and <em>Browse message</em> check boxes are cleared.</td>
</tr>
<tr>
<td><strong>Backout messages to backout queue (when backoutCount of message reach the threshold value)</strong></td>
<td>Select this check box to backout the messages to the backout queue defined in the WebSphere MQ manager when the backout count reaches the configured threshold which is a property of the queue in the WebSphere MQ server. This check box is available only when <em>WebSphere MQ</em> is selected from the <em>MQ server</em> list and the <em>Keep Listening</em>, <em>Commit (delete message after read from the queue)</em> and <em>Browse message</em> check boxes are cleared.</td>
</tr>
</tbody>
</table>
Set Transacted

Select this check box to transact the session. For further information about this parameter, see https://publib.boulder.ibm.com/iseries/v5r2/ic2924/books/csqzaw07.pdf.

**Note:**
Selecting this check box will ignore the settings in the **Acknowledgement Mode** list in the **Advanced settings** view of tMomInput.

This check box is available only when **ActiveMQ** is selected from the **MQ server** list.

start server

Select this check box to force a start of the ActiveMQ server.

This check box is available only when **ActiveMQ** is selected from the **MQ server** list.

**Advanced settings**

**Additional options**

Define the additional transport options in the table. This table is available only if you select the **Failover** or **Static Discovery** check box in the **Basic settings** view.

- **Option name**: the name of the option.
- **Option value**: the value of the option.

For example, enter `maxReconnectAttempts` in the **Option name** field and then `0` in the **Option value** field so that no attempt is made to retry the connection when no server is available for the failover mode.

For more information about the failover transport options, see **Failover Transport Reference**.

For more information about the static discovery transport options, see **Static Transport Reference**.

**Acknowledgement Mode**

Select an acknowledgement mode from the list to indicate that the client will acknowledge any messages it receives:

- **Auto Acknowledge**: With this acknowledgement mode, the client automatically acknowledges a message when it has either successfully returned from a call to receive, or the message listener it has called to process the message successfully returns.

- **Client Acknowledge**: With this acknowledgement mode, the client acknowledges a message by calling a message’s acknowledge method.

- **Dups OK Acknowledge**: This acknowledgement mode instructs the session to lazily acknowledge the delivery of messages.

For further information about the usage of Jms headers, see https://publib.boulder.ibm.com/iseries/v5r2/ic2924/books/csqzaw07.pdf.
### Get Jms Header
Select this check box to receive the Jms headers through the mapping from Jms fields onto MQ Series fields. When this check box is checked, you can specify the Jms header and the corresponding reference column name in the line(s) you added by clicking the plus button in the Parameters table. For further information about the usage of Jms headers, see https://publib.boulder.ibm.com/iseries/v5r2/ic2924/books/csqzaw07.pdf.

**Note:**
This check box is enabled when the MQ server is ActiveMQ or JBoss Messaging.

### Get Jms Properties
Select this check box to receive the Jms properties mapped to MQMD fields. When this check box is checked, you can specify the property name, the property type and the reference column name in the line(s) you added by clicking the plus button in the Parameters table. For further information about the usage of Jms properties, see https://publib.boulder.ibm.com/iseries/v5r2/ic2924/books/csqzaw07.pdf.

(Available when ActiveMQ or JBoss Messaging is selected in the MQ Server list.)

### Browse message
Select this check box to disable Commit (delete message after read from the queue) check box and Backout messages to input queue check box in the Basic settings view and open the queue to browse messages.

**Note:**
This check box and the Backout messages to input queue check box in the Basic settings view enable you to read messages non-destructively from the queue. Browse message check box is visible only when the MQ server is WebSphere MQ with the Backout messages to input queue check box cleared. For further information, see http://publib.boulder.ibm.com/infocenter/wmqv7/v7r0m0/index.jsp?topic=%2Fcom.ibm.mq.java.doc%2Fcom%2Fibm%2Fmq%2FMQC.html/.

### Get MQMD Fields
Select this check box to set one or more message descriptors by adding new fields for MQMD(message queuing message descriptor) in the Parameters table:

- **Field Name:** Select one or more message descriptors from the list to retrieve header information of the message.
- **Reference Column Name:** The header and properties information of the message.

For further information, see http://publib.boulder.ibm.com/infocenter/wmqv7/v7r0m0/index.jsp?topic=%2Fcom.ibm.mq.csqzak.doc%2Ffr13040_.htm/.
Include Header

Select this check box to specify the header of the message:

MQRFH2 fixed Portion: Select this check box and click the plus button to add one or more lines to specify the Version, Encoding, Format, Flags, NameValueCCSID and CodedCharSetId as needed for the fixed portion of MQRFH2 header.

MCD folder: Select this check box and click the plus button to add one or more lines to specify the fields and the reference column names for the properties that describe the format of the message.

JMS folder: Select this check box and click the plus button to add one or more lines to specify the fields and the reference column names for the transportation of JMS header fields and JMSX properties.

USR folder: Select this check box and click the plus button to add one or more lines to specify the fields and the reference column names for the transportation of application-defined properties associated with the message.

Available when WebSphere MQ is selected in the MQ Server list.

Set Cipher Suite

Select this check box to enable the Cipher Suite list from which you can specify the Cipher Suite to be used with WebSphere MQ SSL.

For further information about Cipher Suite, see CipherSpecs and their equivalent CipherSuites supported by IBM WebSphere MQ.

Available when WebSphere MQ is selected in the MQ Server list.

Custom Cipher Suite

Select this check box to allow you to customize Cipher Suite.

IBM Cipher Mappings: Use the IBM Java Cipher Suite to IBM MQ Cipher Spec Mappings.

Oracle Cipher Mappings: Use the Oracle Cipher Suite to IBM MQ Cipher Spec Mappings.

tStatCatcher Statistics

Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

Global Variables

Global Variables

ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

NB_LINE: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is generally used as a start component. It must be linked to an output component.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic settings</td>
<td>Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your MQ Server connection dynamically from multiple connections planned in your Job.</td>
</tr>
<tr>
<td></td>
<td>The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.</td>
</tr>
<tr>
<td></td>
<td>For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2457 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 491. For more information on Dynamic settings and context variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

</thead>
<tbody>
<tr>
<td></td>
<td>This component requires installation of its related jar files.</td>
</tr>
</tbody>
</table>

### Asynchronous communication via a MOM server

This scenario is made of two Jobs. The first Job posts messages on a JBoss server queue and the second Job fetches the message from the server.

#### Configuring and executing the first Job

**About this task**

In the first Job, a string message is created using a `tRowGenerator` and put on a JBoss server using a `tMomOutput`. An intermediary `tLogRow` component displays the flow being passed.

**Procedure**

1. Drop the three components required for the first Job from the Palette onto the design workspace and right-click to connect them using a Main row link.
2. Double-click on **tRowGenerator** to set the schema to be randomly generated.

3. Set just one column called **message**. This is the message to be put on the MOM queue.

4. This column is of **String** type and is nullable. To produce the data, use a preset function which concatenates randomly chosen ascii characters to form a 6-char string. This function is **getAsciiRandomString**. (Java version). Click the Preview button to view a random sample of data generated.

5. Set the **Number of rows to be generated** to **10**. Click **OK** to validate.

6. The **tLogRow** is only used to display a intermediary state of the data to be handled. In this example, it doesn’t require any specific configuration.

7. Then select the **tMomOutput** component.

8. In this case, the **MQ server** to be used is **JBoss**. In the **Host** and **Port** fields, fill in the relevant connection information.

9. Select the **Message type** from the list. The message can be of **Queue** or **Topic** type. In this example, select the **Queue** type from the list.

10. In the **To** field, type in the message source information strictly respecting the syntax expected by the server. This should match the Message Type you selected, such as: **queue/A**.

    **Note:**
    The message name is case-sensitive, therefore **queue/A** and **Queue/A** are different.

11. Then click **Sync Columns** to pass on the schema from the preceding component. The schema being read-only, it cannot be changed. The data posted onto the MQ comes from the first schema column encountered.

12. Press **F6** to execute the Job and view the data flow being passed on in the console, thanks to the **tLogRow** component.
Configuring and executing the second Job

About this task

Then set the second Job in order to fetch the queuing messages from the MOM server.

Procedure

1. Drop the **tMomInput** component and a **tLogRow** from the **Palette** to the design workspace.

```
Starting job Mominput at 17:46 14/09/2007
End of job Mominput at 17:46 14/09/2007
```

2. Select the **tMomInput** to set the parameters.

```
Keep Listening  Sleeping Time (in sec)  5
```

```
MQ server         Host          Port
JBoss Messaging   10.42.10.96   1099
```

```
Message From     Message Type  Queue
queue/A          Message      Queue
```

```
Schema          Edit schema
Built-In         
```

3. Select the **MQ server** from the list. In this example, a JBoss messaging server is used.

4. Set the server **Host** and **Port** information.

5. Set the **Message From** and the **Message Type** to match the source and type expected by the messaging server.

6. The **Schema** is read-only and is made of two columns: **From** and **Message**.

7. Select the **Keep listening** check box and set the verification frequency to 5 seconds.

```
Note:
When using the **Keep Listening** option, you'll need to kill the Job to end it.
```

8. No need to change any default setting from the **tLogRow**.

9. Save the Job and run it (when launching for the first time or if you killed it on a previous run).
The messages fetched on the server are displayed on the console.

**Transmitting XML files via a MOM server**

This scenario describes a five-component Job composed of two subJobs that sends XML files from a local folder to a MOM queue, and then fetches the files from the MOM queue and displays the contents of the files on the console.

**Dropping and links the components**

**Procedure**

1. From the Palette, drop the following components one after another onto the design workspace: `tFileList`, `tFileInputXML`, `tMomOutput`, `tMomInput`, and `tLogRow`.
2. Connect `tFileList` to `tFileInputXML` using a Row > Iterate link, and connect `tFileInputXML` to `tMomOutput` using a Row > Main link to form the first subJob. This subJob will read each XML file in a given folder and send it to a MOM queue.
3. Connect `tMomInput` to `tLogRow` using a Row > Main link to form the second subJob. This subJob will fetch the XML files from MOM queue and display the file contents on the console.
4. Connect `tFileInputXML` to `tMomInput` using a `Trigger > On Component Ok` connection to link the two subjobs.

**Configuring the first subJob**

**Configuring the input components**

**Procedure**

1. Double-click the `tFileList` component to open its Basic settings view.

2. In the Directory field, enter the path to the directory to read XML files from, or browse to the path by clicking the [...] button next to the field.

3. Select Use Glob Expressions as Filemask check box, add a new line in the Files field by clicking the [+] button, and enter "*.xml" as the file mask so that all XML files in the directory will be used. Keep all the other settings as they are.

4. Double-click the `tFileInputXML` component to open its Basic settings view.
5. Click the [...] button next to **Edit schema** to open the **Schema** dialog box.

6. Click the [+] button to add a column, give it a name, *message* in this example, and select **Document** from the **Type** list to handle XML format files. Then, click **OK** to close the dialog box.

7. In the **File name/Stream** field, press **Ctrl+Space** to access the global variable list, and select **tFileList_1.CURRENT_FILEPATH** to loop on the context files’ directory.

8. In the **Loop XPath query** fields, enter "/" to define the root as the loop node of the input files’ structure; in the **Mapping** table, fill the **XPath query** column with "." to extract all data from context node of the source files, and select the **Get Nodes** check box to build a **Document** type data flow.

**Configuring the tMomOutput component**

**Procedure**

1. Double-click the **tMomOutput** component to open its **Basic settings** view.
2. Select **WebSphere MQ** from the **MQ server** list, and enter the host name or IP address of the MQ server and the port number.

3. Enter the login authentication information in the **Username** and **Password** fields, and enter the channel name of the transmission queue in the **Channel** field.

4. As we are handling file messages, select **Text Message** from the **Message Body Type** list.

5. Click **Sync columns** to retrieve the schema structure from the preceding component.

6. Fill in the queue manager and message queue details in the corresponding fields, and leave the other settings as they are.

### Configuring the second subJob

**Procedure**

1. Double-click the **tMomInput** component to open its **Basic settings** view.

2. Set the basic parameters of the component using the same settings you have done in the **tMomOutput** component, including the MQ server details, login authentication details, channel, message body type, queue manager and message queue.

3. Click the [...] button next to **Edit schema** to open the **Schema** dialog box.
4. From the **Type** list for the **message** column, select **Document** to handle XML format files, and then click **OK** to close the dialog box.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl+S** to save your Job.
2. Press **F6** or click **Run** on the **Run** tab to execute the Job.
   The XML files in the specified folder are written to the message queue and then retrieved from the queue. The contents of the files are displayed on the console.

**tMomMessageIdList**

Fetches a message ID list from a queue on a Message-Oriented middleware system and passes it to the next component.

*tMomMessageIdList* makes it possible to iterate on certain message IDs. It is usually used with *tMomInput*, for more information, see *tMomInput Standard properties* on page 2241.

**tMomMessageIdList Standard properties**

These properties are used to configure *tMomMessageIdList* running in the Standard Job framework.

The Standard *tMomMessageIdList* component belongs to the Internet family.

The component in this framework is available in all *Talend products*.

**Basic settings**

<table>
<thead>

</tbody>
</table>

**Related scenario**

For a related scenario, see tMomInput on page 2241.
tMomOutput

 Adds a message to a Message-Oriented Middleware system queue in order for it to be fetched asynchronously. tMomOutput makes it possible to set up asynchronous communications via a MOM server. For further information about the messaging brokers supported by this component, see Messaging brokers supported by Talend messaging components.

### tMomOutput Standard properties

These properties are used to configure tMomOutput running in the Standard Job framework. The Standard tMomOutput component belongs to the Internet family. The component in this framework is available in all Talend products.
